The `SELECT ... INTO OUTFILE` statement is intended primarily to let you very quickly dump a table to a text file on the server machine. If you want to create the resulting file on some client host other than the server host, you cannot use `SELECT ... INTO OUTFILE`. In that case, you should instead use a command such as `mysql -e "SELECT ..." > file_name` to generate the file on the client host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`; the syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See Section 13.2.5, “`LOAD DATA INFILE` Syntax”.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII NUL (the zero-valued byte; what is actually written following the escape character is ASCII ‘0’, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII NUL is escaped to make it easier to view with some paggers.

The resulting file does not have to conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
FROM test_table;
```

- If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a BLOB value in a file.

- **Note:** Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.
- The `SELECT` syntax description at the beginning this section shows the `INTO` clause near the end of the statement. It is also possible to use `INTO OUTFILE` or `INTO DUMPFILE` immediately preceding the `FROM` clause.
- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see Section 24.3.1, “Procedure Analyse”.
- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that allows other transactions to read the examined rows but not to update or delete them. See Section 14.2.10.5, “`SELECT ... FOR UPDATE` and `SELECT ... LOCK IN SHARE MODE` Locking Reads”.

Following the `SELECT` keyword, you can use a number of options that affect the operation of the statement.

The `ALL`, `DISTINCT`, and `DISTINCTROW` options specify whether duplicate rows should be returned. If none of these options are given, the default is `ALL` (all matching rows are returned). `DISTINCT` and `DISTINCTROW` are synonyms and specify removal of duplicate rows from the result set.

`HIGH_PRIORITY`, `STRAIGHT_JOIN`, and options beginning with `SQL_` are MySQL extensions to standard SQL.

- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free.

`HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in non-optimal order. See Section 7.2.1, “Optimizing Queries with `EXPLAIN`”. `STRAIGHT_JOIN` also can be used in the `table_references` list. See Section 13.2.7.1, “`JOIN` Syntax”.
- `SQL_BIG_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows. In this case, MySQL directly uses disk-based temporary tables if needed, and prefers sorting to using a temporary table with a key on the `GROUP BY` elements.
- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client.
- `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set is small. In this case, MySQL uses fast temporary tables to store the resulting table instead of using sorting. This should not normally be needed.
- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See Section 12.9.3, “Information Functions”.
- `SQL_CACHE` tells MySQL to store the query result in the query cache if you are using a `query_cache_type` value of 2 or `DEMAND`. For a query that uses `UNION` or subqueries, this option effects any `SELECT` in the query. See Section 5.14, “The MySQL Query Cache”.

- `SQL_NO_CACHE` tells MySQL not to store the query result in the query cache. See Section 5.14, “The MySQL Query Cache”. For a query that uses UNION or subqueries, this option affects any SELECT in the query.

### 13.2.7.1. JOIN Syntax

MySQL supports the following JOIN syntaxes for the *table\_references* part of SELECT statements and multiple-table DELETE and UPDATE statements:

```

table_references:
    table_reference [, table_reference] ...

table_reference:
    table_factor
  | join_table

table_factor:
    tbl_name [[AS] alias]
      [{USE|IGNORE|FORCE} INDEX (key_list)]
  | ( table_references )
  | { OJ table_reference LEFT OUTER JOIN table_reference
      ON conditional_expr }

join_table:
    table_reference [INNER | CROSS] JOIN table_factor [join_condition]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON condition
  | table_reference LEFT [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [LEFT [OUTER]] JOIN table_factor
  | table_reference RIGHT [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [RIGHT [OUTER]] JOIN table_factor

join_condition:
    ON conditional_expr
  | USING (column_list)

```

A table reference is also known as a join expression.

The syntax of *table\_factor* is extended in comparison with the SQL Standard. The latter accepts only *table\_reference*, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of *table\_reference* items as equivalent to an inner join. For example:

```

SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

```

is equivalent to:

```

SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

```

In MySQL, `CROSS JOIN` is a syntactic equivalent to `INNER JOIN` (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause, `CROSS JOIN` is used otherwise.

In versions of MySQL prior to 5.0.1, parentheses in *table\_references* were just omitted and all join operations were grouped to the left. In general, parentheses can be ignored in join expressions containing only inner join operations. As of 5.0.1, nested joins are allowed (see Section 7.2.10, “Nested Join Optimization”).

Further changes in join processing were made in 5.0.12 to make MySQL more compliant with

standard SQL. These changes are described later in this section.

The following list describes general factors to take into account when writing joins.

- A table reference can be aliased using *tbl\_name AS alias\_name* or *tbl\_name alias\_name*:

```
SELECT t1.name, t2.salary
   FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary
   FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

- `INNER JOIN` and `,` (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than that of `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The `ON` conditional is any conditional expression of the form that can be used in a `WHERE` clause. Generally, you should use the `ON` clause for conditions that specify how to join tables, and the `WHERE` clause to restrict which rows you want in the result set.
- If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT table1.* FROM table1
   LEFT JOIN table2 ON table1.id=table2.id
   WHERE table2.id IS NULL;
```

This example finds all rows in `table1` with an `id` value that is not present in `table2` (that is, all rows in `table1` with no corresponding row in `table2`). This assumes that `table2.id` is declared `NOT NULL`. See Section 7.2.9, “`LEFT JOIN` and `RIGHT JOIN` Optimization”.

- The `USING(column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1,c2,c3)
```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.
- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`.
- The `{ OJ ... LEFT OUTER JOIN ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.
- `STRAIGHT_JOIN` is identical to `JOIN`, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer puts the tables in the wrong order.

Some join examples:

```
SELECT * FROM table1, table2;
SELECT * FROM table1 INNER JOIN table2 ON table1.id=table2.id;
SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id;
SELECT * FROM table1 LEFT JOIN table2 USING (id);
SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id
      LEFT JOIN table3 ON table2.id=table3.id;
```

You can provide hints as to which index MySQL should use when retrieving information from a table. By specifying `USE INDEX (key_list)`, you can tell MySQL to use only one of the possible indexes to find rows in the table. The alternative syntax `IGNORE INDEX (key_list)` can be used to tell MySQL to not use some particular index. These hints are useful if `EXPLAIN` shows that MySQL is using the wrong index from the list of possible indexes.

You can also use `FORCE INDEX`, which acts like `USE INDEX (key_list)` but with the addition that a table scan is assumed to be *very* expensive. In other words, a table scan is used only if there is no way to use one of the given indexes to find rows in the table.

`USE INDEX`, `IGNORE INDEX`, and `FORCE INDEX` affect only which indexes are used when MySQL decides how to find rows in the table and how to do the join. They do not affect whether an index is used when resolving an `ORDER BY` or `GROUP BY`.

`USE KEY`, `IGNORE KEY`, and `FORCE KEY` are synonyms for `USE INDEX`, `IGNORE INDEX`, and `FORCE INDEX`.

Examples:

```
SELECT * FROM table1 USE INDEX (key1,key2)
      WHERE key1=1 AND key2=2 AND key3=3;
SELECT * FROM table1 IGNORE INDEX (key3)
      WHERE key1=1 AND key2=2 AND key3=3;
```

### Join Processing Changes in MySQL 5.0.12

Beginning with MySQL 5.0.12, natural joins and joins with `USING`, including outer join variants, are processed according to the SQL:2003 standard. The goal was to align the syntax and semantics of MySQL with respect to `NATURAL JOIN` and `JOIN ... USING` according to SQL:2003. However, these changes in join processing can result in different output columns for some joins. Also, some queries that appeared to work correctly in older versions must be rewritten to comply with the standard.

These changes have five main aspects:

- The way MySQL that determines the result columns of `NATURAL` or `USING` join operations (and thus the result of the entire `FROM` clause).
- Expansion of `SELECT *` and `SELECT tbl_name.*` into a list of selected columns.
- Resolution of column names in `NATURAL` or `USING` joins.
- Transformation of `NATURAL` or `USING` joins into `JOIN ... ON`.
- Resolution of column names in the `ON` condition of a `JOIN ... ON`.

The following list provides more detail about several effects of the 5.0.12 change in join processing. The term “previously” means “prior to MySQL 5.0.12.”

- The columns of a NATURAL join or a USING join may be different from previously. Specifically, redundant output columns no longer appear, and the order of columns for SELECT \* expansion may be different from before.

Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

Previously, the statements produced this output:

```
+-----+-----+-----+-----+
| i     | j     | k     | j     |
+-----+-----+-----+-----+
|      1 |      1 |      1 |      1 |
+-----+-----+-----+-----+
| i     | j     | k     | j     |
+-----+-----+-----+-----+
|      1 |      1 |      1 |      1 |
+-----+-----+-----+-----+
```

In the first SELECT statement, column i appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second SELECT statement, column j is named in the USING clause and should appear only once in the output, not twice. But in both cases, the redundant column is not eliminated. Also, the order of the columns is not correct according to standard SQL.

Now the statements produce this output:

```
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
|      1 |      1 |      1 |
+-----+-----+-----+
| j     | i     | k     |
+-----+-----+-----+
|      1 |      1 |      1 |
+-----+-----+-----+
```

The redundant column is eliminated and the column order is correct according to standard SQL:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined via the coalesce operation. That is, fro two t1.a and t2.a the resulting single join column a is defined as a = COALESCE(t1.a, t2.a), where:

```
COALESCE(x, y) = (CASE WHEN V1 IS NOT NULL THEN V1 ELSE V2 END)
```

If the join operation is any other join, the result columns of the join consists of the concatenation of all columns of the joined tables. This is the same as previously.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-NULL column if one of the two columns is always NULL. If neither or both columns are NULL, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a JOIN. Suppose that the tables  $t1(a, b)$  and  $t2(a, c)$  have the following contents:

```
t1      t2
-----
1 x     2 z
2 y     3 w
```

Then:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
|      1 | x     | NULL  |
|      2 | y     | y     |
+-----+-----+-----+
```

Here column a contains the values of  $t1.a$ .

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+-----+-----+-----+
| a     | c     | b     |
+-----+-----+-----+
|      2 | y     | y     |
|      3 | z     | NULL  |
+-----+-----+-----+
```

Here column a contains the values of  $t2.a$ .

Compare these results to the otherwise equivalent queries with JOIN ... ON:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
|      1 | x     | NULL  | NULL  |
|      2 | y     |      2 | y     |
+-----+-----+-----+-----+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
|      2 | y     |      2 | y     |
| NULL  | NULL  |      3 | z     |
+-----+-----+-----+-----+
```

- Previously, a USING clause could be rewritten as an ON clause that compares corresponding columns. For example, the following two clauses were semantically identical:

```
a LEFT JOIN b USING (c1, c2, c3)
a LEFT JOIN b ON a.c1=b.c1 AND a.c2=b.c2 AND a.c3=b.c3
```

Now the two clauses no longer are quite the same:

- With respect to determining which rows satisfy the join condition, both joins remain semantically identical.
- With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The `USING` join selects the coalesced value of corresponding columns, whereas the `ON` join selects all columns from all tables. For the preceding `USING` join, `SELECT *` selects these values:

```
COALESCE(a.c1,b.c1), COALESCE(a.c2,b.c2), COALESCE(a.c3,b.c3)
```

For the `ON` join, `SELECT *` selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, `COALESCE(a.c1,b.c1)` is the same as either `a.c1` or `b.c1` because both columns will have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be `NULL`. That column will be omitted from the result.

- The evaluation of multi-way natural joins differs in a very important way that affects the result of `NATURAL` or `USING` joins and that can require query rewriting. Suppose that you have three tables `t1(a,b)`, `t2(c,b)`, and `t3(a,c)` that each have one row: `t1(1,2)`, `t2(10,2)`, and `t3(7,10)`. Suppose also that you have this `NATURAL JOIN` on the three tables:

```
SELECT ... FROM t1 NATURAL JOIN t2 NATURAL JOIN t3;
```

Previously, the left operand of the second join was considered to be `t2`, whereas it should be the nested join (`t1 NATURAL JOIN t2`). As a result, the columns of `t3` are checked for common columns only in `t2`, and, if `t3` has common columns with `t1`, these columns are not used as equi-join columns. Thus, previously, the preceding query was transformed to the following equi-join:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c;
```

That join is missing one more equi-join predicate (`t1.a = t3.a`). As a result, it produces one row, not the empty result that it should. The correct equivalent query is this:

```
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c AND t1.a = t3.a;
```

If you require the same query result in current versions of MySQL as in older versions, rewrite the natural join as the first equi-join.

- Previously, the comma operator (`,`) and `JOIN` both had the same precedence, so the join expression `t1, t2 JOIN t3` was interpreted as `((t1, t2) JOIN t3)`. Now `JOIN` has higher precedence, so the expression is interpreted as `(t1, (t2 JOIN t3))`. This change affects statements that use an `ON` clause, because that clause can refer only to columns in the operands of the join, and the change in precedence changes interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
INSERT INTO t3 VALUES(1,1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

Previously, the `SELECT` was legal due to the implicit grouping of `t1, t2` as `(t1, t2)`. Now the `JOIN` takes precedence, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an `Unknown column 't1.i1' in 'on clause'` error. To allow the join to be processed, group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `(t1, t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

Alternatively, avoid the use of the comma operator and use `JOIN` instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

This change also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which now have higher precedence than the comma operator.

- Previously, the `ON` clause could refer to columns in tables named to its right. Now an `ON` clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

Previously, the `SELECT` statement was legal. Now the statement fails with an `Unknown column 'i3' in 'on clause'` error because `i3` is a column in `t3`, which is not an operand of the `ON` clause. The statement should be rewritten as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- Resolution of column names in `NATURAL` or `USING` joins is different than previously. For column names that are outside the `FROM` clause, MySQL now handles a superset of the queries compared to previously. That is, in cases when MySQL formerly issued an error that some column is ambiguous, the query now is handled correctly. This is due to the fact that MySQL now treats the common columns of `NATURAL` or `USING` joins as a single column, so when a query refers to such columns, the query compiler does not consider them as ambiguous.

Example:

```
SELECT * FROM t1 NATURAL JOIN t2 WHERE b > 1;
```

Previously, this query would produce an error `ERROR 1052 (23000): Column 'b' in where clause is ambiguous`. Now the query produces the correct result:

```
+-----+-----+-----+
| b     | c     | y     |
+-----+-----+-----+
| 4     | 2     | 3     |
+-----+-----+-----+
```

One extension of MySQL compared to the SQL:2003 standard is that MySQL allows you to qualify the common (coalesced) columns of `NATURAL` or `USING` joins (just as previously), while the standard disallows that.

### 13.2.7.2. UNION Syntax

```
SELECT ...  
UNION [ALL | DISTINCT] SELECT ...  
[UNION [ALL | DISTINCT] SELECT ...]
```

UNION is used to combine the result from multiple SELECT statements into a single result set.

The column names from the first SELECT statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each SELECT statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If the data types of corresponding SELECT columns do not match, the types and lengths of the columns in the UNION result take into account the values retrieved by all of the SELECT statements. For example, consider the following:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);  
+-----+  
| REPEAT('a',1) |  
+-----+  
| a             |  
| bbbbbbbbbbb  |  
+-----+
```

(In some earlier versions of MySQL, only the type and length from the first SELECT would have been used and the second row would have been truncated to a length of 1.)

The SELECT statements are normal select statements, but with the following restrictions:

- Only the last SELECT statement can use INTO outfile.
- HIGH\_PRIORITY cannot be used with SELECT statements that are part of a UNION. If you specify it for the first SELECT, it has no effect. If you specify it for any subsequent SELECT statements, a syntax error results.

The default behavior for UNION is that duplicate rows are removed from the result. The optional DISTINCT keyword has no effect other than the default because it also specifies duplicate-row removal. With the optional ALL keyword, duplicate-row removal does not occur and the result includes all matching rows from all the SELECT statements.

You can mix UNION ALL and UNION DISTINCT in the same query. Mixed UNION types are treated such that a DISTINCT union overrides any ALL union to its left. A DISTINCT union can be produced explicitly by using UNION DISTINCT or implicitly by using UNION with no following DISTINCT or ALL keyword.

To use an ORDER BY or LIMIT clause to sort or limit the entire UNION result, parenthesize the individual SELECT statements and place the ORDER BY or LIMIT after the last one. The following example uses both clauses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)  
UNION  
(SELECT a FROM t2 WHERE a=11 AND B=2)  
ORDER BY a LIMIT 10;
```

This kind of ORDER BY cannot use column references that include a table name (that is, names in *tbl\_name.col\_name* format). Instead, provide a column alias in the first SELECT statement and refer to the alias in the ORDER BY. (Alternatively, refer to the column in the ORDER BY using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the ORDER BY clause *must* refer to the alias, not the column name. The first of the following statements will work, but the second will fail with an Un-

known column 'a' in 'order clause' error:

```
(SELECT a AS b FROM t) UNION (SELECT ... ) ORDER BY b;  
(SELECT a AS b FROM t) UNION (SELECT ... ) ORDER BY a;
```

To apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)  
UNION  
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

Use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. If `ORDER BY` appears with `LIMIT`, it is used to determine the subset of the selected rows to retrieve for the `SELECT`, but does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect anyway.

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` following the last `SELECT`:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)  
UNION  
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)  
UNION  
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, colla;
```

## 13.2.8. Subquery Syntax

A subquery is a `SELECT` statement within another statement.

Starting with MySQL 4.1, all subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, `SELECT * FROM t1 ...` is the *outer query* (or *outer statement*), and `(SELECT column1 FROM t2)` is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- They are, in many people's opinion, readable. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
(SELECT COUNT(*) /* no hint */ FROM t2
WHERE NOT EXISTS
(SELECT * FROM t3
WHERE ROW(5*t2.s1,77)=
(SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
(SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain any of the keywords or clauses that an ordinary `SELECT` can contain: `DISTINCT`, `GROUP BY`, `ORDER BY`, `LIMIT`, joins, index hints, `UNION` constructs, comments, functions, and so on.

One restriction is that a subquery's outer statement must be one of: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `SET`, or `DO`. Another restriction is that currently you cannot modify a table and select from the same table in a subquery. This applies to statements such as `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and (because subqueries can be used in the `SET` clause) `LOAD DATA INFILE`.

A more comprehensive discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, is given in Section I.3, "Restrictions on Subqueries".

### 13.2.8.1. The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication whether it can be `NULL`, and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value ('abcde') that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. In fact, almost all subqueries can be `NULL`. If the table used in the example were empty, the value of the subquery would be `NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement allows only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA INFILE` requires a literal string filename. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct (`SELECT column1 FROM t1`), imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is 2 because there is a row in `t2` containing a column `s1` that has a value of 2.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

### 13.2.8.2. Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where *comparison\_operator* is one of these operators:

```
= > < >= <= <>
```

For example:

```
... 'a' = (SELECT column1 FROM t1)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the values in table `t1` that are equal to a maximum value in table `t2`:

```
SELECT column1 FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison performed with one of these operators, the subquery must return a scalar, with the exception that `=` can be used with row subqueries. See Section 13.2.8.5, “Row Subqueries”.

### 13.2.8.3. Subqueries with ANY, IN, and SOME

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

The `ANY` keyword, which must follow a comparison operator, means “return TRUE if the comparison is TRUE for ANY of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table *t1* containing (10). The expression is TRUE if table *t2* contains (21, 14, 7) because there is a value 7 in *t2* that is less than 10. The expression is FALSE if table *t2* contains (20, 10), or if table *t2* is empty. The expression is UNKNOWN if table *t2* contains (NULL, NULL, NULL).

The word IN is an alias for = ANY. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN   (SELECT s1 FROM t2);
```

However, NOT IN is not an alias for <> ANY, but for <> ALL. See Section 13.2.8.4, “Subqueries with ALL”.

The word SOME is an alias for ANY. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word SOME is rare, but this example shows why it might be useful. To most people's ears, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using <> SOME instead helps ensure that everyone understands the true meaning of the query.

### 13.2.8.4. Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word ALL, which must follow a comparison operator, means “return TRUE if the comparison is TRUE for ALL of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table *t1* containing (10). The expression is TRUE if table *t2* contains (-5, 0, +5) because 10 is greater than all three values in *t2*. The expression is FALSE if table *t2* contains (12, 6, NULL, -100) because there is a single value 12 in table *t2* that is greater than 10. The expression is *unknown* (that is, NULL) if table *t2* contains (0, NULL, 1).

Finally, if table *t2* is empty, the result is TRUE. So, the following statement is TRUE when table *t2* is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this statement is NULL when table *t2* is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following statement is NULL when table *t2* is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing NULL values* and *empty tables* are “edge cases.” When writing subquery code, always consider whether you have taken those two possibilities into account.

NOT IN is an alias for <> ALL. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

### 13.2.8.5. Row Subqueries

The discussion to this point has been of scalar or column subqueries; that is, subqueries that return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Here are two examples:

```
SELECT * FROM t1 WHERE (1,2) = (SELECT column1, column2 FROM t2);
SELECT * FROM t1 WHERE ROW(1,2) = (SELECT column1, column2 FROM t2);
```

The queries here are both TRUE if table t2 has a row where column1 = 1 and column2 = 2.

The expressions (1,2) and ROW(1,2) are sometimes called *row constructors*. The two are equivalent. They are legal in other contexts as well. For example, the following two statements are semantically equivalent (although currently only the second one can be optimized):

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The normal use of row constructors is for comparisons with subqueries that return two or more columns. For example, the following query answers the request, “find all rows in table t1 that also exist in table t2”:

```
SELECT column1,column2,column3
FROM t1
WHERE (column1,column2,column3) IN
(SELECT column1,column2,column3 FROM t2);
```

### 13.2.8.6. EXISTS and NOT EXISTS

If a subquery returns any rows at all, EXISTS *subquery* is TRUE, and NOT EXISTS *subquery* is FALSE. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an EXISTS subquery starts with SELECT \*, but it could begin with SELECT 5 or SELECT column1 or anything at all. MySQL ignores the SELECT list in such a subquery, so it makes no difference.

For the preceding example, if t2 contains any rows, even rows with nothing but NULL values, the EXISTS condition is TRUE. This is actually an unlikely example because a [NOT] EXISTS subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
  WHERE NOT EXISTS (
    SELECT * FROM cities WHERE NOT EXISTS (
      SELECT * FROM cities_stores
        WHERE cities_stores.city = cities.city
          AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested NOT EXISTS query. That is, it has a NOT EXISTS clause within a NOT EXISTS clause. Formally, it answers the question “does a city exist with a store that is not in Stores”? But it is easier to say that a nested NOT EXISTS answers the question “is  $x$  TRUE for all  $y$ ?”

### 13.2.8.7. Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1 WHERE column1 = ANY
(SELECT column1 FROM t2 WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's FROM clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be TRUE, but in this example, the WHERE clause within the subquery is FALSE (because  $(5, 6)$  is not equal to  $(5, 7)$ ), so the subquery as a whole is FALSE.

**Scoping rule:** MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
WHERE x.column1 = (SELECT column1 FROM t3
WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is *farther out*.

For subqueries in HAVING or ORDER BY clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Correlated subqueries cannot refer to the results of aggregate functions from the outer query.

### 13.2.8.8. Subqueries in the FROM clause

Subqueries are legal in a `SELECT` statement's `FROM` clause. The actual syntax is:

```
SELECT ... FROM (subquery) [AS] name ...
```

The `[AS] name` clause is mandatory, because every table in a `FROM` clause must have a name. Any columns in the `subquery` select list must have unique names. You can find this syntax described elsewhere in this manual, where the term used is “derived tables.”

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```
INSERT INTO t1 VALUES (1, '1', 1.0);
INSERT INTO t1 VALUES (2, '2', 2.0);
SELECT sb1, sb2, sb3
FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
WHERE sb1 > 1;
```

Result: 2, '2', 4.0.

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

Subqueries in the `FROM` clause can return a scalar, column, row, or table. Subqueries in the `FROM` clause cannot be correlated subqueries.

Subqueries in the `FROM` clause are executed even for the `EXPLAIN` statement (that is, derived temporary tables are built). This occurs because upper level queries need information about all tables during optimization phase.

### 13.2.8.9. Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Incorrect number of columns from subquery:

```
ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"
```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is comparison. See Sec-

tion 13.2.8.5, “Row Subqueries”. However, in other contexts, the subquery must be a scalar operand.

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery returns more than one row. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x'
for update in FROM clause"
```

This error occurs in cases such as the following:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an `UPDATE` statement because subqueries are legal in `UPDATE` and `DELETE` statements as well as in `SELECT` statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery's `FROM` clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For non-transactional storage engines, data modifications made before the error was encountered are preserved.

## 13.2.8.10. Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with:

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN
(SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN
(SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS
(SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (
SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2
WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See Section 13.2.8.11, “Rewriting Subqueries as Joins for Earlier MySQL Versions”.
- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1
WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```
SELECT * FROM t1
WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
AND t2.column2=t1.column2);
```

- Use NOT (a = ANY (...)) rather than a <> ALL (...).
- Use x = ANY (table containing (1,2)) rather than x=1 OR x=2.
- Use = ANY rather than EXISTS.
- For uncorrelated subqueries that always return one row, IN is always slower than =. For example, use this query:

```
SELECT * FROM t1 WHERE t1.col_name
= (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```
SELECT * FROM t1 WHERE t1.col_name
IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See Section 12.9.3, “Information Functions”.

Some optimizations that MySQL itself makes are:

- MySQL executes non-correlated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is non-correlated.
- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.
- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```
... IN (SELECT indexed_column FROM single_table ...)
```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

```
value {ALL|ANY|SOME} {> | < | >= | <=} (non-correlated subquery)
```

For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

There is a chapter titled “How MySQL Transforms Subqueries” in the MySQL Internals Manual, available at <http://dev.mysql.com/doc/>.

### 13.2.8.11. Rewriting Subqueries as Joins for Earlier MySQL Versions

In previous versions of MySQL (prior to MySQL 4.1), only nested queries of the form `INSERT ... SELECT ...` and `REPLACE ... SELECT ...` were supported. Although this is not the case in MySQL 5.0, it is still true that there are sometimes other ways to test membership in a set of values. It is also true that on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);  
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten using `IN()`:

```
SELECT table1.* FROM table1 LEFT JOIN table2 ON table1.id=table2.id
WHERE table2.id IS NULL;
```

A `LEFT [OUTER] JOIN` can be faster than an equivalent subquery because the server might be able to optimize it better — a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table `DELETE` statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table `UPDATE` statements are also supported.

## 13.2.9. TRUNCATE Syntax

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. Logically, this is equivalent to a `DELETE` statement that deletes all rows, but there are practical differences under some circumstances.

For InnoDB before version 5.0.3, `TRUNCATE TABLE` is mapped to `DELETE`, so there is no difference. Starting with MySQL 5.0.3, fast `TRUNCATE TABLE` is available. However, the operation is still mapped to `DELETE` if there are foreign key constraints that reference the table. (When fast truncate is used, it resets any `AUTO_INCREMENT` counter. From MySQL 5.0.13 on, the `AUTO_INCREMENT` counter is reset by `TRUNCATE TABLE`, regardless of whether there is a foreign key constraint.)

For other storage engines, `TRUNCATE TABLE` differs from `DELETE` in the following ways in MySQL 5.0:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one.
- Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock.
- The number of deleted rows is not returned.
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- The table handler does not remember the last used `AUTO_INCREMENT` value, but starts counting from the beginning. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.

Since truncation of a table does not make any use of `DELETE`, the `TRUNCATE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` is an Oracle SQL extension adopted in MySQL.

## 13.2.10. UPDATE Syntax

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] tbl_name
  SET col_name1=expr1 [, col_name2=expr2 ...]
  [WHERE where_condition]
  [ORDER BY ...]
```

```
[LIMIT row_count]
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references  
  SET col_name1=expr1 [, col_name2=expr2 ...]  
  [WHERE where_condition]
```

For the single-table syntax, the UPDATE statement updates columns of existing rows in *tbl\_name* with new values. The SET clause indicates which columns to modify and the values they should be given. The WHERE clause, if given, specifies the conditions that identify which rows to update. With no WHERE clause, all rows are updated. If the ORDER BY clause is specified, the rows are updated in the order that is specified. The LIMIT clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, UPDATE updates rows in each table named in *table\_references* that satisfy the conditions. In this case, ORDER BY and LIMIT cannot be used.

*where\_condition* is an expression that evaluates to true for each row to be updated. It is specified as described in Section 13.2.7, “SELECT Syntax”.

The UPDATE statement supports the following modifiers:

- If you use the LOW\_PRIORITY keyword, execution of the UPDATE is delayed until no other clients are reading from the table.
- If you use the IGNORE keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur are not updated. Rows for which columns are updated to values that would cause data conversion errors are updated to the closest valid values instead.

If you access a column from *tbl\_name* in an expression, UPDATE uses the current value of the column. For example, the following statement sets the age column to one more than its current value:

```
UPDATE persondata SET age=age+1;
```

UPDATE assignments are evaluated from left to right. For example, the following statement doubles the age column, and then increments it:

```
UPDATE persondata SET age=age*2, age=age+1;
```

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared NOT NULL by setting to NULL, the column is set to the default value appropriate for the data type and the warning count is incremented. The default value is 0 for numeric types, the empty string ( ' ' ) for string types, and the “zero” value for date and time types.

UPDATE returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the UPDATE.

You can use LIMIT *row\_count* to restrict the scope of the UPDATE. A LIMIT clause is a rows-matched restriction. The statement stops as soon as it has found *row\_count* rows that satisfy the WHERE clause, whether or not they actually were changed.

If an UPDATE statement includes an ORDER BY clause, the rows are updated in the order specified by the clause.

You can also perform UPDATE operations covering multiple tables. However, you cannot use ORDER BY or LIMIT with a multiple-table UPDATE. The *table\_references* clause lists the tables involved in the join. Its syntax is described in Section 13.2.7.1, “JOIN Syntax”. Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table UPDATE statements can use any type of join allowed in SELECT statements, such as LEFT JOIN.

You need the UPDATE privilege only for columns referenced in a multiple-table UPDATE that are actually updated. You need only the SELECT privilege for any columns that are read but not modified.

If you use a multiple-table UPDATE statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the ON UPDATE capabilities that InnoDB provides to cause the other tables to be modified accordingly. See Section 14.2.6.4, “FOREIGN KEY Constraints”.

Currently, you cannot update a table and select from the same table in a subquery.

## 13.3. MySQL Utility Statements

### 13.3.1. DESCRIBE Syntax

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

DESCRIBE provides information about the columns in a table. It is a shortcut for SHOW COLUMNS FROM. As of MySQL 5.0.1, these statements also display information for views. (See Section 13.5.4.3, “SHOW COLUMNS Syntax”.)

*col\_name* can be a column name, or a string containing the SQL ‘%’ and ‘\_’ wildcard characters to obtain output only for the columns with names matching the string. There is no need to enclose the string within quotes unless it contains spaces or other special characters.

```
mysql> DESCRIBE city;
```

Field	Type	Null	Key	Default	Extra
Id	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	NO			
Country	char(3)	NO	UNI		
District	char(20)	YES	MUL		
Population	int(11)	NO		0	

```
5 rows in set (0.00 sec)
```

Field indicates the column name.

The Null field indicates whether NULL values can be stored in the column.

The Key field indicates whether the column is indexed. A value of PRI indicates that the column is part of the table’s primary key. UNI indicates that the column is part of a UNIQUE index. The MUL value indicates that multiple occurrences of a given value are allowed within the column.

One reason for MUL to be displayed on a UNIQUE index is that several columns form a composite UNIQUE index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value. Note that in a composite index, only the leftmost column of the

index has an entry in the `Key` field.

Before MySQL 5.0.11, if the column allows `NULL` values, the `Key` value can be `MUL` even when a `UNIQUE` index is used. The rationale was that multiple rows in a `UNIQUE` index can hold a `NULL` value if the column is not declared `NOT NULL`. As of MySQL 5.0.11, the display is `UNI` rather than `MUL` regardless of whether the column allows `NULL`; you can see from the `Null` field whether or not the column can contain `NULL`.

The `Default` field indicates the default value that is assigned to the column.

The `Extra` field contains any additional information that is available about a given column. In the example shown, the `Extra` field indicates that the `Id` column was created with the `AUTO_INCREMENT` keyword.

If the data types are different from what you expect them to be based on a `CREATE TABLE` statement, note that MySQL sometimes changes data types. See Section 13.1.5.1, “Silent Column Specification Changes”.

The `DESCRIBE` statement is provided for compatibility with Oracle.

The `SHOW CREATE TABLE` and `SHOW TABLE STATUS` statements also provide information about tables. See Section 13.5.4, “SHOW Syntax”.

## 13.3.2. USE Syntax

```
USE db_name
```

The `USE db_name` statement tells MySQL to use the *db\_name* database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another `USE` statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable;    # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;    # selects from db2.mytable
```

Making a particular database the default by means of the `USE` statement does not preclude you from accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;
SELECT author_name, editor_name FROM author, db2.editor
  WHERE author.editor_id = db2.editor.editor_id;
```

The `USE` statement is provided for compatibility with Sybase.

## 13.4. MySQL Transactional and Locking Statements

MySQL supports local transactions (within a given client connection) through statements such as `SET AUTOCOMMIT`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See Section 13.4.1, “`START TRANSACTION`, `COMMIT`, and `ROLLBACK` Syntax”. Beginning with MySQL 5.0, `XA` transaction support is available, which enables MySQL to participate in distributed transactions as well. See Section 13.4.7, “`XA` Transactions”.

### 13.4.1. `START TRANSACTION`, `COMMIT`, and `ROLLBACK` Syntax

```
START TRANSACTION | BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET AUTOCOMMIT = {0 | 1}
```

The `START TRANSACTION` and `BEGIN` statement begin a new transaction. `COMMIT` commits the current transaction, making its changes permanent. `ROLLBACK` rolls back the current transaction, canceling its changes. The `SET AUTOCOMMIT` statement disables or enables the default autocommit mode for the current connection.

Beginning with MySQL 5.0.3, the optional `WORK` keyword is supported for `COMMIT` and `RELEASE`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See Section 5.2.2, “Server System Variables”.

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client connection after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

By default, MySQL runs with autocommit mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MySQL stores the update on disk.

If you are using a transaction-safe storage engine (such as InnoDB, BDB, or NDB Cluster), you can disable autocommit mode with the following statement:

```
SET AUTOCOMMIT=0;
```

After disabling autocommit mode by setting the `AUTOCOMMIT` variable to zero, you must use `COMMIT` to store your changes to disk or `ROLLBACK` if you want to ignore the changes you have made since the beginning of your transaction.

To disable autocommit mode for a single series of statements, use the `START TRANSACTION` statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With `START TRANSACTION`, autocommit remains disabled until you end the transaction with `COMMIT` or `ROLLBACK`. The autocommit mode then reverts to its previous state.

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax and is the recommended way to start an ad-hoc transaction.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not begin a transaction. See Section 17.2.5, “`BEGIN ... END` Compound Statement Syntax”.

You can also begin a transaction like this:

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

The `WITH CONSISTENT SNAPSHOT` clause starts a consistent read for storage engines that are capable of it. Currently, this applies only to InnoDB. The effect is the same as issuing a `START TRANSACTION` followed by a `SELECT` from any InnoDB table. See Section 14.2.10.4, “Consistent Non-Locking Read”.

The `WITH CONSISTENT SNAPSHOT` clause does not change the current transaction isolation level, so it provides a consistent snapshot only if the current isolation level is one that allows consistent read (`REPEATABLE READ` or `SERIALIZABLE`).

Beginning a transaction causes an implicit `UNLOCK TABLES` to be performed.

For best results, transactions should be performed using only tables managed by a single transactional storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as InnoDB and BDB), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits, another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)
- If you use non-transaction-safe tables within a transaction, any changes to those tables are stored at once, regardless of the status of autocommit mode.

If you issue a `ROLLBACK` statement after updating a non-transactional table within a transaction, an `ER_WARNING_NOT_COMPLETE_ROLLBACK` warning occurs. Changes to transaction-safe tables are rolled back, but not changes to non-transaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon `COMMIT`. Transactions that are rolled back are not logged. (**Exception:** Modifications to non-transactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to non-transactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.) See Section 5.12.3, “The Binary Log”.

You can change the isolation level for transactions with `SET TRANSACTION ISOLATION LEVEL`. See Section 13.4.6, “`SET TRANSACTION` Syntax”.

Rolling back can be a slow operation that may occur without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the connection during implicit and explicit (`ROLLBACK SQL` statement) rollbacks.

## 13.4.2. Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

## 13.4.3. Statements That Cause an Implicit Commit

Each of the following statements (and any synonyms for them) implicitly end a transaction, as if you had done a `COMMIT` before executing the statement:

- `ALTER FUNCTION`, `ALTER PROCEDURE`, `ALTER TABLE`, `BEGIN`, `CREATE DATABASE`, `CREATE FUNCTION`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE TABLE`, `DROP DATABASE`, `DROP FUNCTION`, `DROP INDEX`, `DROP PROCEDURE`, `DROP TABLE`, `LOAD MASTER DATA`, `LOCK TABLES`, `LOAD DATA INFILE`, `RENAME TABLE`, `SET AUTO-COMMIT=1`, `START TRANSACTION`, `TRUNCATE TABLE`, `UNLOCK TABLES`.

- `UNLOCK TABLES` commits a transaction only if any tables currently are locked.
- The `CREATE TABLE`, `CREATE DATABASE DROP DATABASE`, and `TRUNCATE TABLE` statements cause an implicit commit beginning with MySQL 5.0.8. The `ALTER FUNCTION`, `ALTER PROCEDURE`, `CREATE FUNCTION`, `CREATE PROCEDURE`, `DROP FUNCTION`, and `DROP PROCEDURE` statements cause an implicit commit beginning with MySQL 5.0.13.
- The `CREATE TABLE` statement in InnoDB is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

Transactions cannot be nested. This is a consequence of the implicit `COMMIT` performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

## 13.4.4. SAVEPOINT and ROLLBACK TO SAVEPOINT Syntax

```
SAVEPOINT identifier
ROLLBACK [WORK] TO SAVEPOINT identifier
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements `SAVEPOINT` and `ROLLBACK TO SAVEPOINT`. Starting from MySQL 5.0.3, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK` are supported as well.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does *not* release the row locks that were stored in memory after the savepoint. (Note that for a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1181: Got error 153 during ROLLBACK
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

Beginning with MySQL 5.0.17, a new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

## 13.4.5. LOCK TABLES and UNLOCK TABLES Syntax

```
LOCK TABLES
  tbl_name [AS alias] {READ [LOCAL] | [LOW_PRIORITY] WRITE}
  [, tbl_name [AS alias] {READ [LOCAL] | [LOW_PRIORITY] WRITE}] ...
UNLOCK TABLES
```

`LOCK TABLES` locks tables for the current thread. If any of the tables are locked by other threads, it blocks until all locks can be acquired. `UNLOCK TABLES` releases any locks held by the current thread. All tables that are locked by the current thread are implicitly unlocked when the thread issues another `LOCK TABLES`, or when the connection to the server is closed.

A table lock protects only against inappropriate reads or writes by other clients. The client holding the lock, even a read lock, can perform table-level operations such as `DROP TABLE`.

Note the following regarding the use of `LOCK TABLES` with transactional tables:

- `LOCK TABLES` is not transaction-safe and implicitly commits any active transactions before attempting to lock the tables. Also, beginning a transaction (for example, with `START TRANSACTION`) implicitly performs an `UNLOCK TABLES`. (See Section 13.4.3, “Statements That Cause an Implicit Commit”.)
- The correct way to use `LOCK TABLES` with transactional tables, such as InnoDB tables, is to set `AUTOCOMMIT = 0` and not to call `UNLOCK TABLES` until you commit the transaction explicitly. When you call `LOCK TABLES`, InnoDB internally takes its own table lock, and MySQL takes its own table lock. InnoDB releases its table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `AUTOCOMMIT = 1`, because then InnoDB releases its table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. Note that we do not acquire the InnoDB table lock at all if `AUTOCOMMIT=1`, to help old applications avoid unnecessary deadlocks.
- `ROLLBACK` does not release MySQL's non-transactional table locks.

To use `LOCK TABLES`, you must have the `LOCK TABLES` privilege and the `SELECT` privilege for the involved tables.

The main reasons to use `LOCK TABLES` are to emulate transactions or to get more speed when updating tables. This is explained in more detail later.

If a thread obtains a `READ` lock on a table, that thread (and all other threads) can only read from the table. If a thread obtains a `WRITE` lock on a table, only the thread holding the lock can write to the table. Other threads are blocked from reading or writing the table until the lock has been released.

The difference between `READ LOCAL` and `READ` is that `READ LOCAL` allows non-conflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database files outside MySQL while you hold the lock. For InnoDB tables, `READ LOCAL` is the same as `READ` as of MySQL 5.0.13. (Before that, `READ LOCAL` essentially does nothing: It does not lock the table at all, so for InnoDB tables, the use of `READ LOCAL` is deprecated because a plain consistent-read `SELECT` does the same thing, and no locks are needed.)

When you use `LOCK TABLES`, you must lock all tables that you are going to use in your queries. While the locks obtained with a `LOCK TABLES` statement are in effect, you cannot access any tables that were not locked by the statement. Also, you cannot use a locked table multiple times in a single query. Use aliases instead, in which case you must obtain a lock for each alias separately.

```
mysql> LOCK TABLE t WRITE, t AS t1 WRITE;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

If your queries refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your queries using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

WRITE locks normally have higher priority than READ locks to ensure that updates are processed as soon as possible. This means that if one thread obtains a READ lock and then another thread requests a WRITE lock, subsequent READ lock requests wait until the WRITE thread has gotten the lock and released it. You can use `LOW_PRIORITY WRITE` locks to allow other threads to obtain READ locks while the thread is waiting for the WRITE lock. You should use `LOW_PRIORITY WRITE` locks only if you are sure that eventually there will be a time when no threads have a READ lock.

`LOCK TABLES` works as follows:

1. Sort all tables to be locked in an internally defined order. From the user standpoint, this order is undefined.
2. If a table is locked with a read and a write lock, put the write lock before the read lock.
3. Lock one table at a time until the thread gets all locks.

This policy ensures that table locking is deadlock free. There are, however, other things you need to be aware of about this policy: If you are using a `LOW_PRIORITY WRITE` lock for a table, it means only that MySQL waits for this particular lock until there are no threads that want a READ lock. When the thread has gotten the WRITE lock and is waiting to get the lock for the next table in the lock table list, all other threads wait for the WRITE lock to be released. If this becomes a serious problem with your application, you should consider converting some of your tables to transaction-safe tables.

You can safely use `KILL` to terminate a thread that is waiting for a table lock. See Section 13.5.5.3, “`KILL` Syntax”.

Note that you should *not* lock any tables that you are using with `INSERT DELAYED` because in that case the `INSERT` is performed by a separate thread.

Normally, you do not need to lock tables, because all single `UPDATE` statements are atomic; no other thread can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of MyISAM tables, it is much faster to lock the tables you are going to use. Locking MyISAM tables speeds up inserting, updating, or deleting on them. The downside is that no thread can update a READ-locked table (including the one holding the lock) and no thread can access a WRITE-locked table other than the one holding the lock.

The reason some MyISAM operations are faster under `LOCK TABLES` is that MySQL does not flush the key cache for the locked tables until `UNLOCK TABLES` is called. Normally, the key cache is flushed after each SQL statement.

- If you are using a storage engine in MySQL that does not support transactions, you must use `LOCK TABLES` if you want to ensure that no other thread comes between a `SELECT` and an `UPDATE`. The example shown here requires `LOCK TABLES` to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
```

```
UNLOCK TABLES;
```

Without `LOCK TABLES`, it is possible that another thread might insert a new row in the table between execution of the `SELECT` and `UPDATE` statements.

You can avoid using `LOCK TABLES` in many cases by using relative updates (`UPDATE customer SET value=value+new_value`) or the `LAST_INSERT_ID()` function. See Section 1.9.5.3, “Transactions and Atomic Operations”.

You can also avoid locking tables in some cases by using the user-level advisory lock functions `GET_LOCK()` and `RELEASE_LOCK()`. These locks are saved in a hash table in the server and implemented with `pthread_mutex_lock()` and `pthread_mutex_unlock()` for high speed. See Section 12.9.4, “Miscellaneous Functions”.

See Section 7.3.1, “Locking Methods”, for more information on locking policy.

You can lock all tables in all databases with read locks with the `FLUSH TABLES WITH READ LOCK` statement. See Section 13.5.5.2, “FLUSH Syntax”. This is a very convenient way to get backups if you have a filesystem such as Veritas that can take snapshots in time.

**Note:** If you use `ALTER TABLE` on a locked table, it may become unlocked. See Section A.7.1, “Problems with `ALTER TABLE`”.

## 13.4.6. SET TRANSACTION Syntax

```
SET [GLOBAL | SESSION] TRANSACTION ISOLATION LEVEL  
{ READ UNCOMMITTED | READ COMMITTED | REPEATABLE READ | SERIALIZABLE }
```

This statement sets the transaction isolation level for the next transaction, globally, or for the current session.

The default behavior of `SET TRANSACTION` is to set the isolation level for the next (not yet started) transaction. If you use the `GLOBAL` keyword, the statement sets the default transaction level globally for all new connections created from that point on. Existing connections are unaffected. You need the `SUPER` privilege to do this. Using the `SESSION` keyword sets the default transaction level for all future transactions performed on the current connection.

For descriptions of each InnoDB transaction isolation level, see Section 14.2.10.3, “InnoDB and TRANSACTION ISOLATION LEVEL”. InnoDB supports each of these levels in MySQL 5.0. The default level is `REPEATABLE READ`.

To set the initial default global isolation level for `mysqld`, use the `-transaction-isolation` option. See Section 5.2.1, “`mysqld` Command Options”.

## 13.4.7. XA Transactions

MySQL 5.0.3 and up provides server-side support for XA transactions. Currently, this support is available for the InnoDB storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>. Limitations of the current XA implementation are described in Section I.5, “Restrictions on XA Transactions”.

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need to be linked against a recent client library. Older client libraries also will work.

Currently, among the MySQL Connectors, MySQL Connector/J 5.0.0 supports XA directly (by

means of a class interface that handles the XA SQL statement interface for you).

XA supports distributed transactions; that is, the ability to allow multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (However, for a distributed transaction, you must use the `SERIALIZABLE` isolation level to achieve ACID properties. It is enough to use `REPEATABLE READ` for a non-distributed transaction, but not for a distributed transaction.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”
- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.
- A bank keeps account information in an RDBMS and distributes and receives money via automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA MySQL enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the

branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.

2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

### 13.4.7.1. XA Transaction SQL Syntax

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER
```

For XA START, the JOIN and RESUME clauses are not supported.

For XA END the SUSPEND [FOR MIGRATE] clause is not supported.

Each XA statement begins with the XA keyword, and most of them require an *xid* value. An *xid* is an XA transaction identifier. It indicates which transaction the statement applies to. *xid* values are supplied by the client, or generated by the MySQL server. An *xid* value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

*gtrid* is a global transaction identifier, *bqual* is a branch qualifier, and *formatID* is a number that identifies the format used by the *gtrid* and *bqual* values. As indicated by the syntax, *bqual* and *formatID* are optional. The default *bqual* value is ' ' if not given. The default *formatID* value is 1 if not given.

*gtrid* and *bqual* must be string literals, each up to 64 bytes (not characters) long. *gtrid* and *bqual* can be specified in several ways. You can use a quoted string ('ab'), hex string (0x6162, X'ab'), or bit value (b'nnnn').

*formatID* is an unsigned integer.

The *gtrid* and *bqual* values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write *gtrid* and *bqual* as hex strings.

*xid* values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own *xid* values in a list of values returned by the XA RECOVER statement.

XA START *xid* starts an XA transaction with the given *xid* value. Each XA transaction must have a unique *xid* value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the *gtrid* and *bqual* values. All following XA statements for the

XA transaction must be specified using the same *xid* value as that given in the XA `START` statement. If you use any of those statements but specify an *xid* value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same *gtrid* value in the *xid* value. For this reason, *gtrid* values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The *bqual* part of the *xid* value must be different for each XA transaction within a global transaction. (The requirement that *bqual* values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The XA `RECOVER` statement returns information for those XA transactions on the MySQL server that are in the `PREPARED` state. (See Section 13.4.7.2, “XA Transaction States”.) The output includes a row for each such XA transaction on the server, regardless of which client started it.

XA `RECOVER` output rows look like this (for an example *xid* value consisting of the parts 'abc', 'def', and 7):

```
mysql> XA RECOVER;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
|          7 |              3 |              3 | abcdef |
+-----+-----+-----+-----+
```

The output columns have the following meanings:

- `formatID` is the *formatID* part of the transaction *xid*
- `gtrid_length` is the length in bytes of the *gtrid* part of the *xid*
- `bqual_length` is the length in bytes of the *bqual* part of the *xid*
- `data` is the concatenation of the *gtrid* and *bqual* parts of the *xid*

### 13.4.7.2. XA Transaction States

An XA transaction progresses through the following states:

1. Use XA `START` to start an XA transaction and put it in the `ACTIVE` state.
2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an XA `END` statement. XA `END` puts the transaction in the `IDLE` state.
3. For an `IDLE` XA transaction, you can issue either an XA `PREPARE` statement or an XA `COMMIT . . . ONE PHASE` statement:
  - XA `PREPARE` puts the transaction in the `PREPARED` state. An XA `RECOVER` statement at this point will include the transaction's *xid* value in its output, because XA `RECOVER` lists all XA transactions that are in the `PREPARED` state.
  - XA `COMMIT . . . ONE PHASE` prepares and commits the transaction. The *xid* value will not be listed by XA `RECOVER` because the transaction terminates.
4. For a `PREPARED` XA transaction, you can issue an XA `COMMIT` statement to commit and terminate the transaction, or XA `ROLLBACK` to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if XA START has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with START TRANSACTION, no XA statements can be used until the transaction has been committed or rolled back.

## 13.5. Database Administration Statements

### 13.5.1. Account Management Statements

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in Chapter 5, *Database Administration*, which you should consult for additional details.

**Important:** Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

#### 13.5.1.1. CREATE USER Syntax

```
CREATE USER user [IDENTIFIED BY [PASSWORD] 'password']
    [, user [IDENTIFIED BY [PASSWORD] 'password']] ...
```

The CREATE USER statement was added in MySQL 5.0.2. This statement creates new MySQL accounts. To use it, you must have the global CREATE USER privilege or the INSERT privilege for the `mysql` database. For each account, CREATE USER creates a new record in the `mysql.user` table that has no privileges. An error occurs if the account already exists. Each account is named using the same format as for the GRANT statement; for example, '`jeffrey`'@'`localhost`'. The user and host parts of the account name correspond to the User and Host column values of the `user` table row for the account.

The account can be given a password with the optional IDENTIFIED BY clause. The `user` value and the password are given the same way as for the GRANT statement. In particular, to specify the password in plain text, omit the PASSWORD keyword. To specify the password as the hashed value as returned by the PASSWORD() function, include the PASSWORD keyword. See Section 13.5.1.3, “GRANT Syntax”.

#### 13.5.1.2. DROP USER Syntax

```
DROP USER user [, user] ...
```

The DROP USER statement removes one or more MySQL accounts. To use it, you must have the global CREATE USER privilege or the DELETE privilege for the `mysql` database. Each account is named using the same format as for the GRANT statement; for example, '`jef-`

frey'@'localhost'. The user and host parts of the account name correspond to the `User` and `Host` column values of the `user` table row for the account.

`DROP USER` as present in MySQL 5.0.0 removes only accounts that have no privileges. In MySQL 5.0.2, it was modified to remove account privileges as well. This means that the procedure for removing an account depends on your version of MySQL.

As of MySQL 5.0.2, you can remove an account and its privileges as follows:

```
DROP USER user;
```

The statement removes privilege rows for the account from all grant tables.

In MySQL 5.0.0 and 5.0.1, `DROP USER` deletes only MySQL accounts that have no privileges. In these MySQL versions, it serves only to remove each account record from the `user` table. To remove a MySQL account completely (including all of its privileges), you should use the following procedure, performing these steps in the order shown:

1. Use `SHOW GRANTS` to determine what privileges the account has. See Section 13.5.4.12, “`SHOW GRANTS` Syntax”.
2. Use `REVOKE` to revoke the privileges displayed by `SHOW GRANTS`. This removes rows for the account from all the grant tables except the `user` table, and revokes any global privileges listed in the `user` table. See Section 13.5.1.3, “`GRANT` Syntax”.
3. Delete the account by using `DROP USER` to remove the `user` table record.

*Important:* `DROP USER` does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. *This is by design.*

### 13.5.1.3. GRANT Syntax

```
GRANT priv_type [(column_list)] [, priv_type [(column_list)]] ...
  ON [object_type] {tbl_name | * | *.* | db_name.*}
  TO user [IDENTIFIED BY [PASSWORD] 'password']
      [, user [IDENTIFIED BY [PASSWORD] 'password']] ...
  [REQUIRE
    NONE |
    [{SSL | X509}]
    [CIPHER 'cipher' [AND]]
    [ISSUER 'issuer' [AND]]
    [SUBJECT 'subject']]
  [WITH with_option [with_option] ...]
```

```
object_type =
  TABLE
  | FUNCTION
  | PROCEDURE
```

```
with_option =
  GRANT OPTION
  | MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
```

The `GRANT` statement enables system administrators to create MySQL user accounts and to grant rights to from accounts. To use `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting. The `REVOKE` statement is related and enables administrators to remove account privileges. See Section 13.5.1.5, “`REVOKE` Syntax”.

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in Chapter 5, *Database Administration*, which you should consult for additional details.

**Important:** Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a non-zero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

Privileges can be granted at several levels:

- **Global level**

Global privileges apply to all databases on a given server. These privileges are stored in the `mysql.user` table. `GRANT ALL ON *.*` and `REVOKE ALL ON *.*` grant and revoke only global privileges.

- **Database level**

Database privileges apply to all objects in a given database. These privileges are stored in the `mysql.db` and `mysql.host` tables. `GRANT ALL ON db_name.*` and `REVOKE ALL ON db_name.*` grant and revoke only database privileges.

- **Table level**

Table privileges apply to all columns in a given table. These privileges are stored in the `mysql.tables_priv` table. `GRANT ALL ON db_name.tbl_name` and `REVOKE ALL ON db_name.tbl_name` grant and revoke only table privileges.

- **Column level**

Column privileges apply to single columns in a given table. These privileges are stored in the `mysql.columns_priv` table. When using `REVOKE`, you must specify the same columns that were granted.

- **Routine level**

The `CREATE ROUTINE`, `ALTER ROUTINE`, `EXECUTE`, and `GRANT` privileges apply to stored routines (functions and procedures). They can be granted at the global and database levels. Also, except for `CREATE ROUTINE`, these privileges can be granted at the routine level for individual routines and are stored in the `mysql.procs_priv` table.

The `object_type` clause was added in MySQL 5.0.6. It should be specified as `TABLE`, `FUNCTION`, or `PROCEDURE` when the following object is a table, a stored function, or a stored procedure.

For the `GRANT` and `REVOKE` statements, `priv_type` can be specified as any of the following:

Privilege	Meaning
<code>ALL [PRIVILEGES]</code>	Sets all simple privileges except <code>GRANT OPTION</code>
<code>ALTER</code>	Enables use of <code>ALTER TABLE</code>
<code>ALTER ROUTINE</code>	Enables stored routines to be altered or dropped
<code>CREATE</code>	Enables use of <code>CREATE TABLE</code>

CREATE ROUTINE	Enables creation of stored routines
CREATE TEMPORARY TABLES	Enables use of CREATE TEMPORARY TABLE
CREATE USER	Enables use of CREATE USER, DROP USER, RENAME USER, and REVOKE ALL PRIVILEGES.
CREATE VIEW	Enables use of CREATE VIEW
DELETE	Enables use of DELETE
DROP	Enables use of DROP TABLE
EXECUTE	Enables the user to run stored routines
FILE	Enables use of SELECT . . . INTO OUTFILE and LOAD DATA INFILE
INDEX	Enables use of CREATE INDEX and DROP INDEX
INSERT	Enables use of INSERT
LOCK TABLES	Enables use of LOCK TABLES on tables for which you have the SELECT privilege
PROCESS	Enables use of SHOW FULL PROCESSLIST
REFERENCES	Not implemented
RELOAD	Enables use of FLUSH
REPLICATION CLIENT	Enables the user to ask where slave or master servers are
REPLICATION SLAVE	Needed for replication slaves (to read binary log events from the master)
SELECT	Enables use of SELECT
SHOW DATABASES	SHOW DATABASES shows all databases
SHOW VIEW	Enables use of SHOW CREATE VIEW
SHUTDOWN	Enables use of mysqladmin shutdown
SUPER	Enables use of CHANGE MASTER, KILL, PURGE MASTER LOGS, and SET GLOBAL statements, the mysqladmin debug command; allows you to connect (once) even if max_connections is reached
UPDATE	Enables use of UPDATE
USAGE	Synonym for “no privileges”
GRANT OPTION	Enables privileges to be granted

The EXECUTE privilege is not operational until MySQL 5.0.3. CREATE VIEW and SHOW VIEW were added in MySQL 5.0.1. CREATE USER, CREATE ROUTINE, and ALTER ROUTINE were added in MySQL 5.0.3.

The REFERENCES privilege currently is unused.

USAGE can be specified when you want to create a user that has no privileges.

Use SHOW GRANTS to determine what privileges an account has. See Section 13.5.4.12, “SHOW GRANTS Syntax”.

You can assign global privileges by using ON \*.\* syntax or database-level privileges by using ON db\_name.\* syntax. If you specify ON \* and you have selected a default database, the privileges are granted in that database. (**Warning:** If you specify ON \* and you have *not* selected a default database, the privileges granted are global.)

The FILE, PROCESS, RELOAD, REPLICATION CLIENT, REPLICATION SLAVE, SHOW DATABASES, SHUTDOWN, and SUPER privileges are administrative privileges that can only be granted globally (using ON \*.\* syntax).

Other privileges can be granted globally or at more specific levels.

The *priv\_type* values that you can specify for a table are SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, GRANT OPTION, INDEX, ALTER, CREATE VIEW and SHOW VIEW.

The *priv\_type* values that you can specify for a column (that is, when you use a *column\_list* clause) are SELECT, INSERT, and UPDATE.

The *priv\_type* values that you can specify at the routine level are ALTER ROUTINE, EXECUTE, and GRANT OPTION. CREATE ROUTINE is not a routine-level privilege because you must have this privilege to create a routine in the first place.

For the global, database, table, and routine levels, GRANT ALL assigns only the privileges that exist at the level you are granting. For example, GRANT ALL ON *db\_name*.\* is a database-level statement, so it does not grant any global-only privileges such as FILE.

MySQL allows you to grant privileges even on database objects that do not exist. In such cases, the privileges to be granted must include the CREATE privilege. *This behavior is by design*, and is intended to enable the database administrator to prepare user accounts and privileges for database objects that are to be created at a later time.

**Important:** *MySQL does not automatically revoke any privileges when you drop a table or database.* However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

**Note:** the '\_' and '%' wildcards are allowed when specifying database names in GRANT statements that grant privileges at the global or database levels. This means, for example, that if you want to use a '\_' character as part of a database name, you should specify it as '\\_' in the GRANT statement, to prevent the user from being able to access additional databases matching the wildcard pattern; for example, GRANT ... ON `foo\\_bar`.\* TO ....

To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the *user* value in the form *user\_name@host\_name*. If a *user\_name* or *host\_name* value is legal as an unquoted identifier, you need not quote it. However, quotes are necessary to specify a *user\_name* string containing special characters (such as '-'), or a *host\_name* string containing special characters or wildcard characters (such as '%'); for example, 'test-user'@'test-hostname'. Quote the username and hostname separately.

You can specify wildcards in the hostname. For example, *user\_name*@'%.loc.gov' applies to *user\_name* for any host in the loc.gov domain, and *user\_name*@'144.155.166.%' applies to *user\_name* for any host in the 144.155.166 class C subnet.

The simple form *user\_name* is a synonym for *user\_name*@'%'.

*MySQL does not support wildcards in usernames.* Anonymous users are defined by inserting entries with User='' into the mysql.user table or by creating a user with an empty name with the GRANT statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...
```

When specifying quoted values, quote database, table, column, and routine names as identifiers, using backticks ('`'). Quote hostnames, usernames, and passwords as strings, using single quotes ('').

**Warning:** If you allow anonymous users to connect to the MySQL server, you should also grant privileges to all local users as *user\_name*@localhost. Otherwise, the anonymous user account for localhost in the mysql.user table (created during MySQL installation) is used when named users try to log in to the MySQL server from the local machine. For details, see Section 5.8.5, "Access Control, Stage 1: Connection Verification".

You can determine whether this applies to you by executing the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

If you want to delete the local anonymous user account to avoid the problem just described, use these statements:

```
DELETE FROM mysql.user WHERE Host='localhost' AND User='';
FLUSH PRIVILEGES;
```

GRANT supports hostnames up to 60 characters long. Database, table, column, and routine names can be up to 64 characters. Usernames can be up to 16 characters. **Note:** *The allowable length for usernames cannot be changed by altering the `mysql.user` table, and attempting to do so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server.* You should never alter any of the tables in the `mysql` database in any manner whatsoever except by means of the procedure prescribed by MySQL AB that is described in Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

The privileges for a table, column, or routine are formed additively as the logical OR of the privileges at each of the privilege levels. For example, if the `mysql.user` table specifies that a user has a global SELECT privilege, the privilege cannot be denied by an entry at the database, table, or column level.

The privileges for a column can be calculated as follows:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

In most cases, you grant rights to a user at only one of the privilege levels, so life is not normally this complicated. The details of the privilege-checking procedure are presented in Section 5.8, “The MySQL Access Privilege System”.

If you grant privileges for a username/hostname combination that does not exist in the `mysql.user` table, an entry is added and remains there until deleted with a DELETE statement. In other words, GRANT may create user table entries, but REVOKE does not remove them; you must do that explicitly using DROP USER or DELETE.

**Warning:** If you create a new user but do not specify an IDENTIFIED BY clause, the user has no password. This is very insecure. As of MySQL 5.0.2, you can enable the NO\_AUTO\_CREATE\_USER SQL mode to prevent GRANT from creating a new user if it would otherwise do so, unless IDENTIFIED BY is given to provide the new user a non-empty password.

If a new user is created or if you have global grant privileges, the user's password is set to the password specified by the IDENTIFIED BY clause, if one is given. If the user already had a password, this is replaced by the new one.

Passwords can also be set with the SET PASSWORD statement. See Section 13.5.1.6, “SET PASSWORD Syntax”.

In the IDENTIFIED BY clause, the password should be given as the literal password value. It is unnecessary to use the PASSWORD( ) function as it is for the SET PASSWORD statement. For example:

```
GRANT ... IDENTIFIED BY 'mypass';
```

If you do not want to send the password in clear text and you know the hashed value that PASSWORD( ) would return for the password, you can specify the hashed value preceded by the keyword PASSWORD:

```
GRANT ...
```

```
IDENTIFIED BY PASSWORD '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4' ;
```

In a C program, you can get the hashed value by using the `make_scrambled_password()` C API function.

If you grant privileges for a database, an entry in the `mysql.db` table is created if needed. If all privileges for the database are removed with `REVOKE`, this entry is deleted.

The `SHOW DATABASES` privilege enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `-skip-show-database` option.

If a user has no privileges for a table, the table name is not displayed when the user requests a list of tables (for example, with a `SHOW TABLES` statement).

The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level. You should be careful to whom you give the `GRANT OPTION` privilege, because two users with different privileges may be able to join privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a non-administrative user, you should not grant the `ALTER` privilege globally or for the `mysql` database. If you do that, the user can try to subvert the privilege system by renaming tables!

The `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`, and `MAX_CONNECTIONS_PER_HOUR count` options limit the number of queries, updates, and logins a user can perform during any given one-hour period. If `count` is 0 (the default), this means that there is no limitation for that user.

The `MAX_USER_CONNECTIONS count` option, implemented in MySQL 5.0.3, limits the maximum number of simultaneous connections that the account can make. If `count` is 0 (the default), the `max_user_connections` system variable determines the number of simultaneous connections for the account.

Note: To specify any of these resource-limit options for an existing user without affecting existing privileges, use `GRANT USAGE ON *.* ... WITH MAX_...`

See Section 5.9.4, “Limiting Account Resources”.

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the username and password. To specify SSL-related options for a MySQL account, use the `REQUIRE` clause of the `GRANT` statement. (For background information on the use of SSL with MySQL, see Section 5.9.7, “Using Secure Connections”.)

There are a number of different possibilities for limiting connection types for a given account:

- If the account has no SSL or X509 requirements, unencrypted connections are allowed if the username and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files.
- The `REQUIRE SSL` option tells the server to allow only SSL-encrypted connections for the account. Note that this option can be omitted if there are any access-control rows that allow non-SSL connections.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret' REQUIRE SSL;
```

- REQUIRE X509 means that the client must have a valid certificate but that the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret' REQUIRE X509;
```

- REQUIRE ISSUER '*issuer*' places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA '*issuer*'. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the SSL option is unnecessary in this case.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE ISSUER '/C=FI/ST=Some-State/L=Helsinki/
  O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com';
```

Note that the '*issuer*' value should be entered as a single string.

- REQUIRE SUBJECT '*subject*' places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject *subject*. If the client presents a certificate that is valid but has a different subject, the server rejects the connection.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
  O=MySQL demo client certificate/
  CN=Tonu Samuel/Email=tonu@example.com';
```

Note that the '*subject*' value should be entered as a single string.

- REQUIRE CIPHER '*cipher*' is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used. Using this option, you can ask that a specific cipher method is used to allow a connection.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The SUBJECT, ISSUER, and CIPHER options can be combined in the REQUIRE clause like this:

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret'
  REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
  O=MySQL demo client certificate/
  CN=Tonu Samuel/Email=tonu@example.com'
  AND ISSUER '/C=FI/ST=Some-State/L=Helsinki/
  O=MySQL Finland AB/CN=Tonu Samuel/Email=tonu@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The AND keyword is optional between REQUIRE options.

The order of the options does not matter, but no option can be specified twice.

When mysqld starts, all privileges are read into memory. For details, see Section 5.8.7, “When Privilege Changes Take Effect”.

Note that if you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

The biggest differences between the standard SQL and MySQL versions of `GRANT` are:

- In MySQL, privileges are associated with the combination of a hostname and username and not with only a username.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL `TRIGGER` or `UNDER` privileges.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL 5.0.2 and up if you use `DROP USER`. Before 5.0.2, the granted privileges are not automatically revoked; you must revoke them yourself. See Section 13.5.1.2, “`DROP USER` Syntax”.
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped only with explicit `REVOKE` statements or by manipulating values stored in the MySQL grant tables.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you omit those columns for which you do not have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) Section 5.2.5, “The Server SQL Mode”, discusses strict mode. Section 11.1.4, “Data Type Default Values”, discusses implicit default values.

### 13.5.1.4. RENAME USER Syntax

```
RENAME USER old_user TO new_user
      [, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. To use it, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database. An error occurs if any old account does not exist or any new account exists. Each account is named using the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. The user and host parts of the account name correspond to the `User` and `Host` column values of the `user` table row for the account.

The `RENAME USER` statement was added in MySQL 5.0.2.

### 13.5.1.5. REVOKE Syntax

```
REVOKE priv_type [(column_list)] [, priv_type [(column_list)]] ...
      ON [object_type] {tbl_name | * | *.* | db_name.*}
      FROM user [, user] ...
```

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

The `REVOKE` statement enables system administrators to revoke privileges from MySQL accounts. To use `REVOKE`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

For details on the levels at which privileges exist, the allowable *priv\_type* values, and the syntax for specifying users and passwords, see Section 13.5.1.3, “GRANT Syntax”

If the grant tables hold privilege rows that contain mixed-case database or table names and the *lower\_case\_table\_names* system variable is set to a non-zero value, REVOKE cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (GRANT will not create such rows when *lower\_case\_table\_names* is set, but such rows might have been created prior to setting the variable.)

To revoke all privileges, use the following syntax, which drops all global, database-, table-, and column-level privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this REVOKE syntax, you must have the global CREATE USER privilege or the UPDATE privilege for the *mysql* database.

### 13.5.1.6. SET PASSWORD Syntax

```
SET PASSWORD [FOR user] = PASSWORD('some password')
```

The SET PASSWORD statement assigns a password to an existing MySQL user account.

With no FOR clause, this statement sets the password for the current user. Any client that has connected to the server using a non-anonymous account can change the password for that account.

With a FOR clause, this statement sets the password for a specific account on the current server host. Only clients that have the UPDATE privilege for the *mysql* database can do this. The *user* value should be given in *user\_name@host\_name* format, where *user\_name* and *host\_name* are exactly as they are listed in the User and Host columns of the *mysql.user* table entry. For example, if you had an entry with User and Host column values of 'bob' and '%.loc.gov', you would write the statement like this:

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');
```

That is equivalent to the following statements:

```
UPDATE mysql.user SET Password=PASSWORD('newpass')
  WHERE User='bob' AND Host='%.loc.gov';
FLUSH PRIVILEGES;
```

**Note:** If you are connecting to a MySQL 4.1 or later server using a pre-4.1 client program, do not use the preceding SET PASSWORD or UPDATE statement without reading Section 5.8.9, “Password Hashing as of MySQL 4.1”, first. The password format changed in MySQL 4.1, and under certain circumstances it is possible that if you change your password, you might not be able to connect to the server afterward.

You can see which account the server authenticated you as by executing SELECT CURRENT\_USER().

## 13.5.2. Table Maintenance Statements

### 13.5.2.1. ANALYZE TABLE Syntax

```
ANALYZE [LOCAL | NO_WRITE_TO_BINLOG] TABLE tbl_name [, tbl_name] ...
```

ANALYZE TABLE analyzes and stores the key distribution for a table. During the analysis, the table is locked with a read lock. This statement works with MyISAM, BDB, and InnoDB tables. For My-

ISAM tables, this statement is equivalent to using `myisamchk --analyze`.

MySQL uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant.

This statement requires `SELECT` and `INSERT` privileges for the table.

`ANALYZE TABLE` returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always analyze
Msg_type	One of status, error, info, or warning
Msg_text	The message

You can check the stored key distribution with the `SHOW INDEX` statement. See Section 13.5.4.13, “`SHOW INDEX Syntax`”.

If the table has not changed since the last `ANALYZE TABLE` statement, the table is not analyzed again.

`ANALYZE TABLE` statements are written to the binary log unless the optional `NO_WRITE_TO_BINLOG` keyword (or its alias `LOCAL`) is used. This is done so that `ANALYZE TABLE` statements used on a MySQL server acting as a replication master will be replicated by default to the replication slave.

### 13.5.2.2. BACKUP TABLE Syntax

```
BACKUP TABLE tbl_name [, tbl_name] ... TO '/path/to/backup/directory'
```

**Note:** This statement is deprecated. We are working on a better replacement for it that will provide online backup capabilities. In the meantime, the `mysqlhotcopy` script can be used instead.

`BACKUP TABLE` copies to the backup directory the minimum number of table files needed to restore the table, after flushing any buffered changes to disk. The statement works only for `MyISAM` tables. It copies the `.frm` definition and `.MYD` data files. The `.MYI` index file can be rebuilt from those two files. The directory should be specified as a full pathname. To restore the table, use `RESTORE TABLE`.

During the backup, a read lock is held for each table, one at a time, as they are being backed up. If you want to back up several tables as a snapshot (preventing any of them from being changed during the backup operation), issue a `LOCK TABLES` statement first, to obtain a read lock for all tables in the group.

`BACKUP TABLE` returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always backup
Msg_type	One of status, error, info, or warning
Msg_text	The message

### 13.5.2.3. CHECK TABLE Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
```

```
option = {FOR UPGRADE | QUICK | FAST | MEDIUM | EXTENDED | CHANGED}
```

`CHECK TABLE` checks a table or tables for errors. `CHECK TABLE` works for MyISAM, InnoDB, and (as of MySQL 5.0.16) ARCHIVE tables. For MyISAM tables, the key statistics are updated as well.

As of MySQL 5.0.2, `CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

`CHECK TABLE` returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always check
Msg_type	One of status, error, info, or warning
Msg_text	The message

Note that the statement might produce many rows of information for each checked table. The last row has a `Msg_type` value of `status` and the `Msg_text` normally should be OK. If you don't get OK, or `Table` is already up to date you should normally run a repair of the table. See Section 5.10.4, "Table Maintenance and Crash Recovery". `Table is already up to date` means that the storage engine for the table indicated that there was no need to check the table.

The `FOR UPGRADE` option checks whether the named tables are compatible with the current version of MySQL. This option was added in MySQL 5.0.19. With `FOR UPGRADE`, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time). If the full check succeeds, the server marks the table's `.frm` file with the current MySQL version number. Marking the `.frm` file ensures that further checks for the table with the same version of the server will be fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

Currently, `FOR UPGRADE` discovers these incompatibilities:

- The indexing order for end-space in `TEXT` columns for InnoDB and MyISAM tables changed between MySQL 4.1 and 5.0.
- The storage method of the new `DECIMAL` data type changed between MySQL 5.0.3 and 5.0.5.

The other check options that can be given are shown in the following table. These options apply only to checking MyISAM tables and are ignored for InnoDB tables and views.

Type	Meaning
QUICK	Do not scan the rows to check for incorrect links.
FAST	Check only tables that have not been closed properly.
CHANGED	Check only tables that have been changed since the last check or that have not been closed properly.
MEDIUM	Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys.
EXTENDED	Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time.

If none of the options `QUICK`, `MEDIUM`, or `EXTENDED` are specified, the default check type for dynamic-format `MyISAM` tables is `MEDIUM`. This has the same result as running `myisamchk -medium-check tbl_name` on the table. The default check type also is `MEDIUM` for static-format `MyISAM` tables, unless `CHANGED` or `FAST` is specified. In that case, the default is `QUICK`. The row scan is skipped for `CHANGED` and `FAST` because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

**Note:** In some cases, `CHECK TABLE` changes the table. This happens if the table is marked as “corrupted” or “not closed properly” but `CHECK TABLE` does not find any problems in the table. In this case, `CHECK TABLE` marks the table as okay.

If a table is corrupted, it is most likely that the problem is in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

If you just want to check a table that you assume is okay, you should use no check options or the `QUICK` option. The latter should be used when you are in a hurry and can take the very small risk that `QUICK` does not find an error in the data file. (In most cases, under normal usage, `MySQL` should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

`FAST` and `CHANGED` are mostly intended to be used from a script (for example, to be executed from `cron`) if you want to check tables from time to time. In most cases, `FAST` is to be preferred over `CHANGED`. (The only case when it is not preferred is when you suspect that you have found a bug in the `MyISAM` code.)

`EXTENDED` is to be used only after you have run a normal check but still get strange errors from a table when `MySQL` tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Some problems reported by `CHECK TABLE` cannot be corrected automatically:

- Found row where the `auto_increment` column has the value 0.

This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an `UPDATE` statement.)

This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an `ALTER TABLE` on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

To get rid of the warning, simply execute an `UPDATE` statement to set the column to some value other than 0.

### 13.5.2.4. CHECKSUM TABLE Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

`CHECKSUM TABLE` reports a table checksum.

With `QUICK`, the live table checksum is reported if it is available, or `NULL` otherwise. This is very fast. A live checksum is enabled by specifying the `CHECKSUM=1` table option when you create the table; currently, this is supported only for `MyISAM` tables. See Section 13.1.5, “`CREATE TABLE` Syntax”.

With `EXTENDED`, the entire table is read row by row and the checksum is calculated. This can be very slow for large tables.

If neither `QUICK` nor `EXTENDED` is specified, MySQL returns a live checksum if the table storage engine supports it and scans the table otherwise.

For a non-existent table, `CHECKSUM TABLE` returns `NULL` and, as of MySQL 5.0.3, generates a warning.

### 13.5.2.5. OPTIMIZE TABLE Syntax

```
OPTIMIZE [LOCAL | NO_WRITE_TO_BINLOG] TABLE tbl_name [, tbl_name] ...
```

`OPTIMIZE TABLE` should be used if you have deleted a large part of a table or if you have made many changes to a table with variable-length rows (tables that have `VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT` columns). Deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file.

This statement requires `SELECT` and `INSERT` privileges for the table.

In most setups, you need not run `OPTIMIZE TABLE` at all. Even if you do a lot of updates to variable-length rows, it is not likely that you need to do this more than once a week or month and only on certain tables.

`OPTIMIZE TABLE` works only for MyISAM, BDB, and InnoDB tables.

For MyISAM tables, `OPTIMIZE TABLE` works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

For BDB tables, `OPTIMIZE TABLE` currently is mapped to `ANALYZE TABLE`. See Section 13.5.2.1, “`ANALYZE TABLE` Syntax”.

For InnoDB tables, `OPTIMIZE TABLE` is mapped to `ALTER TABLE`, which rebuilds the table to update index statistics and free unused space in the clustered index.

You can make `OPTIMIZE TABLE` work on other storage engines by starting `mysqld` with the `--skip-new` or `--safe-mode` option. In this case, `OPTIMIZE TABLE` is just mapped to `ALTER TABLE`.

`OPTIMIZE TABLE` returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always optimize
Msg_type	One of status, error, info, or warning
Msg_text	The message

Note that MySQL locks the table during the time `OPTIMIZE TABLE` is running.

`OPTIMIZE TABLE` statements are written to the binary log unless the optional `NO_WRITE_TO_BINLOG` keyword (or its alias `LOCAL`) is used. This is done so that `OPTIMIZE`

TABLE statements used on a MySQL server acting as a replication master will be replicated by default to the replication slave.

### 13.5.2.6. REPAIR TABLE Syntax

```
REPAIR [LOCAL | NO_WRITE_TO_BINLOG] TABLE
      tbl_name [, tbl_name] ... [QUICK] [EXTENDED] [USE_FRM]
```

REPAIR TABLE repairs a possibly corrupted table. By default, it has the same effect as `myisamchk --recover tbl_name`. REPAIR TABLE works for MyISAM and for ARCHIVE tables. See Section 14.1, “The MyISAM Storage Engine”, and Section 14.8, “The ARCHIVE Storage Engine”.

This statement requires SELECT and INSERT privileges for the table.

Normally, you should never have to run this statement. However, if disaster strikes, REPAIR TABLE is very likely to get back all your data from a MyISAM table. If your tables become corrupted often, you should try to find the reason for it, to eliminate the need to use REPAIR TABLE. See Section A.4.2, “What to Do If MySQL Keeps Crashing”, and Section 14.1.4, “MyISAM Table Problems”.

**Warning:** If the server dies during a REPAIR TABLE operation, it is essential after restarting it that you immediately execute another REPAIR TABLE statement for the table before performing any other operations on it. (It is always a good idea to start by making a backup.) In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario.

REPAIR TABLE returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always repair
Msg_type	One of status, error, info, or warning
Msg_text	The message

The REPAIR TABLE statement might produce many rows of information for each repaired table. The last row has a Msg\_type value of status and Msg\_text normally should be OK. If you do not get OK, you should try repairing the table with `myisamchk --safe-recover`. (REPAIR TABLE does not yet implement all the options of `myisamchk`.) With `myisamchk --safe-recover`, you can also use options that REPAIR TABLE does not support, such as `--max-record-length`.

If QUICK is given, REPAIR TABLE tries to repair only the index tree. This type of repair is like that done by `myisamchk --recover --quick`.

If you use EXTENDED, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

There is also a USE\_FRM mode available for REPAIR TABLE. Use this if the .MYI index file is missing or if its header is corrupted. In this mode, MySQL re-creates the .MYI file using information from the .frm file. This kind of repair cannot be done with `myisamchk`. **Note:** Use this mode *only* if you cannot use regular REPAIR modes. The .MYI header contains important table metadata (in particular, current AUTO\_INCREMENT value and Delete link) that are lost in REPAIR ... USE\_FRM. Don't use USE\_FRM if the table is compressed because this information is also stored in the .MYI file.

REPAIR TABLE statements are written to the binary log unless the optional NO\_WRITE\_TO\_BINLOG keyword (or its alias LOCAL) is used. This is done so that REPAIR TABLE statements used on a MySQL server acting as a replication master will be replicated by default to the replication slave.

### 13.5.2.7. RESTORE TABLE Syntax

```
RESTORE TABLE tbl_name [, tbl_name] ... FROM '/path/to/backup/directory'
```

RESTORE TABLE restores the table or tables from a backup that was made with BACKUP TABLE. Existing tables are not overwritten; if you try to restore over an existing table, an error occurs. Just as for BACKUP TABLE, RESTORE TABLE currently works only for MyISAM tables. The directory should be specified as a full pathname.

The backup for each table consists of its .frm format file and .MYD data file. The restore operation restores those files, and then uses them to rebuild the .MYI index file. Restoring takes longer than backing up due to the need to rebuild the indexes. The more indexes the table has, the longer it takes.

RESTORE TABLE returns a result set with the following columns:

Column	Value
Table	The table name
Op	Always restore
Msg_type	One of status, error, info, or warning
Msg_text	The message

### 13.5.3. SET Syntax

```
SET variable_assignment [, variable_assignment] ...
```

*variable\_assignment*:

```

  user_var_name = expr
  | [GLOBAL | SESSION] system_var_name = expr
  | [@@global. | @@session. | @@] system_var_name = expr
```

The SET statement assigns values to different types of variables that affect the operation of the server or your client. Older versions of MySQL employed SET OPTION, but this syntax is deprecated in favor of SET without OPTION.

This section describes use of SET for assigning values to system variables or user variables. For general information about these types of variables, see Section 5.2.2, “Server System Variables”, and Section 9.3, “User-Defined Variables”. System variables also can be set at server startup, as described in Section 5.2.3, “Using System Variables”.

Some variants of SET syntax are used in other contexts:

- SET PASSWORD assigns account passwords. See Section 13.5.1.6, “SET PASSWORD Syntax”.
- SET TRANSACTION ISOLATION LEVEL sets the isolation level for transaction processing. See Section 13.4.6, “SET TRANSACTION Syntax”.
- SET is used within stored routines to assign values to local routine variables. See Section 17.2.7.2, “Variable SET Statement”.

The following discussion shows the different SET syntaxes that you can use to set variables. The examples use the = assignment operator, but the := operator also is allowable.

A user variable is written as @*var\_name* and can be set as follows:

```
SET @var_name = expr;
```

Many system variables are dynamic and can be changed while the server runs by using the SET statement. For a list, see Section 5.2.3.2, “Dynamic System Variables”. To change a system variable with SET, refer to it as *var\_name*, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by GLOBAL or @@global.. The SUPER privilege is required to set global variables.
- To indicate explicitly that a variable is a session variable, precede its name by SESSION, @@session., or @@. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.
- LOCAL and @@local. are synonyms for SESSION and @@session..
- If no modifier is present, SET changes the session variable.

A SET statement can contain multiple variable assignments, separated by commas. If you set several system variables, the most recent GLOBAL or SESSION modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

When you assign a value to a system variable with SET, you cannot use suffix letters in the value (as can be done with startup options). However, the value can take the form of an expression:

```
SET sort_buffer_size = 10 * 1024 * 1024;
```

The @@*var\_name* syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the SET GLOBAL statement).

To prevent incorrect usage, MySQL produces an error if you use SET GLOBAL with a variable that can only be used with SET SESSION or if you do not specify GLOBAL (or @@global.) when setting a global variable.

To set a SESSION variable to the GLOBAL value or a GLOBAL value to the compiled-in MySQL default value, use the DEFAULT keyword. For example, the following two statements are identical in setting the session value of max\_join\_size to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to DEFAULT. In such cases, use of DEFAULT results in an error.

You can refer to the values of specific global or session system variables in expressions by using one

of the @@-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as `@@var_name` (that is, when you do not specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. (This differs from `SET @@var_name = value`, which always refers to the session value.)

To display system variables names and values, use the `SHOW VARIABLES` statement. (See Section 13.5.4.24, “`SHOW VARIABLES` Syntax”.)

The following list describes options that have non-standard syntax or that are not described in the list of system variables found in Section 5.2.2, “Server System Variables”. Although the options described here are not displayed by `SHOW VARIABLES`, you can obtain their values with `SELECT` (with the exception of `CHARACTER SET` and `SET NAMES`). For example:

```
mysql> SELECT @@AUTOCOMMIT;
+-----+
| @@AUTOCOMMIT |
+-----+
|              1 |
+-----+
```

The lettercase of these options does not matter.

- `AUTOCOMMIT = {0 | 1}`

Set the autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0 you have to use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. By default, client connections begin with `AUTOCOMMIT` set to 1. If you change `AUTOCOMMIT` mode from 0 to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See Section 13.4.1, “`START TRANSACTION, COMMIT, and ROLLBACK` Syntax”.

- `BIG_TABLES = {0 | 1}`

If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). Normally, you should never need to set this variable, because in-memory tables are automatically converted to disk-based tables as required. (**Note:** This variable was formerly named `SQL_BIG_TABLES`.)

- `CHARACTER SET {charset_name | DEFAULT}`

This maps all strings from and to the client with the given mapping. You can add new mappings by editing `sql/convert.cc` in the MySQL source distribution. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See Section 10.4, “Connection Character Sets and Collations”.

The default mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

Note that the syntax for `SET CHARACTER SET` differs from that for setting most other options.

- `FOREIGN_KEY_CHECKS = {0 | 1}`

If set to 1 (the default), foreign key constraints for InnoDB tables are checked. If set to 0, they are ignored. Disabling foreign key checking can be useful for reloading InnoDB tables in an order different from that required by their parent/child relationships. See Section 14.2.6.4, “FOREIGN KEY Constraints”.

- `IDENTITY = value`

This variable is a synonym for the `LAST_INSERT_ID` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@IDENTITY`, and set it using `SET IDENTITY`.

- `INSERT_ID = value`

Set the value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `LAST_INSERT_ID = value`

Set the value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `NAMES {'charset_name' | DEFAULT}`

`SET NAMES` sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. See Section 10.4, “Connection Character Sets and Collations”.

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

Note that the syntax for `SET NAMES` differs from that for setting most other options.

- `ONE_SHOT`

This option is a modifier, not a variable. It can be used to influence the effect of variables that set the character set, the collation, and the time zone. `ONE_SHOT` is primarily used for replication purposes: `mysqlbinlog` uses `SET ONE_SHOT` to modify temporarily the values of character set, collation, and time zone variables to reflect at rollforward what they were originally. `ONE_SHOT` is available as of MySQL 5.0.

You cannot use `ONE_SHOT` with other than the allowed set of variables; if you try, you get an error like this:

```
mysql> SET ONE_SHOT max_allowed_packet = 1;
ERROR 1382 (HY000): The 'SET ONE_SHOT' syntax is reserved for purposes
internal to the MySQL server
```

If `ONE_SHOT` is used with the allowed variables, it changes the variables as requested, but only for the next non-`SET` statement. After that, the server resets all character set, collation, and time zone-related system variables to their previous values. Example:

```
mysql> SET ONE_SHOT character_set_connection = latin5;

mysql> SET ONE_SHOT collation_connection = latin5_turkish_ci;

mysql> SHOW VARIABLES LIKE '%_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_connection | latin5 |
+-----+-----+
```

```
| collation_connection | latin5_turkish_ci |
+-----+-----+
mysql> SHOW VARIABLES LIKE '%_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_connection | latin1 |
| collation_connection | latin1_swedish_ci |
+-----+-----+
```

- `SQL_AUTO_IS_NULL = {0 | 1}`

If set to 1 (the default), you can find the last inserted row for a table that contains an `AUTO_INCREMENT` column by using the following construct:

```
WHERE auto_increment_column IS NULL
```

This behavior is used by some ODBC programs, such as Access.

- `SQL_BIG_SELECTS = {0 | 1}`

If set to 0, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is 1, which allows all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `SQL_BIG_SELECTS` is set to 0.

- `SQL_BUFFER_RESULT = {0 | 1}`

If set to 1, `SQL_BUFFER_RESULT` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is 0.

- `SQL_LOG_BIN = {0 | 1}`

If set to 0, no logging is done to the binary log for the client. The client must have the `SUPER` privilege to set this option. The default value is 1.

- `SQL_LOG_OFF = {0 | 1}`

If set to 1, no logging is done to the general query log for this client. The client must have the `SUPER` privilege to set this option. The default value is 0.

- `SQL_LOG_UPDATE = {0 | 1}`

This variable is deprecated, and is mapped to `SQL_LOG_BIN`.

- `SQL_NOTES = {0 | 1}`

If set to 1 (the default), warnings of `Note` level are recorded. If set to 0, `Note` warnings are suppressed. `mysqldump` includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation. `SQL_NOTES` was added in MySQL 5.0.3.

- `SQL_QUOTE_SHOW_CREATE = {0 | 1}`

If set to 1 (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If set to 0, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See Section 13.5.4.6, “`SHOW CREATE TABLE` Syntax”, and Section 13.5.4.4, “`SHOW CREATE DATABASE` Syntax”.

- `SQL_SAFE_UPDATES = {0 | 1}`

If set to 1, MySQL aborts `UPDATE` or `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause. This makes it possible to catch `UPDATE` or `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is 0.

- `SQL_SELECT_LIMIT = {value | DEFAULT}`

The maximum number of rows to return from `SELECT` statements. The default value for a new connection is “unlimited.” If you have changed the limit, the default value can be restored by using a `SQL_SELECT_LIMIT` value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `SQL_SELECT_LIMIT`.

`SQL_SELECT_LIMIT` does not apply to `SELECT` statements executed within stored routines. It also does not apply to `SELECT` statements that do not produce a result set to be returned to the client. These include `SELECT` statements in subqueries, `CREATE TABLE ... SELECT`, and `INSERT INTO ... SELECT`.

- `SQL_WARNINGS = {0 | 1}`

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string.

- `TIMESTAMP = {timestamp_value | DEFAULT}`

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. `timestamp_value` should be a Unix epoch timestamp, not a MySQL timestamp.

`SET TIMESTAMP` affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`, in which case `SET TIMESTAMP` affects both functions.

- `UNIQUE_CHECKS = {0 | 1}`

If set to 1 (the default), uniqueness checks for secondary indexes in InnoDB tables are performed. If set to 0, storage engines are allowed to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to InnoDB.

Note that setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still allowed to check for them and issue duplicate-key errors if it detects them.

## 13.5.4. SHOW Syntax

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [LIKE 'pattern']
SHOW CREATE DATABASE db_name
SHOW CREATE FUNCTION funcname
SHOW CREATE PROCEDURE procname
SHOW CREATE TABLE tbl_name
SHOW DATABASES [LIKE 'pattern']
SHOW ENGINE engine_name {LOGS | STATUS }
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW FUNCTION STATUS [LIKE 'pattern']
SHOW GRANTS FOR user
```

```
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW INNODB STATUS
SHOW PROCEDURE STATUS [LIKE 'pattern']
SHOW [BDB] LOGS
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW [GLOBAL | SESSION] STATUS [LIKE 'pattern']
SHOW TABLE STATUS [FROM db_name] [LIKE 'pattern']
SHOW [OPEN] TABLES [FROM db_name] [LIKE 'pattern']
SHOW TRIGGERS
SHOW [GLOBAL | SESSION] VARIABLES [LIKE 'pattern']
SHOW WARNINGS [LIMIT [offset,] row_count]
```

The SHOW statement also has forms that provide information about replication master and slave servers and are described in Section 13.6, “Replication Statements”:

```
SHOW BINLOG EVENTS
SHOW MASTER LOGS
SHOW MASTER STATUS
SHOW SLAVE HOSTS
SHOW SLAVE STATUS
```

If the syntax for a given SHOW statement includes a LIKE '*pattern*' part, '*pattern*' is a string that can contain the SQL '%' and '\_' wildcard characters. The pattern is useful for restricting statement output to matching values.

Several SHOW statements also accept a WHERE clause that provides more flexibility in specifying which rows to display. See Section 20.18, “Extensions to SHOW Statements”.

### 13.5.4.1. SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET [LIKE 'pattern']
```

The SHOW CHARACTER SET statement shows all available character sets. It takes an optional LIKE clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
```

Charset	Description	Default collation	Maxlen
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1

The Maxlen column shows the maximum number of bytes required to store one character.

### 13.5.4.2. SHOW COLLATION Syntax

```
SHOW COLLATION [LIKE 'pattern']
```

The output from SHOW COLLATION includes all available character sets. It takes an optional LIKE clause whose *pattern* indicates which collation names to match. For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_german1_ci	latin1	5			0
latin1_swedish_ci	latin1	8	Yes	Yes	0
latin1_danish_ci	latin1	15			0

latin1_german2_ci	latin1	31		Yes	2
latin1_bin	latin1	47		Yes	0
latin1_general_ci	latin1	48			0
latin1_general_cs	latin1	49			0
latin1_spanish_ci	latin1	94			0

The Default column indicates whether a collation is the default for its character set. Compiled indicates whether the character set is compiled into the server. Sortlen is related to the amount of memory required to sort strings expressed in the character set.

### 13.5.4.3. SHOW COLUMNS Syntax

```
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [LIKE 'pattern']
```

SHOW COLUMNS displays information about the columns in a given table. It also works for views as of MySQL 5.0.1.

If the data types differ from what you expect them to be based on your CREATE TABLE statement, note that MySQL sometimes changes data types when you create or alter a table. The conditions for which this occurs are described in Section 13.1.5.1, “Silent Column Specification Changes”.

The FULL keyword causes the output to include the privileges you have as well as any per-column comments for each column.

You can use *db\_name.tbl\_name* as an alternative to the *tbl\_name* FROM *db\_name* syntax. In other words, these two statements are equivalent:

```
mysql> SHOW COLUMNS FROM mytable FROM mydb;
mysql> SHOW COLUMNS FROM mydb.mytable;
```

SHOW FIELDS is a synonym for SHOW COLUMNS. You can also list a table's columns with the mysqlshow *db\_name tbl\_name* command.

The DESCRIBE statement provides information similar to SHOW COLUMNS. See Section 13.3.1, “DESCRIBE Syntax”.

### 13.5.4.4. SHOW CREATE DATABASE Syntax

```
SHOW CREATE {DATABASE | SCHEMA} db_name
```

Shows the CREATE DATABASE statement that creates the given database. SHOW CREATE SCHEMA is a synonym for SHOW CREATE DATABASE as of MySQL 5.0.2.

```
mysql> SHOW CREATE DATABASE test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */

mysql> SHOW CREATE SCHEMA test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */
```

SHOW CREATE DATABASE quotes table and column names according to the value of the SQL\_QUOTE\_SHOW\_CREATE option. See Section 13.5.3, “SET Syntax”.

### 13.5.4.5. SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION

## Syntax

```
SHOW CREATE {PROCEDURE | FUNCTION} sp_name
```

This statement is a MySQL extension. Similar to `SHOW CREATE TABLE`, it returns the exact string that can be used to re-create the named routine.

```
mysql> SHOW CREATE FUNCTION test.hello\G
***** 1. row *****
      Function: hello
      sql_mode:
Create Function: CREATE FUNCTION `test`.`hello`(s CHAR(20)) RETURNS CHAR(50)
                RETURN CONCAT('Hello, ',s, '!')
```

### 13.5.4.6. SHOW CREATE TABLE Syntax

```
SHOW CREATE TABLE tbl_name
```

Shows the `CREATE TABLE` statement that creates the given table. As of MySQL 5.0.1, this statement also works with views.

```
mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE t (
  id INT(11) default NULL auto_increment,
  s char(60) default NULL,
  PRIMARY KEY (id)
) ENGINE=MyISAM
```

`SHOW CREATE TABLE` quotes table and column names according to the value of the `SQL_QUOTE_SHOW_CREATE` option. See Section 13.5.3, “SET Syntax”.

### 13.5.4.7. SHOW CREATE VIEW Syntax

```
SHOW CREATE VIEW view_name
```

This statement shows a `CREATE VIEW` statement that creates the given view.

```
mysql> SHOW CREATE VIEW v;
+-----+-----+
| View | Create View |
+-----+-----+
| v    | CREATE VIEW `test`.`v` AS select 1 AS `a`,2 AS `b` |
+-----+-----+
```

This statement was added in MySQL 5.0.1.

Prior to MySQL 5.0.11, the output columns from this statement were shown as `Table` and `Create Table`.

You can also obtain information about view objects from `INFORMATION_SCHEMA`, which contains a `VIEWS` table. See Section 20.15, “The `INFORMATION_SCHEMA VIEWS` Table”.

### 13.5.4.8. SHOW DATABASES Syntax

```
SHOW {DATABASES | SCHEMAS} [LIKE 'pattern']
```

SHOW DATABASES lists the databases on the MySQL server host. SHOW SCHEMAS is a synonym for SHOW DATABASES as of MySQL 5.0.2.

You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the SHOW DATABASES privilege.

### 13.5.4.9. SHOW ENGINE Syntax

```
SHOW ENGINE engine_name {LOGS | STATUS }
```

SHOW ENGINE displays log or status information about a storage engine. The following statements currently are supported:

```
SHOW ENGINE BDB LOGS
SHOW ENGINE INNODB STATUS
```

SHOW ENGINE BDB LOGS displays status information about existing BDB log files. It returns the following fields:

- `File`  
The full path to the log file.
- `Type`  
The log file type (BDB for Berkeley DB log files).
- `Status`  
The status of the log file (`FREE` if the file can be removed, or `IN USE` if the file is needed by the transaction subsystem)

SHOW ENGINE INNODB STATUS displays extensive information about the state of the InnoDB storage engine.

The InnoDB Monitors provide additional information about InnoDB processing. See Section 14.2.11.1, “SHOW ENGINE INNODB STATUS and the InnoDB Monitors”.

Older (and now deprecated) synonyms for these statements are SHOW [BDB] LOGS and SHOW INNODB STATUS.

### 13.5.4.10. SHOW ENGINES Syntax

```
SHOW [STORAGE] ENGINES
```

SHOW ENGINES displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. SHOW TABLE TYPES is a deprecated synonym.

```
mysql> SHOW ENGINES\G
***** 1. row *****
  Engine: MyISAM
  Support: DEFAULT
  Comment: Default engine as of MySQL 3.23 with great performance
***** 2. row *****
  Engine: MEMORY
```

```

Support: YES
Comment: Hash based, stored in memory, useful for temporary tables
***** 3. row *****
  Engine: HEAP
Support: YES
Comment: Alias for MEMORY
***** 4. row *****
  Engine: MERGE
Support: YES
Comment: Collection of identical MyISAM tables
***** 5. row *****
  Engine: MRG_MYISAM
Support: YES
Comment: Alias for MERGE
***** 6. row *****
  Engine: ISAM
Support: NO
Comment: Obsolete storage engine, now replaced by MyISAM
***** 7. row *****
  Engine: MRG_ISAM
Support: NO
Comment: Obsolete storage engine, now replaced by MERGE
***** 8. row *****
  Engine: InnoDB
Support: YES
Comment: Supports transactions, row-level locking, and foreign keys
***** 9. row *****
  Engine: INNODB
Support: YES
Comment: Alias for INNODB
***** 10. row *****
  Engine: BDB
Support: YES
Comment: Supports transactions and page-level locking
***** 11. row *****
  Engine: BERKELEYDB
Support: YES
Comment: Alias for BDB
***** 12. row *****
  Engine: NDBCLUSTER
Support: NO
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
  Engine: NDB
Support: NO
Comment: Alias for NDBCLUSTER
***** 14. row *****
  Engine: EXAMPLE
Support: NO
Comment: Example storage engine
***** 15. row *****
  Engine: ARCHIVE
Support: YES
Comment: Archive storage engine
***** 16. row *****
  Engine: CSV
Support: NO
Comment: CSV storage engine
***** 17. row *****
  Engine: FEDERATED
Support: YES
Comment: Federated MySQL storage engine
***** 18. row *****
  Engine: BLACKHOLE
Support: YES
Comment: /dev/null storage engine (anything you write to it disappears)

```

The Support value indicates whether the particular storage engine is supported, and which is the default engine. For example, if the server is started with the `--default-table-type=InnoDB`

option, the `Support` value for the `InnoDB` row has the value `DEFAULT`. See Chapter 14, *Storage Engines and Table Types*.

### 13.5.4.11. SHOW ERRORS Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]  
SHOW COUNT(*) ERRORS
```

This statement is similar to `SHOW WARNINGS`, except that instead of displaying errors, warnings, and notes, it displays only errors.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.7, “`SELECT` Syntax”.

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```
SHOW COUNT(*) ERRORS;  
SELECT @@error_count;
```

For more information, see Section 13.5.4.25, “`SHOW WARNINGS` Syntax”.

### 13.5.4.12. SHOW GRANTS Syntax

```
SHOW GRANTS FOR user
```

This statement lists the `GRANT` statement or statements that must be issued to duplicate the privileges that are granted to a MySQL user account. The account is named using the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. The user and host parts of the account name correspond to the `User` and `Host` column values of the `user` table row for the account.

```
mysql> SHOW GRANTS FOR 'root'@'localhost';  
+-----+-----+-----+-----+-----+-----+  
| Grants for root@localhost |  
+-----+-----+-----+-----+-----+-----+  
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |  
+-----+-----+-----+-----+-----+-----+
```

To list the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;  
SHOW GRANTS FOR CURRENT_USER;  
SHOW GRANTS FOR CURRENT_USER();
```

`SHOW GRANTS` displays only the privileges granted explicitly to the named account. Other privileges might be available to the account, but they are not displayed. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` will not display them.

### 13.5.4.13. SHOW INDEX Syntax

```
SHOW INDEX FROM tbl_name [FROM db_name]
```

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC.

`SHOW INDEX` returns the following fields:

- `Table`  
The name of the table.
- `Non_unique`  
0 if the index cannot contain duplicates, 1 if it can.
- `Key_name`  
The name of the index.
- `Seq_in_index`  
The column sequence number in the index, starting with 1.
- `Column_name`  
The column name.
- `Collation`  
How the column is sorted in the index. In MySQL, this can have values 'A' (Ascending) or NULL (Not sorted).
- `Cardinality`  
An estimate of the number of unique values in the index. This is updated by running `ANALYZE TABLE` or `myisamchk -a`. `Cardinality` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.
- `Sub_part`  
The number of indexed characters if the column is only partly indexed, NULL if the entire column is indexed.
- `Packed`  
Indicates how the key is packed. NULL if it is not.
- `Null`  
Contains YES if the column may contain NULL. If not, the column contains NO as of MySQL 5.0.3, and ' ' before that.
- `Index_type`  
The index method used (BTREE, FULLTEXT, HASH, RTREE).
- `Comment`  
Various remarks.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;  
SHOW INDEX FROM mydb.mytable;
```

`SHOW KEYS` is a synonym for `SHOW INDEX`. You can also list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

### 13.5.4.14. SHOW INNODB STATUS Syntax

```
SHOW INNODB STATUS
```

In MySQL 5.0, this is a deprecated synonym for `SHOW ENGINE INNODB STATUS`. See Section 13.5.4.9, “`SHOW ENGINE Syntax`”.

### 13.5.4.15. SHOW LOGS Syntax

```
SHOW [BDB] LOGS
```

In MySQL 5.0, this is a deprecated synonym for `SHOW ENGINE BDB LOGS`. See Section 13.5.4.9, “`SHOW ENGINE Syntax`”.

### 13.5.4.16. SHOW OPEN TABLES Syntax

```
SHOW OPEN TABLES [FROM db_name] [LIKE 'pattern']
```

`SHOW OPEN TABLES` lists the non-TEMPORARY tables that are currently open in the table cache. See Section 7.4.8, “How MySQL Opens and Closes Tables”.

`SHOW OPEN TABLES` returns the following fields:

- Database  
The database containing the table.
- Table  
The table name.
- In\_use  
The number of times the table currently is in use by queries. If the count is zero, the table is open, but not currently being used.
- Name\_locked  
Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

The `FROM` and `LIKE` clauses may be used as of MySQL 5.0.12.

### 13.5.4.17. SHOW PRIVILEGES Syntax

```
SHOW PRIVILEGES
```

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

```
mysql> SHOW PRIVILEGES\G
***** 1. row *****
Privilege: Alter
Context: Tables
Comment: To alter the table
***** 2. row *****
Privilege: Alter routine
Context: Functions,Procedures
```

```

Comment: To alter or drop stored functions/procedures
***** 3. row *****
Privilege: Create
Context: Databases,Tables,Indexes
Comment: To create new databases and tables
***** 4. row *****
Privilege: Create routine
Context: Functions,Procedures
Comment: To use CREATE FUNCTION/PROCEDURE
***** 5. row *****
Privilege: Create temporary tables
Context: Databases
Comment: To use CREATE TEMPORARY TABLE
...

```

### 13.5.4.18. SHOW PROCEDURE STATUS and SHOW FUNCTION STATUS Syntax

```
SHOW {PROCEDURE | FUNCTION} STATUS [LIKE 'pattern']
```

This statement is a MySQL extension. It returns characteristics of routines, such as the database, name, type, creator, and creation and modification dates. If no pattern is specified, the information for all stored procedures or all stored functions is listed, depending on which statement you use.

```

mysql> SHOW FUNCTION STATUS LIKE 'hello'\G
***** 1. row *****
      Db: test
      Name: hello
      Type: FUNCTION
      Definer: testuser@localhost
      Modified: 2004-08-03 15:29:37
      Created: 2004-08-03 15:29:37
      Security_type: DEFINER
      Comment:

```

You can also get information about stored routines from the ROUTINES table in INFORMATION\_SCHEMA. See Section 20.14, “The INFORMATION\_SCHEMA ROUTINES Table”.

### 13.5.4.19. SHOW PROCESSLIST Syntax

```
SHOW [FULL] PROCESSLIST
```

SHOW PROCESSLIST shows you which threads are running. You can also get this information using the `mysqladmin processlist` command. If you have the SUPER privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). See Section 13.5.5.3, “KILL Syntax”. If you do not use the FULL keyword, only the first 100 characters of each statement are shown in the Info field.

This statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the SUPER privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

The output of SHOW PROCESSLIST may look like this:

```

mysql> SHOW FULL PROCESSLIST\G
***** 1. row *****
Id: 1
User: system user
Host:
db: NULL
Command: Connect

```

```
Time: 1030455
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 2
User: system user
Host:
db: NULL
Command: Connect
Time: 1004
State: Has read all relay log; waiting for the slave I/O thread to update it
Info: NULL
***** 3. row *****
Id: 3112
User: replikator
Host: artemis:2204
db: NULL
Command: Binlog Dump
Time: 2144
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 4. row *****
Id: 3113
User: replikator
Host: iconnect2:45781
db: NULL
Command: Binlog Dump
Time: 2086
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 5. row *****
Id: 3123
User: stefan
Host: localhost
db: apollon
Command: Query
Time: 0
State: NULL
Info: SHOW FULL PROCESSLIST
5 rows in set (0.00 sec)
```

The columns have the following meaning:

- **Id**  
The connection identifier.
- **User**  
The MySQL user who issued the statement. If this is `system user`, it refers to a non-client thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. For `system user`, there is no host specified in the `Host` column.
- **Host**  
The hostname of the client issuing the statement (except for `system user` where there is no host). `SHOW PROCESSLIST` reports the hostname for TCP/IP connections in `host_name:client_port` format to make it easier to determine which client is doing what.
- **db**  
The default database, if one is selected, otherwise `NULL`.
- **Command**

The value of that column corresponds to the COM\_xxx commands of the client/server protocol. See Section 5.2.4, “Server Status Variables”

The Command value may be one of the following: Binlog Dump, Change user, Close stmt, Connect, Connect Out, Create DB, Debug, Delayed insert, Drop DB, Error, Execute, Fetch, Field List, Init DB, Kill, Long Data, Ping, Prepare, Processlist, Query, Quit, Refresh, Register Slave, Reset stmt, Set option, Shutdown, Sleep, Statistics, Table Dump, Time

- Time

The time in seconds between the start of the statement or command and now.

- State

An action, event, or state, which can be one of the following: After create, Analyzing, Changing master, Checking master version, Checking table, Connecting to master, Copying to group table, Copying to tmp table, Creating delayed handler, Creating index, Creating sort index, Creating table from master dump, Creating tmp table, Execution of init\_command, FULLTEXT initialization, Finished reading one binlog; switching to next binlog, Flushing tables, Killed, Killing slave, Locked, Making temp file , Opening master dump table, Opening table, Opening tables, Processing request, Purging old relay logs, Queueing master event to the relay log, Reading event from the relay log, Reading from net, Reading master dump table data, Rebuilding the index on master dump table, Reconnecting after a failed binlog dump request, Reconnecting after a failed master event read, Registering slave on master, Removing duplicates, Reopen tables, Repair by sorting, Repair done, Repair with keycache, Requesting binlog dump, Rolling back, Saving state, Searching rows for update, Sending binlog event to slave, Sending data, Sorting for group, Sorting for order, Sorting index, Sorting result, System lock, Table lock, Thread initialized, Updating, User lock, Waiting for INSERT, Waiting for master to send event, Waiting for master update, Waiting for slave mutex on exit, Waiting for table, Waiting for tables, Waiting for the next event in relay log, Waiting on cond, Waiting to finalize termination, Waiting to reconnect after a failed binlog dump request, Waiting to reconnect after a failed master event read, Writing to net, allocating local table, cleaning up, closing tables, converting HEAP to MyISAM, copy to tmp table, creating table, deleting from main table, deleting from reference tables, discard\_or\_import\_tablespace, end, freeing items, got handler lock, got old table, info, init, insert, logging slow query, login, preparing, purging old relay logs, query end, removing tmp table, rename, rename result table, reschedule, setup, starting slave, statistics, storing row into queue, update, updating, updating main table, updating reference tables, upgrading lock, waiting for delay\_list, waiting for handler insert, waiting for handler lock, waiting for handler open

The most common State values are described in the rest of this section. Most of the other State values are useful only for finding bugs in the server. See also Section 6.3, “Replication Implementation Details”, for additional information about process states for replication servers.

For the SHOW PROCESSLIST statement, the value of State is NULL.

- Info

The statement that the thread is executing, or NULL if it is not executing any statement.

Some State values commonly seen in the output from SHOW PROCESSLIST:

- `Checking table`  
The thread is performing a table check operation.
- `Closing tables`  
Means that the thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, you should verify that you do not have a full disk and that the disk is not in very heavy use.
- `Connect Out`  
A replication slave is connecting to its master.
- `Copying to tmp table`  
The server is copying to a temporary table in memory.
- `Copying to tmp table on disk`  
The server is copying to a temporary table on disk. The temporary result set was larger than `tmp_table_size` and the thread is changing the temporary table from in-memory to disk-based format to save memory.
- `Creating tmp table`  
The thread is creating a temporary table to hold a part of the result for the query.
- `deleting from main table`  
The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving fields and offsets to be used for deleting from the other (reference) tables.
- `deleting from reference tables`  
The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.
- `Flushing tables`  
The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables.
- `FULLTEXT initialization`  
The server is preparing to perform a natural-language full-text search.
- `Killed`  
Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.
- `Locked`  
The query is locked by another query.
- `Sending data`  
The thread is processing rows for a `SELECT` statement and also is sending data to the client.
- `Sorting for group`  
The thread is doing a sort to satisfy a `GROUP BY`.

- `Sorting for order`

The thread is doing a sort to satisfy a `ORDER BY`.
- `Opening tables`

The thread is trying to open a table. This should be a very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished.
- `Reading from net`

The server is reading a packet from the network.
- `Removing duplicates`

The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.
- `Reopen table`

The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.
- `Repair by sorting`

The repair code is using a sort to create indexes.
- `Repair with keycache`

The repair code is using creating keys one by one through the key cache. This is much slower than `Repair by sorting`.
- `Searching rows for update`

The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.
- `Sleeping`

The thread is waiting for the client to send a new statement to it.
- `statistics`

The server is calculating statistics to develop a query execution plan.
- `System lock`

The thread is waiting to get an external system lock for the table. If you are not using multiple `mysqld` servers that are accessing the same tables, you can disable system locks with the `-skip-external-locking` option.
- `Upgrading lock`

The `INSERT DELAYED` handler is trying to get a lock for the table to insert rows.
- `Updating`

The thread is searching for rows to update and is updating them.
- `updating main table`

The server is executing the first part of a multiple-table update. It is updating only the first table,

and saving fields and offsets to be used for updating the other (reference) tables.

- updating reference tables

The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- User Lock

The thread is waiting on a `GET_LOCK()`.

- Waiting for tables

The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- waiting for handler insert

The `INSERT DELAYED` handler has processed all pending inserts and is waiting for new ones.

- Writing to net

The server is writing a packet to the network.

Most states correspond to very quick operations. If a thread stays in any of these states for many seconds, there might be a problem that needs to be investigated.

### 13.5.4.20. SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS [LIKE 'pattern']
```

`SHOW STATUS` provides server status information. This information also can be obtained using the `mysqladmin extended-status` command.

Partial output is shown here. The list of names and values may be different for your server. The meaning of each variable is given in Section 5.2.4, “Server Status Variables”.

```
mysql> SHOW STATUS;
```

Variable_name	Value
Aborted_clients	0
Aborted_connects	0
Bytes_received	155372598
Bytes_sent	1176560426
Connections	30023
Created_tmp_disk_tables	0
Created_tmp_tables	8340
Created_tmp_files	60
..	
Open_tables	1
Open_files	2
Open_streams	0
Opened_tables	44600
Questions	2026873
..	
Table_locks_immediate	1920382

Table_locks_waited	0
Threads_cached	0
Threads_created	30022
Threads_connected	1
Threads_running	1
Uptime	80380

With a `LIKE` clause, the statement displays only those variables that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
```

Variable_name	Value
Key_blocks_used	14955
Key_read_requests	96854827
Key_reads	162040
Key_write_requests	7589728
Key_writes	3813196

The `GLOBAL` and `SESSION` options are new in MySQL 5.0.2. With the `GLOBAL` modifier, `SHOW STATUS` displays the status values for all connections to MySQL. With `SESSION`, it displays the status values for the current connection. If no modifier is present, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`.

Some status variables have only a global value. For these, you get the same value for both `GLOBAL` and `SESSION`.

### 13.5.4.21. SHOW TABLE STATUS Syntax

```
SHOW TABLE STATUS [FROM db_name] [LIKE 'pattern']
```

`SHOW TABLE STATUS` works like `SHOW TABLE`, but provides a lot of information about each table. You can also get this list using the `mysqlshow --status db_name` command.

As of MySQL 5.0.1, this statement also displays information about views.

`SHOW TABLE STATUS` returns the following fields:

- **Name**  
The name of the table.
- **Engine**  
The storage engine for the table. See Chapter 14, *Storage Engines and Table Types*.
- **Version**  
The version number of the table's `.frm` file.
- **Row\_format**  
The row storage format (Fixed, Dynamic, Compressed, Redundant, Compact). Starting with MySQL/InnoDB 5.0.3, the format of InnoDB tables is reported as Redundant or Compact. Prior to 5.0.3, InnoDB tables are always in the Redundant format.
- **Rows**  
The number of rows. Some storage engines, such as MyISAM, store the exact count. For other storage engines, such as InnoDB, this value is an approximation, and may vary from the actual

value by as much as 40 to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

The `Rows` value is `NULL` for tables in the `INFORMATION_SCHEMA` database.

- `Avg_row_length`

The average row length.

- `Data_length`

The length of the data file.

- `Max_data_length`

The maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

- `Index_length`

The length of the index file.

- `Data_free`

The number of allocated but unused bytes.

- `Auto_increment`

The next `AUTO_INCREMENT` value.

- `Create_time`

When the table was created.

- `Update_time`

When the data file was last updated. For some storage engines, this value is `NULL`. For example, `InnoDB` stores multiple tables in its tablespace and the data file timestamp does not apply.

- `Check_time`

When the table was last checked. Not all storage engines update this time, in which case the value is always `NULL`.

- `Collation`

The table's character set and collation.

- `Checksum`

The live checksum value (if any).

- `Create_options`

Extra options used with `CREATE TABLE`.

- `Comment`

The comment used when creating the table (or information as to why `MySQL` could not access the table information).

In the table comment, `InnoDB` tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only

that table.

For MEMORY tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

Beginning with MySQL 5.0.3, for NDB Cluster tables, the output of this statement shows appropriate values for the `Avg_row_length` and `Data_length` columns, with the exception that BLOB columns are not taken into account. In addition, the number of replicas is now shown in the `Comment` column (as `number_of_replicas`).

For views, all the fields displayed by `SHOW TABLE STATUS` are NULL except that `Name` indicates the view name and `Comment` says view.

### 13.5.4.22. SHOW TABLES Syntax

```
SHOW [FULL] TABLES [FROM db_name] [LIKE 'pattern']
```

`SHOW TABLES` lists the non-TEMPORARY tables in a given database. You can also get this list using the `mysqlshow db_name` command.

Before MySQL 5.0.1, the output from `SHOW TABLES` contains a single column of table names. Beginning with MySQL 5.0.1, this statement also lists any views in the database. As of MySQL 5.0.2, the `FULL` modifier is supported such that `SHOW FULL TABLES` displays a second output column. Values for the second column are `BASE TABLE` for a table and `VIEW` for a view.

**Note:** If you have no privileges for a table, the table does not show up in the output from `SHOW TABLES` or `mysqlshow db_name`.

### 13.5.4.23. SHOW TRIGGERS Syntax

```
SHOW TRIGGERS [FROM db_name] [LIKE expr]
```

`SHOW TRIGGERS` lists the triggers currently defined on the MySQL server. This statement requires the `SUPER` privilege. It was implemented in MySQL 5.0.10.

For the trigger `ins_sum` as defined in Section 18.3, “Using Triggers”, the output of this statement is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%\G
***** 1. row *****
  Trigger: ins_sum
    Event: INSERT
    Table: account
Statement: SET @sum = @sum + NEW.amount
   Timing: BEFORE
   Created: NULL
  sql_mode:
  Definer: myname@localhost
```

**Note:** When using a `LIKE` clause with `SHOW TRIGGERS`, the expression to be matched (`expr`) is compared with the name of the table on which the trigger is declared, and not with the name of the trigger:

```
mysql> SHOW TRIGGERS LIKE 'ins%';
Empty set (0.01 sec)
```

A brief explanation of the columns in the output of this statement is shown here:

- Trigger

The name of the trigger.

- Event

The event that causes trigger activation: one of 'INSERT', 'UPDATE', or 'DELETE'.

- Table

The table for which the trigger is defined.

- Statement

The statement to be executed when the trigger is activated. This is the same as the text shown in the ACTION\_STATEMENT column of INFORMATION\_SCHEMA.TRIGGERS.

- Timing

One of the two values 'BEFORE' or 'AFTER'.

- Created

Currently, the value of this column is always NULL.

- sql\_mode

The SQL mode in effect when the trigger executes. This column was added in MySQL 5.0.11.

- Definer

The account that created the trigger. This column was added in MySQL 5.0.17.

You must have the SUPER privilege to execute SHOW TRIGGERS.

See also Section 20.16, “The INFORMATION\_SCHEMA TRIGGERS Table”.

### 13.5.4.24. SHOW VARIABLES Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES [LIKE 'pattern']
```

SHOW VARIABLES shows the values of MySQL system variables. This information also can be obtained using the `mysqladmin variables` command.

With the GLOBAL modifier, SHOW VARIABLES displays the values that are used for new connections to MySQL. With SESSION, it displays the values that are in effect for the current connection. If no modifier is present, the default is SESSION. LOCAL is a synonym for SESSION.

If the default system variable values are unsuitable, you can set them using command options when `mysqld` starts, and most can be changed at runtime with the SET statement. See Section 5.2.3, “Using System Variables”, and Section 13.5.3, “SET Syntax”.

Partial output is shown here. The list of names and values may be different for your server. Section 5.2.2, “Server System Variables”, describes the meaning of each variable, and Section 7.5.2, “Tuning Server Parameters”, provides information about tuning them.

```
mysql> SHOW VARIABLES;
```

Variable_name	Value
auto_increment_increment	1
auto_increment_offset	1
automatic_sp_privileges	ON
back_log	50

basedir	/
bdb_cache_size	8388600
bdb_home	/var/lib/mysql/
bdb_log_buffer_size	32768
..	
max_connections	100
max_connect_errors	10
max_delayed_threads	20
max_error_count	64
max_heap_table_size	16777216
max_join_size	4294967295
max_relay_log_size	0
max_sort_length	1024
..	
time_zone	SYSTEM
timed_mutexes	OFF
tmp_table_size	33554432
tmpdir	
transaction_alloc_block_size	8192
transaction_prealloc_size	4096
tx_isolation	REPEATABLE-READ
updatable_views_with_limit	YES
version	5.0.19-Max
version_comment	MySQL Community Edition - Max (GPL)
version_compile_machine	i686
version_compile_os	pc-linux-gnu
wait_timeout	28800

With a LIKE clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a LIKE clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the '%' wildcard character in a LIKE clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because '\_' is a wildcard that matches any single character, you should escape it as '\\_' to match it literally. In practice, this is rarely necessary.

### 13.5.4.25. SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

SHOW WARNINGS shows the error, warning, and note messages that resulted from the last statement that generated messages, or nothing if the last statement that used a table generated no messages. A related statement, SHOW ERRORS, shows only the errors. See Section 13.5.4.11, "SHOW ERRORS Syntax".

The list of messages is reset for each new statement that uses a table.

The SHOW COUNT(\*) WARNINGS statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the warning\_count variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

The value of `warning_count` might be greater than the number of messages displayed by `SHOW WARNINGS` if the `max_error_count` system variable is set so low that not all messages are stored. An example shown later in this section demonstrates how this can happen.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.7, “`SELECT` Syntax”.

The MySQL server sends back the total number of errors, warnings, and notes resulting from the last statement. If you are using the C API, this value can be obtained by calling `mysql_warning_count()`. See Section 22.2.3.71, “`mysql_warning_count()`”.

Warnings are generated for statements such as `LOAD DATA INFILE` and DML statements such as `INSERT`, `UPDATE`, `CREATE TABLE`, and `ALTER TABLE`.

The following `DROP TABLE` statement results in a note:

```
mysql> DROP TABLE IF EXISTS no_such_table;
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1051 | Unknown table 'no_such_table'           |
+-----+-----+-----+
```

Here is a simple example that shows a syntax warning for `CREATE TABLE` and conversion warnings for `INSERT`:

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4)) TYPE=MyISAM;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1287
Message: 'TYPE=storage_engine' is deprecated, use
        'ENGINE=storage_engine' instead
1 row in set (0.00 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'),(NULL,'test'),
-> (300,'Open Source');
Query OK, 3 rows affected, 4 warnings (0.01 sec)
Records: 3 Duplicates: 0 Warnings: 4

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 1
***** 2. row *****
Level: Warning
Code: 1263
Message: Data truncated, NULL supplied to NOT NULL column 'a' at row 2
***** 3. row *****
Level: Warning
Code: 1264
Message: Data truncated, out of range for column 'a' at row 3
***** 4. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 3
4 rows in set (0.00 sec)
```

The maximum number of error, warning, and note messages to store is controlled by the `max_error_count` system variable. By default, its value is 64. To change the number of messages you want stored, change the value of `max_error_count`. In the following example, the `ALTER TABLE` statement produces three warning messages, but only one is stored because

max\_error\_count has been set to 1:

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
```

```
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 64    |
+-----+-----+
1 row in set (0.00 sec)
```

```
mysql> SET max_error_count=1;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3
```

```
mysql> SELECT @@warning_count;
```

```
+-----+
| @@warning_count |
+-----+
|                3 |
+-----+
1 row in set (0.01 sec)
```

```
mysql> SHOW WARNINGS;
```

```
+-----+-----+-----+
| Level   | Code | Message |
+-----+-----+-----+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

To disable warnings, set max\_error\_count to 0. In this case, warning\_count still indicates how many warnings have occurred, but none of the messages are stored.

As of MySQL 5.0.3, you can set the SQL\_NOTES session variable to 0 to cause Note-level warnings not to be recorded.

## 13.5.5. Other Administrative Statements

### 13.5.5.1. CACHE INDEX Syntax

```
CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  IN key_cache_name
```

```
tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]
```

The CACHE INDEX statement assigns table indexes to a specific key cache. It is used only for MyISAM tables.

The following statement assigns indexes from the tables t1, t2, and t3 to the key cache named hot\_cache:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

```
+-----+-----+-----+-----+
| Table   | Op           | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+-----+-----+-----+-----+
```

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. The current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See Section 5.2.3.1, “Structured System Variables”.

A key cache must exist before you can assign indexes to it:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

### 13.5.5.2. FLUSH Syntax

```
FLUSH [LOCAL | NO_WRITE_TO_BINLOG] flush_option [, flush_option] ...
```

The `FLUSH` statement clears or reloads various internal caches used by MySQL. To execute `FLUSH`, you must have the `RELOAD` privilege.

The `RESET` statement is similar to `FLUSH`. See Section 13.5.5.5, “RESET Syntax”.

*flush\_option* can be any of the following:

- `HOSTS`

Empties the host cache tables. You should flush the host tables if some of your hosts change IP number or if you get the error message `Host 'host_name' is blocked`. When more than `max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host tables allows the host to attempt to connect again. See Section A.2.5, “Host 'host\_name' is blocked”. You can start `mysqld` with `-max_connect_errors=999999999` to avoid this error message.

- `DES_KEY_FILE`

Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- `LOGS`

Closes and reopens all log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file. On Unix, this is the same thing as sending a `SIGHUP` signal to the `mysqld` server (except on some Mac OS X 10.3 versions where `mysqld` ignores `SIGHUP` and `SIGQUIT`).

If the server was started with the `--log-error` option, `FLUSH LOGS` causes the error log is renamed with a suffix of `-old` and `mysqld` creates a new empty log file. No renaming occurs if the `--log-error` option was not given.

- PRIVILEGES

Reloads the privileges from the grant tables in the `mysql` database.

- QUERY CACHE

Defragment the query cache to better utilize its memory. `FLUSH QUERY CACHE` does not remove any queries from the cache, unlike `RESET QUERY CACHE`.

- STATUS

Resets most status variables to zero. This is something you should use only when debugging a query. See Section 1.8, “How to Report Bugs or Problems”.

- {TABLE | TABLES} [*tbl\_name* [, *tbl\_name*] ...]

When no tables are named, closes all open tables and forces all tables in use to be closed. This also flushes the query cache. With one or more table names, flushes only the given tables. `FLUSH TABLES` also removes all query results from the query cache, like the `RESET QUERY CACHE` statement.

- TABLES WITH READ LOCK

Closes all open tables and locks all tables for all databases with a read lock until you execute `UNLOCK TABLES`. This is very convenient way to get backups if you have a filesystem such as Veritas that can take snapshots in time.

- USER\_RESOURCES

Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections. See Section 13.5.1.3, “GRANT Syntax”.

`FLUSH` statements are written to the binary log unless the optional `NO_WRITE_TO_BINLOG` keyword (or its alias `LOCAL`) is used. This is done so that `FLUSH` statements used on a MySQL server acting as a replication master will be replicated by default to the replication slave.

**Note:** `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK` are not logged in any case because they would cause problems if replicated to a slave.

You can also access some of these statements with the `mysqladmin` utility, using the `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, or `flush-tables` commands.

Using `FLUSH` statements within stored functions or triggers is not supported in MySQL 5.0. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See Section I.1, “Restrictions on Stored Routines and Triggers”.

See also Section 13.5.5.5, “RESET Syntax”, for information about how the `RESET` statement is used with replication.

### 13.5.5.3. KILL Syntax

```
KILL [CONNECTION | QUERY] thread_id
```

Each connection to `mysqld` runs in a separate thread. You can see which threads are running with the `SHOW PROCESSLIST` statement and kill a thread with the `KILL thread_id` statement.

In MySQL 5.0.0, `KILL` allows the optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given `thread_id`.
- `KILL QUERY` terminates the statement that the connection is currently executing, but leaves the connection itself intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

**Note:** You cannot use `KILL` with the Embedded MySQL Server library, because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die, because the kill flag is checked only at specific intervals:

- In `SELECT`, `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- During `ALTER TABLE`, the kill flag is checked before each block of rows are read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.
- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. Note that if you are not using transactions, the changes are not rolled back.
- `GET_LOCK( )` aborts and returns `NULL`.
- An `INSERT DELAYED` thread quickly flushes (inserts) all rows it has in memory and then terminates.
- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.
- **Warning:** Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a MyISAM table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

### 13.5.5.4. LOAD INDEX INTO CACHE Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
  [[INDEX|KEY] (index_name [, index_name] ...)]
  [IGNORE LEAVES]
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise. `LOAD INDEX INTO CACHE` is used only for MyISAM tables.

The `IGNORE LEAVES` modifier causes only blocks for the non-leaf nodes of the index to be preloaded.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
```

Table	Op	Msg_type	Msg_text
test.t1	preload_keys	status	OK
test.t2	preload_keys	status	OK

This statement preloads all index blocks from `t1`. It preloads only blocks for the non-leaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. The current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

### 13.5.5.5. RESET Syntax

```
RESET reset_option [, reset_option] ...
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement. See Section 13.5.5.2, “`FLUSH` Syntax”.

*reset\_option* can be any of the following:

- `MASTER`

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file. (Known as `FLUSH MASTER` in versions of MySQL before 3.23.26.) See Section 13.6.1, “SQL Statements for Controlling Master Servers”.

- `QUERY CACHE`

Removes all query results from the query cache.

- `SLAVE`

Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one. (Known as `FLUSH SLAVE` in versions of MySQL before 3.23.26.) See Section 13.6.2, “SQL Statements for Controlling Slave Servers”.

## 13.6. Replication Statements

This section describes SQL statements related to replication. One group of statements is used for controlling master servers. The other is used for controlling slave servers.

### 13.6.1. SQL Statements for Controlling Master Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing master replication servers. Section 13.6.2, “SQL Statements for Controlling Slave Servers”, discusses statements for managing slave servers.

#### 13.6.1.1. PURGE MASTER LOGS Syntax

```
PURGE {MASTER | BINARY} LOGS TO 'log_name'  
PURGE {MASTER | BINARY} LOGS BEFORE 'date'
```

Deletes all the binary logs listed in the log index prior to the specified log or date. The logs also are removed from the list recorded in the log index file, so that the given log becomes the first.

Example:

```
PURGE MASTER LOGS TO 'mysql-bin.010';  
PURGE MASTER LOGS BEFORE '2003-04-02 22:46:26';
```

The BEFORE variant's *date* argument can be in 'YYYY-MM-DD hh:mm:ss' format. MASTER and BINARY are synonyms.

This statement is safe to run while slaves are replicating. You do not need to stop them. If you have an active slave that currently is reading one of the logs you are trying to delete, this statement does nothing and fails with an error. However, if a slave is dormant and you happen to purge one of the logs it has yet to read, the slave will be unable to replicate after it comes up.

To safely purge logs, follow this procedure:

1. On each slave server, use `SHOW SLAVE STATUS` to check which log it is reading.
2. Obtain a listing of the logs on the master server with `SHOW MASTER LOGS`.
3. Determine the earliest log among all the slaves. This is the target log. If all the slaves are up to date, this is the last log on the list.
4. Make a backup of all the logs you are about to delete. (This step is optional, but always advisable.)
5. Purge all logs up to but not including the target log.

### 13.6.1.2. RESET MASTER Syntax

```
RESET MASTER
```

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

### 13.6.1.3. SET SQL\_LOG\_BIN Syntax

```
SET SQL_LOG_BIN = {0|1}
```

Disables or enables binary logging for the current connection (`SQL_LOG_BIN` is a session variable) if the client has the SUPER privilege. The statement is refused with an error if the client does not have that privilege.

### 13.6.1.4. SHOW BINLOG EVENTS Syntax

```
SHOW BINLOG EVENTS  
  [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify 'log\_name', the first binary log is displayed.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.7, "SELECT"

Syntax”.

**Note:** Issuing a `SHOW BINLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to `SHOW BINLOG EVENTS`, use the `mysqlbinlog` utility to save the binary log to a text file for later examination and analysis. See Section 8.9, “`mysqlbinlog` — Utility for Processing Binary Log Files”.

### 13.6.1.5. SHOW MASTER LOGS Syntax

```
SHOW MASTER LOGS
SHOW BINARY LOGS
```

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 13.6.1.1, “`PURGE MASTER LOGS` Syntax”, that shows how to determine which logs can be purged.

```
mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name          | File_size |
+-----+-----+
| binlog.000015     | 724935    |
| binlog.000016     | 733481    |
+-----+-----+
```

`SHOW BINARY LOGS` is equivalent to `SHOW MASTER LOGS`. The `File_size` column is displayed as of MySQL 5.0.7.

### 13.6.1.6. SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

Provides status information about the binary log files of the master. Example:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.003 | 73       | test         | manual,mysql      |
+-----+-----+-----+-----+
```

### 13.6.1.7. SHOW SLAVE HOSTS Syntax

```
SHOW SLAVE HOSTS
```

Displays a list of replication slaves currently registered with the master. Any slave not started with the `--report-host=slave_name` option is not visible in this list.

## 13.6.2. SQL Statements for Controlling Slave Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing slave replication servers. Section 13.6.1, “SQL Statements for Controlling Master Servers”, discusses statements for managing master servers.

### 13.6.2.1. CHANGE MASTER TO Syntax

```
CHANGE MASTER TO master_def [, master_def] ...
```

```
master_def:
  MASTER_HOST = 'host_name'
  MASTER_USER = 'user_name'
  MASTER_PASSWORD = 'password'
  MASTER_PORT = port_num
  MASTER_CONNECT_RETRY = count
  MASTER_LOG_FILE = 'master_log_name'
  MASTER_LOG_POS = master_log_pos
  RELAY_LOG_FILE = 'relay_log_name'
  RELAY_LOG_POS = relay_log_pos
  MASTER_SSL = {0|1}
  MASTER_SSL_CA = 'ca_file_name'
  MASTER_SSL_CAPATH = 'ca_directory_name'
  MASTER_SSL_CERT = 'cert_file_name'
  MASTER_SSL_KEY = 'key_file_name'
  MASTER_SSL_CIPHER = 'cipher_list'
```

CHANGE MASTER TO changes the parameters that the slave server uses for connecting to and communicating with the master server. It also updates the contents of the `master.info` and `relay-log.info` files.

MASTER\_USER, MASTER\_PASSWORD, MASTER\_SSL, MASTER\_SSL\_CA, MASTER\_SSL\_CAPATH, MASTER\_SSL\_CERT, MASTER\_SSL\_KEY, and MASTER\_SSL\_CIPHER provide information to the slave about how to connect to its master.

The SSL options (MASTER\_SSL, MASTER\_SSL\_CA, MASTER\_SSL\_CAPATH, MASTER\_SSL\_CERT, MASTER\_SSL\_KEY, and MASTER\_SSL\_CIPHER) can be changed even on slaves that are compiled without SSL support. They are saved to the `master.info` file, but are ignored unless you use a server that has SSL support enabled.

If you don't specify a given parameter, it keeps its old value, except as indicated in the following discussion. For example, if the password to connect to your MySQL master has changed, you just need to issue these statements to tell the slave about the new password:

```
STOP SLAVE; -- if replication was running
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
START SLAVE; -- if you want to restart replication
```

There is no need to specify the parameters that do not change (host, port, user, and so forth).

MASTER\_HOST and MASTER\_PORT are the hostname (or IP address) of the master host and its TCP/IP port. Note that if MASTER\_HOST is equal to `localhost`, then, like in other parts of MySQL, the port number might be ignored (if Unix socket files can be used, for example).

If you specify MASTER\_HOST or MASTER\_PORT, the slave assumes that the master server is different from before (even if you specify a host or port value that is the same as the current value.) In this case, the old values for the master binary log name and position are considered no longer applicable, so if you do not specify MASTER\_LOG\_FILE and MASTER\_LOG\_POS in the statement, MASTER\_LOG\_FILE='' and MASTER\_LOG\_POS=4 are silently appended to it.

MASTER\_LOG\_FILE and MASTER\_LOG\_POS are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. If you specify either of them, you cannot specify RELAY\_LOG\_FILE or RELAY\_LOG\_POS. If neither of MASTER\_LOG\_FILE or MASTER\_LOG\_POS are specified, the slave uses the last coordinates of the *slave SQL thread* before CHANGE MASTER was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

CHANGE MASTER *deletes all relay log files* and starts a new one, unless you specify RELAY\_LOG\_FILE or RELAY\_LOG\_POS. In that case, relay logs are kept; the `relay_log_purge` global variable is set silently to 0.

CHANGE MASTER is useful for setting up a slave when you have the snapshot of the master and have recorded the log and the offset corresponding to it. After loading the snapshot into the slave,

you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name_on_master', MASTER_LOG_POS=log_offset_on_master` on the slave.

The following example changes the master and master's binary log coordinates. This is used when you want to set up the slave to replicate the master:

```
CHANGE MASTER TO
  MASTER_HOST='master2.mycompany.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='big3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the slave has relay logs that you want it to execute again for some reason. To do this, the master need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
```

You can even use the second operation in a non-replication setup with a standalone, non-slave server for recovery following a crash. Suppose that your server has crashed and you have restored a backup. You want to replay the server's own binary logs (not relay logs, but regular binary logs), named (for example) `myhost-bin.*`. First, make a backup copy of these binary logs in some safe place, in case you don't exactly follow the procedure below and accidentally have the server purge the binary logs. Use `SET GLOBAL relay_log_purge=0` for additional safety. Then start the server without the `--log-bin` option. Instead, use the `--replicate-same-server-id, --relay-log=myhost-bin` (to make the server believe that these regular binary logs are relay logs) and `--skip-slave-start` options. After the server starts, issue these statements:

```
CHANGE MASTER TO
  RELAY_LOG_FILE='myhost-bin.153',
  RELAY_LOG_POS=410,
  MASTER_HOST='some_dummy_string';
START SLAVE SQL_THREAD;
```

The server reads and executes its own binary logs, thus achieving crash recovery. Once the recovery is finished, run `STOP SLAVE`, shut down the server, delete the `master.info` and `relay-log.info` files, and restart the server with its original options.

Specifying the `MASTER_HOST` option (even with a dummy value) is required to make the server think it is a slave.

### 13.6.2.2. LOAD DATA FROM MASTER Syntax

`LOAD DATA FROM MASTER`

This statement takes a snapshot of the master and copies it to the slave. It updates the values of `MASTER_LOG_FILE` and `MASTER_LOG_POS` so that the slave starts replicating from the correct position. Any table and database exclusion rules specified with the `--replicate-*-do-*` and `--replicate-*-ignore-*` options are honored. `--replicate-rewrite-db` is *not* taken into account because a user could use this option to set up a non-unique mapping such as `--replicate-rewrite-db="db1->db3"` and `--replicate-rewrite-db="db2->db3"`, which would confuse the slave when loading tables from the master.

Use of this statement is subject to the following conditions:

- It works only for MyISAM tables. Attempting to load a non-MyISAM table results in the following error:

```
ERROR 1189 (08S01): Net error reading from master
```

- It acquires a global read lock on the master while taking the snapshot, which prevents updates on the master during the load operation.

If you are loading large tables, you might have to increase the values of `net_read_timeout` and `net_write_timeout` on both the master and slave servers. See Section 5.2.2, “Server System Variables”.

Note that `LOAD DATA FROM MASTER` does *not* copy any tables from the `mysql` database. This makes it easy to have different users and privileges on the master and the slave.

To use `LOAD DATA FROM MASTER`, the replication account that is used to connect to the master must have the `RELOAD` and `SUPER` privileges on the master and the `SELECT` privilege for all master tables you want to load. All master tables for which the user does not have the `SELECT` privilege are ignored by `LOAD DATA FROM MASTER`. This is because the master hides them from the user: `LOAD DATA FROM MASTER` calls `SHOW DATABASES` to know the master databases to load, but `SHOW DATABASES` returns only databases for which the user has some privilege. See Section 13.5.4.8, “`SHOW DATABASES` Syntax”. On the slave side, the user that issues `LOAD DATA FROM MASTER` must have privileges for dropping and creating the databases and tables that are copied.

### 13.6.2.3. `LOAD TABLE tbl_name FROM MASTER` Syntax

```
LOAD TABLE tbl_name FROM MASTER
```

Transfers a copy of the table from the master to the slave. This statement is implemented mainly debugging `LOAD DATA FROM MASTER` operations. To use `LOAD TABLE`, the account used for connecting to the master server must have the `RELOAD` and `SUPER` privileges on the master and the `SELECT` privilege for the master table to load. On the slave side, the user that issues `LOAD TABLE FROM MASTER` must have privileges for dropping and creating the table.

The conditions for `LOAD DATA FROM MASTER` apply here as well. For example, `LOAD TABLE FROM MASTER` works only for MyISAM tables. The timeout notes for `LOAD DATA FROM MASTER` apply as well.

### 13.6.2.4. `MASTER_POS_WAIT()` Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos)
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See Section 12.9.4, “Miscellaneous Functions”, for a full description.

### 13.6.2.5. `RESET SLAVE` Syntax

```
RESET SLAVE
```

`RESET SLAVE` makes the slave forget its replication position in the master's binary logs. This statement is meant to be used for a clean start: It deletes the `master.info` and `relay-log.info` files, all the relay logs, and starts a new relay log.

**Note:** All relay logs are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a `STOP SLAVE` statement or if the slave is highly loaded.)

Connection information stored in the `master.info` file is immediately reset using any values specified in the corresponding startup options. This information includes values such as master host, master port, master user, and master password. If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and `RESET SLAVE` is issued, these replicated temporary tables are deleted on the slave.

### 13.6.2.6. SET GLOBAL SQL\_SLAVE\_SKIP\_COUNTER Syntax

```
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = N
```

This statement skips the next *N* events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave thread is not running. Otherwise, it produces an error.

### 13.6.2.7. SHOW SLAVE STATUS Syntax

```
SHOW SLAVE STATUS
```

This statement provides status information on essential parameters of the slave threads. If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: localhost
      Master_User: root
      Master_Port: 3306
      Connect_Retry: 3
      Master_Log_File: gbichot-bin.005
      Read_Master_Log_Pos: 79
      Relay_Log_File: gbichot-relay-bin.005
      Relay_Log_Pos: 548
      Relay_Master_Log_File: gbichot-bin.005
      Slave_IO_Running: Yes
      Slave_SQL_Running: Yes
      Replicate_Do_DB:
      Replicate_Ignore_DB:
      Last_Errno: 0
      Last_Error:
      Skip_Counter: 0
      Exec_Master_Log_Pos: 79
      Relay_Log_Space: 552
      Until_Condition: None
      Until_Log_File:
      Until_Log_Pos: 0
      Master_SSL_Allowed: No
      Master_SSL_CA_File:
      Master_SSL_CA_Path:
      Master_SSL_Cert:
      Master_SSL_Cipher:
      Master_SSL_Key:
      Seconds_Behind_Master: 8
```

`SHOW SLAVE STATUS` returns the following fields:

- `Slave_IO_State`

A copy of the `State` field of the output of `SHOW PROCESSLIST` for the slave I/O thread. This tells you what the thread is doing: trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. Possible states are listed in Section 6.3,

“Replication Implementation Details”. It is necessary to check this field for older versions of MySQL (prior to 5.0.12) because in these versions the thread could be running while unsuccessfully trying to connect to the master; only this field makes you aware of the connection problem. The state of the SQL thread is not copied because it is simpler. If it is running, there is no problem; if it is not, you can find the error in the `Last_Error` field (described below).

- `Master_Host`  
The current master host.
- `Master_User`  
The current user used to connect to the master.
- `Master_Port`  
The current master port.
- `Connect_Retry`  
The current value of the `--master-connect-retry` option.
- `Master_Log_File`  
The name of the master binary log file from which the I/O thread is currently reading.
- `Read_Master_Log_Pos`  
The position up to which the I/O thread has read in the current master binary log.
- `Relay_Log_File`  
The name of the relay log file from which the SQL thread is currently reading and executing.
- `Relay_Log_Pos`  
The position up to which the SQL thread has read and executed in the current relay log.
- `Relay_Master_Log_File`  
The name of the master binary log file containing the most recent event executed by the SQL thread.
- `Slave_IO_Running`  
Whether the I/O thread is started and has connected successfully to the master. For older versions of MySQL (prior to 4.1.14 and 5.0.12) `Slave_IO_Running` is YES if the I/O thread is started, even if the slave hasn't connected to the master yet.
- `Slave_SQL_Running`  
Whether the SQL thread is started.
- `Replicate_Do_DB, Replicate_Ignore_DB`  
The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.
- `Replicate_Do_Table, Replicate_Ignore_Table, Replicate_Wild_Do_Table, Replicate_Wild_Ignore_Table`  
The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.

- `Last_Errno, Last_Error`

The error number and error message returned by the most recently executed query. An error number of 0 and message of the empty string mean “no error.” If the `Last_Error` value is not empty, it also appears as a message in the slave's error log. For example:

```
Last_Errno: 1051
Last_Error: error 'Unknown table 'z'' on query 'drop table z'
```

The message indicates that the table `z` existed on the master and was dropped there, but it did not exist on the slave, so `DROP TABLE` failed on the slave. (This might occur, for example, if you forget to copy the table to the slave when setting up replication.)

- `Skip_Counter`

The most recently used value for `SQL_SLAVE_SKIP_COUNTER`.

- `Exec_Master_Log_Pos`

The position of the last event executed by the SQL thread from the master's binary log (`Relay_Master_Log_File`). (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`) in the master's binary log corresponds to (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

- `Relay_Log_Space`

The total combined size of all existing relay logs.

- `Until_Condition, Until_Log_File, Until_Log_Pos`

The values specified in the `UNTIL` clause of the `START SLAVE` statement.

`Until_Condition` has these values:

- `None` if no `UNTIL` clause was specified
- `Master` if the slave is reading until a given position in the master's binary logs
- `Relay` if the slave is reading until a given position in its relay logs

`Until_Log_File` and `Until_Log_Pos` indicate the log filename and position values that define the point at which the SQL thread stops executing.

- `Master_SSL_Allowed, Master_SSL_CA_File, Master_SSL_CA_Path, Master_SSL_Cert, Master_SSL_Cipher, Master_SSL_Key`

These fields show the SSL parameters used by the slave to connect to the master, if any.

`Master_SSL_Allowed` has these values:

- `Yes` if an SSL connection to the master is permitted
- `No` if an SSL connection to the master is not permitted
- `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the `--master-ca`, `--master-capath`, `--master-cert`, `--master-cipher`, and `--master-key` options.

- `Seconds_Behind_Master`

This field is an indication of how “late” the slave is:

- When the slave SQL thread is actively running (processing updates), this field is the number of seconds that have elapsed since the timestamp of the most recent event on the master executed by that thread.
- When the SQL thread thread has caught up to the slave I/O thread and goes idle waiting for more events from the I/O thread, this field is zero.

In essence, this field measures the time difference in seconds between the slave SQL thread and the slave I/O thread.

If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is *not* a good approximation; the slave SQL thread may quite often be caught up with the slow-reading slave I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the master. In other words, *this column is useful only for fast networks*.

This time difference computation works even though the master and slave do not have identical clocks (the clock difference is computed when the slave I/O thread starts, and assumed to remain constant from then on). `Seconds_Behind_Master` is NULL (which means “unknown”) if the slave SQL thread is not running, or if the slave I/O thread is not running or not connected to master. For example if the slave I/O thread is sleeping for the number of seconds given by the `-master-connect-retry` option before reconnecting, NULL is shown, as the slave cannot know what the master is doing, and so cannot say reliably how late it is.

This field has one limitation. The timestamp is preserved through replication, which means that, if a master M1 is itself a slave of M0, any event from M1's binlog which originates in replicating an event from M0's binlog has the timestamp of that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the drawback for `Seconds_Behind_Master` is that if M1 also receives direct updates from clients, the value randomly deviates, because sometimes the last M1's event is from M0 and sometimes it is the most recent timestamp from a direct update.

### 13.6.2.8. START SLAVE Syntax

```
START SLAVE [thread_type [, thread_type] ... ]
START SLAVE [SQL_THREAD] UNTIL
    MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
START SLAVE [SQL_THREAD] UNTIL
    RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos

thread_type: IO_THREAD | SQL_THREAD
```

`START SLAVE` with no *thread\_type* options starts both of the slave threads. The I/O thread reads queries from the master server and stores them in the relay log. The SQL thread reads the relay log and executes the queries. `START SLAVE` requires the SUPER privilege.

If `START SLAVE` succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary logs, or some other problem). `START SLAVE` does not warn you about this. You must check the slave's error log for error messages generated by the slave threads, or check that they are running satisfactorily with `SHOW SLAVE STATUS`.

You can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start.

An `UNTIL` clause may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary logs or in the slave relay logs. When the SQL thread reaches that point, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only

the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the UNTIL clause is ignored and a warning is issued.

For an UNTIL clause, you must specify both a log filename and position. Do not mix master and relay log options.

Any UNTIL condition is reset by a subsequent STOP SLAVE statement, a START SLAVE statement that includes no UNTIL clause, or a server restart.

The UNTIL clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate a statement. For example, if an unwise DROP TABLE statement was executed on the master, you can use UNTIL to tell the slave to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the master logs or slave relay logs, or by using a `SHOW BINLOG EVENTS` statement.

If you are using UNTIL to have the slave process replicated queries in sections, it is recommended that you start the slave with the `--skip-slave-start` option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the UNTIL condition.

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE START`. This usage is still accepted in MySQL 5.0 for backward compatibility, but is deprecated.

### 13.6.2.9. STOP SLAVE Syntax

```
STOP SLAVE [thread_type [, thread_type] ... ]  
thread_type: IO_THREAD | SQL_THREAD
```

Stops the slave threads. STOP SLAVE requires the SUPER privilege.

Like START SLAVE, this statement may be used with the IO\_THREAD and SQL\_THREAD options to name the thread or threads to be stopped.

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE STOP`. This usage is still accepted in MySQL 5.0 for backward compatibility, but is deprecated.

## 13.7. SQL Syntax for Prepared Statements

MySQL 5.0 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol implemented in MySQL 4.1, provided that you use an appropriate client programming interface. Candidate interfaces include the MySQL C API client library (for C programs), MySQL Connector/J (for Java programs), and MySQL Connector/NET. For example, the C API provides a set of function calls that make up its prepared statement API. See Section 22.2.4, “C API Prepared Statements”. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the `mysql_i` extension [[http://php.net/mysql\\_i](http://php.net/mysql_i)], available in PHP 5.0 and later.

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that allows you to send SQL statements to the server to be executed, such as the `mysql` client program.
- You can use it even if the client is using an old version of the client library. The only require-

ment is that you be able to connect to a server that is recent enough to support SQL syntax for prepared statements.

SQL syntax for prepared statements is intended to be used for situations such as these:

- You want to test how prepared statements work in your application before coding it.
- An application has problems executing prepared statements and you want to determine interactively what the problem is.
- You want to create a test case that describes a problem you are having with prepared statements, so that you can file a bug report.
- You need to use prepared statements but do not have access to a programming API that supports them.

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE stmt_name FROM preparable_stmt`

The `PREPARE` statement prepares a statement and assigns it a name, *stmt\_name*, by which to refer to the statement later. Statement names are not case sensitive. *preparable\_stmt* is either a string literal or a user variable that contains the text of the statement. The text must represent a single SQL statement, not multiple statements. Within the statement, ‘?’ characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The ‘?’ characters should not be enclosed within quotes, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the client session within which it is created. Other clients cannot see it.

- `EXECUTE stmt_name [USING @var_name [, @var_name] ...]`

After preparing a statement, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

- `{DEALLOCATE | DROP} PREPARE stmt_name`

To deallocate a prepared statement, use the `DEALLOCATE PREPARE` statement. Attempting to execute a prepared statement after deallocating it results in an error.

If you terminate a client session without deallocating a previously prepared statement, the server deallocates it automatically.

The following SQL statements can be used in prepared statements: `CREATE TABLE`, `DELETE`, `DO`, `INSERT`, `REPLACE`, `SELECT`, `SET`, `UPDATE`, and most `SHOW` statements. supported. `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` are supported as of MySQL 5.0.22. Other statements are not yet supported.

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|           5 |
+-----+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          10 |
+-----+
mysql> DEALLOCATE PREPARE stmt2;
```

As of MySQL 5.0.7, placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See Section 13.2.7, “`SELECT` Syntax”.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements cannot be used within stored routines (procedures or functions), or triggers. This restriction is lifted as of MySQL 5.0.13 for stored procedures, but not for stored functions or triggers.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by ‘;’ characters).

---

# Chapter 14. Storage Engines and Table Types

MySQL supports several storage engines that act as handlers for different table types. MySQL storage engines include both those that handle transaction-safe tables and those that handle non-transaction-safe tables:

- `MyISAM` manages non-transactional tables. It provides high-speed storage and retrieval, as well as fulltext searching capabilities. `MyISAM` is supported in all MySQL configurations, and is the default storage engine unless you have configured MySQL to use a different one by default.
- The `MEMORY` storage engine provides in-memory tables. The `MERGE` storage engine allows a collection of identical `MyISAM` tables to be handled as a single table. Like `MyISAM`, the `MEMORY` and `MERGE` storage engines handle non-transactional tables, and both are also included in MySQL by default.

**Note:** The `MEMORY` storage engine formerly was known as the `HEAP` engine.

- The `InnoDB` and `BDB` storage engines provide transaction-safe tables. `BDB` is included in MySQL-Max binary distributions on those operating systems that support it. `InnoDB` is also included by default in all MySQL 5.0 binary distributions. In source distributions, you can enable or disable either engine by configuring MySQL as you like.
- The `EXAMPLE` storage engine is a “stub” engine that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them. The purpose of this engine is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.
- `NDB Cluster` is the storage engine used by MySQL Cluster to implement tables that are partitioned over many computers. It is available in MySQL-Max 5.0 binary distributions. This storage engine is currently supported on Linux, Solaris, and Mac OS X only. We intend to add support for this engine on other platforms, including Windows, in future MySQL releases.
- The `ARCHIVE` storage engine is used for storing large amounts of data without indexes with a very small footprint.
- The `CSV` storage engine stores data in text files using comma-separated values format.
- The `BLACKHOLE` storage engine accepts but does not store data and retrievals always return an empty set.
- The `FEDERATED` storage engine was added in MySQL 5.0.3. This engine stores data in a remote database. Currently, it works with MySQL only, using the MySQL C Client API. In future releases, we intend to enable it to connect to other data sources using other drivers or client connection methods.

This chapter describes each of the MySQL storage engines except for `NDB Cluster`, which is covered in Chapter 15, *MySQL Cluster*.

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` or `TYPE` table option to the `CREATE TABLE` statement:

```
CREATE TABLE t (i INT) ENGINE = INNODB;  
CREATE TABLE t (i INT) TYPE = MEMORY;
```

The older term `TYPE` is supported as a synonym for `ENGINE` for backward compatibility, but `ENGINE` is the preferred term and `TYPE` is deprecated.

If you omit the `ENGINE` or `TYPE` option, the default storage engine is used. Normally, this is `MyISAM`, but you can change it by using the `--default-storage-engine` or `--default-table-type` server startup option, or by setting the `default-storage-engine` or `default-table-type` option in the `my.cnf` configuration file.

You can set the default storage engine to be used during the current session by setting the `storage_engine` or `table_type` variable:

```
SET storage_engine=MYISAM;
SET table_type=BDB;
```

When MySQL is installed on Windows using the MySQL Configuration Wizard, the InnoDB storage engine can be selected as the default instead of `MyISAM`. See Section 2.3.4.6, “The Database Usage Dialog”.

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```
ALTER TABLE t ENGINE = MYISAM;
ALTER TABLE t TYPE = BDB;
```

See Section 13.1.5, “`CREATE TABLE` Syntax”, and Section 13.1.2, “`ALTER TABLE` Syntax”.

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine, usually `MyISAM`. This behavior is convenient when you want to copy tables between MySQL servers that support different storage engines. (For example, in a replication setup, perhaps your master server supports transactional storage engines for increased safety, but the slave servers use only non-transactional storage engines for greater speed.)

This automatic substitution of the default storage engine for unavailable engines can be confusing for new MySQL users. A warning is generated whenever a storage engine is automatically changed.

For new tables, MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage.

A database may contain tables of different types. That is, tables need not all be created with the same storage engine.

Transaction-safe tables (TSTs) have several advantages over non-transaction-safe tables (NTSTs):

- They are safer. Even if MySQL crashes or you get hardware problems, you can get your data back, either by automatic recovery or from a backup plus the transaction log.
- You can combine many statements and accept them all at the same time with the `COMMIT` statement (if `autocommit` is disabled).
- You can execute `ROLLBACK` to ignore your changes (if `autocommit` is disabled).
- If an update fails, all of your changes are reverted. (With non-transaction-safe tables, all changes that have taken place are permanent.)
- Transaction-safe storage engines can provide better concurrency for tables that get many updates concurrently with reads.

You can combine transaction-safe and non-transaction-safe tables in the same statements to get the best of both worlds. However, although MySQL supports several transaction-safe storage engines, for best results, you should not mix different storage engines within a transaction with `autocommit`

disabled. For example, if you do this, changes to non-transaction-safe tables still are committed immediately and cannot be rolled back. For information about this and other problems that can occur in transactions that use mixed storage engines, see Section 13.4.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”.

Non-transaction-safe tables have several advantages of their own, all of which occur because there is no transaction overhead:

- Much faster
- Lower disk space requirements
- Less memory required to perform updates

## 14.1. The MyISAM Storage Engine

MyISAM is the default storage engine. It is based on the older ISAM code but has many useful extensions. (Note that MySQL 5.0 does *not* support ISAM.)

Each MyISAM table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format. The data file has an `.MYD` (MYData) extension. The index file has an `.MYI` (MYIndex) extension.

To specify explicitly that you want a MyISAM table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

The older term `TYPE` is supported as a synonym for `ENGINE` for backward compatibility, but `ENGINE` is the preferred term and `TYPE` is deprecated.

Normally, it is unnecessary to use `ENGINE` to specify the MyISAM storage engine. MyISAM is the default engine unless the default has been changed. To ensure that MyISAM is used in situations where the default might have been changed, include the `ENGINE` option explicitly.

You can check or repair MyISAM tables with the `mysqlcheck` client or `myisamchk` utility. You can also compress MyISAM tables with `myisampack` to take up much less space. See Section 8.10, “`mysqlcheck` — A Table Maintenance and Repair Program”, Section 5.10.4.1, “Using `myisamchk` for Crash Recovery”, and Section 8.5, “`myisampack` — Generate Compressed, Read-Only MyISAM Tables”.

MyISAM tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to allow better index compression.
- Large files (up to 63-bit file length) are supported on filesystems and operating systems that support large files.
- There is a limit of  $2^{32}$  (~4.295E+09) rows in a MyISAM table. You can increase this limitation if

you build MySQL with the `--with-big-tables` option then the row limitation is increased to  $(2^{32})^2$  (1.844E+19) rows. See Section 2.9.2, “Typical `configure` Options”. Beginning with MySQL 5.0.4 all standard binaries are built with this option.

- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- The maximum number of indexes per MyISAM table is 64. This can be changed by recompiling. Beginning with MySQL 5.0.18, you can configure the build by invoking `configure` with the `--with-max-indexes=N` option, where *N* is the maximum number of indexes to permit per MyISAM table. *N* must be less than or equal to 128. Before MySQL 5.0.18, you must change the source.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an `AUTO_INCREMENT` column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one `AUTO_INCREMENT` column per table is supported. MyISAM automatically updates this column for `INSERT` and `UPDATE` operations. This makes `AUTO_INCREMENT` columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an `AUTO_INCREMENT` column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The `AUTO_INCREMENT` value can be reset with `ALTER TABLE` or `myisamchk`.
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. (These are known as concurrent inserts.) A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See Section 7.3.3, “Concurrent Inserts”.
- You can put the data file and index file on different directories to get more speed with the `DATA DIRECTORY` and `INDEX DIRECTORY` table options to `CREATE TABLE`. See Section 13.1.5, “`CREATE TABLE` Syntax”.
- BLOB and TEXT columns can be indexed.
- NULL values are allowed in indexed columns. This takes 0–1 bytes per key.
- Each character column can have a different character set. See Chapter 10, *Character Set Support*.
- There is a flag in the MyISAM index file that indicates whether the table was closed correctly. If `mysqld` is started with the `--myisam-recover` option, MyISAM tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.
- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.
- `myisampack` can pack BLOB and VARCHAR columns.

MyISAM also supports the following features:

- Support for a true VARCHAR type; a VARCHAR column starts with a length stored in one or two bytes.
- Tables with VARCHAR columns may have fixed or dynamic row length.
- The sum of the lengths of the VARCHAR and CHAR columns in a table may be up to 64KB.
- A hashed computed index can be used for UNIQUE. This allows you to have UNIQUE on any combination of columns in a table. (However, you cannot search on a UNIQUE computed index.)

#### Additional resources

- A forum dedicated to the MyISAM storage engine is available at <http://forums.mysql.com/list.php?21>.

## 14.1.1. MyISAM Startup Options

The following options to `mysqld` can be used to change the behavior of MyISAM tables. For additional information, see Section 5.2.1, “`mysqld` Command Options”.

- `--myisam-recover=mode`  
Set the mode for automatic recovery of crashed MyISAM tables.
- `--delay-key-write=ALL`  
Don't flush key buffers between writes for any MyISAM table.

**Note:** If you do this, you should not access MyISAM tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of MyISAM tables. For additional information, see Section 5.2.2, “Server System Variables”.

- `bulk_insert_buffer_size`  
The size of the tree cache used in bulk insert optimization. **Note:** This is a limit *per thread*!
- `myisam_max_extra_sort_file_size`  
Used to help MySQL to decide when to use the slow but safe key cache index creation method. **Note:** This parameter was given in bytes before MySQL 5.0.6, when it was removed.
- `myisam_max_sort_file_size`  
The maximum size of the temporary file that MySQL is allowed to use while re-creating a MyISAM index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.
- `myisam_sort_buffer_size`  
Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover` option. In this case, when the server opens a MyISAM table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `--myisam-recover` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

Note that if the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a cron script that automatically moves these files from the database directories to backup media.

## 14.1.2. Space Needed for Keys

MyISAM tables use B-tree indexes. You can roughly calculate the size for the index file as  $(key\_length+4)/0.67$ , summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In MyISAM tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

## 14.1.3. MyISAM Table Storage Formats

MyISAM supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility.

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option. This causes `CHAR` and `VARCHAR` columns to become `CHAR` for `FIXED` format, or `VARCHAR` for `DYNAMIC` format.

You can decompress tables by specifying `ROW_FORMAT=DEFAULT` with `ALTER TABLE`.

See Section 13.1.5, “CREATE TABLE Syntax”, for information about ROW\_FORMAT.

### 14.1.3.1. Static (Fixed-Length) Table Characteristics

Static format is the default for MyISAM tables. It is used when the table contains no variable-length columns (VARCHAR, VARBINARY, BLOB, or TEXT). Each row is stored using a fixed number of bytes.

Of the three MyISAM storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format MyISAM file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. Note that MyISAM table indexes can always be reconstructed based on the data rows.

Static-format tables have these characteristics:

- CHAR columns are space-padded to the column width. This is also true for NUMERIC and DECIMAL columns created before MySQL 5.0.3. BINARY columns are space-padded to the column width before MySQL 5.0.15. As of 5.0.15, BINARY columns are padded with 0x00 bytes.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.
- Usually require more disk space than dynamic-format tables.

### 14.1.3.2. Dynamic Table Characteristics

Dynamic storage format is used if a MyISAM table contains any variable-length columns (VARCHAR, VARBINARY, BLOB, or TEXT), or if the table was created with the ROW\_FORMAT=DYNAMIC table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in non-contiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). Note that this does not include columns that contain NULL values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Non-empty

strings are saved as a length byte plus the string contents.

- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

$$\begin{aligned} & 3 \\ & + (\textit{number of columns} + 7) / 8 \\ & + (\textit{number of char columns}) \\ & + (\textit{packed size of numeric columns}) \\ & + (\textit{length of strings}) \\ & + (\textit{number of NULL columns} + 7) / 8 \end{aligned}$$

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

### 14.1.3.3. Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.
  - Numbers with a value of zero are stored using one bit.
  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
  - If a column has only a small set of possible values, the data type is converted to `ENUM`.
  - A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

### 14.1.4. MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

### 14.1.4.1. Corrupted MyISAM Tables

Even though the MyISAM table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or MyISAM code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a MyISAM table using the `CHECK TABLE` statement, and repair a corrupted MyISAM table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See Section 13.5.2.3, “`CHECK TABLE` Syntax”, Section 13.5.2.6, “`REPAIR TABLE` Syntax”, and Section 8.3, “`myisamchk` — MyISAM Table-Maintenance Utility”.

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See Section A.4.2, “What to Do If MySQL Keeps Crashing”, and Section E.1.6, “Making a Test Case If You Experience Table Corruption”.

### 14.1.4.2. Problems from Tables Not Being Closed Properly

Each MyISAM index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incre-

mented.

- The counter is not changed during further updates.
- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A `MyISAM` table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (Note that the table may still be okay, because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.
- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See Section 5.13, “Running Multiple MySQL Servers on the Same Machine”, for additional discussion.

## 14.2. The InnoDB Storage Engine

### 14.2.1. InnoDB Overview

InnoDB provides MySQL with a transaction-safe (ACID compliant) storage engine that has commit, rollback, and crash recovery capabilities. InnoDB does locking on the row level and also provides an Oracle-style consistent non-locking read in `SELECT` statements. These features increase multi-user concurrency and performance. There is no need for lock escalation in InnoDB because row-level locks fit in very little space. InnoDB also supports `FOREIGN KEY` constraints. You can freely mix InnoDB tables with tables from other MySQL storage engines, even within the same statement.

InnoDB has been designed for maximum performance when processing large data volumes. Its CPU efficiency is probably not matched by any other disk-based relational database engine.

Fully integrated with MySQL Server, the InnoDB storage engine maintains its own buffer pool for caching data and indexes in main memory. InnoDB stores its tables and indexes in a tablespace, which may consist of several files (or raw disk partitions). This is different from, for example, `MyISAM` tables where each table is stored using separate files. InnoDB tables can be of any size even on operating systems where file size is limited to 2GB.

InnoDB is included in binary distributions by default. The Windows Essentials installer makes InnoDB the MySQL default storage engine on Windows.

InnoDB is used in production at numerous large database sites requiring high performance. The famous Internet news site Slashdot.org runs on InnoDB. Myrix, Inc. stores over 1TB of data in

InnoDB, and another site handles an average load of 800 inserts/updates per second in InnoDB.

InnoDB is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see <http://www.mysql.com/company/legal/licensing/>.

#### Additional resources

## 14.2.3. InnoDB Configuration

The InnoDB storage engine is enabled by default. If you don't want to use InnoDB tables, you can add the `skip-innodb` option to your MySQL option file.

**Note:** InnoDB provides MySQL with a transaction-safe (ACID compliant) storage engine that has commit, rollback, and crash recovery capabilities. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very system call that should wait until all unwritten data for a file has been flushed — `fsync()` — might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, you should perform some “pull-the-plug” tests before using anything in production. On Mac OS X 10.3 and up, InnoDB uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.

On ATAPI hard disks, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

Two important disk-based resources managed by the InnoDB storage engine are its tablespace data files and its log files.

**Note:** If you specify no InnoDB configuration options, MySQL creates an auto-extending 10MB data file named `ibdata1` and two 5MB log files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. To get good performance, you should explicitly provide InnoDB parameters as discussed in the following examples. Naturally, you should edit the settings to suit your hardware and requirements.

The examples shown here are representative. See Section 14.2.4, “InnoDB Startup Options and System Variables” for additional information about InnoDB-related configuration parameters.

To set up the InnoDB tablespace files, use the `innodb_data_file_path` option in the `[mysqld]` section of the `my.cnf` option file. On Windows, you can use `my.ini` instead. The

value of `innodb_data_file_path` should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (‘;’) characters:

```
innodb_data_file_path=datafile_spec1[;datafile_spec2]...
```

For example, a setting that explicitly creates a tablespace having the same characteristics as the default is as follows:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend
```

This setting configures a single 10MB data file named `ibdata1` that is auto-extending. No location for the file is given, so by default, InnoDB creates it in the MySQL data directory.

Sizes are specified using M or G suffix letters to indicate units of MB or GB.

A tablespace containing a fixed-size 50MB data file named `ibdata1` and a 50MB auto-extending file named `ibdata2` in the data directory can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the filename, its size, and several optional attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The `autoextend` attribute and those following can be used only for the last data file in the `innodb_data_file_path` line.

If you specify the `autoextend` option for the last data file, InnoDB extends the data file if it runs out of free space in the tablespace. The increment is 8MB at a time by default. It can be modified by changing the `innodb_autoextend_increment` system variable.

If the disk becomes full, you might want to add another data file on another disk. Instructions for reconfiguring an existing tablespace are given in Section 14.2.7, “Adding and Removing InnoDB Data and Log Files”.

InnoDB is not aware of the filesystem maximum file size, so be cautious on filesystems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute. The following configuration allows `ibdata1` to grow up to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend:max:500M
```

InnoDB creates tablespace files in the MySQL data directory by default. To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to use two files named `ibdata1` and `ibdata2` but create them in the `/ibdata` directory, configure InnoDB like this:

```
[mysqld]
innodb_data_home_dir = /ibdata
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

**Note:** InnoDB does not create directories, so make sure that the `/ibdata` directory exists before you start the server. This is also true of any log file directories that you configure. Use the Unix or DOS `mkdir` command to create any necessary directories.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name, adding a pathname separator (slash or backslash)

between values if necessary. If the `innodb_data_home_dir` option is not mentioned in `my.cnf` at all, the default value is the “dot” directory `./`, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for the data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=/ibdata/ibdata1:50M;/ibdata/ibdata2:50M:autoextend
```

**A simple `my.cnf` example.** Suppose that you have a computer with 128MB RAM and one hard disk. The following example shows possible configuration parameters in `my.cnf` or `my.ini` for InnoDB, including the `autoextend` attribute. The example suits most users, both on Unix and Windows, who do not want to distribute InnoDB data files and log files onto several disks. It creates an auto-extending data file `ibdata1` and two InnoDB log files `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Also, the small archived InnoDB log file `ib_arch_log_0000000000` that InnoDB creates automatically ends up in the data directory.

```
[mysqld]
# You can write your other MySQL server options here
# ...
# Data files must be able to hold your data and indexes.
# Make sure that you have enough free disk space.
innodb_data_file_path = ibdata1:10M:autoextend
#
# Set buffer pool size to 50-80% of your computer's memory
innodb_buffer_pool_size=70M
innodb_additional_mem_pool_size=10M
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=20M
innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
```

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files or log files.

Note that data files must be less than 2GB in some filesystems. The combined size of the log files must be less than 4GB. The combined size of data files must be at least 10MB.

When you create an InnoDB tablespace for the first time, it is best that you start the MySQL server from the command prompt. InnoDB then prints the information about the database creation to the screen, so you can see what is happening. For example, on Windows, if `mysqld` is located in `C:\Program Files\MySQL\MySQL Server 5.0\bin`, you can start it like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqld" --console
```

If you do not send server output to the screen, check the server's error log to see what InnoDB prints during the startup process.

See Section 14.2.5, “Creating the InnoDB Tablespace”, for an example of what the information displayed by InnoDB should look like.

You can place InnoDB options in the `[mysqld]` group of any option file that your server reads when it starts. The locations for option files are described in Section 4.3.2, “Using Option Files”.

If you installed MySQL on Windows using the installation and configuration wizards, the option file will be the `my.ini` file located in your MySQL installation directory. See Section 2.3.4.14, “The

Location of the my.ini File”.

If your PC uses a boot loader where the C: drive is not the boot drive, your only option is to use the my.ini file in your Windows directory (typically C:\WINDOWS or C:\WINNT). You can use the SET command at the command prompt in a console window to print the value of WINDIR:

```
C:\> SET WINDIR
windir=C:\WINDOWS
```

If you want to make sure that mysqld reads options only from a specific file, you can use the --defaults-file option as the first option on the command line when starting the server:

```
mysqld --defaults-file=your_path_to_my_cnf
```

**An advanced my.cnf example.** Suppose that you have a Linux computer with 2GB RAM and three 60GB hard disks at directory paths /, /dr2 and /dr3. The following example shows possible configuration parameters in my.cnf for InnoDB.

```
[mysqld]
# You can write your other MySQL server options here
# ...
innodb_data_home_dir =
#
# Data files must be able to hold your data and indexes
innodb_data_file_path = /ibdata/ibdata1:2000M:/dr2/ibdata/ibdata2:2000M:autoext
#
# Set buffer pool size to 50-80% of your computer's memory,
# but make sure on Linux x86 total memory usage is < 2GB
innodb_buffer_pool_size=1G
innodb_additional_mem_pool_size=20M
innodb_log_group_home_dir = /dr3/iblogs
#
innodb_log_files_in_group = 2
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=250M
innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
innodb_lock_wait_timeout=50
#
# Uncomment the next lines if you want to use them
#innodb_thread_concurrency=5
```

In some cases, database performance improves if all data is not placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. The example illustrates how to do this. It places the two data files on different disks and places the log files on the third disk. InnoDB fills the tablespace beginning with the first data file. You can also use raw disk partitions (raw devices) as InnoDB data files, which may speed up I/O. See Section 14.2.3.2, “Using Raw Devices for the Shared Tablespace”.

**Warning:** On 32-bit GNU/Linux x86, you must be careful not to set memory usage too high. glibc may allow the process heap to grow over thread stacks, which crashes your server. It is a risk if the value of the following expression is close to or exceeds 2GB:

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL AB binaries) and in the worst case also uses sort\_buffer\_size + read\_buffer\_size additional memory.

By compiling MySQL yourself, you can use up to 64GB of physical memory in 32-bit Windows.

See the description for `innodb_buffer_pool_awesome_mem_mb` in Section 14.2.4, “InnoDB Startup Options and System Variables”.

**How to tune other `mysqld` server parameters?** The following values are typical and suit most users:

```
[mysqld]
skip-external-locking
max_connections=200
read_buffer_size=1M
sort_buffer_size=1M
#
# Set key_buffer to 5 - 50% of your RAM depending on how much
# you use MyISAM tables, but keep key_buffer_size + InnoDB
# buffer pool size < 80% of your RAM
key_buffer_size=value
```

### 14.2.3.1. Using Per-Table Tablespaces

You can store each InnoDB table and its indexes in its own file. This feature is called “multiple tablespaces” because in effect each table has its own tablespace.

Using multiple tablespaces can be beneficial to users who want to move specific tables to separate physical disks or who wish to restore backups of single tables quickly without interrupting the use of the remaining InnoDB tables.

You can enable multiple tablespaces by adding this line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table
```

After restarting the server, InnoDB stores each newly created table into its own file `tbl_name.ibd` in the database directory where the table belongs. This is similar to what the MyISAM storage engine does, but MyISAM divides the table into a data file `tbl_name.MYD` and the index file `tbl_name.MYI`. For InnoDB, the data and the indexes are stored together in the `.ibd` file. The `tbl_name.frm` file is still created as usual.

If you remove the `innodb_file_per_table` line from `my.cnf` and restart the server, InnoDB creates tables inside the shared tablespace files again.

`innodb_file_per_table` affects only table creation, not access to existing tables. If you start the server with this option, new tables are created using `.ibd` files, but you can still access tables that exist in the shared tablespace. If you remove the option and restart the server, new tables are created in the shared tablespace, but you can still access any tables that were created using multiple tablespaces.

**Note:** InnoDB always needs the shared tablespace because it puts its internal data dictionary and undo logs there. The `.ibd` files are not sufficient for InnoDB to operate.

**Note:** You cannot freely move `.ibd` files between database directories as you can with MyISAM table files. This is because the table definition that is stored in the InnoDB shared tablespace includes the database name, and because InnoDB must preserve the consistency of transaction IDs and log sequence numbers.

To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. Issue this ALTER TABLE statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

**Caution:** This statement deletes the current .ibd file.

2. Put the backup .ibd file back in the proper database directory.
3. Issue this ALTER TABLE statement:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

In this context, a “clean” .ibd file backup means:

- There are no uncommitted modifications by transactions in the .ibd file.
- There are no unmerged insert buffer entries in the .ibd file.
- Purge has removed all delete-marked index records from the .ibd file.
- mysqld has flushed all modified pages of the .ibd file from the buffer pool to the file.

You can make a clean backup .ibd file using the following method:

1. Stop all activity from the mysqld server and commit all transactions.
2. Wait until SHOW ENGINE INNODB STATUS shows that there are no active transactions in the database, and the main thread status of InnoDB is Waiting for server activity. Then you can make a copy of the .ibd file.

Another method for making a clean copy of an .ibd file is to use the commercial InnoDB Hot Backup tool:

1. Use InnoDB Hot Backup to back up the InnoDB installation.
2. Start a second mysqld server on the backup and let it clean up the .ibd files in the backup.

### 14.2.3.2. Using Raw Devices for the Shared Tablespace

You can use raw disk partitions as data files in the shared tablespace. By using a raw disk, you can perform non-buffered I/O on Windows and on some Unix systems without filesystem overhead, which may improve performance.

When you create a new data file, you must put the keyword `newraw` immediately after the data file size in `innodb_data_file_path`. The partition must be at least as large as the size that you specify. Note that 1MB in InnoDB is  $1024 \times 1024$  bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Gnewraw;/dev/hdd2:2Gnewraw
```

The next time you start the server, InnoDB notices the `newraw` keyword and initializes the new partition. However, do not create or change any InnoDB tables yet. Otherwise, when you next restart the server, InnoDB reinitializes the partition and your changes are lost. (As a safety measure

InnoDB prevents users from modifying data when any partition with `newraw` is specified.)

After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:5Graw:/dev/hdd2:2Graw
```

Then restart the server and InnoDB allows changes to be made.

On Windows, you can allocate a disk partition as a data file like this:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D:10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\\.\` for accessing physical drives.

When you use raw disk partitions, be sure that they have permissions that allow read and write access by the account used for running the MySQL server.

## 14.2.4. InnoDB Startup Options and System Variables

This section describes the InnoDB-related command options and system variables. System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `skip-` prefix. For example, to enable or disable InnoDB checksums, you can use `--innodb_checksums` or `--skip-innodb_checksums` on the command line, or `innodb_checksums` or `skip-innodb_checksums` in an option file. System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files. For more information on specifying options and system variables, see Section 4.3, “Specifying Program Options”. Many of the system variables can be changed at runtime (see Section 5.2.3.2, “Dynamic System Variables”).

InnoDB command options:

- `--innodb`  
Enables the InnoDB storage engine, if the server was compiled with InnoDB support. Use `--skip-innodb` to disable InnoDB.
- `--innodb_status_file`  
Causes InnoDB to create a file named `<datadir>/innodb_status.<pid>` in the MySQL data directory. InnoDB periodically writes the output of `SHOW ENGINE INNODB STATUS` to this file.

InnoDB system variables:

- `innodb_additional_mem_pool_size`  
The size in bytes of a memory pool InnoDB uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you need to allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 1MB.
- `innodb_autoextend_increment`  
The increment size (in MB) for extending the size of an auto-extending tablespace when it be-

comes full. The default value is 8.

- `innodb_buffer_pool_awe_mem_mb`

The size of the buffer pool (in MB), if it is placed in the AWE memory. This is relevant only in 32-bit Windows. If your 32-bit Windows operating system supports more than 4GB memory, using so-called “Address Windowing Extensions,” you can allocate the InnoDB buffer pool into the AWE physical memory using this variable. The maximum possible value for this variable is 63000. If it is greater than 0, `innodb_buffer_pool_size` is the window in the 32-bit address space of `mysqld` where InnoDB maps that AWE memory. A good value for `innodb_buffer_pool_size` is 500MB.

To take advantage of AWE memory, you will need to recompile MySQL yourself. The current project settings needed for doing this can be found in the `innobase/os/os0proj.c` source file.

- `innodb_buffer_pool_size`

The size in bytes of the memory buffer InnoDB uses to cache data and indexes of its tables. The larger you set this value, the less disk I/O is needed to access data in tables. On a dedicated database server, you may set this to up to 80% of the machine physical memory size. However, do not set it too large because competition for physical memory might cause paging in the operating system.

- `innodb_checksums`

InnoDB can use checksum validation on all pages read from the disk to ensure extra fault tolerance against broken hardware or data files. This validation is enabled by default. However, under some rare circumstances (such as when running benchmarks) this extra safety feature is unneeded and can be disabled with `--skip-innodb_checksums`. This variable was added in MySQL 5.0.3.

- `innodb_commit_concurrency`

The number of threads that can commit at the same time. A value of 0 disables concurrency control. This variable was added in MySQL 5.0.12.

- `innodb_concurrency_tickets`

The number of threads that can enter InnoDB concurrently is determined by the `innodb_thread_concurrency` variable. A thread is placed in a queue when it tries to enter InnoDB if the number of threads has already reached the concurrency limit. When a thread is allowed to enter InnoDB, it is given a number of “free tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave InnoDB freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter InnoDB. This variable was added in MySQL 5.0.3.

- `innodb_data_file_path`

The paths to individual data files and their sizes. The full directory path to each data file is formed by concatenating `innodb_data_home_dir` to each path specified here. The file sizes are specified in MB or GB (1024MB) by appending M or G to the size value. The sum of the sizes of the files must be at least 10MB. If you do not specify `innodb_data_file_path`, the default behavior is to create a single 10MB auto-extending data file named `ibdata1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on those operating systems that support big files. You can also use raw disk partitions as data files. See Section 14.2.3.2, “Using Raw Devices for the Shared Tablespace”.

- `innodb_data_home_dir`

The common part of the directory path for all InnoDB data files. If you do not set this value, the default is the MySQL data directory. You can specify the value as an empty string, in which case you can use absolute file paths in `innodb_data_file_path`.

- `innodb_doublewrite`

By default, InnoDB stores all data twice, first to the doublewrite buffer, and then to the actual data files. This variable is enabled by default. It can be turned off with `-skip-innodb_doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures. This variable was added in MySQL 5.0.3.

- `innodb_fast_shutdown`

If you set this variable to 0, InnoDB does a full purge and an insert buffer merge before a shutdown. These operations can take minutes, or even hours in extreme cases. If you set this variable to 1, InnoDB skips these operations at shutdown. The default value is 1. If you set it to 2, InnoDB will just flush its logs and then shut down cold, as if MySQL had crashed; no committed transaction will be lost, but crash recovery will be done at the next startup. The value of 2 can be used as of MySQL 5.0.5, except that it cannot be used on NetWare.

- `innodb_file_io_threads`

The number of file I/O threads in InnoDB. Normally, this should be left at the default value of 4, but disk I/O on Windows may benefit from a larger number. On Unix, increasing the number has no effect; InnoDB always uses the default value.

- `innodb_file_per_table`

If this variable is enabled, InnoDB creates each new table using its own `.ibd` file for storing data and indexes, rather than in the shared tablespace. The default is to create tables in the shared tablespace. See Section 14.2.3.1, “Using Per-Table Tablespaces”.

- `innodb_flush_log_at_trx_commit`

When `innodb_flush_log_at_trx_commit` is set to 0, the log buffer is written out to the log file once per second and the flush to disk operation is performed on the log file, but nothing is done at a transaction commit. When this value is 1 (the default), the log buffer is written out to the log file at each transaction commit and the flush to disk operation is performed on the log file. When set to 2, the log buffer is written out to the file at each commit, but the flush to disk operation is not performed on it. However, the flushing on the log file takes place once per second also when the value is 2. Note that the once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues.

The default value of this variable is 1, which is the value that is required for ACID compliance. You can achieve better performance by setting the value different from 1, but then you can lose at most one second worth of transactions in a crash. If you set the value to 0, then any `mysqld` process crash can erase the last second of transactions. If you set the value to 2, then only an operating system crash or a power outage can erase the last second of transactions. However, InnoDB's crash recovery is not affected and thus crash recovery does work regardless of the value. Note that many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. Then the durability of transactions is not guaranteed even with the setting 1, and in the worst case a power outage can even corrupt the InnoDB database. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try using the Unix command `hdparm` to disable the caching of disk writes in hardware caches, or use some other command specific to the hardware vendor.

- `innodb_flush_method`

If set to `fdatasync` (the default), InnoDB uses `fsync()` to flush both the data and log files. If set to `O_DSYNC`, InnoDB uses `O_SYNC` to open and flush the log files, but uses `fsync()` to

flush the data files. If `O_DIRECT` is specified (available on some GNU/Linux versions), InnoDB uses `O_DIRECT` to open the data files, and uses `fsync()` to flush both the data and log files. Note that InnoDB uses `fsync()` instead of `fdatasync()`, and it does not use `O_DSYNC` by default because there have been problems with it on many varieties of Unix. This variable is relevant only for Unix. On Windows, the flush method is always `async_unbuffered` and cannot be changed.

- `innodb_force_recovery`

The crash recovery mode. Warning: This variable should be set greater than 0 only in an emergency situation when you want to dump your tables from a corrupt database! Possible values are from 1 to 6. The meanings of these values are described in Section 14.2.8.1, “Forcing InnoDB Recovery”. As a safety measure, InnoDB prevents any changes to its data when this variable is greater than 0.

- `innodb_lock_wait_timeout`

The timeout in seconds an InnoDB transaction may wait for a lock before being rolled back. InnoDB automatically detects transaction deadlocks in its own lock table and rolls back the transaction. InnoDB notices locks set using the `LOCK TABLES` statement. The default is 50 seconds.

Note: For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should use `innodb_flush_log_at_trx_commit=1`, `sync_binlog=1`, and, before MySQL 5.0.3, `innodb_safe_binlog` in your master server `my.cnf` file. (`innodb_safe_binlog` is not needed from 5.0.3 on.)

- `innodb_locks_unsafe_for_binlog`

This variable controls next-key locking in InnoDB searches and index scans. By default, this variable is 0 (disabled), which means that next-key locking is enabled.

Normally, InnoDB uses an algorithm called *next-key locking*. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on any index records it encounters. Thus, the row-level locks are actually index record locks. The locks that InnoDB sets on index records also affect the “gap” preceding that index record. If a user has a shared or exclusive lock on record *R* in an index, another user cannot insert a new index record immediately before *R* in the order of the index. Enabling this variable causes InnoDB not to use next-key locking in searches or index scans. Next-key locking is still used to ensure foreign key constraints and duplicate key checking. Note that enabling this variable may cause phantom problems: Suppose that you want to read and lock all children from the child table with an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

Suppose that there is an index on the `id` column. The query scans that index starting from the first record where `id` is greater than 100. If the locks set on the index records do not lock out inserts made in the gaps, another client can insert a new row into the table. If you execute the same `SELECT` within the same transaction, you see a new row in the result set returned by the query. This also means that if new items are added to the database, InnoDB does not guarantee serializability. Therefore, if this variable is enabled InnoDB guarantees at most isolation level `READ COMMITTED`. (Conflict serializability is still guaranteed.)

Starting from MySQL 5.0.2, this option is even more unsafe. InnoDB in an `UPDATE` or a `DELETE` only locks rows that it updates or deletes. This greatly reduces the probability of deadlocks, but they can happen. Note that enabling this variable still does not allow operations such as `UPDATE` to overtake other similar operations (such as another `UPDATE`) even in the case when they affect different rows. Consider the following example, beginning with this table:

```
CREATE TABLE A(A INT NOT NULL, B INT) ENGINE = InnoDB;  
INSERT INTO A VALUES (1,2), (2,3), (3,2), (4,3), (5,2);
```

```
COMMIT;
```

Suppose that one client executes these statements:

```
SET AUTOCOMMIT = 0;  
UPDATE A SET B = 5 WHERE B = 3;
```

Then suppose that another client executes these statements following those of the first client:

```
SET AUTOCOMMIT = 0;  
UPDATE A SET B = 4 WHERE B = 2;
```

In this case, the second UPDATE must wait for a commit or rollback of the first UPDATE. The first UPDATE has an exclusive lock on row (2,3), and the second UPDATE while scanning rows also tries to acquire an exclusive lock for the same row, which it cannot have. This is because UPDATE two first acquires an exclusive lock on a row and then determines whether the row belongs to the result set. If not, it releases the unnecessary lock, when the `innodb_locks_unsafe_for_binlog` variable is enabled.

Therefore, InnoDB executes UPDATE one as follows:

```
x-lock(1,2)  
unlock(1,2)  
x-lock(2,3)  
update(2,3) to (2,5)  
x-lock(3,2)  
unlock(3,2)  
x-lock(4,3)  
update(4,3) to (4,5)  
x-lock(5,2)  
unlock(5,2)
```

InnoDB executes UPDATE two as follows:

```
x-lock(1,2)  
update(1,2) to (1,4)  
x-lock(2,3) - wait for query one to commit or rollback
```

- `innodb_log_arch_dir`

The directory where fully written log files would be archived if we used log archiving. If used, the value of this variable should be set the same as `innodb_log_group_home_dir`. However, it is not required.

- `innodb_log_archive`

Whether to log InnoDB archive files. This variable is present for historical reasons, but is unused. Recovery from a backup is done by MySQL using its own log files, so there is no need to archive InnoDB log files. The default for this variable is 0.

- `innodb_log_buffer_size`

The size in bytes of the buffer that InnoDB uses to write to the log files on disk. Sensible values range from 1MB to 8MB. The default is 1MB. A large log buffer allows large transactions to run without a need to write the log to disk before the transactions commit. Thus, if you have big transactions, making the log buffer larger saves disk I/O.

- `innodb_log_file_size`

The size in bytes of each log file in a log group. The combined size of log files must be less than

4GB on 32-bit computers. The default is 5MB. Sensible values range from 1MB to 1/*N*-th of the size of the buffer pool, where *N* is the number of log files in the group. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. But larger log files also mean that recovery is slower in case of a crash.

- `innodb_log_files_in_group`

The number of log files in the log group. InnoDB writes to the files in a circular fashion. The default (and recommended) is 2.

- `innodb_log_group_home_dir`

The directory path to the InnoDB log files. It must have the same value as `innodb_log_arch_dir`. If you do not specify any InnoDB log variables, the default is to create two 5MB files names `ib_logfile0` and `ib_logfile1` in the MySQL data directory.

- `innodb_max_dirty_pages_pct`

This is an integer in the range from 0 to 100. The default is 90. The main thread in InnoDB tries to write pages from the buffer pool so that the percentage of dirty (not yet written) pages will not exceed this value.

- `innodb_max_purge_lag`

This variable controls how to delay INSERT, UPDATE and DELETE operations when the purge operations are lagging (see Section 14.2.12, “Implementation of Multi-Versioning”). The default value of this variable is 0, meaning that there are no delays.

The InnoDB transaction system maintains a list of transactions that have delete-marked index records by UPDATE or DELETE operations. Let the length of this list be *purge\_lag*. When *purge\_lag* exceeds `innodb_max_purge_lag`, each INSERT, UPDATE and DELETE operation is delayed by  $((\text{purge\_lag}/\text{innodb\_max\_purge\_lag}) \times 10) - 5$  milliseconds. The delay is computed in the beginning of a purge batch, every ten seconds. The operations are not delayed if purge cannot run because of an old consistent read view that could see the rows to be purged.

A typical setting for a problematic workload might be 1 million, assuming that our transactions are small, only 100 bytes in size, and we can allow 100MB of unpurged rows in our tables.

- `innodb_mirrored_log_groups`

The number of identical copies of log groups to keep for the database. Currently, this should be set to 1.

- `innodb_open_files`

This variable is relevant only if you use multiple tablespaces in InnoDB. It specifies the maximum number of `.ibd` files that InnoDB can keep open at one time. The minimum value is 10. The default is 300.

The file descriptors used for `.ibd` files are for InnoDB only. They are independent of those specified by the `--open-files-limit` server option, and do not affect the operation of the table cache.

- `innodb_safe_binlog`

Adds consistency guarantees between the content of InnoDB tables and the binary log. See Section 5.12.3, “The Binary Log”. This variable was removed in MySQL 5.0.3, having been made obsolete by the introduction of XA transaction support.

- `innodb_support_xa`

When set to ON or 1 (the default), this variable enables InnoDB support for two-phase commit

in XA transactions. Enabling `innodb_support_xa` causes an extra disk flush for transaction preparation. If you don't care about using XA, you can disable this variable by setting it to `OFF` or `0` to reduce the number of disk flushes and get better InnoDB performance. This variable was added in MySQL 5.0.3.

- `innodb_sync_spin_loops`

The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended. This variable was added in MySQL 5.0.3.

- `innodb_table_locks`

InnoDB honors `LOCK TABLES`; MySQL does not return from `LOCK TABLE ... WRITE` until all other threads have released all their locks to the table. The default value is `1`, which means that `LOCK TABLES` causes InnoDB to lock a table internally. In applications using `AUTOCOMMIT=1`, InnoDB's internal table locks can cause deadlocks. You can set `innodb_table_locks=0` in the server option file to remove that problem.

- `innodb_thread_concurrency`

InnoDB tries to keep the number of operating system threads concurrently inside InnoDB less than or equal to the limit given by this variable. Before MySQL 5.0.8, the default value is `8`. If you have performance issues, and `SHOW ENGINE INNODB STATUS` reveals many threads waiting for semaphores, you may have thread “thrashing” and should try setting this variable lower or higher. If you have a computer with many processors and disks, you can try setting the value higher to make better use of your computer's resources. A recommended value is the sum of the number of processors and disks your system has. A value of `500` or greater disables concurrency checking. Starting with MySQL 5.0.8, the default value is `20`, and concurrency checking will be disabled if the setting is greater than or equal to `20`.

- `innodb_thread_sleep_delay`

How long InnoDB threads sleep before joining the InnoDB queue, in microseconds. The default value is `10,000`. A value of `0` disables sleep. This variable was added in MySQL 5.0.3.

- `sync_binlog`

If the value of this variable is positive, the MySQL server synchronizes its binary log to disk (`fsync()`) after every `sync_binlog` writes to this binary log. Note that there is one write to the binary log per statement if in autocommit mode, and otherwise one write per transaction. The default value is `0` which does no synchronizing to disk. A value of `1` is the safest choice, because in the event of a crash you lose at most one statement/transaction from the binary log; however, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

## 14.2.5. Creating the InnoDB Tablespace

Suppose that you have installed MySQL and have edited your option file so that it contains the necessary InnoDB configuration parameters. Before starting MySQL, you should verify that the directories you have specified for InnoDB data files and log files exist and that the MySQL server has access rights to those directories. InnoDB does not create directories, only files. Check also that you have enough disk space for the data and log files.

It is best to run the MySQL server `mysqld` from the command prompt when you first start the server with InnoDB enabled, not from the `mysqld_safe` wrapper or as a Windows service. When you run from a command prompt you see what `mysqld` prints and what is happening. On Unix, just invoke `mysqld`. On Windows, use the `--console` option.

When you start the MySQL server after initially configuring InnoDB in your option file, InnoDB creates your data files and log files, and prints something like this:

```
InnoDB: The first specified datafile /home/heikki/data/ibdata1
```

```
did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file /home/heikki/data/ibdata1 size to 134217728
InnoDB: Database physically writes the file full: wait...
InnoDB: datafile /home/heikki/data/ibdata2 did not exist:
new to be created
InnoDB: Setting file /home/heikki/data/ibdata2 size to 262144000
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file /home/heikki/data/logs/ib_logfile0 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile0 size
to 5242880
InnoDB: Log file /home/heikki/data/logs/ib_logfile1 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile1 size
to 5242880
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: Creating foreign key constraint system tables
InnoDB: Foreign key constraint system tables created
InnoDB: Started
mysqld: ready for connections
```

At this point InnoDB has initialized its tablespace and log files. You can connect to the MySQL server with the usual MySQL client programs like `mysql`. When you shut down the MySQL server with `mysqladmin shutdown`, the output is like this:

```
010321 18:33:34 mysqld: Normal shutdown
010321 18:33:34 mysqld: Shutdown Complete
InnoDB: Starting shutdown...
InnoDB: Shutdown completed
```

You can look at the data file and log directories and you see the files created there. The log directory also contains a small file named `ib_arch_log_0000000000`. That file resulted from the database creation, after which InnoDB switched off log archiving. When MySQL is started again, the data files and log files have been created already, so the output is much briefer:

```
InnoDB: Started
mysqld: ready for connections
```

If you add the `innodb_file_per_table` option to `my.cnf`, InnoDB stores each table in its own `.ibd` file in the same MySQL database directory where the `.frm` file is created. See Section 14.2.3.1, “Using Per-Table Tablespaces”.

### 14.2.5.1. Dealing with InnoDB Initialization Problems

If InnoDB prints an operating system error during a file operation, usually the problem has one of the following causes:

- You did not create the InnoDB data file directory or the InnoDB log directory.
- `mysqld` does not have access rights to create files in those directories.
- `mysqld` cannot read the proper `my.cnf` or `my.ini` option file, and consequently does not see the options that you specified.
- The disk is full or a disk quota is exceeded.
- You have created a subdirectory whose name is equal to a data file that you specified, so the name cannot be used as a filename.
- There is a syntax error in the `innodb_data_home_dir` or `innodb_data_file_path`

value.

If something goes wrong when InnoDB attempts to initialize its tablespace or its log files, you should delete all files created by InnoDB. This means all `ibdata` files and all `ib_logfile` files. In case you have already created some InnoDB tables, delete the corresponding `.frm` files for these tables (and any `.ibd` files if you are using multiple tablespaces) from the MySQL database directories as well. Then you can try the InnoDB database creation again. It is best to start the MySQL server from a command prompt so that you see what is happening.

## 14.2.6. Creating and Using InnoDB Tables

To create an InnoDB table, specify an `ENGINE = InnoDB` option in the `CREATE TABLE` statement:

```
CREATE TABLE customers (a INT, b CHAR (20), INDEX (a)) ENGINE=InnoDB;
```

The older term `TYPE` is supported as a synonym for `ENGINE` for backward compatibility, but `ENGINE` is the preferred term and `TYPE` is deprecated.

The statement creates a table and an index on column `a` in the InnoDB tablespace that consists of the data files that you specified in `my.cnf`. In addition, MySQL creates a file `customers.frm` in the `test` directory under the MySQL database directory. Internally, InnoDB adds an entry for the table to its own data dictionary. The entry includes the database name. For example, if `test` is the database in which the `customers` table is created, the entry is for `'test/customers'`. This means you can create a table of the same name `customers` in some other database, and the table names do not collide inside InnoDB.

You can query the amount of free space in the InnoDB tablespace by issuing a `SHOW TABLE STATUS` statement for any InnoDB table. The amount of free space in the tablespace appears in the `Comment` section in the output of `SHOW TABLE STATUS`. For example:

```
SHOW TABLE STATUS FROM test LIKE 'customers'
```

Note that the statistics `SHOW` displays for InnoDB tables are only approximate. They are used in SQL optimization. Table and index reserved sizes in bytes are accurate, though.

### 14.2.6.1. How to Use Transactions in InnoDB with Different APIs

By default, each client that connects to the MySQL server begins with autocommit mode enabled, which automatically commits every SQL statement as you execute it. To use multiple-statement transactions, you can switch autocommit off with the SQL statement `SET AUTOCOMMIT = 0` and use `COMMIT` and `ROLLBACK` to commit or roll back your transaction. If you want to leave autocommit on, you can enclose your transactions within `START TRANSACTION` and either `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test

mysql> CREATE TABLE CUSTOMER (A INT, B CHAR (20), INDEX (A))
      -> ENGINE=InnoDB;
Query OK, 0 rows affected (0.00 sec)
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO CUSTOMER VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> SET AUTOCOMMIT=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO CUSTOMER VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM CUSTOMER;
+-----+-----+
| A      | B      |
+-----+-----+
| 10    | Heikki |
+-----+-----+
1 row in set (0.00 sec)
mysql>
```

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as COMMIT to the MySQL server as strings just like any other SQL statements such as SELECT or INSERT. Some APIs also offer separate special transaction commit and rollback functions or methods.

### 14.2.6.2. Converting MyISAM Tables to InnoDB

Important: Do not convert MySQL system tables in the `mysql` database (such as `user` or `host`) to the InnoDB type. This is an unsupported operation. The system tables must always be of the MyISAM type.

If you want all your (non-system) tables to be created as InnoDB tables, you can simply add the line `default-storage-engine=innodb` to the `[mysqld]` section of your server option file.

InnoDB does not have a special optimization for separate index creation the way the MyISAM storage engine does. Therefore, it does not pay to export and import the table and create indexes afterward. The fastest way to alter a table to InnoDB is to do the inserts directly to an InnoDB table. That is, use `ALTER TABLE ... ENGINE=INNODB`, or create an empty InnoDB table with identical definitions and insert the rows with `INSERT INTO ... SELECT * FROM ...`.

If you have UNIQUE constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET UNIQUE_CHECKS=0;
... import operation ...
SET UNIQUE_CHECKS=1;
```

For big tables, this saves a lot of disk I/O because InnoDB can then use its insert buffer to write secondary index records as a batch. Be certain that the data contains no duplicate keys. UNIQUE\_CHECKS allows but does not require storage engines to ignore duplicate keys.

To get better control over the insertion process, it might be good to insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
  WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records have been inserted, you can rename the tables.

During the conversion of big tables, you should increase the size of the InnoDB buffer pool to reduce disk I/O. Do not use more than 80% of the physical memory, though. You can also increase the sizes of the InnoDB log files.

Make sure that you do not fill up the tablespace: InnoDB tables require a lot more disk space than MyISAM tables. If an ALTER TABLE operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, InnoDB uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see Section 14.2.8.1, “Forcing InnoDB Recovery”.

### 14.2.6.3. How AUTO\_INCREMENT Columns Work in InnoDB

If you specify an AUTO\_INCREMENT column for an InnoDB table, the table handle in the InnoDB data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

InnoDB uses the following algorithm to initialize the auto-increment counter for a table *T* that contains an AUTO\_INCREMENT column named *ai\_col*: After a server startup, for the first insert into a table *T*, InnoDB executes the equivalent of this statement:

```
SELECT MAX(ai_col) FROM T FOR UPDATE;
```

InnoDB increments by one the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. If the table is empty, InnoDB uses the value 1. If a user invokes a SHOW TABLE STATUS statement that displays output for the table *T* and the auto-increment counter has not been initialized, InnoDB initializes but does not increment the value and stores it for use by later inserts. Note that this initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction.

InnoDB follows the same procedure for initializing the auto-increment counter for a freshly created table.

After the auto-increment counter has been initialized, if a user does not explicitly specify a value for an AUTO\_INCREMENT column, InnoDB increments the counter by one and assigns the new value to the column. If the user inserts a row that explicitly specifies the column value, and the value is bigger than the current counter value, the counter is set to the specified column value.

You may see gaps in the sequence of values assigned to the AUTO\_INCREMENT column if you roll back transactions that have generated numbers using the counter.

If a user specifies NULL or 0 for the AUTO\_INCREMENT column in an INSERT, InnoDB treats the row as if the value had not been specified and generates a new value for it.

The behavior of the auto-increment mechanism is not defined if a user assigns a negative value to the column or if the value becomes bigger than the maximum integer that can be stored in the specified integer type.

When accessing the auto-increment counter, InnoDB uses a special table-level AUTO-INC lock that it keeps to the end of the current SQL statement, not to the end of the transaction. The special lock release strategy was introduced to improve concurrency for inserts into a table containing an AUTO\_INCREMENT column. Nevertheless, two transactions cannot have the AUTO-INC lock on the same table simultaneously, which can have a performance impact if the AUTO-INC lock is held for a long time. That might be the case for a statement such as INSERT INTO *t1* ... SELECT ... FROM *t2* that inserts all rows from one table into another.

InnoDB uses the in-memory auto-increment counter as long as he server runs. When the server is stopped and restarted, InnoDB reinitializes the counter for each table for the first INSERT to the table, as described earlier.

Beginning with MySQL 5.0.3, InnoDB supports the AUTO\_INCREMENT = *N* table option in CREATE TABLE and ALTER TABLE statements, to set the initial counter value or alter the current counter value. The effect of this option is canceled by a server restart, for reasons discussed earlier in this section.

### 14.2.6.4. FOREIGN KEY Constraints

InnoDB also supports foreign key constraints. The syntax for a foreign key constraint definition in InnoDB looks like this:

```
[CONSTRAINT symbol] FOREIGN KEY [id] (index_col_name, ...)
  REFERENCES tbl_name (index_col_name, ...)
  [ON DELETE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
```

[ ON UPDATE { RESTRICT | CASCADE | SET NULL | NO ACTION } ]

Foreign keys definitions are subject to the following conditions:

- Both tables must be InnoDB tables and they must not be TEMPORARY tables.
- In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist.
- In the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- Index prefixes on foreign key columns are not supported. One consequence of this is that BLOB and TEXT columns cannot be included in a foreign key, because indexes on those columns must always include a prefix length.
- If the CONSTRAINT *symbol* clause is given, the *symbol* value must be unique in the database. If the clause is not given, InnoDB creates the name automatically.

InnoDB rejects any INSERT or UPDATE operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table. The action InnoDB takes for any UPDATE or DELETE operation that attempts to update or delete a candidate key value in the parent table that has some matching rows in the child table is dependent on the *referential action* specified using ON UPDATE and ON DELETE subclauses of the FOREIGN KEY clause. When the user attempts to delete or update a row from a parent table, and there are one or more matching rows in the child table, InnoDB supports five options regarding the action to be taken:

- CASCADE: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both ON DELETE CASCADE and ON UPDATE CASCADE are supported. Between two tables, you should not define several ON UPDATE CASCADE clauses that act on the same column in the parent table or in the child table.
- SET NULL: Delete or update the row from the parent table and set the foreign key column or columns in the child table to NULL. This is valid only if the foreign key columns do not have the NOT NULL qualifier specified. Both ON DELETE SET NULL and ON UPDATE SET NULL clauses are supported.
- NO ACTION: In standard SQL, NO ACTION means *no action* in the sense that an attempt to delete or update a primary key value is not allowed to proceed if there is a related foreign key value in the referenced table. InnoDB rejects the delete or update operation for the parent table.
- RESTRICT: Rejects the delete or update operation for the parent table. NO ACTION and RESTRICT are the same as omitting the ON DELETE or ON UPDATE clause. (Some database systems have deferred checks, and NO ACTION is a deferred check. In MySQL, foreign key constraints are checked immediately, so NO ACTION and RESTRICT are the same.)
- SET DEFAULT: This action is recognized by the parser, but InnoDB rejects table definitions containing ON DELETE SET DEFAULT or ON UPDATE SET DEFAULT clauses.

Note that InnoDB supports foreign key references within a table. In these cases, “child table records” really refers to dependent records within the same table.

InnoDB requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. The index on the foreign key is created automatically. This is in contrast to some older versions, in which indexes had to be created explicitly or the creation of foreign key constraints would fail.

Corresponding columns in the foreign key and the referenced key must have similar internal data types inside InnoDB so that they can be compared without a type conversion. *The size and sign of*

*integer types must be the same.* The length of string types need not be the same. If you specify a SET NULL action, *make sure that you have not declared the columns in the child table as NOT NULL.*

If MySQL reports an error number 1005 from a CREATE TABLE statement, and the error message refers to errno 150, table creation failed because a foreign key constraint was not correctly formed. Similarly, if an ALTER TABLE fails and it refers to errno 150, that means a foreign key definition would be incorrectly formed for the altered table. You can use SHOW ENGINE INNODB STATUS to display a detailed explanation of the most recent InnoDB foreign key error in the server.

**Note:** InnoDB does not check foreign key constraints on those foreign key or referenced key values that contain a NULL column.

**Note:** Currently, triggers are not activated by cascaded foreign key actions.

**Deviation from SQL standards:** If there are several rows in the parent table that have the same referenced key value, InnoDB acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a RESTRICT type constraint, and there is a child row with several parent rows, InnoDB does not allow the deletion of any of those parent rows.

InnoDB performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.

**Deviation from SQL standards:** A FOREIGN KEY constraint that references a non-UNIQUE key is not standard SQL. It is an InnoDB extension to standard SQL.

**Deviation from SQL standards:** If ON UPDATE CASCADE or ON UPDATE SET NULL recurses to update the *same table* it has previously updated during the cascade, it acts like RESTRICT. This means that you cannot use self-referential ON UPDATE CASCADE or ON UPDATE SET NULL operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential ON DELETE SET NULL, on the other hand, is possible, as is a self-referential ON DELETE CASCADE. Cascading operations may not be nested more than 15 levels deep.

**Deviation from SQL standards:** Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, InnoDB checks UNIQUE and FOREIGN KEY constraints row-by-row. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. Until InnoDB implements deferred constraint checking, some things will be impossible, such as deleting a record that refers to itself via a foreign key.

Here is a simple example that relates parent and child tables through a single-column foreign key:

```
CREATE TABLE parent (id INT NOT NULL,
                     PRIMARY KEY (id)
) ENGINE=INNODB;
CREATE TABLE child (id INT, parent_id INT,
                    INDEX par_ind (parent_id),
                    FOREIGN KEY (parent_id) REFERENCES parent(id)
                    ON DELETE CASCADE
) ENGINE=INNODB;
```

A more complex example in which a product\_order table has foreign keys for two other tables. One foreign key references a two-column index in the product table. The other references a single-column index in the customer table:

```
CREATE TABLE product (category INT NOT NULL, id INT NOT NULL,
                      price DECIMAL,
                      PRIMARY KEY(category, id)) ENGINE=INNODB;
CREATE TABLE customer (id INT NOT NULL,
                       PRIMARY KEY (id)) ENGINE=INNODB;
CREATE TABLE product_order (no INT NOT NULL AUTO_INCREMENT,
                             product_category INT NOT NULL,
                             product_id INT NOT NULL,
```

```

customer_id INT NOT NULL,
PRIMARY KEY(no),
INDEX (product_category, product_id),
FOREIGN KEY (product_category, product_id)
REFERENCES product(category, id)
ON UPDATE CASCADE ON DELETE RESTRICT,
INDEX (customer_id),
FOREIGN KEY (customer_id)
REFERENCES customer(id)) ENGINE=INNODB;

```

InnoDB allows you to add a new foreign key constraint to a table by using ALTER TABLE:

```

ALTER TABLE tbl_name
ADD [CONSTRAINT symbol] FOREIGN KEY [id] (index_col_name, ...)
REFERENCES tbl_name (index_col_name, ...)
[ON DELETE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
[ON UPDATE {RESTRICT | CASCADE | SET NULL | NO ACTION}]

```

**Remember to create the required indexes first.** You can also add a self-referential foreign key constraint to a table using ALTER TABLE.

InnoDB also supports the use of ALTER TABLE to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the FOREIGN KEY clause included a CONSTRAINT name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the *fk\_symbol* value is internally generated by InnoDB when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use the SHOW CREATE TABLE statement. For example:

```

mysql> SHOW CREATE TABLE ibtest11c\G
***** 1. row *****
      Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY (`A`,`D`,`B`),
  KEY `B` (`B`,`C`),
  KEY `C` (`C`),
  CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`)
REFERENCES `ibtest11a` (`A`, `D`)
ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`)
REFERENCES `ibtest11a` (`B`, `C`)
ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=latin1
1 row in set (0.01 sec)

```

```
mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY `0_38775`;
```

You cannot add a foreign key and drop a foreign key in separate clauses of a single ALTER TABLE statement. Separate statements are required.

The InnoDB parser allows table and column identifiers in a FOREIGN KEY ... REFERENCES ... clause to be quoted within backticks. (Alternatively, double quotes can be used if the ANSI\_QUOTES SQL mode is enabled.) The InnoDB parser also takes into account the setting of the lower\_case\_table\_names system variable.

InnoDB returns a table's foreign key definitions as part of the output of the SHOW CREATE TABLE statement:

```
SHOW CREATE TABLE tbl_name;
```

`mysqldump` also produces correct definitions of tables to the dump file, and does not forget about the foreign keys.

You can also display the foreign key constraints for a table like this:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name';
```

The foreign key constraints are listed in the `Comment` column of the output.

When performing foreign key checks, InnoDB sets shared row-level locks on child or parent records it has to look at. InnoDB checks foreign key constraints immediately; the check is not deferred to transaction commit.

To make it easier to reload dump files for tables that have foreign key relationships, `mysqldump` automatically includes a statement in the dump output to set `FOREIGN_KEY_CHECKS` to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```
mysql> SET FOREIGN_KEY_CHECKS = 0;
mysql> SOURCE dump_file_name;
mysql> SET FOREIGN_KEY_CHECKS = 1;
```

This allows you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting `FOREIGN_KEY_CHECKS` to 0 can also be useful for ignoring foreign key constraints during `LOAD DATA` and `ALTER TABLE` operations. However, even if `FOREIGN_KEY_CHECKS=0`, InnoDB does not allow the creation of a foreign key constraint where a column references a non-matching column type.

InnoDB does not allow you to drop a table that is referenced by a `FOREIGN KEY` constraint, unless you do `SET FOREIGN_KEY_CHECKS=0`. When you drop a table, the constraints that were defined in its create statement are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the right column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns error number 1005 and refers to `errno 150` in the error message.

## 14.2.6.5. InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave.

To set up a new slave for a master, you have to make a copy of the InnoDB tablespace and the log files, as well as the `.frm` files of the InnoDB tables, and move the copies to the slave. If the `innodb_file_per_table` variable is enabled, you must also copy the `.ibd` files as well. For the proper procedure to do this, see Section 14.2.8, “Backing Up and Recovering an InnoDB Database”.

If you can shut down the master or an existing slave, you can take a cold backup of the InnoDB tablespace and log files and use that to set up a slave. To make a new slave without taking down any server you can also use the non-free (commercial) InnoDB Hot Backup tool [<http://www.innodb.com/order.html>].

You cannot set up replication for InnoDB using the `LOAD TABLE FROM MASTER` statement, which works only for MyISAM tables. There are two possible workarounds:

- Dump the table on the master and import the dump file into the slave.
- Use `ALTER TABLE tbl_name ENGINE=MyISAM` on the master before setting up replication with `LOAD TABLE tbl_name FROM MASTER`, and then use `ALTER TABLE` to convert the master table back to InnoDB afterward. However, this should not be done for tables that have foreign key definitions because the definitions will be lost.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See Section 13.4.1, “`START TRANSACTION, COMMIT, and ROLLBACK Syntax`”.

## 14.2.7. Adding and Removing InnoDB Data and Log Files

This section describes what you can do when your InnoDB tablespace runs out of room or when you want to change the size of the log files.

The easiest way to increase the size of the InnoDB tablespace is to configure it from the beginning to be auto-extending. Specify the `autoextend` attribute for the last data file in the tablespace definition. Then InnoDB increases the size of that file automatically in 8MB increments when it runs out of space. The increment size can be changed by setting the value of the `innodb_autoextend_increment` system variable, which is measured in MB.

Alternatively, you can increase the size of your tablespace by adding another data file. To do this, you have to shut down the MySQL server, change the tablespace configuration to add a new data file to the end of `innodb_data_file_path`, and start the server again.

If your last data file was defined with the keyword `autoextend`, the procedure for reconfiguring the tablespace must take into account the size to which the last data file has grown. Obtain the size of the data file, round it down to the closest multiple of  $1024 \times 1024$  bytes (= 1MB), and specify the rounded size explicitly in `innodb_data_file_path`. Then you can add another data file. Remember that only the last data file in the `innodb_data_file_path` can be specified as auto-extending.

As an example, assume that the tablespace has just one auto-extending data file `ibdata1`:

```
innodb_data_home_dir =  
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after modifying the original data file to not be auto-extending and adding another auto-extending data file:

```
innodb_data_home_dir =  
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When you add a new file to the tablespace configuration, make sure that it does not exist. InnoDB will create and initialize the file when you restart the server.

Currently, you cannot remove a data file from the tablespace. To decrease the size of your tablespace, use this procedure:

1. Use `mysqldump` to dump all your InnoDB tables.
2. Stop the server.
3. Remove all the existing tablespace files.

4. Configure a new tablespace.
5. Restart the server.
6. Import the dump files.

If you want to change the number or the size of your InnoDB log files, you have to stop the MySQL server and make sure that it shuts down without errors (to ensure that there is no information for outstanding transactions in the logs). Then copy the old log files into a safe place just in case something went wrong in the shutdown and you need them to recover the tablespace. Delete the old log files from the log file directory, edit `my.cnf` to change the log file configuration, and start the MySQL server again. `mysqld` sees that no log files exist at startup and tells you that it is creating new ones.

## 14.2.8. Backing Up and Recovering an InnoDB Database

The key to safe database management is making regular backups.

InnoDB Hot Backup is an online backup tool you can use to backup your InnoDB database while it is running. InnoDB Hot Backup does not require you to shut down your database and it does not set any locks or disturb your normal database processing. InnoDB Hot Backup is a non-free (commercial) add-on tool with an annual license fee of €390 per computer on which the MySQL server is run. See the InnoDB Hot Backup home page [<http://www.innodb.com/order.html>] for detailed information and screenshots.

If you are able to shut down your MySQL server, you can make a binary backup that consists of all files used by InnoDB to manage its tables. Use the following procedure:

1. Shut down your MySQL server and make sure that it shuts down without errors.
2. Copy all your data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all your `ib_logfile` files to a safe place.
4. Copy your `my.cnf` configuration file or files to a safe place.
5. Copy all the `.frm` files for your InnoDB tables to a safe place.

Replication works with InnoDB tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability.

In addition to making binary backups as just described, you should also regularly make dumps of your tables with `mysqldump`. The reason for this is that a binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option that you can use to make a consistent snapshot without locking out other clients.

To be able to recover your InnoDB database to the present from the binary backup just described, you have to run your MySQL server with binary logging turned on. Then you can apply the binary log to the backup database to achieve point-in-time recovery:

```
mysqlbinlog yourhostname-bin.123 | mysql
```

To recover from a crash of your MySQL server, the only requirement is to restart it. InnoDB automatically checks the logs and performs a roll-forward of the database to the present. InnoDB automatically rolls back uncommitted transactions that were present at the time of the crash. During re-

covery, `mysqld` displays output something like this:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

If your database gets corrupted or your disk fails, you have to do the recovery from a backup. In the case of corruption, you should first find a backup that is not corrupted. After restoring the base backup, do the recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes performed after the backup was made.

In some cases of database corruption it is enough just to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE SQL` statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption. You can use `innodb_tablespace_monitor` to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best first to try restarting your computer. Doing so may eliminate errors that appeared to be database page corruption.

### 14.2.8.1. Forcing InnoDB Recovery

If there is database page corruption, you may want to dump your tables from the database with `SELECT INTO OUTFILE`. Usually, most of the data obtained in this way is intact. Even so, the corruption may cause `SELECT * FROM tbl_name` statements or InnoDB background operations to crash or assert, or even to cause InnoDB roll-forward recovery to crash. However, you can force the InnoDB storage engine to start up while preventing background operations from running, so that you are able to dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 4
```

The allowable non-zero values for `innodb_force_recovery` follow. A larger number includes all precautions of smaller numbers. If you are able to dump your tables with an option value of at most 4, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 6 is more drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

- 1 (SRV\_FORCE\_IGNORE\_CORRUPT)

Let the server run even if it detects a corrupt page. Try to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- 2 (SRV\_FORCE\_NO\_BACKGROUND)  
Prevent the main thread from running. If a crash would occur during the purge operation, this recovery value prevents it.
- 3 (SRV\_FORCE\_NO\_TRX\_UNDO)  
Do not run transaction rollbacks after recovery.
- 4 (SRV\_FORCE\_NO\_IBUF\_MERGE)  
Prevent also insert buffer merge operations. If they would cause a crash, do not do them. Do not calculate table statistics.
- 5 (SRV\_FORCE\_NO\_UNDO\_LOG\_SCAN)  
Do not look at undo logs when starting the database: InnoDB treats even incomplete transactions as committed.
- 6 (SRV\_FORCE\_NO\_LOG\_REDO)  
Do not do the log roll-forward in connection with recovery.

You can `SELECT` from tables to dump them, or `DROP` or `CREATE` tables even if forced recovery is used. If you know that a given table is causing a crash on rollback, you can drop it. You can also use this to stop a runaway rollback caused by a failing mass import or `ALTER TABLE`. You can kill the `mysqld` process and set `innodb_force_recovery` to 3 to bring the database up without the rollback, then `DROP` the table that is causing the runaway rollback.

*The database must not otherwise be used with any non-zero value of `innodb_force_recovery`. As a safety measure, InnoDB prevents users from performing `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0.*

### 14.2.8.2. Checkpoints

InnoDB implements a checkpoint mechanism known as “fuzzy” checkpointing. InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would in practice stop processing of user SQL statements during the checkpointing process.

During crash recovery, InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.

InnoDB writes to its log files on a rotating basis. All committed modifications that make the database pages in the buffer pool different from the images on disk must be available in the log files in case InnoDB has to do a recovery. This means that when InnoDB starts to reuse a log file, it has to make sure that the database page images on disk contain the modifications logged in the log file that InnoDB is going to reuse. In other words, InnoDB must create a checkpoint and this often involves flushing of modified database pages to disk.

The preceding description explains why making your log files very large may save disk I/O in checkpointing. It often makes sense to set the total size of the log files as big as the buffer pool or even bigger. The drawback of using large log files is that crash recovery can take longer because there is more logged information to apply to the database.

### 14.2.9. Moving an InnoDB Database to Another Machine

On Windows, InnoDB always stores database and table names internally in lowercase. To move

databases in a binary format from Unix to Windows or from Windows to Unix, you should have all table and database names in lowercase. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

Like MyISAM data files, InnoDB data and log files are binary-compatible on all platforms having the same floating-point number format. You can move an InnoDB database simply by copying all the relevant files listed in Section 14.2.8, “Backing Up and Recovering an InnoDB Database”. If the floating-point formats differ but you have not used `FLOAT` or `DOUBLE` data types in your tables, then the procedure is the same: simply copy the relevant files. If the formats differ and your tables contain floating-point data, you must use `mysqldump` to dump your tables on one machine and then import the dump files on the other machine.

One way to increase performance is to switch off autocommit mode when importing data, assuming that the tablespace has enough space for the big rollback segment that the import transactions generate. Do the commit only after importing a whole table or a segment of a table.

## 14.2.10. InnoDB Transaction Model and Locking

In the InnoDB transaction model, the goal is to combine the best properties of a multi-versioning database with traditional two-phase locking. InnoDB does locking on the row level and runs queries as non-locking consistent reads by default, in the style of Oracle. The lock table in InnoDB is stored so space-efficiently that lock escalation is not needed: Typically several users are allowed to lock every row in the database, or any random subset of the rows, without InnoDB running out of memory.

### 14.2.10.1. InnoDB Lock Modes

InnoDB implements standard row-level locking where there are two types of locks:

- A shared (*S*) lock allows a transaction to read a row (tuple).
- An exclusive (*X*) lock allows a transaction to update or delete a row.

If transaction *T*<sub>1</sub> holds a shared (*S*) lock on tuple *t*, then

- A request from some distinct transaction *T*<sub>2</sub> for an *S* lock on *t* can be granted immediately. As a result, both *T*<sub>1</sub> and *T*<sub>2</sub> hold an *S* lock on *t*.
- A request from some distinct transaction *T*<sub>2</sub> for an *X* lock on *t* cannot be granted immediately.

If a transaction *T*<sub>1</sub> holds an exclusive (*X*) lock on tuple *t*, then a request from some distinct transaction *T*<sub>2</sub> for a lock of either type on *t* cannot be granted immediately. Instead, transaction *T*<sub>2</sub> has to wait for transaction *T*<sub>1</sub> to release its lock on tuple *t*.

Additionally, InnoDB supports *multiple granularity locking* which allows coexistence of record locks and locks on entire tables. To make locking at multiple granularity levels practical, additional types of locks called *intention locks* are used. Intention locks are table locks in InnoDB. The idea behind intention locks is for a transaction to indicate which type of lock (shared or exclusive) it will require later for a row in that table. There are two types of intention locks used in InnoDB (assume that transaction *T* has requested a lock of the indicated type on table *R*):

- Intention shared (*IS*): Transaction *T* intends to set *S* locks on individual rows in table *R*.
- Intention exclusive (*IX*): Transaction *T* intends to set *X* locks on those rows.

The intention locking protocol is as follows:

- Before a given transaction can acquire an *S* lock on a given row, it must first acquire an *IS* or stronger lock on the table containing that row.
- Before a given transaction can acquire an *X* lock on a given row, it must first acquire an *IX* lock on the table containing that row.

These rules can be conveniently summarized by means of a *lock type compatibility matrix*:

	<i>X</i>	<i>IX</i>	<i>S</i>	<i>IS</i>
<i>X</i>	Conflict	Conflict	Conflict	Conflict
<i>IX</i>	Conflict	Compatible	Conflict	Compatible
<i>S</i>	Conflict	Conflict	Compatible	Compatible
<i>IS</i>	Conflict	Compatible	Compatible	Compatible

A lock is granted to a requesting transaction if it is compatible with existing locks. A lock is not granted to a requesting transaction if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause deadlock, an error occurs.

Thus, intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of *IX* and *IS* locks is to show that someone is locking a row, or going to lock a row in the table.

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an *S* lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
+-----+
| i     |
+-----+
|     1 |
+-----+
1 row in set (0.10 sec)
```

Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an *X* lock. The lock cannot be granted because it is incompatible with the *S* lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

Deadlock occurs here because client A needs an *X* lock to delete the row. However, that lock request cannot be granted because client B is already has a request for an *X* lock and is waiting for client A to release its *S* lock. Nor can the *S* lock held by A be upgraded to an *X* lock because of the prior request by B for an *X* lock. As a result, InnoDB generates an error for client A and releases its locks. At that point, the lock request for client B can be granted and B deletes the row from the table.

### 14.2.10.2. InnoDB and AUTOCOMMIT

In InnoDB, all user activity occurs inside a transaction. If the autocommit mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts new connections with autocommit enabled.

If the autocommit mode is switched off with `SET AUTOCOMMIT = 0`, then we can consider that a user always has a transaction open. A SQL `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts. A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other users. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both statements release all InnoDB locks that were set during the current transaction.

If the connection has autocommit enabled, the user can still perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with `COMMIT` or `ROLLBACK`.

### 14.2.10.3. InnoDB and TRANSACTION ISOLATION LEVEL

In terms of the SQL:1992 transaction isolation levels, the InnoDB default is `REPEATABLE READ`. InnoDB offers all four transaction isolation levels described by the SQL standard. You can set the default isolation level for all connections by using the `--transaction-isolation` option on the command line or in an option file. For example, you can set the option in the `[mysqld]` section of an option file like this:

```
[mysqld]
transaction-isolation = {READ-UNCOMMITTED | READ-COMMITTED
                        | REPEATABLE-READ | SERIALIZABLE}
```

A user can change the isolation level for a single session or for all new incoming connections with the `SET TRANSACTION` statement. Its syntax is as follows:

```
SET [SESSION | GLOBAL] TRANSACTION ISOLATION LEVEL
    {READ UNCOMMITTED | READ COMMITTED
     | REPEATABLE READ | SERIALIZABLE}
```

Note that there are hyphens in the level names for the `--transaction-isolation` option, but not for the `SET TRANSACTION` statement.

The default behavior is to set the isolation level for the next (not started) transaction. If you use the `GLOBAL` keyword, the statement sets the default transaction level globally for all new connections created from that point on (but not for existing connections). You need the `SUPER` privilege to do this. Using the `SESSION` keyword sets the default transaction level for all future transactions performed on the current connection.

Any client is free to change the session isolation level (even in the middle of a transaction), or the isolation level for the next transaction.

You can determine the global and session transaction isolation levels by checking the value of the

tx\_isolation system variable with these statements:

```
SELECT @@global.tx_isolation;  
SELECT @@tx_isolation;
```

In row-level locking, InnoDB uses next-key locking. That means that besides index records, InnoDB can also lock the “gap” preceding an index record to block insertions by other users immediately before the index record. A next-key lock refers to a lock that locks an index record and the gap before it. A gap lock refers to a lock that only locks a gap before some index record.

A detailed description of each isolation level in InnoDB follows:

- READ UNCOMMITTED

SELECT statements are performed in a non-locking fashion, but a possible earlier version of a record might be used. Thus, using this isolation level, such reads are not consistent. This is also called a “dirty read.” Otherwise, this isolation level works like READ COMMITTED.

- READ COMMITTED

A somewhat Oracle-like isolation level. All SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE statements lock only the index records, not the gaps before them, and thus allow the free insertion of new records next to locked records. UPDATE and DELETE statements using a unique index with a unique search condition lock only the index record found, not the gap before it. In range-type UPDATE and DELETE statements, InnoDB must set next-key or gap locks and block insertions by other users to the gaps covered by the range. This is necessary because “phantom rows” must be blocked for MySQL replication and recovery to work.

Consistent reads behave as in Oracle: Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. See Section 14.2.10.4, “Consistent Non-Locking Read”.

- REPEATABLE READ

This is the default isolation level of InnoDB. SELECT ... FOR UPDATE, SELECT ... LOCK IN SHARE MODE, UPDATE, and DELETE statements that use a unique index with a unique search condition lock only the index record found, not the gap before it. With other search conditions, these operations employ next-key locking, locking the index range scanned with next-key or gap locks, and block new insertions by other users.

In consistent reads, there is an important difference from the READ COMMITTED isolation level: All consistent reads within the same transaction read the same snapshot established by the first read. This convention means that if you issue several plain SELECT statements within the same transaction, these SELECT statements are consistent also with respect to each other. See Section 14.2.10.4, “Consistent Non-Locking Read”.

- SERIALIZABLE

This level is like REPEATABLE READ, but InnoDB implicitly commits all plain SELECT statements to SELECT ... LOCK IN SHARE MODE.

#### 14.2.10.4. Consistent Non-Locking Read

A consistent read means that InnoDB uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by those transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. Note that the exception to the rule causes the following anomaly: if you update some rows in a table, a SELECT will see the latest version of the updated rows, while it sees the old version of other rows. If other users simultaneously update the same table, the anomaly means that you may see the table in a state that never existed in the database.

If you are running with the default `REPEATABLE READ` isolation level, all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

Consistent read is the default mode in which `InnoDB` processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other users are free to modify those tables at the same time a consistent read is being performed on the table.

Note that consistent read does not work over `DROP TABLE` and over `ALTER TABLE`. Consistent read does not work over `DROP TABLE` because `MySQL` can't use a table that has been dropped and `InnoDB` destroys the table. Consistent read does not work over `ALTER TABLE` because `ALTER TABLE` works by making a temporary copy of the original table and deleting the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken.

### 14.2.10.5. `SELECT ... FOR UPDATE` and `SELECT ... LOCK IN SHARE MODE` Locking Reads

In some circumstances, a consistent read is not convenient. For example, you might want to add a new row into your table `child`, and make sure that the child has a parent in table `parent`. The following example shows how to implement referential integrity in your application code.

Suppose that you use a consistent read to read the table `parent` and indeed see the parent of the child in the table. Can you safely add the child row to table `child`? No, because it may happen that meanwhile some other user deletes the parent row from the table `parent` without you being aware of it.

The solution is to perform the `SELECT` in a locking mode using `LOCK IN SHARE MODE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

Performing a read in share mode means that we read the latest available data, and set a shared mode lock on the rows we read. A shared mode lock prevents others from updating or deleting the row we have read. Also, if the latest data belongs to a yet uncommitted transaction of another client connection, we wait until that transaction commits. After we see that the preceding query returns the parent 'Jones', we can safely add the child record to the `child` table and commit our transaction.

Let us look at another example: We have an integer counter field in a table `child_codes` that we use to assign a unique identifier to each child added to table `child`. Obviously, using a consistent read or a shared mode read to read the present value of the counter is not a good idea because two users of the database may then see the same value for the counter, and a duplicate-key error occurs if two users attempt to add children with the same identifier to the table.

Here, `LOCK IN SHARE MODE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when attempting to update the counter.

In this case, there are two good ways to implement the reading and incrementing of the counter: (1) update the counter first by incrementing it by 1 and only after that read it, or (2) read the counter first with a lock mode `FOR UPDATE`, and increment after that. The latter approach can be implemented as follows:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched `SQL UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In `MySQL`, the specific task of generating a unique identifier actually can be accomplished using only

a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

Locks set by `IN SHARE MODE` and `FOR UPDATE` reads are released when the transaction is committed or rolled back.

### 14.2.10.6. Next-Key Locking: Avoiding the Phantom Problem

In row-level locking, InnoDB uses an algorithm called *next-key locking*. InnoDB performs the row-level locking in such a way that when it searches or scans an index of a table, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index record locks.

The locks InnoDB sets on index records also affect the “gap” before that index record. If a user has a shared or exclusive lock on record `R` in an index, another user cannot insert a new index record immediately before `R` in the index order. This locking of gaps is done to prevent the so-called “phantom problem.” Suppose that you want to read and lock all children from the `child` table having an identifier value greater than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

Suppose that there is an index on the `id` column. The query scans that index starting from the first record where `id` is bigger than 100. If the locks set on the index records would not lock out inserts made in the gaps, a new row might meanwhile be inserted to the table. If you execute the same `SELECT` within the same transaction, you would see a new row in the result set returned by the query. This is contrary to the isolation principle of transactions: A transaction should be able to run so that the data it has read does not change during the transaction. If we regard a set of rows as a data item, the new “phantom” child would violate this isolation principle.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the previous example: The locks set by InnoDB prevent any insert to the table where `id` would be bigger than 100.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking allows you to “lock” the non-existence of something in your table.

### 14.2.10.7. An Example of Consistent Read in InnoDB

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

You can advance your timepoint by committing your transaction and then doing another `SELECT`.

This is called *multi-versioned concurrency control*.

	User A	User B
	<code>SET AUTOCOMMIT=0;</code>	<code>SET AUTOCOMMIT=0;</code>
time	<code>SELECT * FROM t;</code>	

```

|
|
|
|
v
    empty set
                                INSERT INTO t VALUES (1, 2);

    SELECT * FROM t;
    empty set
                                COMMIT;

    SELECT * FROM t;
    empty set

    COMMIT;

    SELECT * FROM t;
    -----
    |    1    |    2    |
    -----
    1 row in set

```

In this example, user A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

If you want to see the “freshest” state of the database, you should use either the `READ COMMITTED` isolation level or a locking read:

```
SELECT * FROM t LOCK IN SHARE MODE;
```

#### 14.2.10.8. Locks Set by Different SQL Statements in InnoDB

A locking read, an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter if there are `WHERE` conditions in the statement that would exclude the row. InnoDB does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The record locks are normally next-key locks that also block inserts to the “gap” immediately before the record.

If the locks to be set are exclusive, InnoDB always retrieves also the clustered index record and sets a lock on it.

If you do not have indexes suitable for your statement and MySQL has to scan the whole table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily need to scan many rows.

InnoDB sets specific types of locks as follows:

- `SELECT ... FROM` is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to `SERIALIZABLE`. For `SERIALIZABLE` level, this sets shared next-key locks on the index records it encounters.
- `SELECT ... FROM ... LOCK IN SHARE MODE` sets shared next-key locks on all index records the read encounters.
- `SELECT ... FROM ... FOR UPDATE` sets exclusive next-key locks on all index records the read encounters.
- `INSERT INTO ... VALUES (...)` sets an exclusive lock on the inserted row. Note that this lock is not a next-key lock and does not prevent other users from inserting to the gap before the inserted row. If a duplicate-key error occurs, a shared lock on the duplicate index record is set.
- While initializing a previously specified `AUTO_INCREMENT` column on a table, InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, InnoDB uses a specific table lock mode `AUTO-INC`

where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Note that other clients cannot insert into the table while the `AUTO-INC` table lock is held; see Section 14.2.10.2, “InnoDB and AUTOCOMMIT”.

InnoDB fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- `INSERT INTO T SELECT ... FROM S WHERE ...` sets an exclusive (non-next-key) lock on each row inserted into T. InnoDB sets shared next-key locks on S, unless `innodb_locks_unsafe_for_binlog` is enabled, in which case it does the search on S as a consistent read. InnoDB has to set locks in the latter case: In roll-forward recovery from a backup, every SQL statement has to be executed in exactly the same way it was done originally.
- `CREATE TABLE ... SELECT ...` performs the `SELECT` as a consistent read or with shared locks, as in the previous item.
- `REPLACE` is done like an insert if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row that has to be updated.
- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.
- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.
- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. InnoDB also sets these locks in the case where the constraint fails.
- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the InnoDB layer that sets these locks. InnoDB is aware of table locks if `innodb_table_locks=1` (the default) and `AUTOCOMMIT=0`, and the MySQL layer above InnoDB knows about row-level locks. Otherwise, InnoDB's automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another user currently has row-level locks. However, this does not endanger transaction integrity, as discussed in Section 14.2.10.10, “Deadlock Detection and Rollback”. See also Section 14.2.16, “Restrictions on InnoDB Tables”.

### 14.2.10.9. Implicit Transaction Commit and Rollback

By default, MySQL begins each client connection with autocommit mode enabled. When autocommit is enabled, MySQL does a commit after each SQL statement if that statement did not return an error. If an SQL statement returns an error, the commit or rollback behavior depends on the error. See Section 14.2.15, “InnoDB Error Handling”.

If you have the autocommit mode off and close a connection without explicitly committing the final transaction, MySQL rolls back that transaction.

Each of the following statements (and any synonyms for them) implicitly end a transaction, as if you had done a `COMMIT` before executing the statement:

- `ALTER FUNCTION`, `ALTER PROCEDURE`, `ALTER TABLE`, `BEGIN`, `CREATE DATABASE`, `CREATE FUNCTION`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE TABLE`, `DROP DATABASE`, `DROP FUNCTION`, `DROP INDEX`, `DROP PROCEDURE`, `DROP TABLE`, `LOAD MASTER DATA`, `LOCK TABLES`, `RENAME TABLE`, `SET AUTOCOMMIT=1`, `START TRANSACTION`, `TRUNCATE`, `UNLOCK TABLES`.
- `UNLOCK TABLES` commits a transaction only if any tables are currently locked.
- The `CREATE TABLE`, `CREATE DATABASE`, `DROP DATABASE`, and `TRUNCATE TABLE`

statements cause an implicit commit beginning with MySQL 5.0.8. The `ALTER FUNCTION`, `ALTER PROCEDURE`, `CREATE FUNCTION`, `CREATE PROCEDURE`, `DROP FUNCTION`, and `DROP PROCEDURE` statements cause an implicit commit beginning with MySQL 5.0.13.

- The `CREATE TABLE` statement in InnoDB is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

Transactions cannot be nested. This is a consequence of the implicit `COMMIT` performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

### 14.2.10.10. Deadlock Detection and Rollback

InnoDB automatically detects a deadlock of transactions and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if `innodb_table_locks=1` (the default) and `AUTOCOMMIT=0`, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot detect deadlocks where a table lock set by a `MySQL LOCK TABLES` statement or a lock set by a storage engine other than InnoDB is involved. You must resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the statement may be preserved. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

### 14.2.10.11. How to Cope with Deadlocks

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really “atomic”; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- Use `SHOW ENGINE INNODB STATUS` to determine the cause of the latest deadlock. That can help you to tune your application to avoid deadlocks.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Commit your transactions often. Small transactions are less prone to collision.
- If you are using locking reads (`SELECT ... FOR UPDATE` or `... LOCK IN SHARE MODE`), try using a lower isolation level such as `READ COMMITTED`.
- Access your tables and rows in a fixed order. Then transactions form well-defined queues and do not deadlock.
- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.

- Use less locking. If you can afford to allow a `SELECT` to return data from an old snapshot, do not add the clause `FOR UPDATE` or `LOCK IN SHARE MODE` to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as InnoDB tables, is to set `AUTOCOMMIT = 0` and not to call `UNLOCK TABLES` until after you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET AUTOCOMMIT=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks make your transactions queue nicely, and deadlocks are avoided.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.
- In applications that use the `LOCK TABLES` command, MySQL does not set InnoDB table locks if `AUTOCOMMIT=1`.

## 14.2.11. InnoDB Performance Tuning Tips

- In InnoDB, having a long `PRIMARY KEY` wastes a lot of disk space because its value must be stored with every secondary index record. (See Section 14.2.13, “InnoDB Table and Index Structures”.) Create an `AUTO_INCREMENT` column as the primary key if your primary key is long.
- If the Unix `top` tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound. Maybe you are making too many transaction commits, or the buffer pool is too small. Making the buffer pool bigger can help, but do not set it equal to more than 80% of physical memory.
- Wrap several modifications into one transaction. InnoDB must flush the log to disk at each transaction commit if that transaction made modifications to the database. The rotation speed of a disk is typically at most 167 revolutions/second, which constrains the number of commits to the same 167<sup>th</sup> of a second if the disk does not “fool” the operating system.
- If you can afford the loss of some of the latest committed transactions if a crash occurs, you can set the `innodb_flush_log_at_trx_commit` parameter to 0. InnoDB tries to flush the log once per second anyway, although the flush is not guaranteed.
- Make your log files big, even as big as the buffer pool. When InnoDB has written the log files full, it has to write the modified contents of the buffer pool to disk in a checkpoint. Small log files cause many unnecessary disk writes. The drawback of big log files is that the recovery time is longer.
- Make the log buffer quite large as well (on the order of 8MB).
- Use the `VARCHAR` data type instead of `CHAR` if you are storing variable-length strings or if the column may contain many `NULL` values. A `CHAR(N)` column always takes `N` characters to store data, even if the string is shorter or its value is `NULL`. Smaller tables fit better in the buffer pool and reduce disk I/O.

When using `row_format=compact` (the default InnoDB record format in MySQL 5.0) and variable-length character sets, such as `utf8` or `sjis`, `CHAR(N)` will occupy a variable amount of space, at least  $N$  bytes.

- In some versions of GNU/Linux and Unix, flushing files to disk with the Unix `fsync()` call (which InnoDB uses by default) and other similar methods is surprisingly slow. If you are dissatisfied with database write performance, you might try setting the `innodb_flush_method` parameter to `O_DSYNC`. Although `O_DSYNC` seems to be slower on most systems, yours might not be one of them.
- When using the InnoDB storage engine on Solaris 10 for x86\_64 architecture (AMD Opteron), it is important to mount any filesystems used for storing InnoDB-related files using the `forcedirectio` option. (The default on Solaris 10/x86\_64 is *not* to use this option.) Failure to use `forcedirectio` causes a serious degradation of InnoDB's speed and performance on this platform.

When using the InnoDB storage engine with a large `innodb_buffer_pool_size` value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), a significant performance gain can be achieved by placing InnoDB data files and log files on raw devices or on a separate direct I/O UFS filesystem (using mount option `forcedirectio`; see `mount_ufs(1M)`). Users of the Veritas filesystem VxFS should use the mount option `convsync=direct`.

Other MySQL data files, such as those for MyISAM tables, should not be placed on a direct I/O filesystem. Executables or libraries *must not* be placed on a direct I/O filesystem.

- When importing data into InnoDB, make sure that MySQL does not have autocommit mode enabled because that requires a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET AUTOCOMMIT` and `COMMIT` statements:

```
SET AUTOCOMMIT=0;
... SQL import statements ...
COMMIT;
```

If you use the `mysqldump` option `--opt`, you get dump files that are fast to import into an InnoDB table, even without wrapping them with the `SET AUTOCOMMIT` and `COMMIT` statements.

- Beware of big rollbacks of mass inserts: InnoDB uses the insert buffer to save disk I/O in inserts, but no such mechanism is used in a corresponding rollback. A disk-bound rollback can take 30 times as long to perform as the corresponding insert. Killing the database process does not help because the rollback starts again on server startup. The only way to get rid of a runaway rollback is to increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or to use a special procedure. See Section 14.2.8.1, “Forcing InnoDB Recovery”.
- Beware also of other big disk-bound operations. Use `DROP TABLE` and `CREATE TABLE` to empty a table, not `DELETE FROM tbl_name`.
- Use the multiple-row `INSERT` syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just InnoDB tables.

- If you have `UNIQUE` constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```
SET UNIQUE_CHECKS=0;
... import operation ...
SET UNIQUE_CHECKS=1;
```

For big tables, this saves a lot of disk I/O because InnoDB can use its insert buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys. `UNIQUE_CHECKS` allows but does not require storage engines to ignore duplicate keys.

- If you have `FOREIGN KEY` constraints in your tables, you can speed up table imports by turning the foreign key checks off for the duration of the import session:

```
SET FOREIGN_KEY_CHECKS=0;
... import operation ...
SET FOREIGN_KEY_CHECKS=1;
```

For big tables, this can save a lot of disk I/O.

- If you often have recurring queries for tables that are not updated frequently, use the query cache:

```
[mysqld]
query_cache_type = ON
query_cache_size = 10M
```

### 14.2.11.1. SHOW ENGINE INNODB STATUS and the InnoDB Monitors

InnoDB includes InnoDB Monitors that print information about the InnoDB internal state. You can use the `SHOW ENGINE INNODB STATUS` SQL statement at any time to fetch the output of the standard InnoDB Monitor to your SQL client. This information is useful in performance tuning. (If you are using the `mysql` interactive SQL client, the output is more readable if you replace the usual semicolon statement terminator with `\G`.) For a discussion of InnoDB lock modes, see Section 14.2.10.1, “InnoDB Lock Modes”.

```
mysql> SHOW ENGINE INNODB STATUS\G
```

Another way to use InnoDB Monitors is to let them periodically write data to the standard output of the `mysqld` server. In this case, no output is sent to clients. When switched on, InnoDB Monitors print data about every 15 seconds. Server output usually is directed to the `.err` log in the MySQL data directory. This data is useful in performance tuning. On Windows, you must start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

Monitor output includes the following types of information:

- Table and record locks held by each active transaction
- Lock waits of a transactions
- Semaphore waits of threads
- Pending file I/O requests
- Buffer pool statistics
- Purge and insert buffer merge activity of the main InnoDB thread

To cause the standard InnoDB Monitor to write to the standard output of `mysqld`, use the following SQL statement:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

The monitor can be stopped by issuing the following statement:

```
DROP TABLE innodb_monitor;
```

The CREATE TABLE syntax is just a way to pass a command to the InnoDB engine through MySQL's SQL parser: The only things that matter are the table name `innodb_monitor` and that it be an InnoDB table. The structure of the table is not relevant at all for the InnoDB Monitor. If you shut down the server, the monitor does not restart automatically when you restart the server. You must drop the monitor table and issue a new CREATE TABLE statement to start the monitor. (This syntax may change in a future release.)

You can use `innodb_lock_monitor` in a similar fashion. This is the same as `innodb_monitor`, except that it also provides a great deal of lock information. A separate `innodb_tablespace_monitor` prints a list of created file segments existing in the tablespace and validates the tablespace allocation data structures. In addition, there is `innodb_table_monitor` with which you can print the contents of the InnoDB internal data dictionary.

A sample of InnoDB Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
Status:
=====

END OF INNODB MONITOR OUTPUT
=====

```

Some notes on the output:

- If the `TRANSACTIONS` section reports lock waits, your applications may have lock contention. The output can also help to trace the reasons for transaction deadlocks.
- The `SEMAPHORES` section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside InnoDB. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting `innodb_thread_concurrency` smaller than the default value can help in such situations.
- The `BUFFER POOL AND MEMORY` section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.
- The `ROW OPERATIONS` section shows what the main thread is doing.

InnoDB sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of `SHOW ENGINE INNODB STATUS` is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. InnoDB removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see whether they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is created only if the configuration option `innodb_status_file=1` is set.

## 14.2.12. Implementation of Multi-Versioning

Because InnoDB is a multi-versioned storage engine, it must keep information about old versions of rows in the tablespace. This information is stored in a data structure called a *rollback segment* (after an analogous data structure in Oracle).

Internally, InnoDB adds two fields to each row stored in the database. A 6-byte field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated.

InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which InnoDB has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

You must remember to commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, InnoDB cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space need for your rollback segment.

In the InnoDB multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. Only when InnoDB can discard the update undo log record written for the deletion can it also physically remove the corresponding row and its index records from the database. This removal operation is called a purge, and it is quite fast, usually tak-

ing the same order of time as the SQL statement that did the deletion.

In a scenario where the user inserts and deletes rows in smallish batches at about the same rate in the table, it is possible that the purge thread starts to lag behind, and the table grows bigger and bigger, making everything disk-bound and very slow. Even if the table carries just 10MB of useful data, it may grow to occupy 10GB with all the “dead” rows. In such a case, it would be good to throttle new row operations, and allocate more resources to the purge thread. The `innodb_max_purge_lag` system variable exists for exactly this purpose. See Section 14.2.4, “InnoDB Startup Options and System Variables”, for more information.

## 14.2.13. InnoDB Table and Index Structures

MySQL stores its data dictionary information for tables in `.frm` files in database directories. This is true for all MySQL storage engines. But every InnoDB table also has its own entry in the InnoDB internal data dictionary inside the tablespace. When MySQL drops a table or a database, it has to delete both an `.frm` file or files, and the corresponding entries inside the InnoDB data dictionary. This is the reason why you cannot move InnoDB tables between databases simply by moving the `.frm` files.

Every InnoDB table has a special index called the *clustered index* where the data for the rows is stored. If you define a `PRIMARY KEY` on your table, the index of the primary key is the clustered index.

If you do not define a `PRIMARY KEY` for your table, MySQL picks the first `UNIQUE` index that has only `NOT NULL` columns as the primary key and InnoDB uses it as the clustered index. If there is no such index in the table, InnoDB internally generates a clustered index where the rows are ordered by the row ID that InnoDB assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

Accessing a row through the clustered index is fast because the row data is on the same page where the index search leads. If a table is large, the clustered index architecture often saves a disk I/O when compared to the traditional solution. (In many database systems, data storage uses a different page from the index record.)

In InnoDB, the records in non-clustered indexes (also called secondary indexes) contain the primary key value for the row. InnoDB uses this primary key value to search for the row from the clustered index. Note that if the primary key is long, the secondary indexes use more space.

InnoDB compares `CHAR` and `VARCHAR` strings of different lengths such that the remaining length in the shorter string is treated as if padded with spaces.

### 14.2.13.1. Physical Structure of an Index

All InnoDB indexes are B-trees where the index records are stored in the leaf pages of the tree. The default size of an index page is 16KB. When new records are inserted, InnoDB tries to leave 1/16 of the page free for future insertions and updates of the index records.

If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full. If the fill factor of an index page drops below 1/2, InnoDB tries to contract the index tree to free the page.

### 14.2.13.2. Insert Buffering

It is a common situation in database applications that the primary key is a unique identifier and new rows are inserted in the ascending order of the primary key. Thus, the insertions to the clustered index do not require random reads from a disk.

On the other hand, secondary indexes are usually non-unique, and insertions into secondary indexes happen in a relatively random order. This would cause a lot of random disk I/O operations without a special mechanism used in InnoDB.

If an index record should be inserted to a non-unique secondary index, InnoDB checks whether the secondary index page is in the buffer pool. If that is the case, InnoDB does the insertion directly to the index page. If the index page is not found in the buffer pool, InnoDB inserts the record to a special insert buffer structure. The insert buffer is kept so small that it fits entirely in the buffer pool, and insertions can be done very fast.

Periodically, the insert buffer is merged into the secondary index trees in the database. Often it is possible to merge several insertions to the same page of the index tree, saving disk I/O operations. It has been measured that the insert buffer can speed up insertions into a table up to 15 times.

The insert buffer merging may continue to happen *after* the inserting transaction has been committed. In fact, it may continue to happen after a server shutdown and restart (see Section 14.2.8.1, “Forcing InnoDB Recovery”).

The insert buffer merging may take many hours, when many secondary indexes must be updated, and many rows have been inserted. During this time, disk I/O will be increased, which can cause significant slowdown on disk-bound queries. Another significant background I/O operation is the purge thread (see Section 14.2.12, “Implementation of Multi-Versioning”).

### 14.2.13.3. Adaptive Hash Indexes

If a table fits almost entirely in main memory, the fastest way to perform queries on it is to use hash indexes. InnoDB has a mechanism that monitors index searches made to the indexes defined for a table. If InnoDB notices that queries could benefit from building a hash index, it does so automatically.

Note that the hash index is always built based on an existing B-tree index on the table. InnoDB can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that InnoDB observes for the B-tree index. A hash index can be partial: It is not required that the whole B-tree index is cached in the buffer pool. InnoDB builds hash indexes on demand for those pages of the index that are often accessed.

In a sense, InnoDB tailors itself through the adaptive hash index mechanism to ample main memory, coming closer to the architecture of main-memory databases.

### 14.2.13.4. Physical Row Structure

The physical record structure for InnoDB tables is dependent on the MySQL version and the optional `ROW_FORMAT` option used when the table was created. For InnoDB tables in MySQL earlier than 5.0.3, only the `REDUNDANT` row format was available. For MySQL 5.0.3 and later, the default is to use the `COMPACT` row format, but you can use the `REDUNDANT` format to retain compatibility with older versions of InnoDB tables.

Records in InnoDB `ROW_FORMAT=REDUNDANT` tables have the following characteristics:

- Each index record contains a six-byte header. The header is used to link together consecutive records, and also in row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a six-byte field for the transaction ID and a seven-byte field for the roll pointer.
- If no primary key was defined for a table, each clustered index record also contains a six-byte row ID field.
- Each secondary index record contains also all the fields defined for the clustered index key.
- A record contains also a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.
- Internally, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length

format. InnoDB truncates trailing spaces from VARCHAR columns.

- An SQL NULL value reserves 1 or 2 bytes in the record directory. Besides that, an SQL NULL value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. The motivation behind reserving the fixed space for NULL values is that it enables an update of the column from NULL to a non-NULL value to be done in place without causing fragmentation of the index page.

Records in InnoDB ROW\_FORMAT=COMPACT tables have the following characteristics:

- Each index record contains a five-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and also in row-level locking.
- The record header contains a bit vector for indicating NULL columns. The bit vector occupies  $(n\_nullable+7)/8$  bytes. Columns that are NULL will not occupy other space than the bit in this vector.
- For each non-NULL variable-length field, the record header contains the length of the column in one or two bytes. Two bytes will only be needed if part of the column is stored externally or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes.
- The record header is followed by the data contents of the columns. Columns that are NULL are omitted.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a six-byte field for the transaction ID and a seven-byte field for the roll pointer.
- If no primary key was defined for a table, each clustered index record also contains a six-byte row ID field.
- Each secondary index record contains also all the fields defined for the clustered index key.
- Internally, InnoDB stores fixed-length, fixed-width character columns such as CHAR(10) in a fixed-length format. InnoDB truncates trailing spaces from VARCHAR columns.
- Internally, InnoDB attempts to store UTF-8 CHAR(n) columns in n bytes by trimming trailing spaces. In ROW\_FORMAT=REDUNDANT, such columns occupy 3\*n bytes. The motivation behind reserving the minimum space n is that it in many cases enables an update of the column to be done in place without causing fragmentation of the index page.

## 14.2.14. InnoDB File Space Management and Disk I/O

### 14.2.14.1. InnoDB Disk I/O

InnoDB uses simulated asynchronous disk I/O: InnoDB creates a number of threads to take care of I/O operations, such as read-ahead.

There are two read-ahead heuristics in InnoDB:

- In sequential read-ahead, if InnoDB notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if InnoDB notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

InnoDB uses a novel file flush technique called *doublewrite*. It adds safety to recovery following an operating system crash or a power outage, and improves performance on most varieties of Unix by

reducing the need for `fsync()` operations.

Doublewrite means that before writing pages to a data file, InnoDB first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does InnoDB write the pages to their proper positions in the data file. If the operating system crashes in the middle of a page write, InnoDB can later find a good copy of the page from the doublewrite buffer during recovery.

### 14.2.14.2. File Space Management

The data files that you define in the configuration file form the tablespace of InnoDB. The files are simply concatenated to form the tablespace. There is no striping in use. Currently, you cannot define where within the tablespace your tables are allocated. However, in a newly created tablespace, InnoDB allocates space starting from the first data file.

The tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of 64 consecutive pages. The “files” inside a tablespace are called *segments* in InnoDB. The term “rollback segment” is somewhat confusing because it actually contains many tablespace segments.

Two segments are allocated for each index in InnoDB. One is for non-leaf nodes of the B-tree, the other is for the leaf nodes. The idea here is to achieve better sequentiality for the leaf nodes, which contain the data.

When a segment grows inside the tablespace, InnoDB allocates the first 32 pages to it individually. After that InnoDB starts to allocate whole extents to the segment. InnoDB can add to a large segment up to 4 extents at a time to ensure good sequentiality of data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an InnoDB tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, InnoDB reports the extents that are definitely free in the tablespace. InnoDB always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, InnoDB contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only in an (automatic) purge operation after they are no longer needed for transaction rollbacks or consistent reads. (See Section 14.2.12, “Implementation of Multi-Versioning”.)

### 14.2.14.3. Defragmenting a Table

If there are random insertions into or deletions from the indexes of a table, the indexes may become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

A symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All InnoDB data and indexes are stored in B-trees, and their fill factor may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE a_non_indexed_column <> 12345;
```

(In the preceding query, we are “fooling” the SQL optimizer into scanning the clustered index, rather than a secondary index.) Most disks can read 10 to 50MB/s, which can be used to estimate how fast a table scan should run.

It can speed up index scans if you periodically perform a “null” `ALTER TABLE` operation:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

That causes MySQL to rebuild the table. Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions to an index are always ascending and records are deleted only from the end, the InnoDB filespace management algorithm guarantees that fragmentation in the index does not occur.

## 14.2.15. InnoDB Error Handling

Error handling in InnoDB is not always the same as specified in the SQL standard. According to the standard, any error during an SQL statement should cause the rollback of that statement. InnoDB sometimes rolls back only part of the statement, or the whole transaction. The following items describe how InnoDB performs error handling:

- If you run out of file space in the tablespace, a `MySQL Table is full` error occurs and InnoDB rolls back the SQL statement.
- A transaction deadlock causes InnoDB to roll back the entire transaction. In the case of a lock wait timeout, InnoDB also rolls back the entire transaction before MySQL 5.0.13; as of 5.0.13, InnoDB rolls back only the most recent SQL statement.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.
- A `row too long error` rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the InnoDB storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK SQL` command, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

### 14.2.15.1. InnoDB Error Codes

The following is a non-exhaustive list of common InnoDB-specific errors that you may encounter, with information about why each occurs and how to resolve the problem.

- 1005 (`ER_CANT_CREATE_TABLE`)  
Cannot create table. If the error message refers to `errno 150`, table creation failed because a foreign key constraint was not correctly formed. If the error message refers to `errno -1`, table creation probably failed because the table included a column name that matched the name of an internal InnoDB table.
- 1016 (`ER_CANT_OPEN_FILE`)  
Cannot find the InnoDB table from the InnoDB data files, although the `.frm` file for the table exists. See Section 14.2.17.1, “Troubleshooting InnoDB Data Dictionary Operations”.

- 1114 (ER\_RECORD\_FILE\_FULL)  
InnoDB has run out of free space in the tablespace. You should reconfigure the tablespace to add a new data file.
- 1205 (ER\_LOCK\_WAIT\_TIMEOUT)  
Lock wait timeout expired. Transaction was rolled back.
- 1213 (ER\_LOCK\_DEADLOCK)  
Transaction deadlock. You should rerun the transaction.
- 1216 (ER\_NO\_REFERENCED\_ROW)  
You are trying to add a row but there is no parent row, and a foreign key constraint fails. You should add the parent row first.
- 1217 (ER\_ROW\_IS\_REFERENCED)  
You are trying to delete a parent row that has children, and a foreign key constraint fails. You should delete the children first.

### 14.2.15.2. Operating System Error Codes

To print the meaning of an operating system error number, use the `pererror` program that comes with the MySQL distribution.

The following table provides a list of some common Linux system error codes. For a more complete list, see Linux source code [<http://www.iglu.org.il/lxr/source/include/asm-i386/errno.h>].

- 1 (EPERM)  
Operation not permitted
- 2 (ENOENT)  
No such file or directory
- 3 (ESRCH)  
No such process
- 4 (EINTR)  
Interrupted system call
- 5 (EIO)  
I/O error
- 6 (ENXIO)  
No such device or address
- 7 (E2BIG)  
Arg list too long
- 8 (ENOEXEC)  
Exec format error

- 9 (EBADF)  
Bad file number
- 10 (ECHILD)  
No child processes
- 11 (EAGAIN)  
Try again
- 12 (ENOMEM)  
Out of memory
- 13 (EACCES)  
Permission denied
- 14 (EFAULT)  
Bad address
- 15 (ENOTBLK)  
Block device required
- 16 (EBUSY)  
Device or resource busy
- 17 (EEXIST)  
File exists
- 18 (EXDEV)  
Cross-device link
- 19 (ENODEV)  
No such device
- 20 (ENOTDIR)  
Not a directory
- 21 (EISDIR)  
Is a directory
- 22 (EINVAL)  
Invalid argument
- 23 (ENFILE)  
File table overflow
- 24 (EMFILE)  
Too many open files
- 25 (ENOTTY)

Inappropriate ioctl for device

- 26 (ETXTBSY)

Text file busy

- 27 (EFBIG)

File too large

- 28 (ENOSPC)

No space left on device

- 29 (ESPIPE)

Illegal seek

- 30 (EROFS)

Read-only file system

- 31 (EMLINK)

Too many links

The following table provides a list of some common Windows system error codes. For a complete list see the Microsoft Web site [[http://msdn.microsoft.com/library/default.asp?url=/library/en-us/debug/base/system\\_error\\_codes.asp](http://msdn.microsoft.com/library/default.asp?url=/library/en-us/debug/base/system_error_codes.asp)].

- 1 (ERROR\_INVALID\_FUNCTION)

Incorrect function.

- 2 (ERROR\_FILE\_NOT\_FOUND)

The system cannot find the file specified.

- 3 (ERROR\_PATH\_NOT\_FOUND)

The system cannot find the path specified.

- 4 (ERROR\_TOO\_MANY\_OPEN\_FILES)

The system cannot open the file.

- 5 (ERROR\_ACCESS\_DENIED)

Access is denied.

- 6 (ERROR\_INVALID\_HANDLE)

The handle is invalid.

- 7 (ERROR\_ARENA\_TRASHED)

The storage control blocks were destroyed.

- 8 (ERROR\_NOT\_ENOUGH\_MEMORY)

Not enough storage is available to process this command.

- 9 (ERROR\_INVALID\_BLOCK)  
The storage control block address is invalid.
- 10 (ERROR\_BAD\_ENVIRONMENT)  
The environment is incorrect.
- 11 (ERROR\_BAD\_FORMAT)  
An attempt was made to load a program with an incorrect format.
- 12 (ERROR\_INVALID\_ACCESS)  
The access code is invalid.
- 13 (ERROR\_INVALID\_DATA)  
The data is invalid.
- 14 (ERROR\_OUTOFMEMORY)  
Not enough storage is available to complete this operation.
- 15 (ERROR\_INVALID\_DRIVE)  
The system cannot find the drive specified.
- 16 (ERROR\_CURRENT\_DIRECTORY)  
The directory cannot be removed.
- 17 (ERROR\_NOT\_SAME\_DEVICE)  
The system cannot move the file to a different disk drive.
- 18 (ERROR\_NO\_MORE\_FILES)  
There are no more files.
- 19 (ERROR\_WRITE\_PROTECT)  
The media is write protected.
- 20 (ERROR\_BAD\_UNIT)  
The system cannot find the device specified.
- 21 (ERROR\_NOT\_READY)  
The device is not ready.
- 22 (ERROR\_BAD\_COMMAND)  
The device does not recognize the command.
- 23 (ERROR\_CRC)  
Data error (cyclic redundancy check).
- 24 (ERROR\_BAD\_LENGTH)  
The program issued a command but the command length is incorrect.
- 25 (ERROR\_SEEK)

The drive cannot locate a specific area or track on the disk.

- 26 (ERROR\_NOT\_DOS\_DISK)

The specified disk or diskette cannot be accessed.

- 27 (ERROR\_SECTOR\_NOT\_FOUND)

The drive cannot find the sector requested.

- 28 (ERROR\_OUT\_OF\_PAPER)

The printer is out of paper.

- 29 (ERROR\_WRITE\_FAULT)

The system cannot write to the specified device.

- 30 (ERROR\_READ\_FAULT)

The system cannot read from the specified device.

- 31 (ERROR\_GEN\_FAILURE)

A device attached to the system is not functioning.

- 32 (ERROR\_SHARING\_VIOLATION)

The process cannot access the file because it is being used by another process.

- 33 (ERROR\_LOCK\_VIOLATION)

The process cannot access the file because another process has locked a portion of the file.

- 34 (ERROR\_WRONG\_DISK)

The wrong diskette is in the drive. Insert %2 (Volume Serial Number: %3) into drive %1.

- 36 (ERROR\_SHARING\_BUFFER\_EXCEEDED)

Too many files opened for sharing.

- 38 (ERROR\_HANDLE\_EOF)

Reached the end of the file.

- 39 (ERROR\_HANDLE\_DISK\_FULL)

The disk is full.

- 87 (ERROR\_INVALID\_PARAMETER)

The parameter is incorrect. (If this error occurs on Windows and you have enabled `innodb_file_per_table` in a server option file, add the line `innodb_flush_method=unbuffered` to the file as well.)

- 112 (ERROR\_DISK\_FULL)

The disk is full.

- 123 (ERROR\_INVALID\_NAME)

The filename, directory name, or volume label syntax is incorrect.

- 1450 (ERROR\_NO\_SYSTEM\_RESOURCES)

Insufficient system resources exist to complete the requested service.

## 14.2.16. Restrictions on InnoDB Tables

- **Warning:** Do *not* convert MySQL system tables in the `mysql` database from MyISAM to InnoDB tables! This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or re-generate them with the `mysql_install_db` script.
- A table cannot contain more than 1000 columns.
- The internal maximum key length is 3500 bytes, but MySQL itself restricts this to 1024 bytes.
- The maximum row length, except for VARCHAR, BLOB and TEXT columns, is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes. LONGBLOB and LONGTEXT columns must be less than 4GB, and the total row length, including also BLOB and TEXT columns, must be less than 4GB. InnoDB stores the first 768 bytes of a VARCHAR, BLOB, or TEXT column in the row, and the rest into separate pages.

- Although InnoDB supports row sizes larger than 65535 internally, you cannot define a row containing VARCHAR columns with a combined size larger than 65535:

```
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
-> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
-> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

- On some older operating systems, files must be less than 2GB. This is not a limitation of InnoDB itself, but if you require a large tablespace, you will need to configure it using several smaller data files rather than one or a file large data files.
- The combined size of the InnoDB log files must be less than 4GB.
- The minimum tablespace size is 10MB. The maximum tablespace size is four billion database pages (64TB). This is also the maximum size for a table.
- InnoDB tables do not support FULLTEXT indexes.
- InnoDB tables do not support spatial data types before MySQL 5.0.16.
- ANALYZE TABLE determines index cardinality (as displayed in the Cardinality column of SHOW INDEX output) by doing eight random dives to each of the index trees and updating index cardinality estimates accordingly. Note that because these are only estimates, repeated runs of ANALYZE TABLE may produce different numbers. This makes ANALYZE TABLE fast on InnoDB tables but not 100% accurate as it doesn't take all rows into account.

MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you can try using ANALYZE TABLE. In the few cases that ANALYZE TABLE doesn't produce values good enough for your particular tables, you can use FORCE INDEX with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See Section 5.2.2, "Server System Variables", and Section A.6, "Optimizer-Related Issues".

- SHOW TABLE STATUS does not give accurate statistics on InnoDB tables, except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

- InnoDB does not keep an internal count of rows in a table. (In practice, this would be somewhat complicated due to multi-versioning.) To process a `SELECT COUNT(*) FROM t` statement, InnoDB must scan an index of the table, which takes some time if the index is not entirely in the buffer pool. To get a fast count, you have to use a counter table you create yourself and let your application update it according to the inserts and deletes it does. If your table does not change often, using the MySQL query cache is a good solution. `SHOW TABLE STATUS` also can be used if an approximate row count is sufficient. See Section 14.2.11, “InnoDB Performance Tuning Tips”.
- On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in binary format from Unix to Windows or from Windows to Unix, you should always use explicitly lowercase names when creating databases and tables.
- For an `AUTO_INCREMENT` column, you must always define an index for the table, and that index must contain just the `AUTO_INCREMENT` column. In MyISAM tables, the `AUTO_INCREMENT` column may be part of a multi-column index.
- In MySQL 5.0 before MySQL 5.0.3, InnoDB does not support the `AUTO_INCREMENT` table option for setting the initial sequence value in a `CREATE TABLE` or `ALTER TABLE` statement. To set the value with InnoDB, insert a dummy row with a value one less and delete that dummy row, or insert the first row with an explicit value specified.
- While initializing a previously specified `AUTO_INCREMENT` column on a table, InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, InnoDB uses a specific table lock mode `AUTO-INC` where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Note that other clients cannot insert into the table while the `AUTO-INC` table lock is held; see Section 14.2.10.2, “InnoDB and AUTOCOMMIT”.
- When you restart the MySQL server, InnoDB may reuse an old value that was generated for an `AUTO_INCREMENT` column but never stored (that is, a value that was generated during an old transaction that was rolled back).
- When an `AUTO_INCREMENT` column runs out of values, InnoDB wraps a `BIGINT` to `-9223372036854775808` and `BIGINT UNSIGNED` to `1`. However, `BIGINT` values have 64 bits, so do note that if you were to insert one million rows per second, it would still take nearly three hundred thousand years before `BIGINT` reached its upper bound. With all other integer type columns, a duplicate-key error results. This is similar to how MyISAM works, because it is mostly general MySQL behavior and not about any storage engine in particular.
- `DELETE FROM tbl_name` does not regenerate the table but instead deletes all rows, one by one.
- Under some conditions, `TRUNCATE tbl_name` for an InnoDB table is mapped to `DELETE FROM tbl_name` and doesn't reset the `AUTO_INCREMENT` counter. See Section 13.2.9, “TRUNCATE Syntax”.
- In MySQL 5.0, the `MySQL LOCK TABLES` operation acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an InnoDB table lock. Older versions of MySQL did not acquire InnoDB table locks; the old behavior can be selected by setting `innodb_table_locks=0`. If no InnoDB table lock is acquired, `LOCK TABLES` completes even if some records of the tables are being locked by other transactions.
- All InnoDB locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke `LOCK TABLES` on InnoDB tables in `AUTO-COMMIT=1` mode, because the acquired InnoDB table locks would be released immediately.
- Sometimes it would be useful to lock further tables in the course of a transaction. Unfortunately, `LOCK TABLES` in MySQL performs an implicit `COMMIT` and `UNLOCK TABLES`. An InnoDB variant of `LOCK TABLES` has been planned that can be executed in the middle of a transaction.
- The `LOAD TABLE FROM MASTER` statement for setting up replication slave servers does not

work for InnoDB tables. A workaround is to alter the table to MyISAM on the master, do then the load, and after that alter the master table back to InnoDB. Do not do this if the tables use InnoDB-specific features such as foreign keys.

- The default database page size in InnoDB is 16KB. By recompiling the code, you can set it to values ranging from 8KB to 64KB. You must update the values of `UNIV_PAGE_SIZE` and `UNIV_PAGE_SIZE_SHIFT` in the `univ.i` source file.
- Currently, triggers are not activated by cascaded foreign key actions.
- You cannot create a table with a column name that matches the name of an internal InnoDB column (including `DB_ROW_ID`, `DB_TRX_ID`, `DB_ROLL_PTR` and `DB_MIX_ID`). In versions of MySQL before 5.0.21 this would cause a crash, since 5.0.21 the server will report error 1005 and refers to `errno -1` in the error message.
- As of MySQL 5.0.19, InnoDB does not ignore trailing spaces when comparing `BINARY` or `VARBINARY` column values. See Section 11.4.2, “The `BINARY` and `VARBINARY` Types” and Section D.1.5, “Changes in release 5.0.19 (04 March 2006)”.

## 14.2.17. InnoDB Troubleshooting

The following general guidelines apply to troubleshooting InnoDB problems:

- When an operation fails or you suspect a bug, you should look at the MySQL server error log, which is the file in the data directory that has a suffix of `.err`.
- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through the `mysqld_safe` wrapper or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, you must start the server with the `--console` option to direct the output to the console window.
- Use the InnoDB Monitors to obtain information about a problem (see Section 14.2.11.1, “`SHOW ENGINE INNODB STATUS` and the InnoDB Monitors”). If the problem is performance-related, or your server appears to be hung, you should use `innodb_monitor` to print information about the internal state of InnoDB. If the problem is with locks, use `innodb_lock_monitor`. If the problem is in creation of tables or other data dictionary operations, use `innodb_table_monitor` to print the contents of the InnoDB internal data dictionary.
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

### 14.2.17.1. Troubleshooting InnoDB Data Dictionary Operations

A specific issue with tables is that the MySQL server keeps data dictionary information in `.frm` files it stores in the database directories, whereas InnoDB also stores the information into its own data dictionary inside the tablespace files. If you move `.frm` files around, or if the server crashes in the middle of a data dictionary operation, the locations of the `.frm` files may end up out of synchrony with the locations recorded in the InnoDB internal data dictionary.

A symptom of an out-of-sync data dictionary is that a `CREATE TABLE` statement fails. If this occurs, you should look in the server's error log. If the log says that the table already exists inside the InnoDB internal data dictionary, you have an orphaned table inside the InnoDB tablespace files that has no corresponding `.frm` file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
```

```
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphaned table by following the instructions given in the error message. If you are still unable to use `DROP TABLE` successfully, the problem may be due to name completion in the `mysql` client. To work around this problem, start the `mysql` client with the `-skip-auto-rehash` option and try `DROP TABLE` again. (With name completion on, `mysql` tries to construct a list of table names, which fails when a problem such as just described exists.)

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open a `.InnoDB` file:

```
ERROR 1016: Can't open file: 'child2.InnoDB'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphaned `.frm` file without a corresponding table inside InnoDB. You can drop the orphaned `.frm` file by deleting it manually.

If MySQL crashes in the middle of an `ALTER TABLE` operation, you may end up with an orphaned temporary table inside the InnoDB tablespace. Using `innodb_table_monitor` you can see listed a table whose name is `#sql-...`. You can perform SQL statements on tables whose name contains the character `#` if you enclose the name within backticks. Thus, you can drop such an orphaned table like any other orphaned table using the method described earlier. Note that to copy or rename a file in the Unix shell, you need to put the file name in double quotes if the file name contains `#`.

## 14.3. The MERGE Storage Engine

The MERGE storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical MyISAM tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge MyISAM tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the MyISAM tables can be compressed with `myisampack`. See Section 8.5, “`myisampack` — Generate Compressed, Read-Only MyISAM Tables”. Differences in table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` do not matter.

When you create a MERGE table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and an `.MRG` file contains the names of the tables that should be used as one. The tables do not have to be in the same database as the MERGE table itself.

You can use `SELECT`, `DELETE`, `UPDATE`, and `INSERT` on MERGE tables. You must have `SELECT`, `UPDATE`, and `DELETE` privileges on the MyISAM tables that you map to a MERGE table.

If you `DROP` the MERGE table, you are dropping only the MERGE specification. The underlying tables are not affected.

To create a MERGE table, you must specify a `UNION=(list-of-tables)` clause that indicates which MyISAM tables you want to use as one. You can optionally specify an `INSERT_METHOD` option if you want inserts for the MERGE table to take place in the first or last table of the UNION list. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last table, respectively.

If you do not specify an `INSERT_METHOD` option or if you specify it with a value of `NO`, attempts to insert rows into the `MERGE` table result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
->   a INT NOT NULL AUTO_INCREMENT,
->   message CHAR(20), INDEX(a))
->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

The older term `TYPE` is supported as a synonym for `ENGINE` for backward compatibility, but `ENGINE` is the preferred term and `TYPE` is deprecated.

Note that the `a` column is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables.

After creating the `MERGE` table, you can issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+----+-----+
| a | message |
+----+-----+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+----+-----+
```

To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

- `DROP` the `MERGE` table and re-create it.
- Use `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `mysampack`, and then create a `MERGE` table to use them as one.
- Obtain more speed. You can split a big read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table on this could be much faster than using the big table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the split tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual tables that are mapped to a `MERGE` table than to repair a single large table.

- Instantly map many tables as one. A MERGE table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, MERGE table collections are *very* fast to create or remap. (Note that you must still specify the index definitions when you create a MERGE table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you should instead create a MERGE table on them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each MyISAM table is bound by this limit, but a collection of MyISAM tables is not.
- You can create an alias or synonym for a MyISAM table by defining a MERGE table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of MERGE tables are:

- You can use only identical MyISAM tables for a MERGE table.
- You cannot use a number of MyISAM features in MERGE tables. For example, you cannot create FULLTEXT indexes on MERGE tables. (You can, of course, create FULLTEXT indexes on the underlying MyISAM tables, but you cannot search the MERGE table with a full-text search.)
- If the MERGE table is non-temporary, all underlying MyISAM tables must be non-temporary, too. If the MERGE table is temporary, the MyISAM tables can be any mix of temporary and non-temporary.
- MERGE tables use more file descriptors. If 10 clients are using a MERGE table that maps to 10 tables, the server uses  $(10 \times 10) + 10$  file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Key reads are slower. When you read a key, the MERGE storage engine needs to issue a read on all underlying tables to check which one most closely matches the given key. To read the next key, the MERGE storage engine needs to search the read buffers to find the next key. Only when one key buffer is used up does the storage engine need to read the next key block. This makes MERGE keys much slower on `eq_ref` searches, but not much slower on `ref` searches. See Section 7.2.1, “Optimizing Queries with EXPLAIN”, for more information about `eq_ref` and `ref`.

#### Additional resources

- A forum dedicated to the MERGE storage engine is available at <http://forums.mysql.com/list.php?93>.

## 14.3.1. MERGE Table Problems

The following are known problems with MERGE tables:

- If you use `ALTER TABLE` to change a MERGE table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying MyISAM tables are copied into the altered table, which then uses the specified storage engine.
- `REPLACE` does not work.
- You cannot use `DROP TABLE`, `ALTER TABLE`, `DELETE` without a `WHERE` clause, `REPAIR TABLE`, `TRUNCATE TABLE`, `OPTIMIZE TABLE`, or `ANALYZE TABLE` on any of the tables that are mapped into an open MERGE table. If you do so, the MERGE table may still refer to the

original table, which yields unexpected results. The easiest way to work around this deficiency is to ensure that no MERGE tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of those operations.

- `DROP TABLE` on a table that is in use by a MERGE table does not work on Windows because the MERGE storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not allow open files to be deleted, so you first must flush all MERGE tables (with `FLUSH TABLES`) or drop the MERGE table before dropping the table.
- A MERGE table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last MyISAM table (depending on the value of the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that MyISAM table, but not across all the tables in the collection.
- When you create a MERGE table, there is no check to ensure that the underlying tables exist and have identical structures. When the MERGE table is used, MySQL checks that the row length for all mapped tables is equal, but this is not foolproof. If you create a MERGE table from dissimilar MyISAM tables, you are very likely to run into strange problems.
- The order of indexes in the MERGE table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a MERGE table, and then use `ALTER TABLE` to add a non-unique index on the MERGE table, the index ordering is different for the tables if there was already a non-unique index in the underlying table. (This happens because `ALTER TABLE` puts `UNIQUE` indexes before non-unique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to `ERROR 1017 (HY000): Can't find file: 'mm.MRG' (errno: 2)` it generally indicates that some of the base tables are not using the MyISAM storage engine. Confirm that all tables are MyISAM.
- There is a limit of  $2^{32}$  (~4.295E+09) rows to a MERGE table, just as there is with a MyISAM, it is therefore not possible to merge multiple MyISAM tables that exceed this limitation. However, you build MySQL with the `--with-big-tables` option then the row limitation is increased to  $(2^{32})^2$  (1.844E+19) rows. See Section 2.9.2, "Typical configure Options". Beginning with MySQL 5.0.4 all standard binaries are built with this option.

## 14.4. The MEMORY (HEAP) Storage Engine

The MEMORY storage engine creates tables with contents that are stored in memory. Formerly, these were known as HEAP tables. MEMORY is the preferred term, although HEAP remains supported for backward compatibility.

Each MEMORY table is associated with one disk file. The filename begins with the table name and has an extension of `.frm` to indicate that it stores the table definition.

To specify explicitly that you want to create a MEMORY table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

The older term `TYPE` is supported as a synonym for `ENGINE` for backward compatibility, but `ENGINE` is the preferred term and `TYPE` is deprecated.

As indicated by the name, MEMORY tables are stored in memory. They use hash indexes by default, which makes them very fast, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in MEMORY tables are lost. The tables themselves continue to exist because their definitions are stored in `.frm` files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a MEMORY table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
->     SELECT ip,SUM(downloads) AS down
->     FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

MEMORY tables have the following characteristics:

- Space for MEMORY tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. MEMORY tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
- MEMORY tables can have up to 32 indexes per table, 16 columns per index and a maximum key length of 500 bytes.
- The MEMORY storage engine implements both HASH and BTREE indexes. You can specify one or the other for a given index by adding a USING clause as shown here:

```
CREATE TABLE lookup
  (id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

General characteristics of B-tree and hash indexes are described in Section 7.4.5, “How MySQL Uses Indexes”.

- You can have non-unique keys in a MEMORY table. (This is an uncommon feature for implementations of hash indexes.)
- If you have a hash index on a MEMORY table that has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a BTREE index to avoid this problem.
- Columns that are indexed can contain NULL values.
- MEMORY tables use a fixed-length row storage format.
- MEMORY tables cannot contain BLOB or TEXT columns.
- MEMORY includes support for AUTO\_INCREMENT columns.
- You can use INSERT DELAYED with MEMORY tables. See Section 13.2.4.2, “INSERT DELAYED Syntax”.
- MEMORY tables are shared among all clients (just like any other non-TEMPORARY table).
- MEMORY table contents are stored in memory, which is a property that MEMORY tables share with internal tables that the server creates on the fly while processing queries. However, the two types of tables differ in that MEMORY tables are not subject to storage conversion, whereas internal tables are:
  - If an internal table becomes too large, the server automatically converts it to an on-disk table. The size limit is determined by the value of the tmp\_table\_size system variable.
  - MEMORY tables are never converted to disk tables. To ensure that you don't accidentally do anything foolish, you can set the max\_heap\_table\_size system variable to impose a

maximum size on MEMORY tables. For individual tables, you can also specify a MAX\_ROWS table option in the CREATE TABLE statement.

- The server needs sufficient memory to maintain all MEMORY tables that are in use at the same time.
- To free memory used by a MEMORY table when you no longer require its contents, you should execute DELETE or TRUNCATE TABLE, or remove the table altogether using DROP TABLE.
- If you want to populate a MEMORY table when the MySQL server starts, you can use the --init-file option. For example, you can put statements such as INSERT INTO ... SELECT or LOAD DATA INFILE into this file to load the table from a persistent data source. See Section 5.2.1, “mysqld Command Options”, and Section 13.2.5, “LOAD DATA INFILE Syntax”.
- If you are using replication, the master server's MEMORY tables become empty when it is shut down and restarted. However, a slave is not aware that these tables have become empty, so it returns out-of-date content if you select data from them. When a MEMORY table is used on the master for the first time since the master was started, a DELETE statement is written to the master's binary log automatically, thus synchronizing the slave to the master again. Note that even with this strategy, the slave still has outdated data in the table during the interval between the master's restart and its first use of the table. However, if you use the --init-file option to populate the MEMORY table on the master at startup, it ensures that this time interval is zero.
- The memory needed for one row in a MEMORY table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) × 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) × 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

ALIGN() represents a round-up factor to cause the row length to be an exact multiple of the char pointer size. sizeof(char\*) is 4 on 32-bit machines and 8 on 64-bit machines.

#### Additional resources

- A forum dedicated to the MEMORY storage engine is available at <http://forums.mysql.com/list.php?92>.

## 14.5. The BDB (BerkeleyDB) Storage Engine

Sleepycat Software has provided MySQL with the Berkeley DB transactional storage engine. This storage engine typically is called BDB for short. BDB tables may have a greater chance of surviving crashes and are also capable of COMMIT and ROLLBACK operations on transactions.

Support for the BDB storage engine is included in MySQL source distributions is activated in MySQL-Max binary distributions. The MySQL source distribution comes with a BDB distribution that is patched to make it work with MySQL. You cannot use a non-patched version of BDB with MySQL.

We at MySQL AB work in close cooperation with Sleepycat to keep the quality of the MySQL/BDB interface high. (Even though Berkeley DB is in itself very tested and reliable, the MySQL interface is still considered gamma quality. We continue to improve and optimize it.)

When it comes to support for any problems involving BDB tables, we are committed to helping our users locate the problem and create reproducible test cases. Any such test case is forwarded to Sleepycat, which in turn helps us find and fix the problem. As this is a two-stage operation, any problems with BDB tables may take a little longer for us to fix than for other storage engines.

However, we anticipate no significant difficulties with this procedure because the Berkeley DB code itself is used in many applications other than MySQL.

For general information about Berkeley DB, please visit the Sleepycat Web site, <http://www.sleepycat.com/>.

## 14.5.1. Operating Systems Supported by BDB

Currently, we know that the BDB storage engine works with the following operating systems:

- Linux 2.x Intel
- Sun Solaris (SPARC and x86)
- FreeBSD 4.x/5.x (x86, sparc64)
- IBM AIX 4.3.x
- SCO OpenServer
- SCO UnixWare 7.1.x
- Windows NT/2000/XP

The BDB storage engine does *not* work with the following operating systems:

- Linux 2.x Alpha
- Linux 2.x AMD64
- Linux 2.x IA-64
- Linux 2.x s390
- Mac OS X

**Note:** The preceding lists are not complete. We update them as we receive more information.

If you build MySQL from source with support for BDB tables, but the following error occurs when you start `mysqld`, it means that the BDB storage engine is not supported for your architecture:

```
bdb: architecture lacks fast mutexes: applications cannot be threaded
Can't init databases
```

In this case, you must rebuild MySQL without BDB support or start the server with the `--skip-bdb` option.

## 14.5.2. Installing BDB

If you have downloaded a binary version of MySQL that includes support for Berkeley DB, simply follow the usual binary distribution installation instructions. (MySQL-Max distributions include BDB support.)

If you build MySQL from source, you can enable BDB support by invoking `configure` with the `--with-berkeley-db` option in addition to any other options that you normally use. Download a MySQL 5.0 distribution, change location into its top-level directory, and run this command:

```
shell> ./configure --with-berkeley-db [other-options]
```

For more information, see Section 5.3, “The `mysqld-max` Extended MySQL Server”, Section 2.8, “Installing MySQL on Other Unix-Like Systems”, and Section 2.9, “MySQL Installation Using a Source Distribution”.

## 14.5.3. BDB Startup Options

The following options to `mysqld` can be used to change the behavior of the BDB storage engine. For more information, see Section 5.2.1, “`mysqld` Command Options”.

- `--bdb-home=path`  
The base directory for BDB tables. This should be the same directory that you use for `--datadir`.
- `--bdb-lock-detect=method`  
The BDB lock detection method. The option value should be `DEFAULT`, `OLDEST`, `RANDOM`, or `YOUNGEST`.
- `--bdb-logdir=file_name`  
The BDB log file directory.
- `--bdb-no-recover`  
Do not start Berkeley DB in recover mode.
- `--bdb-no-sync`  
Don't synchronously flush the BDB logs. This option is deprecated; use `--skip-sync-bdb-logs` instead (see the description for `--sync-bdb-logs`).
- `--bdb-shared-data`  
Start Berkeley DB in multi-process mode. (Do not use `DB_PRIVATE` when initializing Berkeley DB.)
- `--bdb-tmpdir=path`  
The BDB temporary file directory.
- `--skip-bdb`  
Disable the BDB storage engine.
- `--sync-bdb-logs`  
Synchronously flush the BDB logs. This option is enabled by default. Use `--skip-sync-bdb-logs` to disable it.

If you use the `--skip-bdb` option, MySQL does not initialize the Berkeley DB library and this saves a lot of memory. However, if you use this option, you cannot use BDB tables. If you try to create a BDB table, MySQL uses the default storage engine instead.

Normally, you should start `mysqld` without the `--bdb-no-recover` option if you intend to use BDB tables. However, this may cause problems when you try to start `mysqld` if the BDB log files are corrupted. See Section 2.10.2.3, “Starting and Troubleshooting the MySQL Server”.

With the `bdb_max_lock` variable, you can specify the maximum number of locks that can be active on a BDB table. The default is 10,000. You should increase this if errors such as the following occur when you perform long transactions or when `mysqld` has to examine many rows to execute a

query:

```
bdb: Lock table is out of available locks
Got error 12 from ...
```

You may also want to change the `binlog_cache_size` and `max_binlog_cache_size` variables if you are using large multiple-statement transactions. See Section 5.12.3, “The Binary Log”.

See also Section 5.2.2, “Server System Variables”.

## 14.5.4. Characteristics of BDB Tables

Each BDB table is stored on disk in two files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and a `.db` file contains the table data and indexes.

To specify explicitly that you want a BDB table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = BDB;
```

The older term `TYPE` is supported as a synonym for `ENGINE` for backward compatibility, but `ENGINE` is the preferred term and `TYPE` is deprecated.

BerkeleyDB is a synonym for BDB in the `ENGINE` table option.

The BDB storage engine provides transactional tables. The way you use these tables depends on the autocommit mode:

- If you are running with autocommit enabled (which is the default), changes to BDB tables are committed immediately and cannot be rolled back.
- If you are running with autocommit disabled, changes do not become permanent until you execute a `COMMIT` statement. Instead of committing, you can execute `ROLLBACK` to forget the changes.

You can start a transaction with the `START TRANSACTION` or `BEGIN` statement to suspend autocommit, or with `SET AUTOCOMMIT=0` to disable autocommit explicitly.

For more information about transactions, see Section 13.4.1, “`START TRANSACTION`, `COMMIT`, and `ROLLBACK` Syntax”.

The BDB storage engine has the following characteristics:

- BDB tables can have up to 31 indexes per table, 16 columns per index, and a maximum key size of 1024 bytes.
- MySQL requires a primary key in each BDB table so that each row can be uniquely identified. If you don't create one explicitly by declaring a `PRIMARY KEY`, MySQL creates and maintains a hidden primary key for you. The hidden key has a length of five bytes and is incremented for each insert attempt. This key does not appear in the output of `SHOW CREATE TABLE` or `DESCRIBE`.
- The primary key is faster than any other index, because it is stored together with the row data. The other indexes are stored as the key data plus the primary key, so it's important to keep the primary key as short as possible to save disk space and get better speed.

This behavior is similar to that of InnoDB, where shorter primary keys save space not only in the primary index but in secondary indexes as well.

- If all columns that you access in a BDB table are part of the same index or part of the primary key, MySQL can execute the query without having to access the actual row. In a MyISAM table, this can be done only if the columns are part of the same index.
- Sequential scanning is slower for BDB tables than for MyISAM tables because the data in BDB tables is stored in B-trees and not in a separate data file.
- Key values are not prefix- or suffix-compressed like key values in MyISAM tables. In other words, key information takes a little more space in BDB tables compared to MyISAM tables.
- There are often holes in the BDB table to allow you to insert new rows in the middle of the index tree. This makes BDB tables somewhat larger than MyISAM tables.
- `SELECT COUNT(*) FROM tbl_name` is slow for BDB tables, because no row count is maintained in the table.
- The optimizer needs to know the approximate number of rows in the table. MySQL solves this by counting inserts and maintaining this in a separate segment in each BDB table. If you don't issue a lot of `DELETE` or `ROLLBACK` statements, this number should be accurate enough for the MySQL optimizer. However, MySQL stores the number only on close, so it may be incorrect if the server terminates unexpectedly. It should not be fatal even if this number is not 100% correct. You can update the row count by using `ANALYZE TABLE` or `OPTIMIZE TABLE`. See Section 13.5.2.1, “ANALYZE TABLE Syntax”, and Section 13.5.2.5, “OPTIMIZE TABLE Syntax”.
- Internal locking in BDB tables is done at the page level.
- `LOCK TABLES` works on BDB tables as with other tables. If you do not use `LOCK TABLES`, MySQL issues an internal multiple-write lock on the table (a lock that does not block other writers) to ensure that the table is properly locked if another thread issues a table lock.
- To support transaction rollback, the BDB storage engine maintains log files. For maximum performance, you can use the `--bdb-logdir` option to place the BDB logs on a different disk than the one where your databases are located.
- MySQL performs a checkpoint each time a new BDB log file is started, and removes any BDB log files that are not needed for current transactions. You can also use `FLUSH LOGS` at any time to checkpoint the Berkeley DB tables.

For disaster recovery, you should use table backups plus MySQL's binary log. See Section 5.10.1, “Database Backups”.

**Warning:** If you delete old log files that are still in use, BDB is not able to do recovery at all and you may lose data if something goes wrong.

- Applications must always be prepared to handle cases where any change of a BDB table may cause an automatic rollback and any read may fail with a deadlock error.
- If you get a full disk with a BDB table, you get an error (probably error 28) and the transaction should roll back. This contrasts with MyISAM tables, for which `mysqld` waits for sufficient free disk space before continuing.

## 14.5.5. Things We Need to Fix for BDB

- Opening many BDB tables at the same time may be quite slow. If you are going to use BDB tables, you should not have a very large table cache (for example, with a size larger than 256) and you should use the `--no-auto-rehash` option when you use the `mysql` client.
- `SHOW TABLE STATUS` does not provide some information for BDB tables:

```
mysql> SHOW TABLE STATUS LIKE 'bdbtest'\G
```

```
***** 1. row *****
      Name: bdbtest
      Engine: BerkeleyDB
      Version: 10
      Row_format: Dynamic
      Rows: 154
      Avg_row_length: 0
      Data_length: 0
      Max_data_length: 0
      Index_length: 0
      Data_free: 0
      Auto_increment: NULL
      Create_time: NULL
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options:
      Comment:
```

- Optimize performance.
- Change to use no page locks for table scanning operations.

## 14.5.6. Restrictions on BDB Tables

The following list indicates restrictions that you must observe when using BDB tables:

- Each BDB table stores in its `.db` file the path to the file as it was created. This is done to enable detection of locks in a multi-user environment that supports symlinks. As a consequence of this, it is not possible to move BDB table files from one database directory to another.
- When making backups of BDB tables, you must either use `mysqldump` or else make a backup that includes the files for each BDB table (the `.frm` and `.db` files) as well as the BDB log files. The BDB storage engine stores unfinished transactions in its log files and requires them to be present when `mysqld` starts. The BDB logs are the files in the data directory with names of the form `log.NNNNNNNNNN` (ten digits).
- If a column that allows `NULL` values has a unique index, only a single `NULL` value is allowed. This differs from other storage engines, which allow multiple `NULL` values in unique indexes.

## 14.5.7. Errors That May Occur When Using BDB Tables

- If the following error occurs when you start `mysqld` after upgrading, it means that the current version of BDB doesn't support the old log file format:

```
bdb: Ignoring log file: ../log.NNNNNNNNNN:
unsupported log version #
```

In this case, you must delete all BDB logs from your data directory (the files that have names of the form `log.NNNNNNNNNN`) and restart `mysqld`. We also recommend that you then use `mysqldump --opt` to dump your BDB tables, drop the tables, and restore them from the dump file.

- If autocommit mode is disabled and you drop a BDB table that is referenced in another transaction, you may get error messages of the following form in your MySQL error log:

```
001119 23:43:56 bdb: Missing log fileid entry
```

```
001119 23:43:56 bdb: txn_abort: Log undo failed for LSN:
1 3644744: Invalid
```

This is not fatal, but the fix is not trivial. Until the problem is fixed, we recommend that you not drop BDB tables except while autocommit mode is enabled.

## 14.6. The **EXAMPLE** Storage Engine

The **EXAMPLE** storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

The **EXAMPLE** storage engine is included in MySQL-Max binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `--with-example-storage-engine` option.

To examine the source for the **EXAMPLE** engine, look in the `sql/examples` directory of a MySQL source distribution.

When you create an **EXAMPLE** table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The **EXAMPLE** storage engine does not support indexing.

## 14.7. The **FEDERATED** Storage Engine

The **FEDERATED** storage engine is available beginning with MySQL 5.0.3. It is a storage engine that accesses data in tables of remote databases rather than in local tables.

The **FEDERATED** storage engine is included in MySQL-Max binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `--with-federated-storage-engine` option.

To examine the source for the **FEDERATED** engine, look in the `sql` directory of a source distribution for MySQL 5.0.3 or newer.

### Additional resources

- A forum dedicated to the **FEDERATED** storage engine is available at <http://forums.mysql.com/list.php?105>.

### 14.7.1. Description of the **FEDERATED** Storage Engine

When you create a **FEDERATED** table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created, because the actual data is in a remote table. This differs from the way that storage engines for local

tables work.

For local database tables, data files are local. For example, if you create a MyISAM table named `users`, the MyISAM handler creates a data file named `users.MYD`. A handler for local tables reads, inserts, deletes, and updates data in local data files, and rows are stored in a format particular to the handler. To read rows, the handler must parse data into columns. To write rows, column values must be converted to the row format used by the handler and written to the local data file.

With the MySQL FEDERATED storage engine, there are no local data files for a table (for example, there is no `.MYD` file). Instead, a remote database stores the data that normally would be in the table. The local server connects to a remote server, and uses the MySQL client API to read, delete, update, and insert data in the remote table. Data retrieval is initiated via a `SELECT * FROM tbl_name` SQL statement. To read the result, rows are fetched one at a time by using the `mysql_fetch_row()` C API function, and then converting the columns in the `SELECT` result set to the format that the FEDERATED handler expects.

The flow of information is as follows:

1. SQL calls issued locally
2. MySQL handler API (data in handler format)
3. MySQL client API (data converted to SQL calls)
4. Remote database -> MySQL client API
5. Convert result sets (if any) to handler format
6. Handler API -> Result rows or rows-affected count to local

## 14.7.2. How to use FEDERATED Tables

The procedure for using FEDERATED tables is very simple. Normally, you have two servers running, either both on the same host or on different hosts. (It is possible for a FEDERATED table to use another table that is managed by the same server, although there is little point in doing so.)

First, you must have a table on the remote server that you want to access by using a FEDERATED table. Suppose that the remote table is in the `federated` database and is defined like this:

```
CREATE TABLE test_table (  
  id      INT(20) NOT NULL AUTO_INCREMENT,  
  name    VARCHAR(32) NOT NULL DEFAULT '',  
  other   INT(20) NOT NULL DEFAULT '0',  
  PRIMARY KEY (id),  
  INDEX name (name),  
  INDEX other_key (other)  
)  
ENGINE=MyISAM  
DEFAULT CHARSET=latin1;
```

The example uses a MyISAM table, but the table could use any storage engine.

Next, create a FEDERATED table on the local server for accessing the remote table:

```
CREATE TABLE federated_table (  
  id      INT(20) NOT NULL AUTO_INCREMENT,  
  name    VARCHAR(32) NOT NULL DEFAULT '',  
  other   INT(20) NOT NULL DEFAULT '0',  
  PRIMARY KEY (id),  
  INDEX name (name),  
  INDEX other_key (other)  
)  
ENGINE=FEDERATED
```

```
DEFAULT CHARSET=latin1
CONNECTION='mysql://root@remote_host:9306/federated/test_table';
```

(Before MySQL 5.0.13, use COMMENT rather than CONNECTION.)

The structure of this table must be exactly the same as that of the remote table, except that the ENGINE table option should be FEDERATED and the CONNECTION table option is a connection string that indicates to the FEDERATED engine how to connect to the remote server.

The FEDERATED engine creates only the `test_table.frm` file in the federated database.

The remote host information indicates the remote server to which your local server connects, and the database and table information indicates which remote table to use as the data source. In this example, the remote server is indicated to be running as `remote_host` on port 9306, so there must be a MySQL server running on the remote host and listening to port 9306.

The general form of the connection string in the CONNECTION option is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Only `mysql` is supported as the *scheme* value at this point; the password and port number are optional.

Here are some example connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

The use of CONNECTION for specifying the connection string is non-optimal and is likely to change in future. Keep this in mind for applications that use FEDERATED tables. Such applications are likely to need modification if the format for specifying connection information changes.

Because any password given in the connection string is stored as plain text, it can be seen by any user who can use SHOW CREATE TABLE or SHOW TABLE STATUS for the FEDERATED table, or query the TABLES table in the INFORMATION\_SCHEMA database.

### 14.7.3. Limitations of the FEDERATED Storage Engine

The following items indicate features that the FEDERATED storage engine does and does not support:

- In the first version, the remote server must be a MySQL server. Support by FEDERATED for other database engines may be added in the future.
- The remote table that a FEDERATED table points to *must* exist before you try to access the table through the FEDERATED table.
- It is possible for one FEDERATED table to point to another, but you must be careful not to create a loop.
- There is no support for transactions.
- There is no way for the FEDERATED engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database. The integrity of the data in the local table could be breached if there was any change to the remote database.
- The FEDERATED storage engine supports SELECT, INSERT, UPDATE, DELETE, and indexes. It does not support ALTER TABLE, or any Data Definition Language statements other than

`DROP TABLE`. The current implementation does not use Prepared statements.

- Any `DROP TABLE` statement issued against a `FEDERATED` table will only drop the local table, not the remote table.
- The implementation uses `SELECT`, `INSERT`, `UPDATE`, and `DELETE`, but not `HANDLER`.
- `FEDERATED` tables do not work with the query cache.

Some of these limitations may be lifted in future versions of the `FEDERATED` handler.

## 14.8. The ARCHIVE Storage Engine

The `ARCHIVE` storage engine is used for storing large amounts of data without indexes in a very small footprint.

The `ARCHIVE` storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `-with-archive-storage-engine` option.

To examine the source for the `ARCHIVE` engine, look in the `sql` directory of a MySQL source distribution.

You can check whether the `ARCHIVE` storage engine is available with this statement:

```
mysql> SHOW VARIABLES LIKE 'have_archive';
```

When you create an `ARCHIVE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data and metadata files have extensions of `.ARZ` and `.ARM`, respectively. An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT` and `SELECT`, but not `DELETE`, `REPLACE`, or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see Section 16.4.1, “MySQL Spatial Data Types”). The `ARCHIVE` engine uses row-level locking.

**Storage:** Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). Beginning with MySQL 5.0.15, the engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur, unless the only insertions that have come in were `INSERT DELAYED` (those flush as necessary). See Section 13.2.4.2, “`INSERT DELAYED` Syntax”.
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

**Retrieval:** On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See Section 13.5.2.5, “`OPTIMIZE TABLE` Syntax”, Section 13.5.2.6, “`REPAIR TABLE` Syntax”, and Section 13.5.4.21, “`SHOW TABLE STATUS` Syntax”.

**Additional resources**

- A forum dedicated to the ARCHIVE storage engine is available at <http://forums.mysql.com/list.php?112>.

## 14.9. The CSV Storage Engine

The CSV storage engine stores data in text files using comma-separated values format.

To enable this storage engine, use the `--with-csv-storage-engine` option to configure when you build MySQL.

The CSV storage engine is included in MySQL-Max binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `--with-csv-storage-engine` option.

To examine the source for the CSV engine, look in the `sql/examples` directory of a MySQL source distribution.

When you create a CSV table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
+-----+-----+
| i     | c           |
+-----+-----+
| 1     | record one  |
| 2     | record two  |
+-----+-----+
2 rows in set (0.00 sec)
```

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

The CSV storage engine does not support indexing.

## 14.10. The BLACKHOLE Storage Engine

The BLACKHOLE storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)
```

```
mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

The BLACKHOLE storage engine is included in MySQL-Max binary distributions. To enable this storage engine if you build MySQL from source, invoke `configure` with the `--with-blackhole-storage-engine` option.

To examine the source for the BLACKHOLE engine, look in the `sql` directory of a MySQL source distribution.

When you create a BLACKHOLE table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The BLACKHOLE storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the BLACKHOLE storage engine is available with this statement:

```
mysql> SHOW VARIABLES LIKE 'have_blackhole_engine';
```

Inserts into a BLACKHOLE table do not store any data, but if the binary log is enabled, the SQL statements are logged (and replicated to slave servers). This can be useful as a repeater or filter mechanism. For example, suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is BLACKHOLE, depicted as follows:

The master writes to its binary log. The “dummy” `mysqld` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See Section 6.8, “Replication Startup Options”.) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

Other possible uses for the BLACKHOLE storage engine include:

- Verification of dump file syntax.

- Measurement of the overhead from binary logging, by comparing performance using BLACKHOLE with and without binary logging enabled.
- BLACKHOLE is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

---

# Chapter 15. MySQL Cluster

MySQL Cluster is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. It uses the `NDB Cluster` storage engine to enable running several MySQL servers in a cluster. This storage engine is available in MySQL 5.0 binary releases and in RPMs compatible with most modern Linux distributions. (If you install using RPM files, note that both the `mysql-server` and `mysql-max` RPMs must be installed to have MySQL Cluster capability.)

The operating systems on which MySQL Cluster is currently available are Linux, Mac OS X, and Solaris. (Some users have reported success with running MySQL Cluster on FreeBSD, although this is not yet officially supported by MySQL AB.) We are working to make Cluster run on all operating systems supported by MySQL, including Windows, and will update this page as new platforms are supported.

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL AB Web site at <http://www.mysql.com/products/cluster/>.

## Additional resources

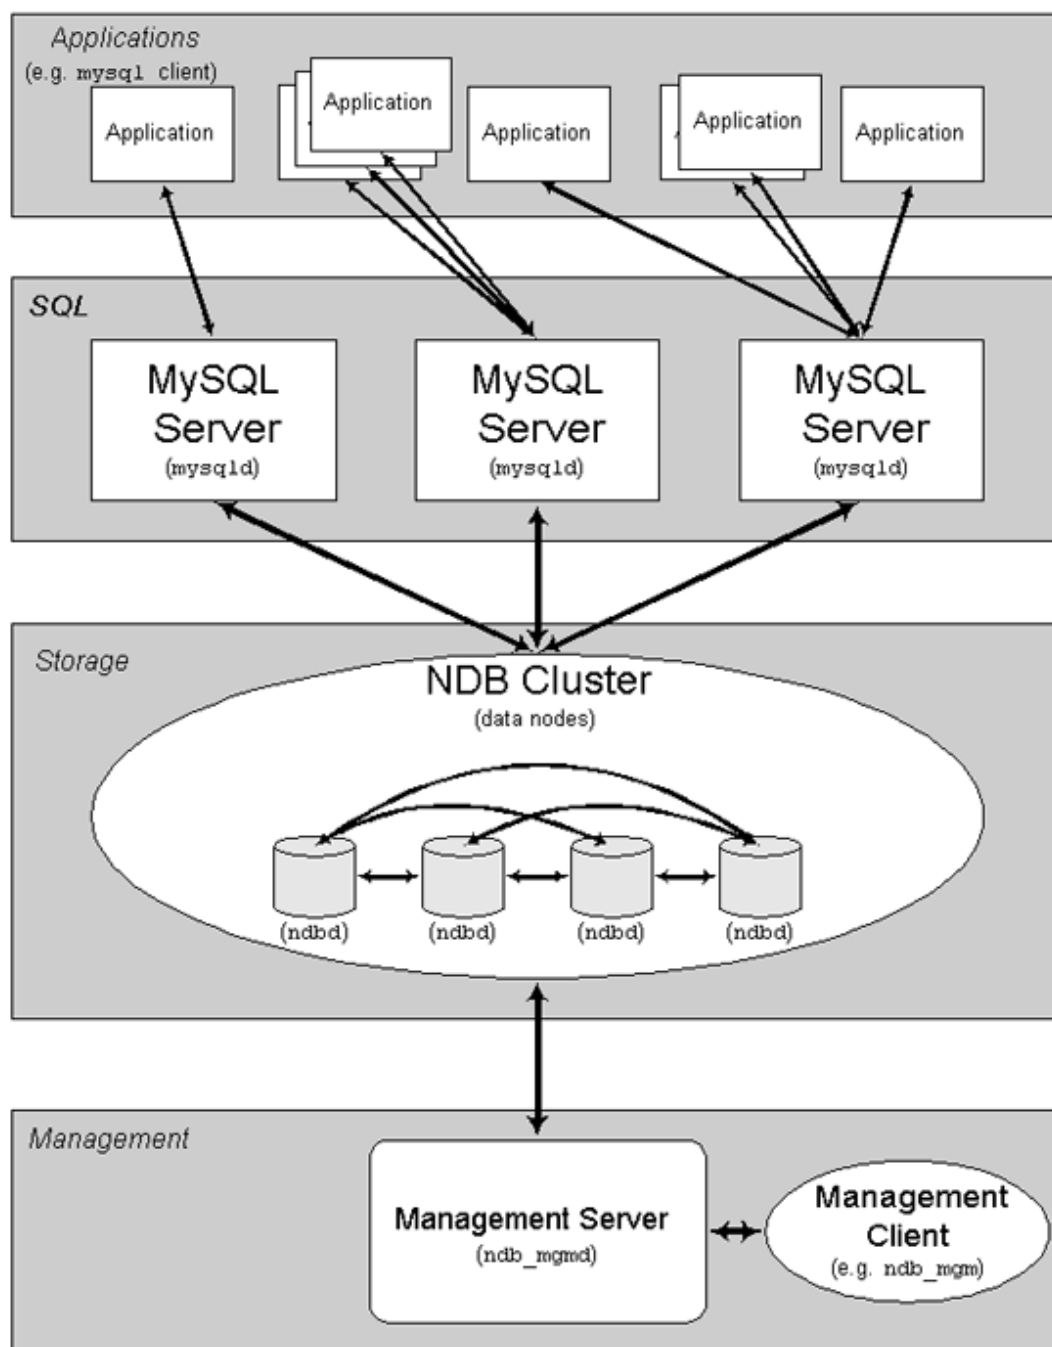

- Answers to some commonly asked questions about Cluster may be found in the Section 15.11, “MySQL Cluster FAQ”.
- The MySQL Cluster mailing list: <http://lists.mysql.com/cluster>.
- The MySQL Cluster Forum: <http://forums.mysql.com/list.php?25>.
- If you are new to MySQL Cluster, you may find our Developer Zone article [How to set up a MySQL Cluster for two servers](http://dev.mysql.com/tech-resources/articles/mysql-cluster-for-two-servers.html) [<http://dev.mysql.com/tech-resources/articles/mysql-cluster-for-two-servers.html>] to be helpful.

## 15.1. MySQL Cluster Overview

*MySQL Cluster* is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture allows the system to work with very inexpensive hardware, and without any specific requirements on hardware or software. It also does not have any single point of failure because each component has its own memory and disk.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called NDB. In our documentation, the term NDB refers to the part of the setup that is specific to the storage engine, whereas “MySQL Cluster” refers to the combination of MySQL and the NDB storage engine.

A MySQL Cluster consists of a set of computers, each running a number of processes including MySQL servers, data nodes for NDB Cluster, management servers, and (possibly) specialized data access programs. The relationship of these components in a cluster is shown here:

All these programs work together to form a MySQL Cluster. When data is stored in the NDB Cluster storage engine, the tables are stored in the data nodes. Such tables are directly accessible from all other MySQL servers in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

By bringing MySQL Cluster to the Open Source world, MySQL AB makes clustered data management with high availability, high performance, and scalability available to all who need it.

## 15.2. Basic MySQL Cluster Concepts

**NDB** is an in-memory storage engine offering high-availability and data-persistence features.

The NDB storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's NDB storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The cluster portion of MySQL Cluster is currently configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a *node*.

**Note:** In many contexts, the term “node” is used to indicate a computer, but when discussing MySQL Cluster it means a *process*. There can be any number of nodes on a single computer, for which we use the term **cluster host**.

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- The **management node** (MGM node): The role of this type of node is to manage the other nodes within the MySQL Cluster, such as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.
- The **data node**: This is the type of node that stores the cluster's data. There are as many data nodes as there are replicas, times the number of fragments. For example, with two replicas, each having two fragments, you will need four data nodes. It is not necessary to have more than one replica. A data node is started with the command `ndbd`.
- The **SQL node**: This is the node that accesses the cluster data. In the case of MySQL Cluster, a client node is a traditional MySQL server that uses the NDB Cluster storage engine. An SQL node is typically started with the command `mysqld --ndbcluster` or by using `mysqld` with the `ndbcluster` option added to `my.cnf`.

**Important:** It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; in order to benefit from MySQL Cluster's high-availability features, you must use multiple data and SQL nodes.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see Section 15.2.1, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”.

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server (MGM node) manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These are of two types:

- **Standard MySQL clients:** These are no different for MySQL Cluster than they are for standard (non-Cluster) MySQL. In other words, MySQL Cluster can be accessed from existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on.
- **Management clients:** These clients connect to the management server and provide commands

for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on.

## 15.2.1. MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

Central to an understanding of this topic are the following concepts, listed here with brief definitions:

- **(Data) Node:** An `ndbd` process, which stores a *replica*—that is, a copy of the *partition* (see below) assigned to the node group of which the node is a member.

Each data node is usually located on a separate computer. However, it is also possible to host multiple data nodes on a single computer having more than one processor. In such cases, it is feasible to run one instance of `ndbd` per physical CPU. (Note that a processor with multiple cores is still a single processor.)

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` process; where mentioned, management (MGM) nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

- **Node Group:** A node group consists of one or more nodes, and stores partitions, or sets of *replicas* (see next item).

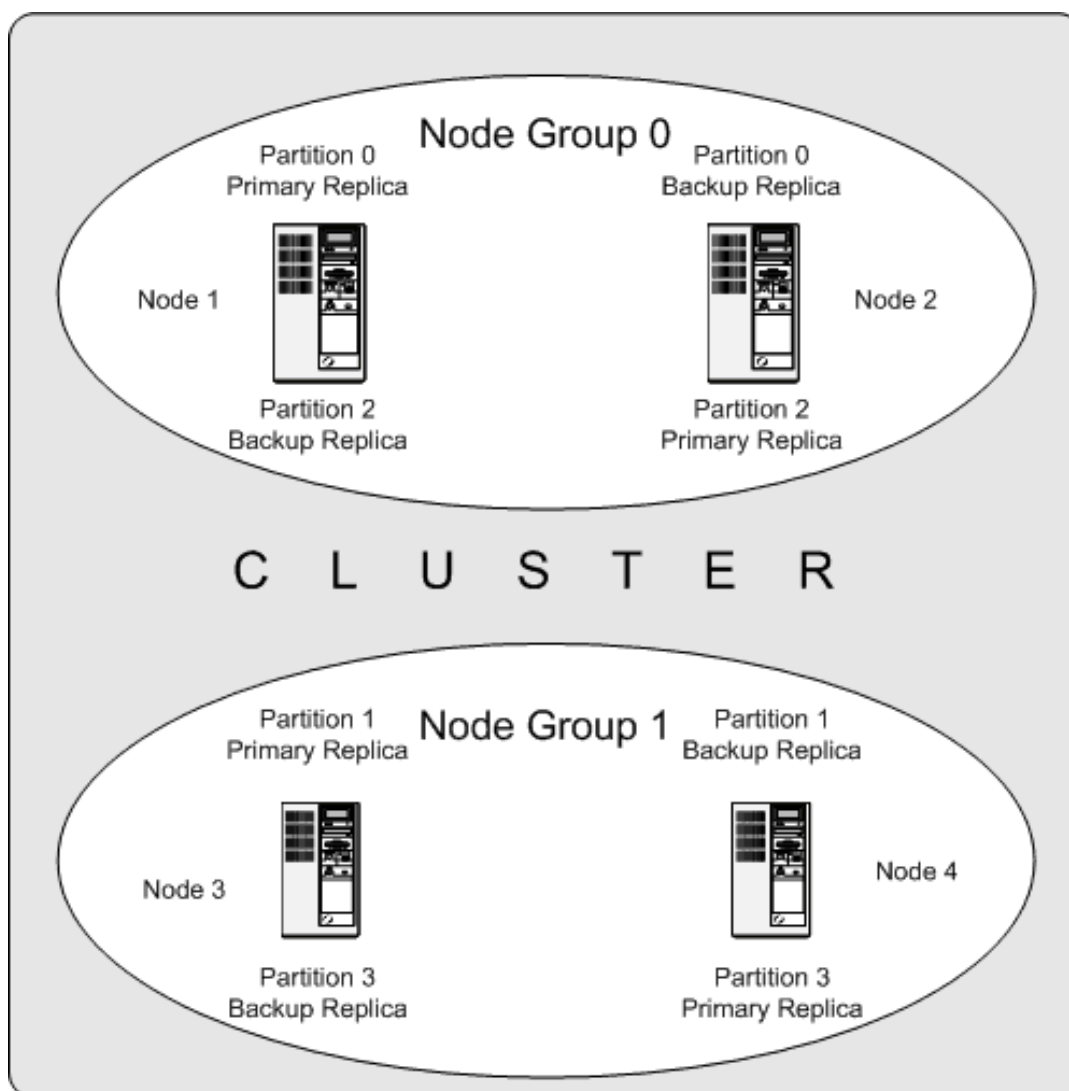

**Note:** Currently, all node groups in a cluster must have the same number of nodes.

- **Partition:** This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

- **Replica:** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a *partition replica*. The number of replicas is equal to the number of nodes per node group.

The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note that only data (`ndbd`) nodes are shown here; although a working cluster requires an `ndb_mgm` process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored — in multiple copies — on the same node group. Partitions are stored on alternate node groups: Partition 2 is stored on .

- Partition 0 is stored on node group 0; a *primary replica* (primary copy) is stored on node 1, and a *backup replica* (backup copy of the partition) is stored on node 2.
- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.
- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if *both* nodes from *either* node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an **X**); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

## 15.3. Simple Multi-Computer How-To

This section is a “How-To” that describes the basics for how to plan, install, configure, and run a MySQL Cluster. Whereas the examples in Section 15.4, “MySQL Cluster Configuration” provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the *minimum* requirements for availability and safeguarding of data.

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

### Basic Assumptions

This How-To makes the following assumptions:

1. The cluster setup has four nodes, each on a separate host, and each with a fixed network address on a typical Ethernet as shown here:

Node	IP Address
Management (MGM) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Data (NDBD) node "A"	192.168.0.30

Data (NDBD) node "B"	192.168.0.40
----------------------	--------------

This may be made clearer in the following diagram:

**Note:** In the interest of simplicity (and reliability), this How-To uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host-names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `/etc/hosts` file or your operating system's equivalent for providing a means to do host look-up if such is available.

- Each host in our scenario is an Intel-based desktop PC running a common, generic Linux distribution installed to disk in a standard configuration, and running no unnecessary services. The core OS with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the filesystems on all hosts are set up identically. In the event that they are not, you will need to adapt these instructions accordingly.
- Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected via a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards *or* all four machines should have 1 Gbps cards.) MySQL Cluster will work in a 100 Mbps network; however, gigabit Ethernet will provide better performance.

Note that MySQL Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps. For this reason (among others), attempting to run a MySQL Cluster over a public network such as the Internet is not likely to be successful, and is not recommended.

- For our sample data, we will use the `world` database which is available for download from the MySQL AB Web site. As this database takes up a relatively small amount of space, we assume that each machine has 256MB RAM, which should be sufficient for running the operating system, host NDB process, and (for the data nodes) for storing the database.

Although we refer to a Linux operating system in this How-To, the instructions and procedures that we provide here should be easily adaptable to either Solaris or Mac OS X. We also assume that you already know how to perform a minimal installation and configuration of the operating system with networking capability, or that you are able to obtain assistance in this elsewhere if needed.

We discuss MySQL Cluster hardware, software, and networking requirements in somewhat greater detail in the next section. (See Section 15.3.1, “Hardware, Software, and Networking”.)

### 15.3.1. Hardware, Software, and Networking

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (Note that this is subject to change, and that we intend to implement disk-based storage in a future MySQL Cluster release.) Naturally, multiple and faster CPUs will enhance performance. Memory requirements for Cluster processes are relatively small.

The software requirements for Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For Mac OS X or Solaris, the standard installation is sufficient. For Linux, a standard, “out of the box” installation should be all that is necessary. The MySQL software requirements are simple: all that is needed is a production release of MySQL-max 5.0; you must use the `-max` version of MySQL to have Cluster support. (See Section 5.3, “The `mysqld-max` Extended MySQL Server”.) It is not necessary to compile MySQL yourself merely to be able to use Cluster. In this How-To, we assume that you are using the `-max` binary appropriate to your Linux, Solaris, or Mac OS X operating system, available via the MySQL software downloads page at <http://dev.mysql.com/downloads/>.

For inter-node communication, Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with non-Cluster machines for the following reasons:

- **Security:** Communications between Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ [[http://compnetworking.about.com/cs/networksecurity/g/bldef\\_dmz.htm](http://compnetworking.about.com/cs/networksecurity/g/bldef_dmz.htm)]) or elsewhere.
- **Efficiency:** Setting up a MySQL Cluster on a private or protected network allows the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to Cluster data, it also ensures that Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See Section 15.8, “Using High-Speed Interconnects with MySQL Cluster”, for more about this protocol and its use with MySQL Cluster.

### 15.3.2. Multi-Computer Installation

Each MySQL Cluster host computer running storage or SQL nodes must have installed on it a MySQL-max binary. For management nodes, it is not necessary to install the MySQL server binary, but you do have to install the MGM server daemon and client binaries (`ndb_mgmd` and `ndb_mgm`, respectively). This section covers the steps necessary to install the correct binaries for each type of Cluster node.

MySQL AB provides precompiled binaries that support Cluster, and there is generally no need to compile these yourself. Therefore, the first step in the installation process for each cluster host is to

download the file `mysql-max-5.0.22-pc-linux-gnu-i686.tar.gz` from the MySQL downloads area [<http://dev.mysql.com/downloads/>]. We assume that you have placed it in each machine's `/var/tmp` directory. (If you do require a custom binary, see Section 2.9.3, “Installing from the Development Source Tree”.)

RPMs are also available for both 32-bit and 64-bit Linux platforms; as of MySQL 4.1.10a, the `-max` binaries installed by the RPMs support the `NDBCluster` storage engine. If you choose to use these rather than the binary files, be aware that you must install *both* the `-server` and `-max` packages on all machines that are to host cluster nodes. (See Section 2.4, “Installing MySQL on Linux”, for more information about installing MySQL using the RPMs.) After installing from RPM, you will still need to configure the cluster as discussed in Section 15.3.3, “Multi-Computer Configuration”.

**Note:** After completing the installation, do not yet start any of the binaries. We will show you how to do so following the configuration of all nodes.

### Storage and SQL Node Installation

On each of the three machines designated to host storage or SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
```

The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symlink to the `mysql-max` directory named `mysql`. Note that the actual file and directory names will vary according to the MySQL version number.

```
shell> cd /var/tmp
shell> tar -xzvf -C /usr/local mysql-max-5.0.22-pc-linux-gnu-i686.tar.gz
shell> ln -s /usr/local/mysql-max-5.0.22-pc-linux-gnu-i686 /usr/local/mysql
```

3. Change location to the `mysql` directory and run the supplied script for creating the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

Note that the data directory on each machine hosting a data node is `/usr/local/mysql/data`. We will use this piece of information when we configure the management node. (See Section 15.3.3, “Multi-Computer Configuration”.)

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/  
shell> chmod +x /etc/rc.d/init.d/mysql.server  
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version — for example, in some Linux distributions, it is `/etc/init.d`.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your operating system and distribution, such as `update-rc.d` on Debian.

Remember that the preceding steps must be performed separately for each machine on which a storage or SQL node is to reside.

### Management Node Installation

Installation for the management (MGM) node does not require installation of the `mysqld` binary. Only the binaries for the MGM server and client are required, which can be found in the downloaded archive. Again, we assume that you have placed this file in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install `ndb_mgmd` and `ndb_mgm` on the Cluster management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local`:

```
shell> cd /var/tmp  
shell> tar -zxvf mysql-max-5.0.22-pc-linux-gnu-i686.tar.gz \  
        /usr/local '*/bin/ndb_mgm*'
```

2. Change location to the directory into which you unpacked the files, and then make both of them executable:

```
shell> cd /usr/local  
shell> chmod +x ndb_mgm*
```

In Section 15.3.3, “Multi-Computer Configuration”, we will create and write configuration files for all of the nodes in our example Cluster.

## 15.3.3. Multi-Computer Configuration

For our four-node, four-host MySQL Cluster, we will need to write four configuration files, one per node/host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a **connectstring** telling the node where to find the MGM node, and a line telling the MySQL server on this host (the machine hosting the data node) to run in NDB mode.

For more information on connectstrings, see Section 15.4.4.2, “The MySQL Cluster `connect-string`”.

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

## Configuring the Storage and SQL Nodes

The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
# Options for mysqld process:
[MYSQLD]
ndbcluster                # run NDB engine
ndb-connectstring=192.168.0.10 # location of MGM node

# Options for ndbd process:
[MYSQL_CLUSTER]
ndb-connectstring=192.168.0.10 # location of MGM node
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

**Important:** Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[MYSQLD]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

## Configuring the Management Node

The first step in configuring the MGM node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as root):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
# Options affecting ndbd processes on all data nodes:
[NDBD DEFAULT]
NoOfReplicas=2      # Number of replicas
DataMemory=80M     # How much memory to allocate for data storage
IndexMemory=18M    # How much memory to allocate for index storage
                   # For DataMemory and IndexMemory, we have used the
                   # default values. Since the "world" database takes up
                   # only about 500KB, this should be more than enough for
                   # this example Cluster setup.

# TCP/IP options:
[TCP DEFAULT]
portnumber=2202    # This the default; however, you can use any
                   # port that is free for all the hosts in cluster
                   # Note: It is recommended beginning with MySQL 5.0 that
                   # you do not specify the portnumber at all and simply allow
                   # the default value to be used instead

# Management process options:
[NDB_MGMD]
hostname=192.168.0.10 # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster # Directory for MGM node logfiles

# Options for data node "A":
```

```

[NDBD]
hostname=192.168.0.30          # (one [NDBD] section per data node)
                             # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's datafiles

# Options for data node "B":
[NDBD]
hostname=192.168.0.40        # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's datafiles

# SQL node options:
[MYSQLD]
hostname=192.168.0.20        # Hostname or IP address
                             # (additional mysqld connections can be
                             # specified for this node for various
                             # purposes such as running ndb_restore)

```

**Note:** The `world` database can be downloaded from <http://dev.mysql.com/doc/>, where it can be found listed under “Examples.”)

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 15.3.4, “Initial Startup”.

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see Section 15.4.4, “Configuration File”, and Section 15.4, “MySQL Cluster Configuration”. For configuration of MySQL Cluster as relates to making backups, see Section 15.7.5.4, “Configuration for Cluster Backup”.

**Note:** The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. Beginning with MySQL 5.0.3, this restriction is lifted, and the cluster automatically allocates ports for data nodes from those that are already free.

## 15.3.4. Initial Startup

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. Although it is possible to start the nodes in any order, it is recommended that the management node be started first, followed by the storage nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the MGM node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

Note that `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `-config-file` option. (See Section 15.5.3, “`ndb_mgmd`, the Management Server Process”, for details.)

2. On each of the data node hosts, run this command to start the `ndbd` process for the first time:

```
shell> ndbd --initial
```

Note that it is very important to use the `--initial` parameter *only* when starting `ndbd` for the first time, or when restarting after a backup/restore operation or a configuration change. This is because the `--initial` option causes the node to delete any files created by earlier `ndbd` instances that are needed for recovery, including the recovery log files.

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the startup script installed in `/etc/init.d` to start the MySQL server process on the SQL node. Note that you need to install the `-max` server RPM *in addi-*

tion to the Standard server RPM to run the `-max` server binary.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=2      @192.168.0.30  (Version: 5.0.22, Nodegroup: 0, Master)
id=3      @192.168.0.40  (Version: 5.0.22, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1      @192.168.0.10  (Version: 5.0.22)

[mysqld(SQL)]   1 node(s)
id=4      (Version: 5.0.22)
```

**Note:** If you are using an older version of MySQL, you may see the SQL node referenced as `[mysqld(API)]`. This reflects an older usage that is now deprecated.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See Section 15.3.5, “Loading Sample Data and Performing Queries”, for a brief discussion.

## 15.3.5. Loading Sample Data and Performing Queries

Working with data in MySQL Cluster is not much different from doing so in MySQL without Cluster. There are two points to keep in mind:

- For a table to be replicated in the cluster, it must use the `NDB Cluster` storage engine. To specify this, use the `ENGINE=NDB` or `ENGINE=NDBCLUSTER` table option. You can add this option when creating the table:

```
CREATE TABLE tbl_name ( ... ) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDB Cluster`:

```
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

- Each `NDB` table *must* have a primary key. If no primary key is defined by the user when a table is created, the `NDB Cluster` storage engine automatically generates a hidden one. (**Note:** This hidden key takes up space just as does any other table index. It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` (or `TYPE`) options. Suppose that you have the `world` sample database on another MySQL server that does not support MySQL Cluster, and you want to export the `City` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabul',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You will need to make sure that MySQL uses the NDB storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition *before* importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabul',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the non-cluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

It is important to note that NDB Cluster in MySQL 5.0 does not support autodiscovery of databases. (See Section 15.9, “Known Limitations of MySQL Cluster”.) This means that, once the world database and its tables have been created on one data node, you need to issue the `CREATE SCHEMA world` statement (beginning with MySQL 5.0.2, you may use `CREATE SCHEMA world` instead), followed by `FLUSH TABLES` on each SQL node in the cluster. This will cause the node to recognize the database and read its table definitions.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the root password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.0.22

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

We simply use the MySQL server's root account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong root password. For more information, see Section 2.10.3, “Securing the Initial MySQL Accounts”.

It is worth taking into account that Cluster nodes do not make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the root account) effects only applications that access the SQL node, not interaction between nodes.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name          | Population |
+-----+-----+
| Bombay        | 10500000  |
| Seoul         | 9981619   |
| São Paulo     | 9968485   |
| Shanghai      | 9696300   |
| Jakarta       | 9604900   |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the MGM or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using PHP 5's `mysqli` extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
```

```

"http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
# connect to SQL node:
$link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
# parameters for mysqli constructor are:
#   host, user, password, database

if( mysqli_connect_errno() )
  die("Connect failed: " . mysqli_connect_error());

$query = "SELECT Name, Population
         FROM City
         ORDER BY Population DESC
         LIMIT 5";

# if no errors...
if( $result = $link->query($query) )
{
?>
<table border="1" width="40%" cellpadding="4" cellspacing="1">
  <tbody>
    <tr>
      <th width="10%">City</th>
      <th>Population</th>
    </tr>
  <?
    # then display the results...
    while($row = $result->fetch_object())
      printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
            $row->Name, $row->Population);
  ?>
  </tbody>
</table>
<?
# ...and verify the number of rows that were retrieved
printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
}
else
  # otherwise, tell us what went wrong
  echo mysqli_error();

# free the result set and the mysqli connection object
$result->close();
$link->close();
?>
</body>
</html>

```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL AB's own Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

### 15.3.6. Safe Shutdown and Restart

To shut down the cluster, enter the following command in a shell on the machine hosting the MGM node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. See Section 4.3.1, “Using Options on the Command Line”. The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means.

To restart the cluster, run these commands:

- On the management host (192.168.0.10 in our example setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40):

```
shell> ndbd
```

Remember *not* to invoke this command with the `--initial` option when restarting an NDBD node normally.

- On the SQL host (192.168.0.20):

```
shell> mysqld &
```

For information on making Cluster backups, see Section 15.7.5.2, “Using The Management Server to Create a Backup”.

To restore the cluster from backup requires the use of the `ndb_restore` command. This is covered in Section 15.7.5.3, “How to Restore a Cluster Backup”.

More information on configuring MySQL Cluster can be found in Section 15.4, “MySQL Cluster Configuration”.

## 15.4. MySQL Cluster Configuration

A MySQL server that is part of a MySQL Cluster differs in only one respect from a normal (non-clustered) MySQL server, in that it employs the `NDB Cluster` storage engine. This engine is also referred to simply as `NDB`, and the two forms of the name are synonymous.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

The MySQL server is a part of the cluster, so it also must know how to access an `MGM` node to obtain the cluster configuration data. The default behavior is to look for the `MGM` node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf` or on the MySQL server command line. Before the `NDB` storage engine can be used, at least one `MGM` node must be operational, as well as any desired data nodes.

### 15.4.1. Building MySQL Cluster from Source Code

`NDB`, the Cluster storage engine, is available in binary distributions for Linux, Mac OS X, and Solaris. We are working to make Cluster run on all operating systems supported by MySQL, including Windows.

If you choose to build from a source tarball or the MySQL 5.0 BitKeeper tree, be sure to use the `--with-ndbcluster` option when running `configure`. You can also use the `BUILD/com-`

pile-pentium-max build script. Note that this script includes OpenSSL, so you must either have or obtain OpenSSL to build successfully, or else modify `compile-pentium-max` to exclude this requirement. Of course, you can also just follow the standard instructions for compiling your own binaries, and then perform the usual tests and installation procedure. See Section 2.9.3, “Installing from the Development Source Tree”.

## 15.4.2. Installing the Software

In the next few sections, we assume that you are already familiar with installing MySQL, and here we cover only the differences between configuring MySQL Cluster and configuring MySQL without clustering. (See Chapter 2, *Installing and Upgrading MySQL*, if you require more information about the latter.)

You will find Cluster configuration easiest if you have already have all management and data nodes running first; this is likely to be the most time-consuming part of the configuration. Editing the `my.cnf` file is fairly straightforward, and this section will cover only any differences from configuring MySQL without clustering.

## 15.4.3. Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system root user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: DB, API, and MGM are aliases for NDBD, MYSQLD, and NDB_MGMD
# respectively. DB and API are deprecated and should not be used in new
# installations.
[NDBD DEFAULT]
NoOfReplicas= 1

[MYSQLD DEFAULT]
[NDB_MGMD DEFAULT]
[TCP DEFAULT]

[NDB_MGMD]
HostName= myhost.example.com

[NDBD]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[MYSQLD]
[MYSQLD]
[MYSQLD]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is

located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`. When starting `ndbd` for a given data node for the very first time, you should use the `--initial` option as shown here:

```
shell> ndbd --initial
```

For subsequent `ndbd` starts, you will generally want to *omit* the `--initial` option:

```
shell> ndbd
```

The reason for omitting `--initial` on subsequent restarts is that this option causes `ndbd` to delete and re-create all existing data and log files (as well as all table metadata) for this data node. One exception to this rule about not using `--initial` except for the first `ndbd` invocation is that you use it when restarting the cluster and restoring from backup after adding new data nodes.

By default, `ndbd` looks for the management server at `localhost` on port 1186.

**Note:** If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the NDBCLUSTER storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.0.22-Max

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES\G
...
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on

your system, depending upon how your server is configured.

Try to create an NDBCLUSTER table:

```
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
      Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the SHOW command from within the management client to obtain a report on the cluster's status:

```
NDB> SHOW
Cluster Configuration
-----
[ndbd(NDB)]      1 node(s)
id=2      @127.0.0.1  (Version: 3.5.3, Nodegroup: 0, Master)

[ndb_mgmd(MGM)] 1 node(s)
id=1      @127.0.0.1  (Version: 3.5.3)

[mysqld(API)]   3 node(s)
id=3      @127.0.0.1  (Version: 3.5.3)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with ENGINE=NDBCLUSTER or its alias ENGINE=NDB.

## 15.4.4. Configuration File

Configuring MySQL Cluster requires working with two files:

- `my.cnf`: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster.

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.8, “How to Report Bugs or

Problems”.

### 15.4.4.1. Example Configuration for a MySQL Cluster

To support MySQL Cluster, you will need to update `my.cnf` as shown in the following example. Note that the options shown here should not be confused with those that are used in `config.ini` files. You may also specify these parameters on the command line when invoking the executables.

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid in MySQL 5.0)

# enable ndbcluster storage engine, and provide connectstring for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connectstrings, see Section 15.4.4.2, “The MySQL Cluster connect-string”).

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connectstring for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

**Important:** Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[MYSQLD]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. *This is by design.*

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional NDB variables that can be set in the `my.cnf` file, see Section 5.2.2, “Server System Variables”.

The configuration file is named `config.ini` by default. It is read by `ndb_mgmd` at startup and can be placed anywhere. Its location and name are specified by using `--config-file=path_name` on the `ndb_mgmd` command line. If the configuration file is not specified, `ndb_mgmd` by default tries to read a file named `config.ini` located in the current working directory.

Currently, the configuration file is in INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (':') as well as the equals sign ('='). Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `DEFAULT` to the section name. For example, an `[NDBD]` section contains parameters that apply to a particular data node, whereas an `[NDBD DEFAULT]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[NDBD DEFAULT]` section that contains a `DataMemory` line to specify the data memory size.

At a minimum, the configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[NDBD DEFAULT]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[NDB_MGMD]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[NDBD]
HostName= ndbd_2.mysql.com

[NDBD]
HostName= ndbd_3.mysql.com

[MYSQLD]
[MYSQLD]
HostName= mysqld_5.mysql.com
```

Note that each node has its own section in the `config.ini`. For instance, this cluster has two data nodes, so the preceding configuration file contains two `[NDBD]` sections defining these nodes.

There are six different sections in that you can use in the `config.ini` configuration file:

- `[COMPUTER]`: Defines the cluster hosts.
- `[NDBD]`: Defines the cluster's data nodes.
- `[MYSQLD]`: Defines the cluster's MySQL server nodes.
- `[MGM]` or `[NDB_MGMD]`: Defines the cluster's management server node.
- `[TCP]`: Defines TCP/IP connections between nodes in the cluster, with TCP/IP being the default connection protocol.
- `[SHM]`: Defines shared-memory connections between nodes. Formerly, this type of connection was available only in binaries that were built using the `--with-ndb-shm` option. In MySQL 5.0-Max, it is enabled by default, but should still be considered experimental.

You can define DEFAULT values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in `my.cnf` or `my.ini` files.

### 15.4.4.2. The MySQL Cluster connectstring

With the exception of the MySQL Cluster management server (`ndb_mgmd`), each node that is part of a MySQL Cluster requires a *connectstring* that points to the management server's location. This connectstring is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connectstring is as follows:

```
<connectstring> :=
    [<nodeid-specification> , ]<host-specification> [ , <host-specification> ]
```

```
<nodeid-specification> := node_id
```

```
<host-specification> := host_name[:port_num]
```

`node_id` is an integer larger than 1 which identifies a node in `config.ini`. `host_name` is a string representing a valid Internet host name or IP address. `port_num` is an integer referring to a TCP/IP port number.

```
example 1 (long):    "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):  "myhost1"
```

All nodes will use `localhost:1186` as the default connectstring value if none is provided. If `port_num` is omitted from the connectstring, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple `<host-specification>` values, it is possible to designate several redundant management servers. A cluster node will attempt to contact successive management servers on each host in the order specified, until a successful connection has been established.

There are a number of different ways to specify the connectstring:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- It is also possible to set the connectstring for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.
- For backward compatibility, two other options are available, using the same syntax:
  1. Set the `NDB_CONNECTSTRING` environment variable to contain the connectstring.
  2. Write the connectstring for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connectstring is to set it on the command line or in the `my.cnf` file for each executable.

### 15.4.4.3. Defining the Computers Making up a MySQL Cluster

The `[COMPUTER]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- `Id`

This is an integer value, used to refer to the host computer elsewhere in the configuration file.

- `HostName`

This is the computer's hostname or IP address.

#### 15.4.4.4. Defining the MySQL Cluster Management Server

The `[NDB_MGMD]` section is used to configure the behavior of the management server. `[MGM]` can be used as an alias; the two section names are equivalent. All parameters in the following list are optional and assume their default values if omitted. **Note:** If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- 

`Id`

Each node in the cluster has a unique identity, which is represented by an integer value in the range 1 to 63 inclusive. This ID is used by all internal cluster messages for addressing the node.

- 

`ExecuteOnComputer`

This refers to one of the computers defined in the `[COMPUTER]` section.

- 

`PortNumber`

This is the port number on which the management server listens for configuration requests and management commands.

- 

`LogDestination`

This parameter specifies where to send cluster logging information. There are three options in this regard: `CONSOLE`, `SYSLOG`, and `FILE`:

- `CONSOLE` outputs the log to `stdout`:

`CONSOLE`

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

**Note:** Not every facility is necessarily supported by every operating system.

`SYSLOG:facility=syslog`

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- `filename`: The name of the logfile.
- `maxsize`: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old logfile is renamed by appending `.N` to the filename, where `N` is the next number not yet used with this name.
- `maxfiles`: The maximum number of logfiles.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

The default value for the FILE parameter is `_cluster.log,maxsize=1000000,maxfiles=6,FILE:filename=ndb_node_id=6`, where `node_id` is the ID of the node.

- 

#### ArbitrationRank

This parameter is used to define which nodes can act as arbitrators. Only MGM nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- 0: The node will never be used as an arbitrator.
- 1: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- 2: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default value) and that of all SQL nodes to 0.

- 

#### ArbitrationDelay

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- 

#### DataDir

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the FILE parameter for `LogDestination` as discussed previously in this section.)

### 15.4.4.5. Defining MySQL Cluster Data Nodes

The [NDBD] section is used to configure the behavior of the cluster's data nodes. There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`.
- The parameter `NoOfReplicas`

These mandatory parameters must be defined in the [NDBD DEFAULT] section.

Most data node parameters are set in the [NDBD DEFAULT] section. Only those parameters explicitly stated as being able to set local values are allowed to be changed in the [NDBD] section. `HostName`, `Id` and `ExecuteOnComputer` *must* be defined in the local [NDBD] section.

## Identifying Data Nodes

The `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

For each parameter it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, 100K means  $100 \times 1024 = 102400$ .) Parameter names and values are currently case-sensitive.

- 

`Id`

This is the node ID used as the address of the node for all cluster internal messages. This is an integer in the range 1 to 63 inclusive. Each node in the cluster must have a unique identity.

- 

`ExecuteOnComputer`

This refers to one of the computers (hosts) defined in the `COMPUTER` section.

- 

`HostName`

Specifying this parameter has an effect similar to specifying `ExecuteOnComputer`. It defines the hostname of the computer on which the storage node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- 

`ServerPort` (*OBSOLETE*)

Each node in the cluster uses a port to connect to other nodes. This port is used also for non-TCP transporters in the connection setup phase. The default port is allocated dynamically in such a way as to ensure that no two nodes on the same computer receive the same port number, so it should not normally be necessary to specify a value for this parameter.

- 

`NoOfReplicas`

This global parameter can be set only in the `[NDBD DEFAULT]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to crash.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` statement.

There is no default value for `NoOfReplicas`; the maximum possible value is 4.

- 

`DataDir`

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

-

#### FileSystemPath

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs and data files are placed. The default is the directory specified by `DataDir`. **Note:** This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's filesystem is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- #### BackupDataDir

This parameter specifies the directory in which backups are placed. If omitted, the default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter. (See above.)

### Data Memory and Index Memory

`DataMemory` and `IndexMemory` are [NDBD] parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated to reflect actual usage by the cluster:

- #### DataMemory

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. Each record is currently of fixed size. (Even `VARCHAR` columns are stored as fixed-width columns.) There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page. The maximum record size is currently 8052 bytes.

The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`. Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. Performing a node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the

largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason. In addition, it is also possible to run more than one `nbd` process per machine, and this may prove advantageous on machines with multiple CPUs.

- `IndexMemory`

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. Note that when defining a primary key and a unique index, two indexes will be created, one of which is a hash index used for all tuple accesses as well as lock handling. It is also used to enforce unique constraints.

The size of the hash index is 25 bytes per record, plus the size of the primary key. For primary keys larger than 32 bytes another 8 bytes is added.

The default value for `IndexMemory` is 18MB. The minimum is 1MB.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (  
  a INT NOT NULL,  
  b INT NOT NULL,  
  c INT NOT NULL,  
  PRIMARY KEY(a),  
  UNIQUE(b)  
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns `a` and `b` consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with `b` as primary key and `a` as a column. This other table consumes an additional 29 bytes of index memory per record in the `example` table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the

sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is  $2 \times \text{DataMemory}$  for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

### Transaction Parameters

The next three [NDBD] parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

- `MaxNoOfConcurrentTransactions`

For each active transaction in the cluster there must be a record in one of the cluster nodes. The task of coordinating transactions is spread among the nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Normally, there is at least one transaction record allocated per connection that using any table in the cluster. For this reason, one should ensure that there are more transaction records in the cluster than there are concurrent connections to all MySQL servers in the cluster.

This parameter must be set to the same value for all cluster nodes.

Changing this parameter is never safe and doing so can cause a cluster to crash. When a node crashes, one of the nodes (actually the oldest surviving node) will build up the transaction state of all transactions ongoing in the crashed node at the time of the crash. It is thus important that this node has as many transaction records as the failed node.

The default value is 4096.

- `MaxNoOfConcurrentOperations`

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions of only a few operations each and not involving a great many records, there is no need to set this parameter very high. When performing large transactions involving many records need to set this parameter higher.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle 1,000,000 concurrent updates using transactions, you should set this value to  $1000000 / 4 = 250000$ .

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- `MaxNoOfLocalOperations`

By default, this parameter is calculated as  $1.1 \times \text{MaxNoOfConcurrentOperations}$ . This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

### **Transaction Temporary Storage**

The next set of [NDBD] parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- `MaxNoOfConcurrentIndexOperations`

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter `MaxNoOfConcurrentOperations`.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not re-

quired for the cluster.

- `MaxNoOfFiredTriggers`

The default value of `MaxNoOfFiredTriggers` is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- `TransactionBufferMemory`

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to  $4000 \times 128$  bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains  $4000 \times 16 = 62.5$ KB of buffer space. `Dbtc` is the module that handles transaction coordination.

### Scans and Buffering

There are additional [NDBD] parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to  $10000 \times 128$  bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to  $10000 \times 16$  bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

The default value for `TransactionBufferMemory` is 1MB.

- `MaxNoOfConcurrentScans`

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain `MaxNoOfConcurrentScans` scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

This parameter specifies the number of scans possible in the transaction coordinator. If the number of local scan records is not provided, it is calculated as the product of `MaxNoOfConcurrentScans` and the number of data nodes in the system.

- `MaxNoOfLocalScans`

Specifies the number of local scan records if many scans are not fully parallelized.

- `BatchSizePerLocalScan`

This parameter is used to calculate the number of lock records which must be there to handle many concurrent scan operations.

The default value is 64; this value has a strong connection to the `ScanBatchSize` defined in the SQL nodes.

- `LongMessageBuffer`

This is an internal buffer used for passing messages within individual nodes and between nodes. Although it is highly unlikely that this would need to be changed, it is configurable. By default, it is set to 1MB.

### Logging and Checkpointing

These [NDBD] parameters control log and checkpoint behavior.

- `NoOfFragmentLogFiles`

This parameter sets the size of the node's REDO log files. REDO log files are organized in a ring. It is extremely important that the first and last log files (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until three local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 8, which means 8 sets of 4 16MB files for a total of 512MB. In other words, REDO log space must be allocated in blocks of 64MB. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (Out of log file space temporarily). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

- `MaxNoOfSavedMessages`

This parameter sets the maximum number of trace files that are kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25 trace files.

## Metadata Objects

The next set of [NDBD] parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- `MaxNoOfAttributes`

Defines the number of attributes that can be defined in the cluster.

The default value is 1000, with the minimum possible value being 32. There is no maximum. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used. For example, if a table requires 100 attributes, and you want to be able to alter it later, you need to set the value of `MaxNoOfAttributes` to 300. Assuming that you can create all desired tables without any problems, a good rule of thumb is to add two times the number of attributes in the largest table to `MaxNoOfAttributes` to be sure. You should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of the original value and test it again.

- `MaxNoOfTables`

A table object is allocated for each table, unique hash index, and ordered index. This parameter sets the maximum number of table objects for the cluster as a whole.

For each attribute that has a BLOB data type an extra table is used to store most of the BLOB data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 1600. Each table object consumes approximately 20KB per node.

- `MaxNoOfOrderedIndexes`

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index.

The default value of this parameter is 128. Each object consumes approximately 10KB of data per node.

- `MaxNoOfUniqueHashIndexes`

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

- `MaxNoOfTriggers`

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means

that three triggers are created for each unique hash index.) However, an *ordered* index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- `MaxNoOfIndexes`

This parameter is deprecated in MySQL 5.0; you should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

### Boolean Parameters

The behavior of data nodes is also affected by a set of [NDBD] parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to 1 or `Y`, and as `FALSE` by setting them equal to 0 or `N`.

- `LockPagesInMainMemory`

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This feature is disabled by default.

- `StopOnError`

This parameter specifies whether an `ndbd` process should exit or perform an automatic restart when an error condition is encountered.

This feature is enabled by default.

- `Diskless`

It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

**Important:** This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

`Diskless` is disabled by default.

- `RestartOnErrorInsert`

This feature is accessible only when building the debug version where it is possible to insert er-

rors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

### Controlling Timeouts, Intervals, and Disk Paging

There are a number of [NDBD] parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- `TimeBetweenWatchDogCheck`

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 4000 milliseconds (4 seconds).

- `StartPartialTimeout`

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout. In other words, the cluster may start only if all nodes are available.

- `StartPartitionedTimeout`

If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed.

The default timeout is 60000 milliseconds (60 seconds).

- `StartFailureTimeout`

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 means that no data node timeout is applied.

The default value is 60000 milliseconds (60 seconds). For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600,000 to 1,000,000 milliseconds) might be required to to perform a node restart.

- `HeartbeatIntervalDbDb`

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

The default heartbeat interval is 1500 milliseconds (1.5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

- `HeartbeatIntervalDbApi`

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for `HeartbeatIntervalDbDb`.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

- `TimeBetweenLocalCheckpoints`

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB ( $4 \times 2^{20}$ ) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- `TimeBetweenGlobalCheckpoints`

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases — a complete crash of the cluster — is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- `TimeBetweenInactiveTransactionAbortCheck`

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- `TransactionInactiveTimeout`

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is zero (no timeout). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a much smaller value. The unit is milliseconds.

- `TransactionDeadlockDetectionTimeout`

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection. Setting it too high can cause a undesirable behavior in situations involving deadlocks and node failure.

The default timeout value is 1200 milliseconds (1.2 seconds).

- `NoOfDiskPagesToDiskAfterRestartTUP`

When executing a local checkpoint, the algorithm flushes all data pages to disk. Merely doing so as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a “page” is defined as 8KB. This parameter is specified in units of 80KB per second, so , setting `NoOfDiskPagesToDiskAfterRestartTUP` to a value of 20 entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages. That is, this parameter handles the limitation of writes from data memory. UNDO log records for index pages are handled by the parameter `NoOfDiskPagesToDiskAfterRestartACC`. (See the entry for `IndexMemory` for information about index pages.)

In short, this parameter specifies how quickly to execute local checkpoints. It operates in conjunction with `NoOfFragmentLogFiles`, `DataMemory`, and `IndexMemory`.

The default value is 40 (3.2MB of data pages per second).

- `NoOfDiskPagesToDiskAfterRestartACC`

This parameter uses the same units as `NoOfDiskPagesToDiskAfterRestartTUP` and acts in a similar fashion, but limits the speed of writing index pages from index memory.

The default value of this parameter is 20 (1.6MB of index memory pages per second).

- `NoOfDiskPagesToDiskDuringRestartTUP`

This parameter is used in a fashion similar to `NoOfDiskPagesToDiskAfterRestartTUP`

and `NoOfDiskPagesToDiskAfterRestartACC`, only it does so with regard to local checkpoints executed in the node when a node is restarting. A local checkpoint is always performed as part of all node restarts. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

- `NoOfDiskPagesToDiskDuringRestartACC`

Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

As with `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

The default value is 20 (1.6MB per second).

- `ArbitrationTimeout`

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 1000 milliseconds (1 second).

### Buffering and Logging

Several [NDBD] configuration parameters corresponding to former compile-time parameters are also available. These enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine’s filesystem abstraction layer.

- `UndoIndexBuffer`

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (`Index UNDO buffers overloaded`).

- `UndoDataBuffer`

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (Data UNDO buffers overloaded).

- `RedoBuffer`

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

`RedoBuffer` sets the size of the buffer in which the REDO log is written, and is 8MB by default. The minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (`REDO log buffers overloaded`).

In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- `LogLevelStartup`

The reporting level for events generated during startup of the process.

The default level is 1.

- `LogLevelShutdown`

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- `LogLevelStatistic`  
The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.  
The default level is 0.
- `LogLevelCheckpoint`  
The reporting level for events generated by local and global checkpoints.  
The default level is 0.
- `LogLevelNodeRestart`  
The reporting level for events generated during node restart.  
The default level is 0.
- `LogLevelConnection`  
The reporting level for events generated by connections between cluster nodes.  
The default level is 0.
- `LogLevelError`  
The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.  
The default level is 0.
- `LogLevelInfo`  
The reporting level for events generated for information about the general state of the cluster.  
The default level is 0.

### Backup Parameters

The [NDBD] parameters discussed in this section define memory buffers set aside for execution of online backups.

- `BackupDataBufferSize`  
In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize` (see below), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freed up memory so that scanning may continue.  
The default value is 2MB.
- `BackupLogBufferSize`

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 15.7.5.4, “Configuration for Cluster Backup”.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value is 2MB.

- `BackupMemory`

This parameter is simply the sum of `BackupDataBufferSize` and `BackupLogBufferSize`.

The default value is  $2\text{MB} + 2\text{MB} = 4\text{MB}$ .

- `BackupWriteSize`

This parameter specifies the size of messages written to disk by the backup log and backup data buffers.

The default value is 32KB.

#### 15.4.4.6. Defining the SQL Nodes in a MySQL Cluster

The `[MYSQLD]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL node.

- `Id`

The `Id` value is used to identify the node in all cluster internal messages. It must be an integer in the range 1 to 63 inclusive, and must be unique among all node IDs within the cluster.

- `ExecuteOnComputer`

This refers to one of the computers (hosts) defined in a `[COMPUTER]` section of the configuration file.

- `ArbitrationRank`

This parameter defines which nodes can act as arbitrators. Both MGM nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1 (the default) and those for all SQL nodes to 0.

-

#### ArbitrationDelay

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- `BatchByteSize`

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (`BatchSize`) and in terms of bytes (`BatchByteSize`). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set. In future releases, MySQL Server will make educated guesses on how to set parameters relating to batch size, based on the query type.

This parameter is measured in bytes and by default is equal to 32KB.

- `BatchSize`

This parameter is measured in number of records and is by default set to 64. The maximum size is 992.

- `MaxScanBatchSize`

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

### 15.4.4.7. MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for establishing connections in MySQL Cluster. It is normally not necessary to define connections because Cluster automatically set ups a connection between each of the data nodes, between each data node and all MySQL server nodes, and between each data node and the management server. (For one exception to this rule, see Section 15.4.4.8, “MySQL Cluster TCP/IP Connections Using Direct Connections”.) [TCP] sections in the `config.ini` file explicitly define TCP/IP connections between nodes in the cluster.

It is only necessary to define a connection to override the default connection parameters. In that case, it is necessary to define at least `NodeId1`, `NodeId2`, and the parameters to change.

It is also possible to change the default values for these parameters by setting them in the [TCP DEFAULT] section.

- `NodeId1, NodeId2`

To identify a connection between two nodes it is necessary to provide their node IDs in the [TCP] section of the configuration file. These are the same unique `Id` values for each of these nodes as described in Section 15.4.4.6, “Defining the SQL Nodes in a MySQL Cluster”.

- `SendBufferMemory`

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a

round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer. The default size of the send buffer is 256KB.

- `SendSignalId`

To be able to retrace a distributed message diagram it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default.

- `Checksum`

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- `PortNumber` (*OBSOLETE*)

This formerly specified the port number to be used for listening for connections from other nodes. This parameter should no longer be used.

- `ReceiveBufferMemory`

Specifies the size of the buffer used when receiving data from the TCP/IP socket. There is seldom any need to change this parameter from its default value of 64KB, except possibly to save memory.

#### 15.4.4.8. MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[TCP]` section of the cluster `con-fig.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the `172.23.72.*` subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the `1.1.0.*` address range as shown:

```
# Management Server
[NDB_MGMD]
Id=1
HostName=172.23.72.20

# SQL Node
[MYSQLD]
Id=2
HostName=172.23.72.21

# Data Nodes
[NDBD]
Id=3
HostName=172.23.72.22

[NDBD]
Id=4
HostName=172.23.72.23
```

```
# TCP/IP Connections
[TCP]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The use of direct connections between data nodes can improve the cluster's overall efficiency by allowing the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that to take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 15.4.4.9. MySQL Cluster Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible, chiefly where more than one node runs concurrently on the same cluster host. (In very early versions of MySQL Cluster, shared memory segments functioned only when the `-max` binary was built using `--with-ndb-shm`.) [SHM] sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2` and `ShmKey`. All other parameters have default values that should work well in most cases.

**Important:** *SHM functionality is considered experimental only.* It is not officially supported in any MySQL release series up to and including 5.0. This means that you must determine for yourself or by using our free resources (forums, mailing lists) whether it can be made to work correctly in your specific case.

- `NodeId1`, `NodeId2`

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `ShmKey`

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

- `ShmSize`

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 1MB.

- `SendSignalId`

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default.

- `Checksum`

This parameter is a boolean (Y/N) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

### 15.4.4.10. MySQL Cluster SCI Transport Connections

[*SCI*] sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL-Max binaries are built using `--with-ndb-sci=/your/path/to/SCI`. The *path* should point to a directory that contains at a minimum `lib` and `include` directories containing SISI libraries and header files. (See Section 15.8, “Using High-Speed Interconnects with MySQL Cluster” for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between `ndbd` processes. Note also that using SCI Transporters means that the `ndbd` processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by `ndbd` processes. There should be at least one CPU per `ndbd` process, with at least one CPU left in reserve to handle operating system activities.

- `NodeId1, NodeId2`

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `Host1SciId0`

This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).

- `Host1SciId1`

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- `Host2SciId0`

This identifies the SCI node ID on the second Cluster node (identified by `NodeId2`).

- `Host2SciId1`

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- `SharedBufferSize`

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.

- `SendLimit`

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- `SendSignalId`

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default.

- `Checksum`

This parameter is a boolean value, and is disabled by default. When `Checksum` is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature

prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

## 15.5. Process Management in MySQL Cluster

Understanding how to manage MySQL Cluster requires a knowledge of four essential processes. In the next few sections of this chapter, we cover the roles played by these processes in a cluster, how to use them, and what startup options are available for each of them:

- Section 15.5.1, “MySQL Server Process Usage for MySQL Cluster”
- Section 15.5.2, “ndbd, the Storage Engine Node Process”
- Section 15.5.3, “ndb\_mgmd, the Management Server Process”
- Section 15.5.4, “ndb\_mgm, the Management Client Process”

### 15.5.1. MySQL Server Process Usage for MySQL Cluster

`mysqld` is the traditional MySQL server process. To be used with MySQL Cluster, `mysqld` needs to be built with support for the `NDB Cluster` storage engine, as it is in the precompiled `-max` binaries available from <http://dev.mysql.com/downloads/>. If you build MySQL from source, you must invoke `configure` with the `--with-ndbcluster` option to enable `NDB Cluster` storage engine support.

If the `mysqld` binary has been built with Cluster support, the `NDB Cluster` storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the `NDB Cluster` storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an NDB-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server’s own cluster node ID
- The hostname or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connectstring either on the command line when starting `mysqld` or in `my.cnf`. The connectstring contains the hostname or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server

resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 15.4.4.2, “The MySQL Cluster `connectstring`”, for more information on connectstrings.

Given this information, the MySQL server will be a full participant in the cluster. (We sometimes refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

## 15.5.2. `ndbd`, the Storage Engine Node Process

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. These log files are listed below. Note that `node_id` represents the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

**Note:** *It is very important to be aware that the last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.*

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.
- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon.
- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a

daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the `.pid` file remains in effect even after the process has terminated.

To start `ndbd`, it may also be necessary to specify the hostname of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See Section 15.4.4.2, “The MySQL Cluster `connectstring`”, for additional information about this issue. Section 15.5.5, “Command Options for MySQL Cluster Processes”, describes other options for `ndbd`.

When `ndbd` starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the `ndbd` process if it is configured to do so. Thus, if you attempt to kill `ndbd` via the Unix `kill` command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an `ndbd` process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent activities. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the `ndbd` process. In a system performing a large number of operations, including updates, the `ndbd` process can consume up to 2 CPUs if permitted to do so. For a machine with many CPUs it is recommended to use several `ndbd` processes which belong to different node groups.

### 15.5.3. `ndb_mgmd`, the Management Server Process

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

It is not strictly necessary to specify a `connectstring` when starting the management server. However, if you are using more than one management server, a `connectstring` should be provided and each node in the cluster should specify its node ID explicitly.

See Section 15.4.4.2, “The MySQL Cluster `connectstring`”, for information about using `connectstrings`. Section 15.5.5, “Command Options for MySQL Cluster Processes”, describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Section 15.4, “MySQL Cluster Configuration”, discusses how to set up this file.
- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 15.7, “Management of MySQL Cluster”.

When the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.)

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

## 15.5.4. `ndb_mgm`, the Management Client Process

The management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by `ndb_mgm`.

To start the management client, it is necessary to supply the hostname and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default hostname and port number are `localhost` and `1186`, respectively.

Additional information about using `ndb_mgm` can be found in Section 15.5.5.4, “Command Options for `ndb_mgm`”, and Section 15.7.2, “Commands in the Management Client”.

## 15.5.5. Command Options for MySQL Cluster Processes

All MySQL Cluster executables (except for `mysqld`) take the options described in this section. Users of earlier MySQL Cluster versions should note that some of these options have been changed from those in MySQL 4.1 Cluster to make them consistent with one another as well as with `mysqld`. You can use the `--help` option to view a list of supported options.

The following sections describe options specific to individual NDB programs.

- `--help --usage, -?`

Prints a short list with descriptions of the available command options.

- `--connect-string=connect_string, -c connect_string`

`connect_string` sets the connectstring to the management server as a command option.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

- `--debug[=options]`

This option can only be used for versions compiled with debugging enabled. It is used to enable

output from debug calls in the same manner as for the `mysqld` process.

- `--execute=command -e command`

Can be used to send a command to a Cluster executable from the system shell. For example, either of the following:

```
shell> ndb_mgm -e show
```

or

```
shell> ndb_mgm --execute="SHOW"
```

is equivalent to

```
NDB> SHOW;
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See Section 4.3.1, “Using Options on the Command Line”.

- `--version, -V`

Prints the version number of the `ndbd` process. The version number is the MySQL Cluster version number. The version number is relevant because not all versions can be used together, and at startup the MySQL Cluster processes verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online software upgrade of MySQL Cluster.

### 15.5.5.1. MySQL Cluster-Related Command Options for `mysqld`

- `--ndb-connectstring=connect_string`

When using the NDB Cluster storage engine, this option specifies the management server that distributes cluster configuration data.

- `--ndbcluster`

The NDB Cluster storage engine is necessary for using MySQL Cluster. If a `mysqld` binary includes support for the NDB Cluster storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

### 15.5.5.2. Command Options for `ndbd`

For options common to NDB programs, see Section 15.5.5, “Command Options for MySQL Cluster Processes”.

- `--daemon, -d`

Instructs `ndbd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to not start the process as a daemon.

- `--initial`

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. Note that on some

operating systems this process can take a substantial amount of time.

An `--initial` start is to be used only the very first time that the `ndbd` process is started because it removes all files from the Cluster filesystem and re-creates all REDO log files. The exceptions to this rule are:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the datafiles.

This option does not affect any backup files that have already been created by the affected node.

- `--nodaemon`

Instructs `ndbd` not to start as a daemon process. This is useful when `ndbd` is being debugged and you want output to be redirected to the screen.

- `--nostart`

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper command to the management client.

### 15.5.5.3. Command Options for `ndb_mgmd`

For options common to NDB programs, see Section 15.5.5, “Command Options for MySQL Cluster Processes”.

- `--config-file=file_name, -f file_name,`

Instructs the management server as to which file it should use for its configuration file. This option must be specified. The filename defaults to `config.ini`.

**Note:** This option also can be given as `-c file_name`, but this shortcut is obsolete and should *not* be used in new installations.

- `--daemon, -d`

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

- `--nodaemon`

Instructs `ndb_mgmd` not to start as a daemon process.

### 15.5.5.4. Command Options for `ndb_mgm`

For options common to NDB programs, see Section 15.5.5, “Command Options for MySQL Cluster Processes”.

- `--try-reconnect=number`

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to

*number* before giving up and reporting an error instead.

## 15.5.6. Using CLUSTERLOG STATISTICS

The NDB management client's `CLUSTERLOG STATISTICS` command can provide a number of useful statistics in its output. The following statistics are reported by the transaction coordinator:

Statistic	Description (Number of...)
Trans. Count	Transactions attempted with this node as coordinator
Commit Count	Transactions committed with this node as coordinator
Read Count	Primary key reads (all)
Simple Read Count	Primary key reads reading the latest committed value
Write Count	Primary key writes (includes all INSERT, UPDATE, and DELETE operations)
AttrInfoCount	Data words used to describe all reads and writes received
Concurrent Operations	All concurrent operations ongoing at the moment the report is taken
Abort Count	Transactions with this node as coordinator that were aborted
Scans	Scans (all)
Range Scans	Index scans

The `ndbd` process has a scheduler that runs in an infinite loop. During each loop scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

The number of loops executed in the third step is reported as the `Mean Loop Counter`. This statistic increases in size as the utilisation of the TCP/IP buffer improves. You can use this to monitor performance as you add new processes to the cluster.

The `Mean send size` and `Mean receive size` statistics allow you to gauge the efficiency of writes and reads (respectively) between nodes. These values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum is 64k.

To generate a report of all cluster log statistics, you can use the following command in the NDB management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

## 15.6. Upgrading and Downgrading MySQL Cluster

This portion of the MySQL Cluster chapter covers upgrading and downgrading a MySQL Cluster

from one MySQL release to another. It discusses different types of Cluster upgrades and downgrades, and provides a Cluster upgrade/downgrade compatibility matrix (see Section 15.6.2, “Cluster Upgrade and Downgrade Compatibility”).

**Important:** You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See Section 15.4, “MySQL Cluster Configuration”.

This section remains in development, and will be updated and expanded considerably during the second quarter of 2006.

## 15.6.1. Performing a Rolling Upgrade or Downgrade

This section discusses how to perform a *rolling upgrade* of a MySQL Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This type of upgrade is done where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. The information provided here also applies to downgrades as well.

There are a number of reasons why a rolling upgrade (or downgrade) might be desired:

- **Cluster Configuration Change:** To make a change in the cluster's configuration, such as adding an SQL node or setting a configuration parameter to a new value
- **Cluster Software Upgrade/Downgrade:** To upgrade the cluster to a newer version of the MySQL Cluster software (or to downgrade it to an older version)
- **Change on Node Host:** To make changes in the hardware or operating system on which one or more cluster nodes are running
- **Cluster Reset:** To reset the cluster because it has reached an undesirable state

The process for performing a rolling upgrade may be generalised as follows:

1. Stop, reconfigure, then restart each cluster management node (`ndb_mgmd` process) in turn
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn

The specifics for implementing a particular rolling upgrade depend upon the actual changes being made. A more detailed view of the process is presented in the table shown here:

## 15.6.2. Cluster Upgrade and Downgrade Compatibility

This section provides information regarding Cluster software and table file compatibility between differing versions of the MySQL Server for purposes of performing upgrades and downgrades.

**Important:** Only compatibility between MySQL versions with regard to NDB Cluster is taken into account in this section, and there are likely other issues to be considered. *As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software.* See Section 2.11, “Upgrading MySQL”.

The following table shows Cluster upgrade and downgrade compatibility between different versions of the MySQL Server.

**Notes:**

- **4.1 Series:**

You cannot upgrade directly from 4.1.8 to 4.1.10 (or newer); you must first upgrade from 4.1.8 to 4.1.9, then upgrade to 4.1.10. Similarly, you cannot downgrade directly from 4.1.10 (or newer) to 4.1.8; you must first downgrade from 4.1.10 to 4.1.9, then downgrade from 4.1.9 to 4.1.8.

Cluster downgrades from 4.1.15 to 4.1.14 (or earlier versions) are not supported.

Cluster upgrades from MySQL Server versions previous to 4.1.8 are not supported; when upgrading from these, you must dump all NDB tables, install the new version of the software, and then reload the tables from the dump.

- **5.0 Series:**

MySQL 5.0.2 was the first public release in this series.

Cluster downgrades from MySQL 5.0 to MySQL 4.1 are not supported.

Cluster downgrades from 5.0.12 to 5.0.11 (or earlier) are not supported.

- **5.1 Series:**

MySQL 5.1.3 was the first public release in this series.

You cannot downgrade a MySQL 5.1.6 or later Cluster using Disk Data tables to MySQL 5.1.5 or earlier unless you convert all such tables to in-memory Cluster tables first.

There was no public release for MySQL 5.1.8.

## 15.7. Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in Section 15.4, “MySQL Cluster Configuration”, and Section 15.5, “Process Management in MySQL Cluster”.

The following sections cover the management of a running MySQL Cluster.

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log` in the management server's `DataDir` directory. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

### 15.7.1. MySQL Cluster Startup Phases

This section describes the steps involved when the cluster is started.

There are several different startup types and modes, as shown here:

- **Initial Start:** The cluster starts with a clean filesystem on all data nodes. This occurs either when the cluster started for the very first time, or when it is restarted using the `--initial` option.
- **System Restart:** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.
- **Node Restart:** This is the online restart of a cluster node while the cluster itself is running.

- **Initial Node Restart:** This is the same as a node restart, except that the node is reinitialized and started with a clean filesystem.

Prior to startup, each data node (nbd process) must be initialized. Initialization consists of the following steps:

1. Obtain a Node ID.
2. Fetch configuration data.
3. Allocate ports to be used for inter-node communications.
4. Allocate memory according to settings obtained from the configuration file.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

- **Stage 0**

Clear the cluster filesystem. This stage occurs *only* if the cluster was started with the `--initial` option.

- **Stage 1**

This stage sets up Cluster connections, establishes inter-node communications are established, and starts Cluster heartbeats.

- **Stage 2**

The arbitrator node is elected. If this is a system restart, the cluster determines the latest restorable global checkpoint.

- **Stage 3**

This stage initializes a number of internal cluster variables.

- **Stage 4**

For an initial start or initial node restart, the redo log files are created. The number of these files is equal to `NoOfFragmentLogFiles`.

For a system restart:

- Read schema or schemas.
- Read data from the local checkpoint and undo logs.
- Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

- **Stage 5**

If this is an initial start, create the `SYSTAB_0` and `NDB$EVENTS` internal system tables.

For a node restart or an initial node restart:

1. The node is included in transaction handling operations.
2. The node schema is compared with that of the master and synchronized with it.

3. Synchronize data received in the form of `INSERT` from the other data nodes in this node's node group.
  4. In all cases, wait for complete local checkpoint as determined by the arbitrator.
- **Stage 6**  
Update internal variables.
  - **Stage 7**  
Update internal variables.
  - **Stage 8**  
In a system restart, rebuild all indexes.
  - **Stage 9**  
Update internal variables.
  - **Stage 10**  
At this point in a node restart or initial node restart, APIs may connect to the node and begin to receive events.
  - **Stage 11**  
At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

## 15.7.2. Commands in the Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in Section 15.7.3, “Event Reports Generated in MySQL Cluster”. Commands for creating backups and restoring from backup are provided in Section 15.7.5, “On-line Backup of MySQL Cluster”.

The management client has the following basic commands. In the listing that follows, *node\_id* denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `HELP`  
Displays information on all available commands.
- `SHOW`  
Displays information on the cluster's status.

**Note:** In a cluster where multiple management nodes are in use, this command displays information only for data nodes that are actually connected to the current management server.

- `node_id START`  
Starts the data node identified by `node_id` (or all data nodes).  
Beginning with MySQL 5.0.19, this command can also be used to start individual management nodes. **Note:** ALL START continues to affect data nodes only.
- `node_id STOP`  
Stops the data node identified by `node_id` (or all data nodes).  
Beginning with MySQL 5.0.19, this command can also be used to stop individual management nodes. **Note:** ALL STOP continues to affect data nodes only.
- `node_id RESTART [-N] [-I]`  
Restarts the data node identified by `node_id` (or all data nodes).
- `node_id STATUS`  
Displays status information for the data node identified by `node_id` (or for all data nodes).
- `ENTER SINGLE USER MODE node_id`  
Enters single-user mode, whereby only the MySQL server identified by the node ID `node_id` is allowed to access the database.
- `EXIT SINGLE USER MODE`  
Exits single-user mode, allowing all SQL nodes (that is, all running `mysqld` processes) to access the database.
- `QUIT`  
Terminates the management client.
- `SHUTDOWN`  
Shuts down all cluster nodes, except for SQL nodes, and exits.

### 15.7.3. Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log. These are the **cluster log**, which includes events generated by all cluster nodes, and **node logs**, which are local to each data node.

Output generated by cluster event logging can have multiple destinations including a file, the management server console window, or `syslog`. Output generated by node event logging is written to the data node's console window.

Both types of event logs can be set to log different subsets of events.

**Note:** The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single file. Node logs are intended to be used only during application development, or for debugging application code.

Each reportable event can be distinguished according to three different criteria:

- *Category:* This can be any one of the following values: STARTUP, SHUTDOWN, STATISTICS, CHECKPOINT, NODERESTART, CONNECTION, ERROR, or INFO.

- *Priority*: This is represented by one of the numbers from 1 to 15 inclusive, where 1 indicates “most important” and 15 “least important.”
- *Severity Level*: This can be any one of the following values: ALERT, CRITICAL, ERROR, WARNING, INFO, or DEBUG.

Both the cluster log and the node log can be filtered on these properties.

### 15.7.3.1. Logging Management Commands

The following management commands are related to the cluster log:

- `CLUSTERLOG ON`  
Turns the cluster log on.
- `CLUSTERLOG OFF`  
Turns the cluster log off.
- `CLUSTERLOG INFO`  
Provides information about cluster log settings.
- `node_id CLUSTERLOG category=threshold`  
Logs *category* events with priority less than or equal to *threshold* in the cluster log.
- `CLUSTERLOG FILTER severity_level`  
Toggles cluster logging of events of the specified *severity\_level*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

Category	Default threshold (All data nodes)
STARTUP	7
SHUTDOWN	7
STATISTICS	7
CHECKPOINT	7
NODERESTART	7
CONNECTION	7
ERROR	15
INFO	7

Thresholds are used to filter events within each category. For example, a STARTUP event with a priority of 3 is not logged unless the threshold for STARTUP is changed to 3 or lower. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels. (**Note:** These correspond to Unix syslog levels, except for LOG\_EMERG and LOG\_NOTICE, which are not used or mapped.)

<b>1</b>	ALERT	A condition that should be corrected immediately, such as a corrupted system database
<b>2</b>	CRITICAL	Critical conditions, such as device errors or insufficient resources
<b>3</b>	ERROR	Conditions that should be corrected, such as configuration errors
<b>4</b>	WARNING	Conditions that are not errors, but that might require special handling
<b>5</b>	INFO	Informational messages
<b>6</b>	DEBUG	Debugging messages used for NDB Cluster development

Event severity levels can be turned on or off (using `CLUSTERLOG FILTER` — see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

### 15.7.3.2. Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
09:19:30 2005-07-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint,” respectively.

#### CONNECTION Events

These events are associated with connections between Cluster nodes.

Event	Priority	Severity Level	Description
data nodes connected	8	INFO	Data nodes connected
data nodes disconnected	8	INFO	Data nodes disconnected
Communication closed	8	INFO	SQL node or data node connection closed
Communication opened	8	INFO	SQL node or data node connection opened

#### CHECKPOINT Events

The logging messages shown here are associated with checkpoints.

Event	Priority	Severity Level	Description
LCP stopped in calc keep GCI	0	ALERT	LCP stopped
Local checkpoint fragment completed	11	INFO	LCP on a fragment has been completed
Global checkpoint completed	10	INFO	GCP finished
Global checkpoint started	9	INFO	Start of GCP: REDO log is written to disk
Local checkpoint completed	8	INFO	LCP completed normally
Local checkpoint started	7	INFO	Start of LCP: data written to disk

Report undo log blocked	7	INFO	UNDO logging blocked; buffer near overflow
-------------------------	---	------	--

### STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Event	Priority	Severity Level	Description
Internal start signal received ST-TORRY	15	INFO	Blocks received after completion of restart
Undo records executed	15	INFO	
New REDO log started	10	INFO	GCI keep <i>X</i> , newest restorable GCI <i>Y</i>
New log started	10	INFO	Log part <i>X</i> , start MB <i>Y</i> , stop MB <i>Z</i>
Node has been refused for inclusion in the cluster	8	INFO	Node cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem
data node neighbors	8	INFO	Shows neighboring data nodes
data node start phase <i>X</i> completed	4	INFO	A data node start phase has been completed
Node has been successfully included into the cluster	3	INFO	Displays the node, managing node, and dynamic ID
data node start phases initiated	1	INFO	NDB Cluster nodes starting
data node all start phases completed	1	INFO	NDB Cluster nodes started
data node shutdown initiated	1	INFO	Shutdown of data node has commenced
data node shutdown aborted	1	INFO	Unable to shut down data node normally

### NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Event	Priority	Severity Level	Description
Node failure phase completed	8	ALERT	Reports completion of node failure phases
Node has failed, node state was <i>X</i>	8	ALERT	Reports that a node has failed
Report arbitrator results	2	ALERT	There are eight different possible results for arbitration attempts: <ul style="list-style-type: none"> <li>Arbitration check failed — less than 1/2 nodes left</li> <li>Arbitration check succeeded — node group majority</li> <li>Arbitration check failed — missing node group</li> <li>Network partitioning — arbitration required</li> <li>Arbitration succeeded — affirmative re-</li> </ul>

			<p>sponse from node <i>X</i></p> <ul style="list-style-type: none"> <li>• Arbitration failed - negative response from node <i>X</i></li> <li>• Network partitioning - no arbitrator available</li> <li>• Network partitioning - no arbitrator configured</li> </ul>
Completed copying a fragment	10	INFO	
Completed copying of dictionary information	8	INFO	
Completed copying distribution information	8	INFO	
Starting to copy fragments	8	INFO	
Completed copying all fragments	8	INFO	
GCP takeover started	7	INFO	
GCP takeover completed	7	INFO	
LCP takeover started	7	INFO	
LCP takeover completed (state = <i>X</i> )	7	INFO	
Report whether an arbitrator is found or not	6	INFO	<p>There are seven different possible outcomes when seeking an arbitrator:</p> <ul style="list-style-type: none"> <li>• Management server restarts arbitration thread [state=<i>X</i>]</li> <li>• Prepare arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Receive arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Started arbitrator node <i>X</i> [ticket=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> - process failure [state=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> - process exit [state=<i>Y</i>]</li> <li>• Lost arbitrator node <i>X</i> &lt;error msg&gt; [state=<i>Y</i>]</li> </ul>

**STATISTICS Events**

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Event	Priority	Severity Level	Description
Report job scheduling statistics	9	INFO	Mean internal job scheduling statistics
Sent number of bytes	9	INFO	Mean number of bytes sent to node <i>X</i>

Received # of bytes	9	INFO	Mean number of bytes received from node <i>X</i>
Report transaction statistics	8	INFO	Numbers of: transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts
Report operations	8	INFO	Number of operations
Report table create	7	INFO	
Memory usage	5	INFO	Data and index memory usage (80%, 90%, and 100%)

#### ERROR Events

These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

Event	Priority	Severity	Description
Dead due to missed heartbeat	8	ALERT	Node <i>X</i> declared “dead” due to missed heartbeat
Transporter errors	2	ERROR	
Transporter warnings	8	WARN- ING	
Missed heartbeats	8	WARN- ING	Node <i>X</i> missed heartbeat # <i>Y</i>
General warning events	2	WARN- ING	

#### INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Event	Priority	Severity	Description
Sent heartbeat	12	INFO	Heartbeat sent to node <i>X</i>
Create log bytes	11	INFO	Log part, log file, MB
General information events	2	INFO	

## 15.7.4. Single-User Mode

Single-user mode allows the database administrator to restrict access to the database system to a single MySQL server (SQL node). When entering single-user mode, all connections to all other MySQL servers are closed gracefully and all running transactions are aborted. No new transactions are allowed to be started.

Once the cluster has entered single-user mode, only the designated SQL node is granted access to the database.

You can use the `ALL STATUS` command to see when the cluster has entered single-user mode.

Example:

```
NDB> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single-user mode, the SQL node whose

node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be a MySQL Server node; An attempt to specify any other type of node will be rejected.

**Note:** When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single-user mode to normal mode. MySQL Servers waiting for a connection (that is, for the cluster to become ready and available), are again permitted to connect. The MySQL Server denoted as the single-user SQL node continues to run (if still connected) during and after the state change.

Example:

```
NDB> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single-user mode:

- Method 1:
  1. Finish all single-user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes
- Method 2:

Restart database nodes prior to entering single-user mode.

## 15.7.5. On-line Backup of MySQL Cluster

This section describes how to create a backup and how to restore the database from a backup at a later time.

### 15.7.5.1. Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata:** the names and definitions of all database tables
- **Table records:** the data actually stored in the database tables at the time that the backup was made
- **Transaction log:** a sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- `BACKUP-backup_id.node_idctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-backup_id-0.node_id.data`

A data file containing the table records, which are saved on a per-fragment basis. That is, differ-

ent nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-backup_id.node_id.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing above, *backup\_id* stands for the backup identifier and *node\_id* is the unique identifier for the node creating the file.

### 15.7.5.2. Using The Management Server to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 15.7.5.4, “Configuration for Cluster Backup”.)

Creating a backup using the management server involves the following steps:

1. Start the management server (`ndb_mgm`).
2. Execute the command `START BACKUP`.
3. The management server will reply with the message `Start of backup ordered`. This means that the management server has submitted the request to the cluster, but has not yet received any response.
4. The management server will reply `Backup backup_id started`, where *backup\_id* is the unique identifier for this particular backup. (This identifier will also be saved in the cluster log, if it has not been configured otherwise.) This means that the cluster has received and processed the backup request. It does *not* mean that the backup has finished.
5. The management server will signal that the backup is finished with the message `Backup backup_id completed`.

To abort a backup that is already in progress:

1. Start the management server.
2. Execute the command `ABORT BACKUP backup_id`. The number *backup\_id* is the identifier of the backup that was included in the response of the management server when the backup was started (in the message `Backup backup_id started`).
3. The management server will acknowledge the abort request with `Abort of backup backup_id ordered`; note that it has received no actual response to this request yet.
4. After the backup has been aborted, the management server will report `Backup backup_id has been aborted for reason XYZ`. This means that the cluster has terminated the backup and that all files related to this backup have been removed from the cluster filesystem.

It is also possible to abort a backup in progress from the system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

**Note:** If there is no backup with ID *backup\_id* running when it is aborted, the management server makes no explicit response. However, the fact that an invalid abort command was sent is indicated

in the cluster log.

### 15.7.5.3. How to Restore a Cluster Backup

The cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which reads the files created by the backup and inserts the stored information into the database. The restore program must be executed once for each set of backup files. That is, as many times as there were database nodes running when the backup was created.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables. (Note that the cluster should have an empty database when starting to restore a backup.) The restore program acts as an API to the cluster and therefore requires a free connection to connect to the cluster. This can be verified with the `ndb_mgm` command `SHOW` (you can accomplish this from a system shell using `ndb_mgm -e SHOW`). The `-c connectstring` option may be used to locate the MGM node (see Section 15.4.4.2, “The MySQL Cluster `connectstring`”, for information on `connectstrings`). The backup files must be present in the directory given as an argument to the restoration program.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two database nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice — once for each database node in the cluster where the backup was taken.

**Note:** For rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. However, the data files must always be applied before the logs.

### 15.7.5.4. Configuration for Cluster Backup

Four configuration parameters are essential for backup:

- `BackupDataBufferSize`  
The amount of memory used to buffer data before it is written to disk.
- `BackupLogBufferSize`  
The amount of memory used to buffer log records before these are written to disk.
- `BackupMemory`  
The total memory allocated in a database node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.
- `BackupWriteSize`  
The size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in Section 15.4, “MySQL Cluster Configuration”.

### 15.7.5.5. Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or insufficient disk space. You should check that there is enough memory allocated for the backup. Also check that there is enough space on the hard drive partition of the backup target.

NDB does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring a MySQL Cluster from backup is not a 100% “hot”

process. This is due to the fact that, for the duration of the restore process, running transactions get non-repeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

## 15.8. Using High-Speed Interconnects with MySQL Cluster

Even before design of `NDB Cluster` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDB Cluster` was designed from the very beginning to allow for the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

Currently, the MySQL Cluster codebase includes support for four different transporters. Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter in MySQL Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: Either a custom transporter can be designed to handle this case, or you can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by Dolphin [<http://www.dolphinics.com/>].

### 15.8.1. Configuring MySQL Cluster to use SCI Sockets

In this section, we show how to adapt a cluster configured for normal TCP/IP communication to use SCI Sockets instead. This documentation is based on SCI Sockets version 2.3.0 as of 01 October 2004.

#### Prerequisites

Any machines with which you wish to use SCI Sockets must be equipped with SCI cards.

It is possible to use SCI Sockets with any version of MySQL Cluster. No special builds are needed because it uses normal socket calls which are already available in MySQL Cluster. However, SCI Sockets are currently supported only on the Linux 2.4 and 2.6 kernels. SCI Transporters have been tested successfully on additional operating systems although we have verified these only with Linux 2.4 to date.

There are essentially four requirements for SCI Sockets:

- Building the SCI Socket libraries.
- Installation of the SCI Socket kernel libraries.
- Installation of one or two configuration files.
- The SCI Socket kernel library must be enabled either for the entire machine or for the shell where the MySQL Cluster processes are started.

This process needs to be repeated for each machine in the cluster where you plan to use SCI Sockets for inter-node communication.

Two packages need to be retrieved to get SCI Sockets working:

- The source code package containing the DIS support libraries for the SCI Sockets libraries.

- The source code package for the SCI Socket libraries themselves.

Currently, these are available only in source code format. The latest versions of these packages at the time of this writing were available as (respectively) `DIS_GPL_2_5_0_SEP_10_2004.tar.gz` and `SCI_SOCKET_2_3_0_OKT_01_2004.tar.gz`. You should be able to find these (or possibly newer versions) at <http://www.dolphinics.no/support/downloads.html>.

### Package Installation

Once you have obtained the library packages, the next step is to unpack them into appropriate directories, with the SCI Sockets library unpacked into a directory below the DIS code. Next, you need to build the libraries. This example shows the commands used on Linux/x86 to perform this task:

```
shell> tar xzf DIS_GPL_2_5_0_SEP_10_2004.tar.gz
shell> cd DIS_GPL_2_5_0_SEP_10_2004/src/
shell> tar xzf ../../SCI_SOCKET_2_3_0_OKT_01_2004.tar.gz
shell> cd ../adm/bin/Linux_pkgs
shell> ./make_PSB_66_release
```

It is possible to build these libraries for some 64-bit processors. To build the libraries for Opteron CPUs using the 64-bit extensions, run `make_PSB_66_X86_64_release` rather than `make_PSB_66_release`. If the build is made on an Itanium machine, you should use `make_PSB_66_IA64_release`. The X86-64 variant should work for Intel EM64T architectures but this has not yet (to our knowledge) been tested.

Once the build process is complete, the compiled libraries will be found in a zipped tar file with a name along the lines of `DIS-<operating-system>-time-date`. It is now time to install the package in the proper place. In this example we will place the installation in `/opt/DIS`. (**Note:** You will most likely need to run the following as the system `root` user.)

```
shell> cp DIS_Linux_2.4.20-8_181004.tar.gz /opt/
shell> cd /opt
shell> tar xzf DIS_Linux_2.4.20-8_181004.tar.gz
shell> mv DIS_Linux_2.4.20-8_181004 DIS
```

### Network Configuration

Now that all the libraries and binaries are in their proper place, we need to ensure that the SCI cards have proper node IDs within the SCI address space.

It is also necessary to decide on the network structure before proceeding. There are three types of network structures which can be used in this context:

- A simple one-dimensional ring
- One or more SCI switches with one ring per switch port
- A two- or three-dimensional torus.

Each of these topologies has its own method for providing node IDs. We discuss each of them in brief.

A simple ring uses node IDs which are non-zero multiples of 4: 4, 8, 12,...

The next possibility uses SCI switches. An SCI switch has 8 ports, each of which can support a ring. It is necessary to make sure that different rings use different node ID spaces. In a typical configuration, the first port uses node IDs below 64 (4 – 60), the next 64 node IDs (68 – 124) are assigned to the next port, and so on, with node IDs 452 – 508 being assigned to the eighth port.

Two- and three-dimensional torus network structures take into account where each node is located in each dimension, incrementing by 4 for each node in the first dimension, by 64 in the second dimension, and (where applicable) by 1024 in the third dimension. See Dolphin's Web site [<http://www.dolphinics.com/support/index.html>] for more thorough documentation.

In our testing we have used switches, although most large cluster installations use 2- or 3-dimensional torus structures. The advantage provided by switches is that, with dual SCI cards and dual switches, it is possible to build with relative ease a redundant network where the average fail-over time on the SCI network is on the order of 100 microseconds. This is supported by the SCI transporter in MySQL Cluster and is also under development for the SCI Socket implementation.

Failover for the 2D/3D torus is also possible but requires sending out new routing indexes to all nodes. However, this requires only 100 milliseconds or so to complete and should be acceptable for most high-availability cases.

By placing cluster data nodes properly within the switched architecture, it is possible to use 2 switches to build a structure whereby 16 computers can be interconnected and no single failure can hinder more than one of them. With 32 computers and 2 switches it is possible to configure the cluster in such a manner that no single failure can cause the loss of more than two nodes; in this case, it is also possible to know which pair of nodes is affected. Thus, by placing the two nodes in separate node groups, it is possible to build a "safe" MySQL Cluster installation.

To set the node ID for an SCI card use the following command in the `/opt/DIS/sbin` directory. In this example, `-c 1` refers to the number of the SCI card (this is always 1 if there is only 1 card in the machine); `-a 0` refers to adapter 0; and 68 is the node ID:

```
shell> ./sciconfig -c 1 -a 0 -n 68
```

If you have multiple SCI cards in the same machine, you can determine which card has which slot by issuing the following command (again we assume that the current working directory is `/opt/DIS/sbin`):

```
shell> ./sciconfig -c 1 -gsn
```

This will give you the SCI card's serial number. Then repeat this procedure with `-c 2`, and so on, for each card in the machine. Once you have matched each card with a slot, you can set node IDs for all cards.

After the necessary libraries and binaries are installed, and the SCI node IDs are set, the next step is to set up the mapping from hostnames (or IP addresses) to SCI node IDs. This is done in the SCI sockets configuration file, which should be saved as `/etc/sci/scisock.conf`. In this file, each SCI node ID is mapped through the proper SCI card to the hostname or IP address that it is to communicate with. Here is a very simple example of such a configuration file:

```
#host          #nodeId
alpha          8
beta           12
192.168.10.20  16
```

It is also possible to limit the configuration so that it applies only to a subset of the available ports for these hosts. An additional configuration file `/etc/sci/scisock_opt.conf` can be used to accomplish this, as shown here:

#-key	-type	-values
EnablePortsByDefault	yes	
EnablePort	tcp	2200
DisablePort	tcp	2201
EnablePortRange	tcp	2202 2219
DisablePortRange	tcp	2220 2231

## Driver Installation

With the configuration files in place, the drivers can be installed.

First, the low-level drivers and then the SCI socket driver need to be installed:

```
shell> cd DIS/sbin/  
shell> ./drv-install add PSB66  
shell> ./scisocket-install add
```

If desired, the installation can be checked by invoking a script which verifies that all nodes in the SCI socket configuration files are accessible:

```
shell> cd /opt/DIS/sbin/  
shell> ./status.sh
```

If you discover an error and need to change the SCI socket configuration, it is necessary to use `ksocketconfig` to accomplish this task:

```
shell> cd /opt/DIS/util  
shell> ./ksocketconfig -f
```

### Testing the Setup

To ensure that SCI sockets are actually being used, you can employ the `latency_bench` test program. Using this utility's server component, clients can connect to the server to test the latency of the connection. Determining whether SCI is enabled should be fairly simple from observing the latency. (**Note:** Before using `latency_bench`, it is necessary to set the `LD_PRELOAD` environment variable as shown later in this section.)

To set up a server, use the following:

```
shell> cd /opt/DIS/bin/socket  
shell> ./latency_bench -server
```

To run a client, use `latency_bench` again, except this time with the `-client` option:

```
shell> cd /opt/DIS/bin/socket  
shell> ./latency_bench -client server_hostname
```

SCI socket configuration should now be complete and MySQL Cluster ready to use both SCI Sockets and the SCI transporter (see Section 15.4.4.10, “MySQL Cluster SCI Transport Connections”).

### Starting the Cluster

The next step in the process is to start MySQL Cluster. To enable usage of SCI Sockets it is necessary to set the environment variable `LD_PRELOAD` before starting `ndbd`, `mysqld`, and `ndb_mgmd`. This variable should point to the kernel library for SCI Sockets.

To start `ndbd` in a bash shell, do the following:

```
bash-shell> export LD_PRELOAD=/opt/DIS/lib/libkscisock.so  
bash-shell> ndbd
```

In a `tcsh` environment the same thing can be accomplished with:

```
tcsh-shell> setenv LD_PRELOAD=/opt/DIS/lib/libkscisock.so  
tcsh-shell> ndbd
```

**Note:** MySQL Cluster can use only the kernel variant of SCI Sockets.

## 15.8.2. Understanding the Impact of Cluster Interconnects

The `ndbd` process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access**

This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, additional TCP/IP messages need to be set up.

- **Unique key access**

Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by `ndbd`. Such requests also benefit from batching.

- **Full table scan**

When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the `ndbd` process, which then divides the table scan into a set of parallel scans on all cluster `ndbd` processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.

- **Range scan using ordered index**

When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

To check the base performance of these access methods, we have developed a set of benchmarks. One such benchmark, `testReadPerf`, tests simple and batched primary and unique key accesses. This benchmark also measures the setup cost of range scans by issuing scans returning a single record. There is also a variant of this benchmark which uses a range scan to fetch a batch of records.

In this way, we can determine the cost of both a single key access and a single record scan access, as well as measure the impact of the communication media used, on base access methods.

In our tests, we ran the base benchmarks for both a normal transporter using TCP/IP sockets and a similar setup using SCI sockets. The figures reported in the following table are for small accesses of 20 records per access. The difference between serial and batched access decreases by a factor of 3 to 4 when using 2KB records instead. SCI Sockets were not tested with 2KB records. Tests were performed on a cluster with 2 data nodes running on 2 dual-CPU machines equipped with AMD MP1900+ processors.

Access Type	TCP/IP Sockets	SCI Socket
Serial pk access	400 microseconds	160 microseconds
Batched pk access	28 microseconds	22 microseconds
Serial uk access	500 microseconds	250 microseconds
Batched uk access	70 microseconds	36 microseconds

Indexed eq-bound	1250 microseconds	750 microseconds
Index range	24 microseconds	12 microseconds

We also performed another set of tests to check the performance of SCI Sockets vis-à-vis that of the SCI transporter, and both of these as compared with the TCP/IP transporter. All these tests used primary key accesses either serially and multi-threaded, or multi-threaded and batched.

The tests showed that SCI sockets were about 100% faster than TCP/IP. The SCI transporter was faster in most cases compared to SCI sockets. One notable case occurred with many threads in the test program, which showed that the SCI transporter did not perform very well when used for the `mysqld` process.

Our overall conclusion was that, for most benchmarks, using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case, the CPU processing in the `ndbd` processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between `ndbd` processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the `ndbd` process because the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the `ndbd` process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, the `ndbd` process will benefit by 10–70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. We have tested MySQL Cluster so far only with SCI sockets. See Section 15.8.1, “Configuring MySQL Cluster to use SCI Sockets” for information on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

## 15.9. Known Limitations of MySQL Cluster

In this section, we provide a list of known limitations in MySQL Cluster releases in the 5.0.x series compared to features available when using the MyISAM and InnoDB storage engines. Currently, there are no plans to address these in coming releases of MySQL 5.0; however, we will attempt to supply fixes for these issues in subsequent release series. If you check the “Cluster” category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs which (if marked “5.0”) we intend to correct in upcoming releases of MySQL 5.0.

The list here is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.8, “How to Report Bugs or Problems”. If we do not plan to fix the problem in MySQL 5.0, we will add it to the list.

(**Note:** See the end of this section for a list of issues in MySQL 4.1 Cluster that have been resolved in the current version.)

- **Noncompliance in syntax** (resulting in errors when running existing applications):
  - Text indexes are not supported. That is, you cannot create indexes on columns of any of the TEXT datatypes, nor does the NDB storage engine support FULLTEXT indexes (these are supported by MyISAM only). However, you can index VARCHAR columns of NDB tables.
  - A BIT column cannot be a primary key or part of a composite primary key.
  - Geometry datatypes (WKT and WKB) are not supported by the NDB storage engine prior to MySQL 5.0.16. (Note that spatial indexes are still not supported in MySQL 5.0.16 and new-

er.)

- In MySQL 5.0.19 and earlier, `INSERT IGNORE`, `UPDATE IGNORE`, and `REPLACE` are supported only for primary keys, but not for unique keys. One possible workaround is to remove the constraint by dropping the unique index, perform any inserts, and then add the unique index again.

This limitation is removed for `INSERT IGNORE` and `REPLACE` in MySQL 5.0.20. (Bug#17431 [<http://bugs.mysql.com/17431>])

- **Non-compliance in limits or behavior** (may result in errors when running existing applications):

- **Error Reporting:**

- A duplicate key error returns the error message `ERROR 23000: Can't write; duplicate key in table 'tbl_name'`.
- Like other MySQL storage engines, the NDB storage engine can handle a maximum of one `AUTO_INCREMENT` column per table. However, in the case of a Cluster table with no explicit primary key, an `AUTO_INCREMENT` column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit `AUTO_INCREMENT` column unless that column is also declared using the `PRIMARY KEY` option.

Attempting to create a table with an `AUTO_INCREMENT` column that is not the table's primary key, and using the NDB storage engine, fails with an error.

- **Transaction Handling:**

- NDB Cluster supports only the `READ COMMITTED` transaction isolation level.
- There is no partial rollback of transactions. A duplicate key or similar error results in a rollback of the entire transaction.
- **Important:** If a `SELECT` from a Cluster table includes a `BLOB`, `TEXT`, or `VARCHAR` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency, due to the fact that parts of the values stored in columns of these types are actually read from a separate table.
- As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations.

Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behaviour of a number of MySQL statements is effected as described in the following list:

- `TRUNCATE` is not transactional when used on NDB tables. If a `TRUNCATE` fails to empty the table, then it is re-run until it is successful.
- `DELETE FROM` (even with no `WHERE` clause) *is* transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM . . . LIMIT . . .` statements to “chunk” the delete operation. If the objective is to empty the table, then you may wish to use `TRUNCATE` instead.
- `LOAD DATA INFILE` is not transactional. During such an operation the NDB engine can and does commit at will.

`LOAD DATA FROM MASTER` is not supported in MySQL Cluster.

- When copying a table as part of an `ALTER TABLE`, the creation of the copy is non-transactional. (In any case, this operation is rolled back when the copy is deleted.)

- **Node Start, Stop, or Restart:** Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:
  - When first starting a node, it is possible that you may see Error 1204 Temporary failure, distribution changed and similar temporary errors.
  - The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

- A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 15.4.4, “Configuration File”. Most configuration parameters can be upgraded online. These hard limits include:
  - Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).
  - The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`. Note that bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.
  - Different limits related to tables and indexes. For example, the maximum number of ordered indexes per table is determined by `MaxNoOfOrderedIndexes`.
  - Database names, table names and attribute names cannot be as long in NDB tables as with other table handlers. Attribute names are truncated to 31 characters, and if not unique after truncation give rise to errors. Database names and table names can total a maximum of 122 characters. (That is, the maximum length for an NDB `Cluster` table name is 122 characters less the number of characters in the name of the database of which that table is a part.)
  - All Cluster table rows are of fixed length. This means (for example) that if a table has one or more `VARCHAR` fields containing only relatively small values, more memory and disk space is required when using the NDB storage engine than would be the case for the same table and data using the `MyISAM` engine. (In other words, in the case of a `VARCHAR` column, the column requires the same amount of storage as a `CHAR` column of the same size.)
  - The maximum number of tables in a Cluster database is limited to 1792.
  - The maximum number of attributes per table is limited to 128.
  - The maximum permitted size of any one row is 8KB, *not including data stored in BLOB columns*.
  - The maximum number of attributes per key is 32.
- **Unsupported features** (do not cause errors, but are not supported or enforced):
  - The foreign key construct is ignored, just as it is in `MyISAM` tables.
  - Savepoints and rollbacks to savepoints are ignored as in `MyISAM`.
  - `OPTIMIZE` operations are not supported.
  - `LOAD TABLE . . . FROM MASTER` is not supported.
- **Performance and limitation-related issues:**

- There are query performance issues due to sequential access to the NDB storage engine; it is also relatively more expensive to do many range scans than it is with either MyISAM or InnoDB.
- The `Records in range` statistic is not supported, resulting in non-optimal query plans in some cases. Employ `USE INDEX` or `FORCE INDEX` as a workaround.
- Unique hash indexes created with `USING HASH` cannot be used for accessing a table if `NULL` is given as part of the key.
- MySQL Cluster does not support durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- `SQL_LOG_BIN` has no effect on data operations; however, it is supported for schema operations.

MySQL Cluster cannot produce a binlog for tables having BLOB columns but no primary key.

Only the following schema operations are logged in a cluster binlog which is *not* on the `mysqld` executing the statement:

- `CREATE TABLE`
- `ALTER TABLE`
- `DROP TABLE`
- `CREATE DATABASE / CREATE SCHEMA`
- `DROP DATABASE / DROP SCHEMA`

- **Missing features:**

- The only supported isolation level is `READ COMMITTED`. (InnoDB supports `READ COMMITTED`, `READ COMMITTED, REPEATABLE READ`, and `SERIALIZABLE`.) See Section 15.7.5.5, “Backup Troubleshooting”, for information on how this can affect backup and restore of Cluster databases.
- No durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

- **Problems relating to multiple MySQL servers** (not relating to MyISAM or InnoDB):

- `ALTER TABLE` is not fully locking when running multiple MySQL servers (no distributed table lock).
- MySQL replication will not work correctly if updates are done on multiple MySQL servers. However, if the database partitioning scheme is done at the application level and no transactions take place across these partitions, replication can be made to work.
- Autodiscovery of databases is not supported for multiple MySQL servers accessing the same MySQL Cluster. However, autodiscovery of tables is supported in such cases. What this means is that after a database named `db_name` is created or imported using one MySQL server, you should issue a `CREATE DATABASE db_name` statement on each additional MySQL server that accesses the same MySQL Cluster. (As of MySQL 5.0.2, you may also use `CREATE SCHEMA db_name`.) Once this has been done for a given MySQL server, that server should be able to detect the database tables without error.
- DDL operations are not node failure safe. If a node fails while trying to perform one of these (such as `CREATE TABLE` or `ALTER TABLE`), the data dictionary is locked and no further DDL statements can be executed without restarting the cluster.

- **Issues exclusive to MySQL Cluster** (not related to MyISAM or InnoDB):
  - All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.
  - It is also not possible to perform a Cluster backup and restore between different architectures. For example, you cannot back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. (Bug#19255 [<http://bugs.mysql.com/19255>])
  - It is not possible to make online schema changes such as those accomplished using `ALTER TABLE` or `CREATE INDEX`, as the NDB Cluster engine does not support autodiscovery of such changes. (However, you can import or create a table that uses a different storage engine, and then convert it to NDB using `ALTER TABLE tbl_name ENGINE=NDBCLUSTER`. In such a case, you must issue a `FLUSH TABLES` statement to force the cluster to pick up the change.)
  - Online adding or dropping of nodes is not possible (the cluster must be restarted in such cases).
  - When using multiple management servers:
    - You must give nodes explicit IDs in connectstrings because automatic allocation of node IDs does not work across multiple management servers.
    - You must take extreme care to have the same configurations for all management servers. No special checks for this are performed by the cluster.
    - In order that management nodes be able to see one another, you must restart all data nodes after bringing up the cluster. (See Bug#13070 [<http://bugs.mysql.com/13070>] for a detailed explanation.)
  - Multiple network interfaces for data nodes are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.
  - The maximum number of data nodes is 48.
  - The total maximum number of nodes in a MySQL Cluster is 63. This number includes all MySQL Servers (SQL nodes), data nodes, and management servers.

The following Cluster limitations in MySQL 4.1 have been resolved in MySQL 5.0 as shown below:

- The NDB Cluster storage engine supports all character sets and collations available in MySQL 5.0.
- Prior to MySQL 5.0.6, the maximum number of metadata objects possible was 1600. Beginning with 5.0.6, this limit is increased to 20320.
- Cluster in MySQL 5.0 supports column indexes that make use of prefixes.
- Unlike the case in MySQL 4.1, the Cluster storage engine in MySQL 5.0 supports MySQL' query cache. See Section 5.14, "The MySQL Query Cache".
- Beginning with MySQL 5.0.21, it is possible to install MySQL with Cluster support to a non-default location and change the search path for font description files using either the `--basedir` or `--character-sets-dir` options. (Previously, `ndbd` in MySQL 5.0 searched only the default path — typically /

`usr/local/mysql/share/mysql/charsets` — for character sets.)

## 15.10. MySQL Cluster Development Roadmap

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.0 as compared to MySQL 4.1. We will also discuss our roadmap for further improvements to MySQL Cluster as currently planned for MySQL 5.1.

There are relatively few changes between the NDB Cluster storage engine implementations in MySQL 4.1 and in 5.0, so the upgrade path should be relatively quick and painless.

All significantly new features being developed for MySQL Cluster are going into the MySQL 5.1 and 5.2 trees. For information on changes in the Cluster implementations in MySQL versions 5.1 and later, see <http://dev.mysql.com/doc/refman/5.1/en/ndbcluster.html>.

### 15.10.1. MySQL Cluster Changes in MySQL 5.0

MySQL Cluster in versions 5.0.3-beta and later contains a number of new features that are likely to be of interest:

- **Push-Down Conditions:** Consider the following query:

```
SELECT * FROM t1 WHERE non_indexed_attribute = 1;
```

This query will use a full table scan and the condition will be evaluated in the cluster's data nodes. Thus, it is not necessary to send the records across the network for evaluation. (That is, function transport is used, rather than data transport.) Please note that this feature is currently disabled by default (pending more thorough testing), but it should work in most cases. This feature can be enabled through the use of the `SET engine_condition_pushdown = On` statement. Alternatively, you can run `mysqld` with this feature enabled by starting the MySQL server with the `--engine-condition-pushdown` option.

A major benefit of this change is that queries can be executed in parallel. This means that queries against non-indexed columns can run faster than previously by a factor of as much as 5 to 10 times, *times the number of data nodes*, because multiple CPUs can work on the query in parallel.

You can use `EXPLAIN` to determine when condition pushdown is being used. See Section 7.2.1, “Optimizing Queries with `EXPLAIN`”.

- **Decreased IndexMemory Usage:** In MySQL 5.0, each record consumes approximately 25 bytes of index memory, and every unique index uses 25 bytes per record of index memory (in addition to some data memory because these are stored in a separate table). This is because the primary key is not stored in the index memory anymore.
- **Query Cache Enabled for MySQL Cluster:** See Section 5.14, “The MySQL Query Cache”, for information on configuring and using the query cache.
- **New Optimizations:** One optimization that merits particular attention is that a batched read interface is now used in some queries. For example, consider the following query:

```
SELECT * FROM t1 WHERE primary_key IN (1,2,3,4,5,6,7,8,9,10);
```

This query will be executed 2 to 3 times more quickly than in previous MySQL Cluster versions due to the fact that all 10 key lookups are sent in a single batch rather than one at a time.

- **Limit On Number of Metadata Objects:** Beginning with MySQL 5.0.6, each Cluster database may contain a maximum of 20320 metadata objects — this includes database tables, system tables, indexes and BLOB values. (Previously, this number was 1600.)

## 15.10.2. MySQL 5.1 Development Roadmap for MySQL Cluster

What is said here is a status report based on recent commits to the MySQL 5.1 source tree. It should be noted all 5.1 development is subject to change.

There are currently 4 major new features being developed for MySQL 5.1:

1. **Integration of MySQL Cluster into MySQL replication:** This will make it possible to update from any MySQL Server in the cluster and still have the MySQL Replication handled by one of the MySQL Servers in the cluster, with the state of the slave side remaining consistent with the cluster acting as the master.
2. **Support for disk-based records:** Records on disk will be supported. Indexed fields including the primary key hash index must still be stored in RAM but all other fields can be on disk.
3. **Variable-sized records:** A column defined as `VARCHAR(255)` currently uses 260 bytes of storage independent of what is stored in any particular record. In MySQL 5.1 Cluster tables, only the portion of the column actually taken up by the record will be stored. This will make possible a reduction in space requirements for such columns by a factor of 5 in many cases.
4. **User-defined partitioning:** Users will be able to define partitions based on columns that are part of the primary key. The MySQL Server will be able to discover whether it is possible to prune away some of the partitions from the `WHERE` clause. Partitioning based on `KEY`, `HASH`, `RANGE`, and `LIST` handlers will be possible, as well as subpartitioning. This feature should also be available for many other handlers, and not only NDB Cluster.

In addition, we are working to increase the 8KB size limit for rows containing columns of types other than `BLOB` or `TEXT` in Cluster tables. This is due to the fact that rows are currently fixed in size and the page size is 32,768 bytes (minus 128 bytes for the row header). Currently, this means that if we allowed more than 8KB per record, any remaining space (up to approximately 14,000 bytes) would be left empty. In MySQL 5.1, we plan to fix this limitation so that using more than 8KB in a given row does not result in the remainder of the page being wasted.

## 15.11. MySQL Cluster FAQ

This section answers questions that are often asked about MySQL Cluster.

- *What does “NDB” mean?*

This stands for “**N**etwork **D**atabase.”

- *What's the difference in using Cluster vs. using replication?*

In a replication setup, a master MySQL server updates one or more slaves. Transactions are committed sequentially, and a slow transaction can cause the slave to lag behind the master. This means that if the master fails, it is possible that the slave might not have recorded the last few transactions. If a transaction-safe engine such as `InnoDB` is being used, a transaction will either be complete on the slave or not applied at all, but replication does not guarantee that all data on the master and the slave will be consistent at all times. In MySQL Cluster, all data nodes are kept in synchrony, and a transaction committed by any one data node is committed for all data nodes. In the event of a data node failure, all remaining data nodes remain in a consistent state.

In short, whereas standard MySQL replication is asynchronous, MySQL Cluster is synchronous.

We are planning to implement (asynchronous) replication for Cluster in MySQL 5.1. This will include the capability to replicate both between two clusters and between a MySQL cluster and a non-Cluster MySQL server.

- *Do I need to do any special networking to run Cluster? (How do computers in a cluster communicate?)*

MySQL Cluster is intended to be used in a high-bandwidth environment, with computers connecting via TCP/IP. Its performance depends directly upon the connection speed between the cluster's computers. The minimum connectivity requirements for Cluster include a typical 100-megabit Ethernet network or the equivalent. We recommend you use gigabit Ethernet whenever available.

The faster SCI protocol is also supported, but requires special hardware. See Section 15.8, “Using High-Speed Interconnects with MySQL Cluster”, for more information about SCI.

- *How many computers do I need to run a cluster, and why?*

A minimum of three computers is required to run a viable cluster. However, the minimum **recommended** number of computers in a MySQL Cluster is four: one each to run the management and SQL nodes, and two computers to serve as data nodes. The purpose of the two data nodes is to provide redundancy; the management node must run on a separate machine to guarantee continued arbitration services in the event that one of the data nodes fails.

- *What do the different computers do in a cluster?*

A MySQL Cluster has both a physical and logical organization, with computers being the physical elements. The logical or functional elements of a cluster are referred to as *nodes*, and a computer housing a cluster node is sometimes referred to as a *cluster host*. Ideally, there will be one node per cluster host, although it is possible to run multiple nodes on a single host. There are three types of nodes, each corresponding to a specific role within the cluster. These are:

- **Management node (MGM node):** Provides management services for the cluster as a whole, including startup, shutdown, backups, and configuration data for the other nodes. The management node server is implemented as the application `ndb_mgmd`; the management client used to control MySQL Cluster via the MGM node is `ndb_mgm`.
  - **Data node:** Stores and replicates data. Data node functionality is handled by an instance of the NDB data node process `ndbd`.
  - **SQL node:** This is simply an instance of MySQL Server (`mysqld`) that is built with support for the NDB Cluster storage engine and started with the `--ndb-cluster` option to enable the engine.
- *With which operating systems can I use Cluster?*

MySQL Cluster is officially supported on Linux, Mac OS X, and Solaris. We are working to add Cluster support for other platforms, including Windows, and our goal is eventually to offer MySQL Cluster on all platforms for which MySQL itself is supported.

It may be possible to run Cluster processes on other operating systems. We have had reports from users who say that they have run Cluster successfully on FreeBSD. However, Cluster on any but the three platforms mentioned here should be considered alpha software (at best), cannot be guaranteed reliable in a production setting, and *is not supported by MySQL AB*.

- *What are the hardware requirements for running MySQL Cluster?*

Cluster should run on any platform for which NDB-enabled binaries are available. Naturally, faster CPUs and more memory will improve performance, and 64-bit CPUs will likely be more effective than 32-bit processors. There must be sufficient memory on machines used for data nodes to hold each node's share of the database (see *How much RAM do I Need?* for more information). Nodes can communicate via a standard TCP/IP network and hardware. For SCI support, special networking hardware is required.

- *How much RAM do I need? Is it possible to use disk memory at all?*

In MySQL-5.0, Cluster is in-memory only. This means that all table data (including indexes) is

stored in RAM. Therefore, if your data takes up 1GB of space and you want to replicate it once in the cluster, you need 2GB of memory to do so. This in addition to the memory required by the operating system and any applications running on the cluster computers.

If a data node's memory usage exceeds what is available in RAM, then the system will attempt to use swap space up to the limit set for `DataMemory`. However, this will at best result in severely degraded performance, and may cause the node to be dropped due to slow response time (missed heartbeats). We do not recommend on relying on disk swapping in a production environment for this reason. In any case, once the `DataMemory` limit is reached, any operations requiring additional memory (such as inserts) will fail.

( We implemented disk data storage for MySQL Cluster in MySQL 5.1, but we have no plans to add this capability in MySQL 5.0.)

You can use the following formula for obtaining a rough estimate of how much RAM is needed for each data node in the cluster:

$$(\text{SizeofDatabase} \times \text{NumberOfReplicas} \times 1.1) / \text{NumberOfDataNodes}$$

To calculate the memory requirements more exactly requires determining, for each table in the cluster database, the storage space required per row (see Section 11.5, “Data Type Storage Requirements”, for details), and multiplying this by the number of rows. You must also remember to account for any column indexes as follows:

- Each primary key or hash index created for an `NDBCluster` table requires 21–25 bytes per record. These indexes use `IndexMemory`.
- Each ordered index requires 10 bytes storage per record, using `DataMemory`.
- Creating a primary key or unique index also creates an ordered index, unless this index is created with `USING HASH`. In other words, if created without `USING HASH`, a primary key or unique index on a Cluster table takes up 31–35 bytes per record in MySQL 5.0.

Note that creating MySQL Cluster tables with `USING HASH` for all primary keys and unique indexes will generally cause table updates to run more quickly. This is due to the fact that less memory is required (because no ordered indexes are created), and that less CPU must be utilized (because fewer indexes must be read and possibly updated).

It is especially important to keep in mind that *every MySQL Cluster table must have a primary key*. The NDB storage engine creates a primary key automatically if none is defined, and this primary key is created without `USING HASH`.

There is no easy way to determine exactly how much memory is being used for storage of Cluster indexes at any given time; however, warnings are written to the Cluster log when 80% of available `DataMemory` or `IndexMemory` is in use, and again when use reaches 85%, 90%, and so on.

We often see questions from users who report that, when they are trying to populate a Cluster database, the loading process terminates prematurely and an error message like this one is observed:

```
ERROR 1114: The table 'my_cluster_table' is full
```

When this occurs, the cause is very likely to be that your setup does not provide sufficient RAM for all table data and all indexes, *including the primary key required by the NDB storage engine and automatically created in the event that the table definition does not include the definition of a primary key*.

It is also worth noting that all data nodes should have the same amount of RAM, as no data node in a cluster can use more memory than the least amount available to any individual data node. In other words, if there are three computers hosting Cluster data nodes, with two of these having

3GB of RAM available to store Cluster data, and one having only 1GB RAM, then each data node can devote only 1GB to clustering.

- *Because MySQL Cluster uses TCP/IP, does that mean I can run it over the Internet, with one or more nodes in a remote location?*

It is very doubtful in any case that a cluster would perform reliably under such conditions, as MySQL Cluster was designed and implemented with the assumption that it would be run under conditions guaranteeing dedicated high-speed connectivity such as that found in a LAN setting using 100 Mbps or gigabit Ethernet (preferably the latter). We neither test nor warrant its performance using anything slower than this.

Also, it is extremely important to keep in mind that communications between the nodes in a MySQL Cluster are not secure; they are neither encrypted nor safeguarded by any other protective mechanism. The most secure configuration for a cluster is in a private network behind a firewall, with no direct access to any Cluster data or management nodes from outside. (For SQL nodes, you should take the same precautions as you would with any other instance of the MySQL server.)

- *Do I have to learn a new programming or query language to use Cluster?*

No. Although some specialized commands are used to manage and configure the cluster itself, only standard (My)SQL queries and commands are required for the following operations:

- Creating, altering, and dropping tables
- Inserting, updating, and deleting table data
- Creating, changing, and dropping primary and unique indexes
- Configuring and managing SQL nodes (MySQL servers)
- *How do I find out what an error or warning message means when using Cluster?*

There are two ways in which this can be done:

- From within the `mysql` client, use `SHOW ERRORS` or `SHOW WARNINGS` immediately upon being notified of the error or warning condition. Errors and warnings also be displayed in MySQL Query Browser.
- From a system shell prompt, use `perror --ndb error_code`.
- *Is MySQL Cluster transaction-safe? What isolation levels are supported?*

*Yes:* For tables created with the NDB storage engine, transactions are supported. In MySQL 5.0, Cluster supports only the `READ COMMITTED` transaction isolation level.

- *What storage engines are supported by MySQL Cluster?*

Clustering in MySQL is supported only by the NDB storage engine. That is, in order for a table to be shared between nodes in a cluster, it must be created using `ENGINE=NDB` (or `ENGINE=NDBCLUSTER`, which is equivalent).

(It is possible to create tables using other storage engines such as MyISAM or InnoDB on a MySQL server being used for clustering, but these non-NDB tables will **not** participate in the cluster.)

- *Which versions of the MySQL software support Cluster? Do I have to compile from source?*

Cluster is supported in all MySQL-max binaries in the 5.0 release series, except as noted in the following paragraph. You can determine whether your server has NDB support using either the `SHOW VARIABLES LIKE 'have_%%'` or `SHOW ENGINES` statement. (See Section 5.3, “The `mysqld-max` Extended MySQL Server”, for more information.)

Linux users, please note that NDB is *not* included in the standard MySQL server RPMs. Beginning with MySQL 5.0.4, there are separate RPM packages for the NDB storage engine and accompanying management and other tools; see the NDB RPM Downloads section of the MySQL 5.0 Downloads page for these. (Prior to 5.0.4, you had to use the `-max` binaries supplied as `.tar.gz` archives. This is still possible, but is not required, so you can use your Linux distribution's RPM manager if you prefer.) You can also obtain NDB support by compiling the `-max` binaries from source, but it is not necessary to do so simply to use MySQL Cluster. To download the latest binary, RPM, or source distribution in the MySQL 5.0 series, visit <http://dev.mysql.com/downloads/mysql/5.0.html>.

- *In the event of a catastrophic failure — say, for instance, the whole city loses power **and** my UPS fails — would I lose all my data?*

All committed transactions are logged. Therefore, although it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimizing the number of operations per transaction. (It is not a good idea to perform large numbers of operations per transaction in any case.)

- *Is it possible to use FULLTEXT indexes with Cluster?*

FULLTEXT indexing is not currently supported by the NDB storage engine, or by any storage engine other than MyISAM. We are working to add this capability in a future release.

- *Can I run multiple nodes on a single computer?*

It is possible but not advisable. One of the chief reasons to run a cluster is to provide redundancy. To enjoy the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. Given that MySQL Cluster can be run on commodity hardware loaded with a low-cost (or even no-cost) operating system, the expense of an extra machine or two is well worth it to safeguard mission-critical data. It also worth noting that the requirements for a cluster host running a management node are minimal. This task can be accomplished with a 200 MHz Pentium CPU and sufficient RAM for the operating system plus a small amount of overhead for the `ndb_mgmd` and `ndb_mgm` processes.

- *Can I add nodes to a cluster without restarting it?*

Not at present. A simple restart is all that is required for adding new MGM or SQL nodes to a Cluster. When adding data nodes the process is more complex, and requires the following steps:

1. Make a complete backup of all Cluster data.
2. Completely shut down the cluster and all cluster node processes.
3. Restart the cluster, using the `--initial` startup option.
4. Restore all cluster data from the backup.

In a future MySQL Cluster release series, we hope to implement a “hot” reconfiguration capability for MySQL Cluster to minimize (if not eliminate) the requirement for restarting the cluster when adding new nodes.

- *Are there any limitations that I should be aware of when using Cluster?*

NDB tables in MySQL are subject to the following limitations:

- Not all character sets and collations are supported.
- FULLTEXT indexes and index prefixes are not supported. Only complete columns may be indexed.
- Spatial data types are not supported. See Chapter 16, *Spatial Extensions*.

- Only complete rollbacks for transactions are supported. Partial rollbacks and rollbacks to savepoints are not supported.
- The maximum number of attributes allowed per table is 128, and attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.
- The maximum size for a table row is 8 kilobytes, not counting BLOB values. There is no set limit for the number of rows per table. Table size limits depend on a number of factors, in particular on the amount of RAM available to each data node.
- The NDB engine does not support foreign key constraints. As with MyISAM tables, these are ignored.
- Query caching is not supported.

For additional information on Cluster limitations, see Section 15.9, “Known Limitations of MySQL Cluster”.

- *How do I import an existing MySQL database into a cluster?*

You can import databases into MySQL Cluster much as you would with any other version of MySQL. Other than the limitation mentioned in the previous question, the only other special requirement is that any tables to be included in the cluster must use the NDB storage engine. This means that the tables must be created with `ENGINE=NDB` or `ENGINE=NDBCLUSTER`. It is also possible to convert existing tables using other storage engines to NDB Cluster using `ALTER TABLE`, but requires an additional workaround. See Section 15.9, “Known Limitations of MySQL Cluster”, for details.

- *How do cluster nodes communicate with one another?*

Cluster nodes can communicate via any of three different protocols: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See Section 15.8, “Using High-Speed Interconnects with MySQL Cluster”, for more about using SCI as a transport mechanism in MySQL Cluster.

- *What is an “arbiter”?*

If one or more nodes in a cluster fail, it is possible that not all cluster nodes will be able to “see” one another. In fact, it is possible that two sets of nodes might become isolated from one another in a network partitioning, also known as a “split brain” scenario. This type of situation is undesirable because each set of nodes tries to behave as though it is the entire cluster.

When cluster nodes go down, there are two possibilities. If more than 50% of the remaining nodes can communicate with each other, we have what is sometimes called a “majority rules” situation, and this set of nodes is considered to be the cluster. The arbiter comes into play when there is an even number of nodes: in such cases, the set of nodes to which the arbiter belongs is considered to be the cluster, and nodes not belonging to this set are shut down.

The preceding information is somewhat simplified. A more complete explanation taking into account node groups follows:

When all nodes in at least one node group are alive, network partitioning is not an issue, because no one portion of the cluster can form a functional cluster. The real problem arises when no single node group has all its nodes alive, in which case network partitioning (the “split-brain” scenario) becomes possible. Then an arbiter is required. All cluster nodes recognize the same node as the arbiter, which is normally the management server; however, it is possible to configure any of the MySQL Servers in the cluster to act as the arbiter instead. The arbiter accepts the first set of cluster nodes to contact it, and tells the remaining set to shut down. Arbitration selection is controlled by the `ArbitrationRank` configuration parameter for MySQL

Server and management server nodes. (See Section 15.4.4.4, “Defining the MySQL Cluster Management Server”, for details.) It should also be noted that the role of arbitrator does not in and of itself impose any heavy demands upon the host so designated, and thus the arbitrator host does not need to be particularly fast or to have extra memory especially for this purpose.

- *What data types are supported by MySQL Cluster?*

MySQL Cluster supports all of the usual MySQL data types, with the exception of those associated with MySQL's spatial extensions. (See Chapter 16, *Spatial Extensions*.) In addition, there are some differences with regard to indexes when used with NDB tables. **Note:** MySQL Cluster tables (that is, tables created with `ENGINE=NDBCLUSTER`) have only fixed-width rows. This means that (for example) each record containing a `VARCHAR(255)` column will require space for 255 characters (as required for the character set and collation being used for the table), regardless of the actual number of characters stored therein. This issue is expected to be fixed in a future MySQL release series.

See Section 15.9, “Known Limitations of MySQL Cluster”, for more information about these issues.

- *How do I start and stop MySQL Cluster?*

It is necessary to start each node in the cluster separately, in the following order:

1. Start the management node with the `ndb_mgmd` command.
2. Start each data node with the `ndbd` command.
3. Start each MySQL server (SQL node) using `mysqld_safe --user=mysql &`.

Each of these commands must be run from a system shell on the machine housing the affected node. You can verify the cluster is running by starting the MGM management client `ndb_mgm` on the machine housing the MGM node.

- *What happens to cluster data when the cluster is shut down?*

The data held in memory by the cluster's data nodes is written to disk, and is reloaded in memory the next time that the cluster is started.

To shut down the cluster, enter the following command in a shell on the machine hosting the MGM node:

```
shell> ndb_mgm -e shutdown
```

This causes the `ndb_mgm`, `ndb_mgm`, and any `ndbd` processes to terminate gracefully. MySQL servers running as Cluster SQL nodes can be stopped using `mysqladmin shutdown`.

For more information, see Section 15.7.2, “Commands in the Management Client”, and Section 15.3.6, “Safe Shutdown and Restart”.

- *Is it helpful to have more than one management node for a cluster?*

It can be helpful as a fail-safe. Only one MGM node controls the cluster at any given time, but it is possible to configure one MGM as primary, and one or more additional management nodes to take over in the event that the primary MGM node fails.

- *Can I mix different kinds of hardware and operating systems in a Cluster?*

Yes, so long as all machines and operating systems have the same endianness (all big-endian or all little-endian). It is also possible to use different MySQL Cluster releases on different nodes. However, we recommend this be done only as part of a rolling upgrade procedure.

- *Can I run two data nodes on a single host? Two SQL nodes?*

Yes, it is possible to do this. In the case of multiple data nodes, each node must use a different data directory. If you want to run multiple SQL nodes on one machine, each instance of `mysqld` must use a different TCP/IP port.

- *Can I use hostnames with MySQL Cluster?*

Yes, it is possible to use DNS and DHCP for cluster hosts. However, if your application requires “five nines” availability, we recommend using fixed IP addresses. Making communication between Cluster hosts dependent on services such as DNS and DHCP introduces additional points of failure, and the fewer of these, the better.

## 15.12. MySQL Cluster Glossary

The following terms are useful to an understanding of MySQL Cluster or have specialized meanings when used in relation to it.

- **Cluster:**

In its generic sense, a cluster is a set of computers functioning as a unit and working together to accomplish a single task.

- **NDB Cluster:**

This is the storage engine used in MySQL to implement data storage, retrieval, and management distributed among several computers.

- **MySQL Cluster:**

This refers to a group of computers working together using the NDB storage engine to support a distributed MySQL database in a *shared-nothing architecture* using *in-memory storage*.

- **Configuration files:**

Text files containing directives and information regarding the cluster, its hosts, and its nodes. These are read by the cluster's management nodes when the cluster is started. See Section 15.4.4, “Configuration File”, for details.

- **Backup:**

A complete copy of all cluster data, transactions and logs, saved to disk or other long-term storage.

- **Restore:**

Returning the cluster to a previous state, as stored in a backup.

- **Checkpoint:**

Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to Cluster, it is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained:

- **Local Checkpoint (LCP):**

This is a checkpoint that is specific to a single node; however, LCP's take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

- **Global Checkpoint (GCP):**

A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

- **Cluster host:**

A computer making up part of a MySQL Cluster. A cluster has both a *physical* structure and a *logical* structure. Physically, the cluster consists of a number of computers, known as *cluster hosts* (or more simply as *hosts*. See also **Node** and **Node group** below.

- **Node:**

This refers to a logical or functional unit of MySQL Cluster, and is sometimes also referred to as a *cluster node*. In the context of MySQL Cluster, we use the term “node” to indicate a *process* rather than a physical component of the cluster. There are three node types required to implement a working MySQL Cluster:

- **Management (MGM) nodes:**

Manages the other nodes within the MySQL Cluster. It provides configuration data to the other nodes; starts and stops nodes; handles network partitioning; creates backups and restores from them, and so forth.

- **SQL (MySQL server) nodes:**

Instances of MySQL Server which serve as front ends to data kept in the cluster's **data nodes**. Clients desiring to store, retrieve, or update data can access an SQL node just as they would any other MySQL Server, employing the usual authentication methods and APIs; the underlying distribution of data between node groups is transparent to users and applications. SQL nodes access the cluster's databases as a whole without regard to the data's distribution across different data nodes or cluster hosts.

- **Data nodes:**

These nodes store the actual data. Table data fragments are stored in a set of node groups; each node group stores a different subset of the table data. Each of the nodes making up a node group stores a replica of the fragment for which that node group is responsible. Currently, a single cluster can support up to 48 data nodes total.

It is possible for more than one node to co-exist on a single machine. (In fact, it is even possible to set up a complete cluster on one machine, although one would almost certainly *not* want to do this in a production environment.) It may be helpful to remember that, when working with MySQL Cluster, the term *host* refers to a physical component of the cluster whereas a *node* is a logical or functional component (that is, a process).

**Note Regarding Terms:** In older versions of the MySQL Cluster documentation, data nodes were sometimes referred to as “database nodes” or “data nodes”. The term “storage nodes” has also been used. In addition, SQL nodes were sometimes known as “client nodes” or “API nodes”. This older terminology has been deprecated to minimize confusion, and for these reasons should be avoided.

- **Node group:**

A set of data nodes. All data nodes in a node group contain the same data (fragments), and all nodes in a single group should reside on different hosts. It is possible to control which nodes belong to which node groups.

- **Node failure:**

MySQL Cluster is not solely dependent upon the functioning of any single node making up the cluster; the cluster can continue to run if one or more nodes fail. The precise number of node failures that a given cluster can tolerate depends upon the number of nodes and the cluster's con-

figuration.

- **Node restart:**

The process of restarting a failed cluster node.

- **Initial node restart:**

The process of starting a cluster node with its filesystem removed. This is sometimes used in the course of software upgrades and in other special circumstances.

- **System crash (or system failure):**

This can occur when so many cluster nodes have failed that the cluster's state can no longer be guaranteed.

- **System restart:**

The process of restarting the cluster and reinitializing its state from disk logs and checkpoints. This is required after either a planned or an unplanned shutdown of the cluster.

- **Fragment:**

A portion of a database table; in the NDB storage engine, a table is broken up into and stored as a number of fragments. A fragment is sometimes also called a “partition”; however, “fragment” is the preferred term. Tables are fragmented in MySQL Cluster in order to facilitate load balancing between machines and nodes.

- **Replica:**

Under the NDB storage engine, each table fragment has number of replicas stored on other data nodes in order to provide redundancy. Currently, there may be up four replicas per fragment.

- **Transporter:**

A protocol providing data transfer between nodes. MySQL Cluster currently supports four different types of transporter connections:

- TCP/IP

This is, of course, the familiar network protocol that underlies HTTP, FTP (and so on) on the Internet. TCP/IP can be used for both local and remote connections.

- SCI

Scalable Coherent Interface is a high-speed protocol used in building multiprocessor systems and parallel-processing applications. Use of SCI with MySQL Cluster requires specialized hardware, as discussed in Section 15.8.1, “Configuring MySQL Cluster to use SCI Sockets”. For a basic introduction to SCI, see this essay at [dolphinics.com](http://www.dolphinics.com/corporate/scitech.html) [<http://www.dolphinics.com/corporate/scitech.html>].

- SHM

Unix-style **shared memory** segments. Where supported, SHM is used automatically to connect nodes running on the same host. The Unix man page for `shmop(2)` [<http://www.scit.wlv.ac.uk/cgi-bin/mansec?2+shmop>] is a good place to begin obtaining additional information about this topic.

**Note:** The cluster transporter is internal to the cluster. Applications using MySQL Cluster communicate with SQL nodes just as they do with any other version of MySQL Server (via TCP/IP, or through the use of Unix socket files or Windows named pipes). Queries can be sent and results retrieved using the standard MySQL client APIs.

- **NDB:**

This stands for **N**etwork **D**atabase, and refers to the storage engine used to enable MySQL Cluster. The NDB storage engine supports all the usual MySQL data types and SQL statements, and is ACID-compliant. This engine also provides full support for transactions (commits and rollbacks).

- **shared-nothing architecture:**

The ideal architecture for a MySQL Cluster. In a true shared-nothing setup, each node runs on a separate host. The advantage such an arrangement is that there no single host or node can act as single point of failure or as a performance bottle neck for the system as a whole.

- **In-memory storage:**

All data stored in each data node is kept in memory on the node's host computer. For each data node in the cluster, you must have available an amount of RAM equal to the size of the database times the number of replicas, divided by the number of data nodes. Thus, if the database takes up 1GB of memory, and you want to set up the cluster with four replicas and eight data nodes, a minimum of 500MB memory will be required per node. Note that this is in addition to any requirements for the operating system and any other applications that might be running on the host.

- **Table:**

As is usual in the context of a relational database, the term “table” denotes a set of identically structured records. In MySQL Cluster, a database table is stored in a data node as a set of fragments, each of which is replicated on additional data nodes. The set of data nodes replicating the same fragment or set of fragments is referred to as a *node group*.

- **Cluster programs:**

These are command-line programs used in running, configuring, and administering MySQL Cluster. They include both server daemons:

- `ndbd`:

The data node daemon (runs a data node process)

- `ndb_mgmd`:

The management server daemon (runs a management server process)

and client programs:

- `ndb_mgm`:

The management client (provides an interface for executing management commands)

- `ndb_waiter`:

Used to verify status of all nodes in a cluster

- `ndb_restore`:

Restores cluster data from backup

For more about these programs and their uses, see Section 15.5, “Process Management in MySQL Cluster”.

- **Event log:**

MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 15.7.3,

“Event Reports Generated in MySQL Cluster”. Event logs are of two types:

- **Cluster log:**

Keeps a record of all desired reportable events for the cluster as a whole.

- **Node log:**

A separate log which is also kept for each individual node.

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

---

# Chapter 16. Spatial Extensions

MySQL supports spatial extensions to allow the generation, storage, and analysis of geographic features. Before MySQL 5.0.16, these features are available for MyISAM tables only. As of MySQL 5.0.16, InnoDB, NDB, BDB, and ARCHIVE also support spatial features. (However, the ARCHIVE engine does not support indexing, so spatial columns in ARCHIVE columns cannot be indexed. MySQL Cluster also does not support indexing of spatial columns.)

Although spatial extensions are supported in InnoDB tables, use of spatial indexes may cause a crash. (Bug#15860 [<http://bugs.mysql.com/15860>])

This chapter covers the following topics:

- The basis of these spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

## Additional resources

- The Open Geospatial Consortium publishes the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>.
- If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: <http://forums.mysql.com/list.php?23>.

## 16.1. Introduction to MySQL Spatial Support

MySQL implements spatial extensions following the specification of the Open Geospatial Consortium (OGC). This is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data. The OGC maintains a Web site at <http://www.opengis.org/>.

In 1997, the Open Geospatial Consortium published the *OpenGIS® Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at <http://www.opengis.org/docs/99-049.pdf>. It contains additional information relevant to this chapter.

MySQL implements a subset of the **SQL with Geometry Types** environment proposed by OGC. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describe a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.

- A space. For example, a postcode area, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term **geospatial feature** to refer to geographic features.

**Geometry** is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

This chapter uses all of these terms synonymously: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. Here, the term most commonly used is **geometry**, defined as *a point or an aggregate of points representing anything in the world that has a location*.

## 16.2. The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a Spatial Reference System, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

### 16.2.1. The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- Geometry (non-instantiable)
  - Point (instantiable)
  - Curve (non-instantiable)
    - LineString (instantiable)
      - Line
      - LinearRing
  - Surface (non-instantiable)
    - Polygon (instantiable)
  - GeometryCollection (instantiable)
    - MultiPoint (instantiable)
    - MultiCurve (non-instantiable)
      - MultiLineString (instantiable)
    - MultiSurface (non-instantiable)
      - MultiPolygon (instantiable)

It is not possible to create objects in non-instantiable classes. It is possible to create objects in in-

stantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

Geometry is the base class. It is an abstract class. The instantiable subclasses of Geometry are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base Geometry class has subclasses for Point, Curve, Surface, and GeometryCollection:

- Point represents zero-dimensional objects.
- Curve represents one-dimensional objects, and has subclass LineString, with subclasses Line and LinearRing.
- Surface is designed for two-dimensional objects and has subclass Polygon.
- GeometryCollection has specialized zero-, one-, and two-dimensional collection classes named MultiPoint, MultiLineString, and MultiPolygon for modeling geometries corresponding to collections of Points, LineStrings, and Polygons, respectively. MultiCurve and MultiSurface are introduced as abstract superclasses that generalize the collection interfaces to handle Curves and Surfaces.

Geometry, Curve, Surface, MultiCurve, and MultiSurface are defined as non-instantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

Point, LineString, Polygon, GeometryCollection, MultiPoint, MultiLineString, and MultiPolygon are instantiable classes.

## 16.2.2. Class Geometry

Geometry is the root class of the hierarchy. It is a non-instantiable class but has a number of properties that are common to all geometry values created from any of the Geometry subclasses. These properties are described in the following list. Particular subclasses have their own specific properties, described later.

### Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.
- Its **SRID**, or Spatial Reference Identifier. This value identifies the geometry's associated Spatial Reference System that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

- Its **coordinates** in its Spatial Reference System, represented as double-precision (eight-byte) numbers. All non-empty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geocentric** system (coordinates on the Earth's surface) are different things.

- Its **interior**, **boundary**, and **exterior**.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (Minimum Bounding Rectangle), or Envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **non-simple**. Geometry values of types (`LineString`, `MultiPoint`, `MultiLineString`) are either simple or non-simple. Each type determines its own assertions for being simple or non-simple.
- Whether the value is **closed** or **not closed**. Geometry values of types (`LineString`, `MultiString`) are either closed or not closed. Each type determines its own assertions for being closed or not closed.
- Whether the value is **empty** or **non-empty**. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a `NULL` value). An empty geometry is defined to be always simple and has an area of 0.
- Its **dimension**. A geometry can have a dimension of -1, 0, 1, or 2:
  - -1 for an empty geometry.
  - 0 for a geometry with no length and no area.
  - 1 for a geometry with non-zero length and zero area.
  - 2 for a geometry with non-zero area.

`Point` objects have a dimension of zero. `LineString` objects have a dimension of 1. `Polygon` objects have a dimension of 2. The dimensions of `MultiPoint`, `MultiLineString`, and `MultiPolygon` objects are the same as the dimensions of the elements they consist of.

### 16.2.3. Class Point

A `Point` is a geometry that represents a single location in coordinate space.

#### Point Examples

- Imagine a large-scale map of the world with many cities. A `Point` object could represent each city.
- On a city map, a `Point` object could represent a bus stop.

#### Point Properties

- X-coordinate value.
- Y-coordinate value.
- `Point` is defined as a zero-dimensional geometry.
- The boundary of a `Point` is the empty set.

## 16.2.4. Class Curve

A `Curve` is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of `Curve` define the type of interpolation between points. `Curve` is a non-instantiable class.

### Curve Properties

- A `Curve` has the coordinates of its points.
- A `Curve` is defined as a one-dimensional geometry.
- A `Curve` is simple if it does not pass through the same point twice.
- A `Curve` is closed if its start point is equal to its endpoint.
- The boundary of a closed `Curve` is empty.
- The boundary of a non-closed `Curve` consists of its two endpoints.
- A `Curve` that is simple and closed is a `LinearRing`.

## 16.2.5. Class LineString

A `LineString` is a `Curve` with linear interpolation between points.

### LineString Examples

- On a world map, `LineString` objects could represent rivers.
- In a city map, `LineString` objects could represent streets.

### LineString Properties

- A `LineString` has coordinates of segments, defined by each consecutive pair of points.
- A `LineString` is a `Line` if it consists of exactly two points.
- A `LineString` is a `LinearRing` if it is both closed and simple.

## 16.2.6. Class Surface

A `Surface` is a two-dimensional geometry. It is a non-instantiable class. Its only instantiable subclass is `Polygon`.

### Surface Properties

- A `Surface` is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple `Surface` as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple `Surface` is the set of closed curves corresponding to its exterior and interior boundaries.

## 16.2.7. Class Polygon

A `Polygon` is a planar `Surface` representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the `Polygon`.

### Polygon Examples

- On a region map, `Polygon` objects could represent forests, districts, and so on.

### Polygon Assertions

- The boundary of a `Polygon` consists of a set of `LinearRing` objects (that is, `LineString` objects that are both simple and closed) that make up its exterior and interior boundaries.
- A `Polygon` has no rings that cross. The rings in the boundary of a `Polygon` may intersect at a `Point`, but only as a tangent.
- A `Polygon` has no lines, spikes, or punctures.
- A `Polygon` has an interior that is a connected point set.
- A `Polygon` may have holes. The exterior of a `Polygon` with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a `Polygon` a simple geometry.

## 16.2.8. Class GeometryCollection

A `GeometryCollection` is a geometry that is a collection of one or more geometries of any class.

All the elements in a `GeometryCollection` must be in the same `Spatial Reference System` (that is, in the same coordinate system). There are no other constraints on the elements of a `GeometryCollection`, although the subclasses of `GeometryCollection` described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a `MultiPoint` may contain only `Point` elements)
- Dimension
- Constraints on the degree of spatial overlap between elements

## 16.2.9. Class MultiPoint

A `MultiPoint` is a geometry collection composed of `Point` elements. The points are not connected or ordered in any way.

### MultiPoint Examples

- On a world map, a `MultiPoint` could represent a chain of small islands.
- On a city map, a `MultiPoint` could represent the outlets for a ticket office.

### MultiPoint Properties

- A `MultiPoint` is a zero-dimensional geometry.
- A `MultiPoint` is simple if no two of its `Point` values are equal (have identical coordinate values).
- The boundary of a `MultiPoint` is the empty set.

## 16.2.10. Class `MultiCurve`

A `MultiCurve` is a geometry collection composed of `Curve` elements. `MultiCurve` is a non-instantiable class.

### **MultiCurve Properties**

- A `MultiCurve` is a one-dimensional geometry.
- A `MultiCurve` is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A `MultiCurve` boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a `MultiCurve` if it is in the boundaries of an odd number of `MultiCurve` elements.
- A `MultiCurve` is closed if all of its elements are closed.
- The boundary of a closed `MultiCurve` is always empty.

## 16.2.11. Class `MultiLineString`

A `MultiLineString` is a `MultiCurve` geometry collection composed of `LineString` elements.

### **MultiLineString Examples**

- On a region map, a `MultiLineString` could represent a river system or a highway system.

## 16.2.12. Class `MultiSurface`

A `MultiSurface` is a geometry collection composed of surface elements. `MultiSurface` is a non-instantiable class. Its only instantiable subclass is `MultiPolygon`.

### **MultiSurface Assertions**

- Two `MultiSurface` surfaces have no interiors that intersect.
- Two `MultiSurface` elements have boundaries that intersect at most at a finite number of points.

## 16.2.13. Class `MultiPolygon`

A `MultiPolygon` is a `MultiSurface` object composed of `Polygon` elements.

### **MultiPolygon Examples**

- On a region map, a `MultiPolygon` could represent a system of lakes.

#### **MultiPolygon Assertions**

- A `MultiPolygon` has no two `Polygon` elements with interiors that intersect.
- A `MultiPolygon` has no two `Polygon` elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A `MultiPolygon` may not have cut lines, spikes, or punctures. A `MultiPolygon` is a regular, closed point set.
- A `MultiPolygon` that has more than one `Polygon` has an interior that is not connected. The number of connected components of the interior of a `MultiPolygon` is equal to the number of `Polygon` values in the `MultiPolygon`.

#### **MultiPolygon Properties**

- A `MultiPolygon` is a two-dimensional geometry.
- A `MultiPolygon` boundary is a set of closed curves (`LineString` values) corresponding to the boundaries of its `Polygon` elements.
- Each `Curve` in the boundary of the `MultiPolygon` is in the boundary of exactly one `Polygon` element.
- Every `Curve` in the boundary of an `Polygon` element is in the boundary of the `MultiPolygon`.

## 16.3. Supported Spatial Data Formats

This section describes the standard spatial data formats that are used to represent geometry objects in queries. They are:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format.

### 16.3.1. Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form.

Examples of WKT representations of geometry objects:

- A `Point`:  
`POINT(15 20)`

Note that point coordinates are specified with no separating comma.

- A `LineString` with four points:

```
LINESTRING(0 0, 10 10, 20 25, 50 60)
```

Note that point coordinate pairs are separated by commas.

- A `Polygon` with one exterior ring and one interior ring:

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
```

- A `MultiPoint` with three `Point` values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

- A `MultiLineString` with two `LineString` values:

```
MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
```

- A `MultiPolygon` with two `Polygon` values:

```
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
```

- A `GeometryCollection` consisting of two `Point` values and one `LineString`:

```
GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))
```

A Backus-Naur grammar that specifies the formal production rules for writing WKT values can be found in the OpenGIS specification document referenced near the beginning of this chapter.

## 16.3.2. Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation for geometric values is defined by the OpenGIS specification. It is also defined in the ISO *SQL/MM Part 3: Spatial* standard.

WKB is used to exchange geometry data as binary streams represented by BLOB values containing geometric WKB information.

WKB uses one-byte unsigned integers, four-byte unsigned integers, and eight-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 1)` consists of this sequence of 21 bytes (each represented here by two hex digits):

```
010100000000000000000000F03F000000000000F03F
```

The sequence may be broken down into these components:

```
Byte order : 01
WKB type   : 01000000
X          : 000000000000F03F
Y          : 000000000000F03F
```

Component representation is as follows:

- The byte order may be either 0 or 1 to indicate little-endian or big-endian storage. The little-

endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.

- The WKB type is a code that indicates the geometry type. Values from 1 through 7 indicate Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, and GeometryCollection.
- A Point value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values are represented by more complex data structures, as detailed in the OpenGIS specification.

## 16.4. Creating a Spatially Enabled MySQL Database

This section describes the data types you can use for representing spatial data in MySQL, and the functions available for creating and retrieving spatial values.

### 16.4.1. MySQL Spatial Data Types

MySQL has data types that correspond to OpenGIS classes. Some of these types hold single geometry values:

- GEOMETRY
- POINT
- LINESTRING
- POLYGON

GEOMETRY can store geometry values of any type. The other single-value types (POINT, LINESTRING, and POLYGON) restrict their values to a particular geometry type.

The other data types hold collections of values:

- MULTIPOINT
- MULTILINESTRING
- MULTIPOLYGON
- GEOMETRYCOLLECTION

GEOMETRYCOLLECTION can store a collection of objects of any type. The other collection types (MULTIPOINT, MULTILINESTRING, MULTIPOLYGON, and GEOMETRYCOLLECTION) restrict collection members to those having a particular geometry type.

### 16.4.2. Creating Spatial Values

This section describes how to create spatial values using Well-Known Text and Well-Known Binary functions that are defined in the OpenGIS standard, and using MySQL-specific functions.

#### 16.4.2.1. Creating Geometry Values Using WKT Functions

MySQL provides a number of functions that take as input parameters a Well-Known Text representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromText()` accepts a WKT of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromText(wkt[,srid])`,  
`GeometryCollectionFromText(wkt[,srid])`  
Constructs a `GEOMETRYCOLLECTION` value using its WKT representation and SRID.
- `GeomFromText(wkt[,srid])`, `GeometryFromText(wkt[,srid])`  
Constructs a geometry value of any type using its WKT representation and SRID.
- `LineFromText(wkt[,srid])`, `LineStringFromText(wkt[,srid])`  
Constructs a `LINESTRING` value using its WKT representation and SRID.
- `MLineFromText(wkt[,srid])`, `MultiLineStringFromText(wkt[,srid])`  
Constructs a `MULTILINESTRING` value using its WKT representation and SRID.
- `MPointFromText(wkt[,srid])`, `MultiPointFromText(wkt[,srid])`  
Constructs a `MULTIPOINT` value using its WKT representation and SRID.
- `MPolyFromText(wkt[,srid])`, `MultiPolygonFromText(wkt[,srid])`  
Constructs a `MULTIPOLYGON` value using its WKT representation and SRID.
- `PointFromText(wkt[,srid])`  
Constructs a `POINT` value using its WKT representation and SRID.
- `PolyFromText(wkt[,srid])`, `PolygonFromText(wkt[,srid])`  
Constructs a `POLYGON` value using its WKT representation and SRID.

The OpenGIS specification also defines the following optional functions, which MySQL does not implement. These functions construct `Polygon` or `MultiPolygon` values based on the WKT representation of a collection of rings or closed `LineString` values. These values may intersect.

- `BdMPolyFromText(wkt,srid)`  
Constructs a `MultiPolygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.
- `BdPolyFromText(wkt,srid)`  
Constructs a `Polygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

## 16.4.2.2. Creating Geometry Values Using WKB Functions

MySQL provides a number of functions that take as input parameters a BLOB containing a Well-Known Binary representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromWKB()` accepts a WKB of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromWKB(wkb[,srid]),`  
`GeometryCollectionFromWKB(wkb[,srid])`  
Constructs a `GEOMETRYCOLLECTION` value using its WKB representation and SRID.
- `GeomFromWKB(wkb[,srid]),` `GeometryFromWKB(wkb[,srid])`  
Constructs a geometry value of any type using its WKB representation and SRID.
- `LineFromWKB(wkb[,srid]),` `LineStringFromWKB(wkb[,srid])`  
Constructs a `LINestring` value using its WKB representation and SRID.
- `MLineFromWKB(wkb[,srid]),` `MultiLineStringFromWKB(wkb[,srid])`  
Constructs a `MULTILINestring` value using its WKB representation and SRID.
- `MPointFromWKB(wkb[,srid]),` `MultiPointFromWKB(wkb[,srid])`  
Constructs a `MULTIPOINT` value using its WKB representation and SRID.
- `MPolyFromWKB(wkb[,srid]),` `MultiPolygonFromWKB(wkb[,srid])`  
Constructs a `MULTIPOLYGON` value using its WKB representation and SRID.
- `PointFromWKB(wkb[,srid])`  
Constructs a `POINT` value using its WKB representation and SRID.
- `PolyFromWKB(wkb[,srid]),` `PolygonFromWKB(wkb[,srid])`  
Constructs a `POLYGON` value using its WKB representation and SRID.

The OpenGIS specification also describes optional functions for constructing `Polygon` or `MultiPolygon` values based on the WKB representation of a collection of rings or closed `LineString` values. These values may intersect. MySQL does not implement these functions:

- `BdMPolyFromWKB(wkb,srid)`  
Constructs a `MultiPolygon` value from a `MultiLineString` value in WKB format containing an arbitrary collection of closed `LineString` values.
- `BdPolyFromWKB(wkb,srid)`  
Constructs a `Polygon` value from a `MultiLineString` value in WKB format containing an arbitrary collection of closed `LineString` values.

### 16.4.2.3. Creating Geometry Values Using MySQL-Specific Functions

MySQL provides a set of useful non-standard functions for creating geometry WKB representations. The functions described in this section are MySQL extensions to the OpenGIS specification. The results of these functions are BLOB values containing WKB representations of geometry values with no SRID. The results of these functions can be substituted as the first argument for any function in the `GeomFromWKB()` function family.

- `GeometryCollection(g1,g2,...)`  
Constructs a WKB `GeometryCollection`. If any argument is not a well-formed WKB representation of a geometry, the return value is `NULL`.
- `LineString(pt1,pt2,...)`  
Constructs a WKB `LineString` value from a number of WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is `NULL`. If the number of `Point` arguments is less than two, the return value is `NULL`.
- `MultiLineString(ls1,ls2,...)`  
Constructs a WKB `MultiLineString` value using WKB `LineString` arguments. If any argument is not a WKB `LineString`, the return value is `NULL`.
- `MultiPoint(pt1,pt2,...)`  
Constructs a WKB `MultiPoint` value using WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is `NULL`.
- `MultiPolygon(poly1,poly2,...)`  
Constructs a WKB `MultiPolygon` value from a set of WKB `Polygon` arguments. If any argument is not a WKB `Polygon`, the return value is `NULL`.
- `Point(x,y)`  
Constructs a WKB `Point` using its coordinates.
- `Polygon(ls1,ls2,...)`  
Constructs a WKB `Polygon` value from a number of WKB `LineString` arguments. If any argument does not represent the WKB of a `LinearRing` (that is, not a closed and simple `LineString`) the return value is `NULL`.

### 16.4.3. Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Currently, spatial columns are supported for `MyISAM`, `InnoDB`, `NDB`, `BDB`, and `ARCHIVE` tables. (Support for storage engines other than `MyISAM` was added in MySQL 5.0.16.) See also the annotations about spatial indexes under Section 16.6.1, “Creating Spatial Indexes”.

- Use the `CREATE TABLE` statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

- Use the `ALTER TABLE` statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;  
ALTER TABLE geom DROP pt;
```

### 16.4.4. Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from

either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values into internal geometry format:

- Perform the conversion directly in the INSERT statement:

```
INSERT INTO geom VALUES (GeomFromText('POINT(1 1)'));

SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (GeomFromText(@g));
```

- Perform the conversion prior to the INSERT:

```
SET @g = GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomFromText(@g));
```

The preceding examples all use `GeomFromText()` to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (PolygonFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomCollFromText(@g));
```

Note that if a client application program wants to use WKB representations of geometry values, it is responsible for sending correctly formed WKB in queries to the server. However, there are several ways of satisfying this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

```
mysql> INSERT INTO geom VALUES
-> (GeomFromWKB(0x010100000000000000000000F03F000000000000F03F));
```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of BLOB type:

```
INSERT INTO geom VALUES (GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string()` and include the result in a query string that is sent to the server. See Section 22.2.3.52, “`mysql_real_escape_string()`”.

## 16.4.5. Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them into WKT or WKB format.

- Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

- Fetching spatial data in WKT format:

The `AsText()` function converts a geometry from internal format into a WKT string.

```
SELECT AsText(g) FROM geom;
```

- Fetching spatial data in WKB format:

The `AsBinary()` function converts a geometry from internal format into a BLOB containing the WKB value.

```
SELECT AsBinary(g) FROM geom;
```

## 16.5. Analyzing Spatial Information

After populating spatial columns with values, you are ready to query and analyze them. MySQL provides a set of functions to perform various operations on spatial data. These functions can be grouped into four major categories according to the type of operation they perform:

- Functions that convert geometries between various formats
- Functions that provide access to qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

Spatial analysis functions can be used in many contexts, such as:

- Any interactive SQL program, such as `mysql` or MySQL Query Browser
- Application programs written in any language that supports a MySQL client API

### 16.5.1. Geometry Format Conversion Functions

MySQL supports the following functions for converting geometry values between internal format and either WKT or WKB format:

- `AsBinary(g)`

Converts a value in internal geometry format to its WKB representation and returns the binary result.

```
SELECT AsBinary(g) FROM geom;
```

- `AsText(g)`

Converts a value in internal geometry format to its WKT representation and returns the string result.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(GeomFromText(@g));
```

```
+-----+
| AsText(GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,2 2,3 3) |
+-----+
```

- `GeomFromText(wkt[, srid])`

Converts a string value from its WKT representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromText()` and `LineFromText()`. See Section 16.4.2.1, “Creating Geometry Values Using WKT Functions”.

- `GeomFromWKB(wkb[, srid])`

Converts a binary value from its WKB representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromWKB()` and `LineFromWKB()`. See Section 16.4.2.2, “Creating Geometry Values Using WKB Functions”.

## 16.5.2. Geometry Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return NULL if the argument is of an incorrect geometry type. For example, `Area()` returns NULL if the object type is neither `Polygon` nor `MultiPolygon`.

### 16.5.2.1. General Geometry Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- `Dimension(g)`

Returns the inherent dimension of the geometry value *g*. The result can be -1, 0, 1, or 2. The meaning of these values is given in Section 16.2.2, “Class Geometry”.

```
mysql> SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
```

```
+-----+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
```

+-----+

- `Envelope(g)`

Returns the Minimum Bounding Rectangle (MBR) for the geometry value *g*. The result is returned as a `Polygon` value.

The polygon is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT AsText(Envelope(GeomFromText('LineString(1 1,2 2)')));
+-----+
| AsText(Envelope(GeomFromText('LineString(1 1,2 2)'))) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

- `GeometryType(g)`

Returns as a string the name of the geometry type of which the geometry instance *g* is a member. The name corresponds to one of the instantiable `Geometry` subclasses.

```
mysql> SELECT GeometryType(GeomFromText('POINT(1 1)'));
+-----+
| GeometryType(GeomFromText('POINT(1 1)')) |
+-----+
| POINT |
+-----+
```

- `SRID(g)`

Returns an integer indicating the Spatial Reference System ID for the geometry value *g*.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

```
mysql> SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
+-----+
| SRID(GeomFromText('LineString(1 1,2 2)',101)) |
+-----+
| 101 |
+-----+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- `Boundary(g)`

Returns a geometry that is the closure of the combinatorial boundary of the geometry value *g*.

- `IsEmpty(g)`

Returns 1 if the geometry value *g* is the empty geometry, 0 if it is not empty, and -1 if the argument is NULL. If the geometry is empty, it represents the empty point set.

- `IsSimple(g)`

Currently, this function is a placeholder and should not be used. If implemented, its behavior

will be as described in the next paragraph.

Returns 1 if the geometry value  $g$  has no anomalous geometric points, such as self-intersection or self-tangency. `IsSimple()` returns 0 if the argument is not simple, and `-1` if it is `NULL`.

The description of each instantiable geometric class given earlier in the chapter includes the specific conditions that cause an instance of that class to be classified as not simple. (See Section 16.2.1, “The Geometry Class Hierarchy”.)

## 16.5.2.2. Point Functions

A `Point` consists of `X` and `Y` coordinates, which may be obtained using the following functions:

- `X( $p$ )`

Returns the `X`-coordinate value for the point  $p$  as a double-precision number.

```
mysql> SET @pt = 'Point(56.7 53.34)';
mysql> SELECT X(GeomFromText(@pt));
+-----+
| X(GeomFromText(@pt)) |
+-----+
|                    56.7 |
+-----+
```

- `Y( $p$ )`

Returns the `Y`-coordinate value for the point  $p$  as a double-precision number.

```
mysql> SET @pt = 'Point(56.7 53.34)';
mysql> SELECT Y(GeomFromText(@pt));
+-----+
| Y(GeomFromText(@pt)) |
+-----+
|                    53.34 |
+-----+
```

## 16.5.2.3. LineString Functions

A `LineString` consists of `Point` values. You can extract particular points of a `LineString`, count the number of points that it contains, or obtain its length.

- `EndPoint( $ls$ )`

Returns the `Point` that is the endpoint of the `LineString` value  $ls$ .

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(EndPoint(GeomFromText(@ls)));
+-----+
| AsText(EndPoint(GeomFromText(@ls))) |
+-----+
| POINT(3 3) |
+-----+
```

- `GLength( $ls$ )`

Returns as a double-precision number the length of the `LineString` value  $ls$  in its associated

spatial reference.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT GLength(GeomFromText(@ls));
+-----+
| GLength(GeomFromText(@ls)) |
+-----+
|                2.8284271247462 |
+-----+
```

GLength() is a non-standard name. It corresponds to the OpenGIS Length() function.

- NumPoints(*ls*)

Returns the number of Point objects in the LineString value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT NumPoints(GeomFromText(@ls));
+-----+
| NumPoints(GeomFromText(@ls)) |
+-----+
|                3 |
+-----+
```

- PointN(*ls*,*N*)

Returns the *N*-th Point in the LineString value *ls*. Points are numbered beginning with 1.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(PointN(GeomFromText(@ls),2));
+-----+
| AsText(PointN(GeomFromText(@ls),2)) |
+-----+
| POINT(2 2) |
+-----+
```

- StartPoint(*ls*)

Returns the Point that is the start point of the LineString value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(StartPoint(GeomFromText(@ls)));
+-----+
| AsText(StartPoint(GeomFromText(@ls))) |
+-----+
| POINT(1 1) |
+-----+
```

The OpenGIS specification also defines the following function, which MySQL does not implement:

- IsRing(*ls*)

Returns 1 if the LineString value *ls* is closed (that is, its StartPoint() and EndPoint() values are the same) and is simple (does not pass through the same point more than once). Returns 0 if *ls* is not a ring, and -1 if it is NULL.

## 16.5.2.4. MultiLineString Functions

- GLength(*mls*)

Returns as a double-precision number the length of the `MultiLineString` value `mIs`. The length of `mIs` is equal to the sum of the lengths of its elements.

```
mysql> SET @mIs = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT GLength(GeomFromText(@mIs));
+-----+
| GLength(GeomFromText(@mIs)) |
+-----+
|                4.2426406871193 |
+-----+
```

`GLength()` is a non-standard name. It corresponds to the OpenGIS `Length()` function.

- `IsClosed(mIs)`

Returns 1 if the `MultiLineString` value `mIs` is closed (that is, the `StartPoint()` and `EndPoint()` values are the same for each `LineString` in `mIs`). Returns 0 if `mIs` is not closed, and -1 if it is NULL.

```
mysql> SET @mIs = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT IsClosed(GeomFromText(@mIs));
+-----+
| IsClosed(GeomFromText(@mIs)) |
+-----+
|                0 |
+-----+
```

## 16.5.2.5. Polygon Functions

- `Area(poly)`

Returns as a double-precision number the area of the `Polygon` value `poly`, as measured in its spatial reference system.

```
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT Area(GeomFromText(@poly));
+-----+
| Area(GeomFromText(@poly)) |
+-----+
|                4 |
+-----+
```

- `ExteriorRing(poly)`

Returns the exterior ring of the `Polygon` value `poly` as a `LineString`.

```
mysql> SET @poly =
-> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(ExteriorRing(GeomFromText(@poly)));
+-----+
| AsText(ExteriorRing(GeomFromText(@poly))) |
+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0) |
+-----+
```

- `InteriorRingN(poly,N)`

Returns the `N`-th interior ring for the `Polygon` value `poly` as a `LineString`. Rings are numbered beginning with 1.

```
mysql> SET @poly =
      -> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
+-----+
| AsText(InteriorRingN(GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1) |
+-----+
```

- `NumInteriorRings(poly)`

Returns the number of interior rings in the `Polygon` value *poly*.

```
mysql> SET @poly =
      -> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT NumInteriorRings(GeomFromText(@poly));
+-----+
| NumInteriorRings(GeomFromText(@poly)) |
+-----+
|                                     1 |
+-----+
```

### 16.5.2.6. MultiPolygon Functions

- `Area(mpoly)`

Returns as a double-precision number the area of the `MultiPolygon` value *mpoly*, as measured in its spatial reference system.

```
mysql> SET @mpoly =
      -> 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT Area(GeomFromText(@mpoly));
+-----+
| Area(GeomFromText(@mpoly)) |
+-----+
|                             8 |
+-----+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- `Centroid(mpoly)`

Returns the mathematical centroid for the `MultiPolygon` value *mpoly* as a `Point`. The result is not guaranteed to be on the `MultiPolygon`.

- `PointOnSurface(mpoly)`

Returns a `Point` value that is guaranteed to be on the `MultiPolygon` value *mpoly*.

### 16.5.2.7. GeometryCollection Functions

- `GeometryN(gc, N)`

Returns the *N*-th geometry in the `GeometryCollection` value *gc*. Geometries are numbered beginning with 1.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT AsText(GeometryN(GeomFromText(@gc),1));
+-----+
| AsText(GeometryN(GeomFromText(@gc),1)) |
+-----+
| POINT(1 1) |
+-----+
```

- NumGeometries(*gc*)

Returns the number of geometries in the GeometryCollection value *gc*.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT NumGeometries(GeomFromText(@gc));
+-----+
| NumGeometries(GeomFromText(@gc)) |
+-----+
| 2 |
+-----+
```

## 16.5.3. Functions That Create New Geometries from Existing Ones

### 16.5.3.1. Geometry Functions That Produce New Geometries

Section 16.5.2, “Geometry Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- Envelope(*g*)
- StartPoint(*ls*)
- EndPoint(*ls*)
- PointN(*ls*,*N*)
- ExteriorRing(*poly*)
- InteriorRingN(*poly*,*N*)
- GeometryN(*gc*,*N*)

### 16.5.3.2. Spatial Operators

OpenGIS proposes a number of other functions that can produce geometries. They are designed to implement spatial operators.

These functions are not implemented in MySQL. They may appear in future releases.

- Buffer(*g*,*d*)

Returns a geometry that represents all points whose distance from the geometry value *g* is less than or equal to a distance of *d*.

- ConvexHull(*g*)

Returns a geometry that represents the convex hull of the geometry value  $g$ .

- `Difference( $g1, g2$ )`

Returns a geometry that represents the point set difference of the geometry value  $g1$  with  $g2$ .

- `Intersection( $g1, g2$ )`

Returns a geometry that represents the point set intersection of the geometry values  $g1$  with  $g2$ .

- `SymDifference( $g1, g2$ )`

Returns a geometry that represents the point set symmetric difference of the geometry value  $g1$  with  $g2$ .

- `Union( $g1, g2$ )`

Returns a geometry that represents the point set union of the geometry values  $g1$  and  $g2$ .

## 16.5.4. Functions for Testing Spatial Relations Between Geometric Objects

The functions described in these sections take two geometries as input parameters and return a qualitative or quantitative relation between them.

## 16.5.5. Relations on Geometry Minimal Bounding Rectangles (MBRs)

MySQL provides several functions that test relations between minimal bounding rectangles of two geometries  $g1$  and  $g2$ . The return values 1 and 0 indicate true and false, respectively.

- `MBRContains( $g1, g2$ )`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of  $g1$  contains the Minimum Bounding Rectangle of  $g2$ .

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRContains(@g2,@g1);
```

MBRContains(@g1,@g2)	MBRContains(@g2,@g1)
1	0

- `MBRDisjoint( $g1, g2$ )`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries  $g1$  and  $g2$  are disjoint (do not intersect).

- `MBREqual( $g1, g2$ )`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries  $g1$  and  $g2$  are the same.

- `MBRIntersects( $g1, g2$ )`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries  $g1$

and  $g2$  intersect.

- `MBROverlaps( $g1$ ,  $g2$ )`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries  $g1$  and  $g2$  overlap.

- `MBRTouches( $g1$ ,  $g2$ )`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries  $g1$  and  $g2$  touch.

- `MBRWithin( $g1$ ,  $g2$ )`

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of  $g1$  is within the Minimum Bounding Rectangle of  $g2$ .

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
```

MBRWithin(@g1,@g2)	MBRWithin(@g2,@g1)
1	0

## 16.5.6. Functions That Test Spatial Relationships Between Geometries

The OpenGIS specification defines the following functions. They test the relationship between two geometry values  $g1$  and  $g2$ .

Currently, MySQL does not implement these functions according to the specification. Those that are implemented return the same result as the corresponding MBR-based functions. This includes functions in the following list other than `Distance()` and `Related()`.

These functions may be implemented in future releases with full support for spatial analysis, not just MBR-based support.

The return values 1 and 0 indicate true and false, respectively.

- `Contains( $g1$ ,  $g2$ )`

Returns 1 or 0 to indicate whether  $g1$  completely contains  $g2$ .

- `Crosses( $g1$ ,  $g2$ )`

Returns 1 if  $g1$  spatially crosses  $g2$ . Returns NULL if  $g1$  is a `Polygon` or a `MultiPolygon`, or if  $g2$  is a `Point` or a `MultiPoint`. Otherwise, returns 0.

The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
- Their intersection is not equal to either of the two given geometries

- `Disjoint(g1, g2)`  
Returns 1 or 0 to indicate whether *g1* is spatially disjoint from (does not intersect) *g2*.
- `Distance(g1, g2)`  
Returns as a double-precision number the shortest distance between any two points in the two geometries.
- `Equals(g1, g2)`  
Returns 1 or 0 to indicate whether *g1* is spatially equal to *g2*.
- `Intersects(g1, g2)`  
Returns 1 or 0 to indicate whether *g1* spatially intersects *g2*.
- `Overlaps(g1, g2)`  
Returns 1 or 0 to indicate whether *g1* spatially overlaps *g2*. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.
- `Related(g1, g2, pattern_matrix)`  
Returns 1 or 0 to indicate whether the spatial relationship specified by *pattern\_matrix* exists between *g1* and *g2*. Returns -1 if the arguments are NULL. The pattern matrix is a string. Its specification will be noted here if this function is implemented.
- `Touches(g1, g2)`  
Returns 1 or 0 to indicate whether *g1* spatially touches *g2*. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.
- `Within(g1, g2)`  
Returns 1 or 0 to indicate whether *g1* is spatially within *g2*.

## 16.6. Optimizing Spatial Analysis

Search operations in non-spatial databases can be optimized using indexes. This is true for spatial databases as well. With the help of a great variety of multi-dimensional indexing methods that have previously been designed, it is possible to optimize spatial searches. The most typical of these are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** to index spatial columns. A spatial index is built using the MBR of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. Beginning with MySQL 5.0.16, you must declare a prefix for any (non-spatial) index on a spatial column except for POINT columns.

### 16.6.1. Creating Spatial Indexes

MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but extended with the `SPATIAL` keyword. Currently, spatial columns that are indexed must be declared `NOT NULL`. The following examples demonstrate how to create spatial indexes:

- With `CREATE TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
```

- With `ALTER TABLE`:

```
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With `CREATE INDEX`:

```
CREATE SPATIAL INDEX sp_index ON geom (g);
```

For MyISAM tables, `SPATIAL INDEX` creates an R-tree index. For other storage engines that support spatial indexing, `SPATIAL INDEX` creates a B-tree index. A B-tree index on spatial values will be useful for exact-value lookups, but not for range scans.

To drop spatial indexes, use `ALTER TABLE` or `DROP INDEX`:

- With `ALTER TABLE`:

```
ALTER TABLE geom DROP INDEX g;
```

- With `DROP INDEX`:

```
DROP INDEX sp_index ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
```

Field	Type	Null	Key	Default	Extra
fid	int(11)		PRI	NULL	auto_increment
g	geometry				

```
2 rows in set (0.00 sec)
```

```
mysql> SELECT COUNT(*) FROM geom;
```

count(*)
32376

```
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
```

```
Query OK, 32376 rows affected (4.05 sec)
Records: 32376 Duplicates: 0 Warnings: 0
```

## 16.6.2. Using a Spatial Index

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,31000 15000,31000 16000,30000 16000,30000 15000))'
mysql> SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g);
```

fid	AsText(g)
21	LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30 ...
22	LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8, ...
23	LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4, ...
24	LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4, ...
25	LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882. ...
26	LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4, ...
249	LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946. ...
1	LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ...
2	LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136, ...
3	LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ...
4	LINESTRING(30155.2 15121.4,30140.4 15118.6,30142 15109,30 ...
5	LINESTRING(30192.4 15085,30177.6 15082.2,30179.2 15072.4, ...
6	LINESTRING(30244 15087,30229 15086.2,30229.4 15076.4,3024 ...
7	LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ...
10	LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ...
11	LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ...
13	LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053,3011 ...
154	LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ...
155	LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ...
157	LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ...

20 rows in set (0.00 sec)

Use `EXPLAIN` to check the way this query is executed:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,31000 15000,31000 16000,30000 16000,30000 15000))'
mysql> EXPLAIN SELECT fid,AsText(g) FROM geom WHERE
-> MBRContains(GeomFromText(@poly),g)\G
```

```
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: range
possible_keys: g
         key: g
        key_len: 32
         ref: NULL
         rows: 50
      Extra: Using where
1 row in set (0.00 sec)
```

Check what would happen without a spatial index:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,31000 15000,31000 16000,30000 16000,30000 15000))'
mysql> EXPLAIN SELECT fid,AsText(g) FROM g IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g)\G
```

```
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: ALL
```

```
possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: 32376
  Extra: Using where
1 row in set (0.00 sec)
```

Executing the SELECT statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,31000 15000,31000 16000,30000 16000,30000 15000))'
mysql> SELECT fid,AsText(g) FROM geom IGNORE INDEX (g) WHERE
-> MBRContains(GeomFromText(@poly),g);
```

fid	AsText(g)
1	LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ...
2	LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136, ...
3	LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ...
4	LINESTRING(30155.2 15121.4,30140.4 15118.6,30142 15109,30 ...
5	LINESTRING(30192.4 15085,30177.6 15082.2,30179.2 15072.4, ...
6	LINESTRING(30244 15087,30229 15086.2,30229.4 15076.4,3024 ...
7	LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ...
10	LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ...
11	LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ...
13	LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053,3011 ...
21	LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30 ...
22	LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8, ...
23	LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4, ...
24	LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4, ...
25	LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882. ...
26	LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4, ...
154	LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ...
155	LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ...
157	LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ...
249	LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946. ...

20 rows in set (0.46 sec)

In future releases, spatial indexes may also be used for optimizing other functions. See Section 16.5.4, “Functions for Testing Spatial Relations Between Geometric Objects”.

## 16.7. MySQL Conformance and Compatibility

MySQL does not yet implement the following GIS features:

- Additional Metadata Views

OpenGIS specifications propose several additional metadata views. For example, a system view named `GEOMETRY_COLUMNS` contains a description of geometry columns, one row for each geometry column in the database.

- The OpenGIS function `Length()` on `LineString` and `MultiLineString` currently should be called in MySQL as `GLength()`

The problem is that there is an existing SQL function `Length()` that calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context. We need either to solve this somehow, or decide on another function name.

---

# Chapter 17. Stored Procedures and Functions

Stored routines (procedures and functions) are supported in MySQL 5.0. A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored procedure instead.

Some situations where stored routines can be particularly useful:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also allow you to have libraries of functions in the database server. This is a feature shared by modern application languages that allow such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2.

The MySQL implementation of stored routines is still in progress. All syntax described in this chapter is supported and any limitations and extensions are documented where appropriate. Further discussion of restrictions on use of stored routines is given in Section I.1, "Restrictions on Stored Routines and Triggers".

Binary logging for stored routines takes place as described in Section 17.4, "Binary Logging of Stored Routines and Triggers".

## 17.1. Stored Routines and the Grant Tables

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.0 installation procedure. If you are upgrading to MySQL 5.0 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See Section 5.6.2, "mysql\_upgrade — Check Tables for MySQL Upgrade".

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

Beginning with MySQL 5.0.3, the grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is gran-

ted automatically to the creator of a routine. Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

## 17.2. Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with `CREATE PROCEDURE` and `CREATE FUNCTION` statements. A procedure is invoked using a `CALL` statement, and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. Stored routines may call other stored routines.

As of MySQL 5.0.1, a stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are disallowed.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

(In MySQL 5.0.0, stored routines are global and not associated with a database. They inherit the default database from the caller. If a `USE db_name` is executed within the routine, the original default database is restored upon routine exit.)

MySQL supports the very useful extension that allows the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_STATEMENTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function (see Section 22.2.3.51, “`mysql_real_connect()`”).

The following sections describe the syntax used to create, alter, drop, and invoke stored procedures and functions.

### 17.2.1. CREATE PROCEDURE and CREATE FUNCTION Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  PROCEDURE sp_name ([proc_parameter[,...]])
  [characteristic ...] routine_body
```

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  FUNCTION sp_name ([func_parameter[,...]])
  RETURNS type
  [characteristic ...] routine_body
```

```
proc_parameter:
  [ IN | OUT | INOUT ] param_name type
```

```
func_parameter:
  param_name type
```

```

type:
    Any valid MySQL data type

characteristic:
    LANGUAGE SQL
    [NOT] DETERMINISTIC
    { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
    SQL SECURITY { DEFINER | INVOKER }
    COMMENT 'string'

routine_body:
    Valid SQL procedure statement
    
```

These statements create stored routines. As of MySQL 5.0.3, to use them, it is necessary to have the `CREATE ROUTINE` privilege. If binary logging is enabled, these statements might also require the `SUPER` privilege, as described in Section 17.4, “Binary Logging of Stored Routines and Triggers”. MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator.

By default, the routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

If the routine name is the same as the name of a built-in SQL function, you must use a space between the name and the following parenthesis when defining the routine, or a syntax error occurs. This is also true when you invoke the routine later. For this reason, we suggest that it is better to avoid re-using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always allowable to have spaces after a routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

**Note:** Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. (`FUNCTION` parameters are always regarded as `IN` parameters.)

Each parameter can be declared to use any valid data type, except that the `COLLATE` attribute cannot be used.

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement.

The `routine_body` consists of a valid SQL procedure statement. This can be a simple statement such as `SELECT` or `INSERT`, or it can be a compound statement written using `BEGIN` and `END`. Compound statement syntax is described in Section 17.2.5, “`BEGIN . . . END` Compound Statement Syntax”. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described later in this chapter. See, for example, Section 17.2.6, “`DECLARE` Statement Syntax”, and Section 17.2.10, “Flow Control Constructs”. Some statements are not allowed in stored routines; see Section I.1, “Restrictions on Stored Routines and Triggers”.

The `CREATE FUNCTION` statement was used in earlier versions of MySQL to support UDFs (user-defined functions). See Section 24.2, “Adding New Functions to MySQL”. UDFs continue to be supported, even with the existence of stored functions. A UDF can be regarded as an external stored function. However, do note that stored functions share their namespace with UDFs.

A procedure or function is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`.

For replication purposes, use of the `NOW()` function (or its synonyms) or `RAND()` does not neces-

sarily make a routine non-deterministic. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is invoked only once within a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Currently, the `DETERMINISTIC` characteristic is accepted, but not yet used by the optimizer. However, if binary logging is enabled, this characteristic affects which routine definitions MySQL accepts. See Section 17.4, “Binary Logging of Stored Routines and Triggers”.

Several characteristics provide information about the nature of data use by the routine. `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. `NO SQL` indicates that the routine contains no SQL statements. `READS SQL DATA` indicates that the routine contains statements that read data, but not statements that write data. `MODIFIES SQL DATA` indicates that the routine contains statements that may write data. `CONTAINS SQL` is the default if none of these characteristics is given explicitly. These characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be allowed to execute.

The `SQL SECURITY` characteristic can be used to specify whether the routine should be executed using the permissions of the user who creates the routine or the user who invokes it. The default value is `DEFINER`. This feature is new in SQL:2003. The creator or invoker must have permission to access the database with which the routine is associated. As of MySQL 5.0.3, it is necessary to have the `EXECUTE` privilege to be able to execute the routine. The user that must have this privilege is either the definer or invoker, depending on how the `SQL SECURITY` characteristic is set.

The optional `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic. The `DEFINER` clause was added in MySQL 5.0.20.

If a `user` value is given, it should be a MySQL account in `'user_name'@'host_name'` format (the same format used in the `GRANT` statement). The `user_name` and `host_name` values both are required. `CURRENT_USER` also can be given as `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` or statement. (This is the same as `DEFINER = CURRENT_USER`.)

If you specify the `DEFINER` clause, you cannot set the value to any account but your own unless you have the `SUPER` privilege. These rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

Although it is possible to create routines with a non-existent `DEFINER` value, an error occurs if the routine executes with definer privileges but the definer does not exist at execution time.

MySQL stores the `sql_mode` system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force.

When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are disallowed.

As of MySQL 5.0.18, the server uses the data type of a routine parameter or function return value as follows. These rules also apply to local routine variables created with the `DECLARE` statement (Section 17.2.7.1, “`DECLARE` Local Variables”).

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict mode.
- For character data types, if there is a `CHARACTER SET` clause in the declaration, the specified

character set and its default collation are used. If there is no such clause, the database character set and collation are used. (These are given by the values of the `character_set_database` and `collation_database` system variables.)

- Only scalar values can be assigned to parameters or variables. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.

Before MySQL 5.0.18, parameters, return values, and local variables are treated as items in expressions, and are subject to automatic (silent) conversion and truncation. Stored functions ignore the `sql_mode` setting.

The `COMMENT` clause is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

MySQL allows routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also allows stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that do explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to allow them.

Stored routines cannot use `LOAD DATA INFILE`.

Statements that return a result set cannot be used within a stored function. This includes `SELECT` statements that do not use `INTO` to fetch column values into variables, `SHOW` statements, and other statements such as `EXPLAIN`. For statements that can be determined at function definition time to return a result set, a Not allowed to return a result set from a function error occurs (`ER_SP_NO_RETSET_IN_FUNC`). For statements that can be determined only at runtime to return a result set, a PROCEDURE %s can't return a result set in the given context error occurs (`ER_SP_BADSELECT`).

**Note:** Before MySQL 5.0.10, stored functions created with `CREATE FUNCTION` must not contain references to tables, with limited exceptions. They may include some `SET` statements that contain table references, for example `SET a := (SELECT MAX(id) FROM t)`, and `SELECT` statements that fetch values directly into variables, for example `SELECT i INTO var1 FROM t`.

The following is an example of a simple stored procedure that uses an `OUT` parameter. The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This allows the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
->   SELECT COUNT(*) INTO param1 FROM t;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
+-----+
| @a    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

When using the `delimiter` command, you should avoid the use of the backslash (`\`) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20)) RETURNS CHAR(50)
      -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

A stored function returns a value of the data type specified in its `RETURNS` clause. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function returns an `ENUM` or `SET` value, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

## 17.2.2. ALTER PROCEDURE and ALTER FUNCTION Syntax

```
ALTER {PROCEDURE | FUNCTION} sp_name [characteristic ...]

characteristic:
  { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'
```

This statement can be used to change the characteristics of a stored procedure or function. As of MySQL 5.0.3, you must have the `ALTER ROUTINE` privilege for the routine. (That privilege is granted automatically to the routine creator.) If binary logging is enabled, this statement might also require the `SUPER` privilege, as described in Section 17.4, “Binary Logging of Stored Routines and Triggers”.

More than one change may be specified in an `ALTER PROCEDURE` or `ALTER FUNCTION` statement.

## 17.2.3. DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. As of MySQL 5.0.3, you must have the `ALTER ROUTINE` privilege for the routine. (That privilege is granted automatically to the routine creator.)

The `IF EXISTS` clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with `SHOW WARNINGS`.

## 17.2.4. CALL Statement Syntax

```
CALL sp_name([parameter[,...]])
```

The `CALL` statement invokes a procedure that was defined previously with `CREATE PROCEDURE`.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. It also “returns” the number of rows affected, which a client program can obtain at the SQL level by calling the `ROW_COUNT()` function and from C by calling the `mysql_affected_rows()` C API function.

## 17.2.5. BEGIN . . . END Compound Statement Syntax

```
[begin_label:] BEGIN
    [statement_list]
END [end_label]
```

`BEGIN . . . END` syntax is used for writing compound statements, which can appear within stored routines and triggers. A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. *statement\_list* represents a list of one or more statements. Each statement within *statement\_list* must be terminated by a semicolon (`;`) statement delimiter. Note that *statement\_list* is optional, which means that the empty compound statement (`BEGIN END`) is legal.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. This is handled in the `mysql` command-line client with the `delimiter` command. Changing the `;` end-of-statement delimiter (for example, to `//`) allows `;` to be used in a routine body. For an example, see Section 17.2.1, “`CREATE PROCEDURE` and `CREATE FUNCTION` Syntax”.

A compound statement can be labeled. *end\_label* cannot be given unless *begin\_label* also is present. If both are present, they must be the same.

The optional `[NOT] ATOMIC` clause is not yet supported. This means that no transactional save-point is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

## 17.2.6. DECLARE Statement Syntax

The `DECLARE` statement is used to define various items local to a routine:

- Local variables. See Section 17.2.7, “Variables in Stored Routines”.
- Conditions and handlers. See Section 17.2.8, “Conditions and Handlers”.
- Cursors. See Section 17.2.9, “Cursors”.

The `SIGNAL` and `RESIGNAL` statements are not currently supported.

`DECLARE` is allowed only inside a `BEGIN . . . END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

## 17.2.7. Variables in Stored Routines

You may declare and use variables within a routine.

### 17.2.7.1. DECLARE Local Variables

```
DECLARE var_name[,...] type [DEFAULT value]
```

This statement is used to declare local variables. To provide a default value for the variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like routine parameters with respect to data type and overflow checking. See Section 17.2.1, “`CREATE PROCEDURE` and `CREATE FUNCTION` Syntax”.

The scope of a local variable is within the `BEGIN . . . END` block where it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

### 17.2.7.2. Variable `SET` Statement

```
SET var_name = expr [, var_name = expr] ...
```

The `SET` statement in stored routines is an extended version of the general `SET` statement. Referenced variables may be ones declared inside a routine, or global system variables.

The `SET` statement in stored routines is implemented as part of the pre-existing `SET` syntax. This allows an extended syntax of `SET a=x, b=y, . . .` where different variable types (locally declared variables and global and session server variables) can be mixed. This also allows combinations of local variables and some options that make sense only for system variables; in that case, the options are recognized but ignored.

### 17.2.7.3. `SELECT . . . INTO` Statement

```
SELECT col_name[,...] INTO var_name[,...] table_expr
```

This `SELECT` syntax stores selected columns directly into variables. Therefore, only a single row may be retrieved.

```
SELECT id,data INTO x,y FROM test.t1 LIMIT 1;
```

User variable names are not case sensitive. See Section 9.3, “User-Defined Variables”.

**Important:** SQL variable names should not be the same as column names. If an SQL statement, such as a `SELECT . . . INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. For example, in the following statement, `xname` is interpreted as a reference to the `xname` *variable* rather than the `xname` *column*:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;

  SELECT xname,id INTO newname,xid
  FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

When this procedure is called, the `newname` variable returns the value `'bob'` regardless of the value of the `table1.xname` column.

See also Section I.1, “Restrictions on Stored Routines and Triggers”.

## 17.2.8. Conditions and Handlers

Certain conditions may require specific handling. These conditions can relate to errors, as well as to general flow control inside a routine.

### 17.2.8.1. DECLARE Conditions

```
DECLARE condition_name CONDITION FOR condition_value
```

```
condition_value:
    SQLSTATE [VALUE] sqlstate_value
    | mysql_error_code
```

This statement specifies conditions that need specific handling. It associates a name with a specified error condition. The name can subsequently be used in a `DECLARE HANDLER` statement. See Section 17.2.8.2, “`DECLARE HANDLERS`”.

A *condition\_value* can be an SQLSTATE value or a MySQL error code.

### 17.2.8.2. DECLARE Handlers

```
DECLARE handler_type HANDLER FOR condition_value[,...] statement
```

```
handler_type:
    CONTINUE
    | EXIT
    | UNDO

condition_value:
    SQLSTATE [VALUE] sqlstate_value
    | condition_name
    | SQLWARNING
    | NOT FOUND
    | SQLEXCEPTION
    | mysql_error_code
```

The `DECLARE ... HANDLER` statement specifies handlers that each may deal with one or more conditions. If one of these conditions occurs, the specified *statement* is executed. *statement* can be a simple statement (for example, `SET var_name = value`), or it can be a compound statement written using `BEGIN` and `END` (see Section 17.2.5, “`BEGIN ... END Compound Statement Syntax`”).

For a `CONTINUE` handler, execution of the current routine continues after execution of the handler statement. For an `EXIT` handler, execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. (This is true even if the condition occurs in an inner block.) The `UNDO` handler type statement is not yet supported.

If a condition occurs for which no handler has been declared, the default action is `EXIT`.

A *condition\_value* can be any of the following values:

- An SQLSTATE value or a MySQL error code.
- A condition name previously specified with `DECLARE ... CONDITION`. See Section 17.2.8.1, “`DECLARE Conditions`”.
- `SQLWARNING` is shorthand for all SQLSTATE codes that begin with 01.
- `NOT FOUND` is shorthand for all SQLSTATE codes that begin with 02.
- `SQLEXCEPTION` is shorthand for all SQLSTATE codes not caught by `SQLWARNING` or `NOT FOUND`.

Example:

```
mysql> CREATE TABLE test.t (s1 int,primary key (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
-> DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
-> SET @x = 1;
-> INSERT INTO test.t VALUES (1);
-> SET @x = 2;
-> INSERT INTO test.t VALUES (1);
-> SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo();//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

The example associates a handler with SQLSTATE 23000, which occurs for a duplicate-key error. Notice that @x is 3, which shows that MySQL executed to the end of the procedure. If the line `DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;` had not been present, MySQL would have taken the default path (EXIT) after the second INSERT failed due to the PRIMARY KEY constraint, and `SELECT @x` would have returned 2.

If you want to ignore a condition, you can declare a CONTINUE handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

## 17.2.9. Cursors

Simple cursors are supported inside stored procedures and functions. The syntax is as in embedded SQL. Cursors are currently asensitive, read-only, and non-scrolling. Asensitive means that the server may or may not make a copy of its result table.

Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT 0;
  DECLARE a CHAR(16);
  DECLARE b,c INT;
  DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
  DECLARE CONTINUE HANDLER FOR SQLSTATE '02000' SET done = 1;

  OPEN cur1;
  OPEN cur2;
```

```

REPEAT
  FETCH cur1 INTO a, b;
  FETCH cur2 INTO c;
  IF NOT done THEN
    IF b < c THEN
      INSERT INTO test.t3 VALUES (a,b);
    ELSE
      INSERT INTO test.t3 VALUES (a,c);
    END IF;
  END IF;
UNTIL done END REPEAT;

CLOSE cur1;
CLOSE cur2;
END

```

### 17.2.9.1. Declaring Cursors

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor. Multiple cursors may be declared in a routine, but each cursor in a given block must have a unique name.

The SELECT statement cannot have an INTO clause.

### 17.2.9.2. Cursor OPEN Statement

```
OPEN cursor_name
```

This statement opens a previously declared cursor.

### 17.2.9.3. Cursor FETCH Statement

```
FETCH cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row (if a row exists) using the specified open cursor, and advances the cursor pointer.

### 17.2.9.4. Cursor CLOSE Statement

```
CLOSE cursor_name
```

This statement closes a previously opened cursor.

If not closed explicitly, a cursor is closed at the end of the compound statement in which it was declared.

## 17.2.10. Flow Control Constructs

The IF, CASE, LOOP, WHILE, REPLACE ITERATE, and LEAVE constructs are fully implemented.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an IF statement might contain a WHILE loop, which itself contains a CASE statement.

FOR loops are not currently supported.

### 17.2.10.1. IF Statement

```
IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF
```

IF implements a basic conditional construct. If the *search\_condition* evaluates to true, the corresponding SQL statement list is executed. If no *search\_condition* matches, the statement list in the ELSE clause is executed. Each *statement\_list* consists of one or more statements.

**Note:** There is also an `IF()` function, which differs from the IF statement described here. See Section 12.2, “Control Flow Functions”.

### 17.2.10.2. CASE Statement

```
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

Or:

```
CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

The CASE statement for stored routines implements a complex conditional construct. If a *search\_condition* evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the ELSE clause is executed. Each *statement\_list* consists of one or more statements.

**Note:** The syntax of the CASE statement shown here for use inside stored routines differs slightly from that of the SQL CASE expression described in Section 12.2, “Control Flow Functions”. The CASE statement cannot have an ELSE NULL clause, and it is terminated with END CASE instead of END.

### 17.2.10.3. LOOP Statement

```
[begin_label:] LOOP
  statement_list
END LOOP [end_label]
```

LOOP implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements. The statements within the loop are repeated until the loop is exited; usually this is accomplished with a LEAVE statement.

A LOOP statement can be labeled. *end\_label* cannot be given unless *begin\_label* also is present. If both are present, they must be the same.

### 17.2.10.4. LEAVE Statement

```
LEAVE label
```

This statement is used to exit any labeled flow control construct. It can be used within BEGIN ... END or loop constructs (LOOP, REPEAT, WHILE).

### 17.2.10.5. ITERATE Statement

ITERATE *label*

ITERATE can appear only within LOOP, REPEAT, and WHILE statements. ITERATE means “do the loop again.”

Example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END
```

### 17.2.10.6. REPEAT Statement

```
[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a REPEAT statement is repeated until the *search\_condition* is true. Thus, a REPEAT always enters the loop at least once. *statement\_list* consists of one or more statements.

A REPEAT statement can be labeled. *end\_label* cannot be given unless *begin\_label* also is present. If both are present, they must be the same.

Example:

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

### 17.2.10.7. WHILE Statement

```
[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
```

The statement list within a WHILE statement is repeated as long as the *search\_condition* is

true. *statement\_list* consists of one or more statements.

A WHILE statement can be labeled. *end\_label* cannot be given unless *begin\_label* also is present. If both are present, they must be the same.

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
  DECLARE v1 INT DEFAULT 5;

  WHILE v1 > 0 DO
    ...
    SET v1 = v1 - 1;
  END WHILE;
END
```

## 17.3. Stored Procedures, Functions, Triggers, and Replication: Frequently Asked Questions

- Do MySQL 5.0 stored procedures and functions work with replication?

Yes, standard actions carried out in stored procedures and functions are replicated from a master MySQL server to a slave server. There are a few limitations that are described in detail in Section 17.4, “Binary Logging of Stored Routines and Triggers”.

- Are stored procedures and functions created on a master server replicated to a slave?

Yes, creation of stored procedures and functions carried out through normal DDL statements on a master server are replicated to a slave, so the objects will exist on both servers. ALTER and DROP statements for stored procedures and functions are also replicated.

- How are actions that take place inside stored procedures and functions replicated?

MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a slave server. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

- Are there special security requirements for using stored procedures and functions together with replication?

Yes. Because a slave server has authority to execute any statement read from a master's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

- Any user wishing to create stored functions must be granted the SUPER privilege.
- Alternatively, a DBA can set the `log_bin_trust_function_creators` system variable to 1, which enables anyone with the standard CREATE ROUTINE privilege to create stored functions.

Note: Before MySQL 5.0.16, these restrictions also apply to stored procedures and the system variable is named `log_bin_trust_routine_creators`.

- What limitations exist for replicating stored procedure and function actions?

Non-deterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot

be exactly reproduced, and therefore, random actions replicated to a slave will not mirror those performed on a master. Note that declaring stored functions to be `DETERMINISTIC` or setting the `log_bin_trust_function_creators` system variable to 0 will not allow random-valued operations to be invoked.

In addition, time-based actions cannot be reproduced on a slave because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, non-transactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a master may be partially updated from DML activity, but no updates are done to the slave because of the errors that occurred. A workaround is for a function's DML actions to be carried out with the `IGNORE` keyword so that updates on the master that cause errors are ignored and updates that do not cause errors are replicated to the slave.

- Do the preceding limitations affect MySQL's ability to do point-in-time recovery?

The same limitations that affect replication do affect point-in-time recovery.

- What will MySQL do to correct the aforementioned limitations?

A future release of MySQL is expected to feature a choice in how replication should be handled:

- Statement-based replication (current implementation).
- Row-level replication (that will solve all the limitations described earlier).

- Do triggers work with replication?

Triggers and replication in MySQL 5.0 work the same as in most other database engines: Actions carried out through triggers on a master are not replicated to a slave server. Instead, triggers that exist on tables that reside on a MySQL master server need to be created on the corresponding tables on any MySQL slave servers so that the triggers activate on the slaves as well as the master.

- How are actions carried out through triggers on a master replicated to a slave?

First, the triggers that exist on a master must be re-created on the slave server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table `EMP` that has an `AFTER` insert trigger, which exists on a master MySQL server. The same `EMP` table and `AFTER` insert trigger exist on the slave server as well. The replication flow would be:

1. An `INSERT` statement is made to `EMP`.
2. The `AFTER` trigger on `EMP` activates.
3. The `INSERT` statement is written to the binary log.
4. The replication slave picks up the `INSERT` statement to `EMP` and executes it.
5. The `AFTER` trigger on `EMP` that exists on the slave activates.

## 17.4. Binary Logging of Stored Routines and Triggers

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Section 6.2, “Replication Implementation Overview”.
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 5.10.2.2, “Using Backups for Recovery”.

This section describes the development of binary logging in MySQL 5.0 with respect to stored routines (procedures and functions) and triggers. The discussion first summarizes the changes that have taken place in the logging implementation, and then states the current conditions that the implementation places on the use of stored routines. Finally, implementation details are given that provide information about when and why various changes were made. These details show how several aspects of the current logging behavior were implemented in response to shortcomings identified in earlier versions.

In general, the issues described here result from the fact that binary logging occurs at the SQL statement level. A future MySQL release is expected to implement row-level binary logging, which specifies the changes to make to individual rows as a result of executing SQL statements.

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See Section 5.12.3, “The Binary Log”.) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The development of stored routine logging in MySQL 5.0 can be summarized as follows:

- Before MySQL 5.0.6: In the initial implementation of stored routine logging, statements that create stored routines and `CALL` statements are not logged. These omissions can cause problems for replication and data recovery.
- MySQL 5.0.6: Statements that create stored routines and `CALL` statements are logged. Stored function invocations are logged when they occur in statements that update data (because those statements are logged). However, function invocations are not logged when they occur in statements such as `SELECT` that do not change data, even if a data change occurs within a function itself; this can cause problems. Under some circumstances, functions and procedures can have different effects if executed at different times or on different (master and slave) machines, and thus can be unsafe for data recovery or replication. To handle this, measures are implemented to allow identification of safe routines and to prevent creation of unsafe routines except by users with sufficient privileges.
- MySQL 5.0.12: For stored functions, when a function invocation that changes data occurs within a non-logged statement such as `SELECT`, the server logs a `DO func_name()` statement that invokes the function so that the function gets executed during data recovery or replication to slave servers. For stored procedures, the server does not log `CALL` statements. Instead, it logs individual statements within a procedure that are executed as a result of a `CALL`. This eliminates problems that may occur when a procedure would follow a different execution path on a slave than on the master.
- MySQL 5.0.16: The procedure logging changes made in 5.0.12 allow the conditions on unsafe routines to be relaxed for stored procedures. Consequently, the user interface for controlling these conditions is revised to apply only to functions. Procedure creators are no longer bound by them.
- MySQL 5.0.17: Logging of stored functions as `DO func_name()` statements (per the changes made in 5.0.12) are logged as `SELECT func_name()` statements instead for better control over error checking.

As a consequence of the preceding changes, the following conditions currently apply to stored function creation when binary logging is enabled. These conditions do not apply to stored procedure cre-

ation.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required.
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication. Two sets of function characteristics apply here:
  - The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given, so you must specify `DETERMINISTIC` explicitly to declare that a function is deterministic.

Use of the `NOW()` function (or its synonyms) or `RAND()` does not necessarily make a function non-deterministic. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is invoked only once within a function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

`SYSDATE()` is not affected by the timestamps in the binary log, so it causes stored routines to be non-deterministic if statement-based logging is used. This does not occur if the server is started with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`.

- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, `DETERMINISTIC` or one of `NO SQL` and `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` contains no statements that produce non-deterministic results.

- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators` option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply and `SUPER` is not required for routine creation.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is non-deterministic (and does

not replicate). You should be careful about using such functions in triggers.

Triggers can update tables (as of MySQL 5.0.10), so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the `SUPER` privilege and `log_bin_trust_function_creators` is 0.

The rest of this section provides details on the development of stored routine logging. Some of these details give additional background on the rationale for the current logging-related conditions on stored routine use.

**Routine logging before MySQL 5.0.6:** Statements that create and use stored routines are not written to the binary log, but statements invoked within stored routines are logged. Suppose that you issue the following statements:

```
CREATE PROCEDURE mysp INSERT INTO t VALUES(1);
CALL mysp();
```

For this example, only the `INSERT` statement appears in the binary log. The `CREATE PROCEDURE` and `CALL` statements do not appear. The absence of routine-related statements in the binary log means that stored routines are not replicated correctly. It also means that for a data recovery operation, re-executing events in the binary log does not recover stored routines.

**Routine logging changes in MySQL 5.0.6:** To address the absence of logging for stored routine creation and `CALL` statements (and the consequent replication and data recovery concerns), the characteristics of binary logging for stored routines were changed as described here. (Some of the items in the following list point out issues that are dealt with in later versions.)

- The server writes `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log. Also, the server logs `CALL` statements, not the statements executed within procedures. Suppose that you issue the following statements:

```
CREATE PROCEDURE mysp INSERT INTO t VALUES(1);
CALL mysp();
```

For this example, the `CREATE PROCEDURE` and `CALL` statements appear in the binary log, but the `INSERT` statement does not appear. This corrects the problem that occurred before MySQL 5.0.6 such that only the `INSERT` was logged.

- Logging `CALL` statements has a security implication for replication, which arises from two factors:
  - It is possible for a procedure to follow different execution paths on master and slave servers.
  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a routine, the user can write a routine containing a dangerous statement that will execute only on the slave where the statement is processed by the SQL thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe procedure `unsafe_sp()` as follows:

```
mysql> delimiter //
mysql> CREATE PROCEDURE unsafe_sp ()
-> BEGIN
-> IF @@server_id=2 THEN DROP DATABASE accounting; END IF;
-> END;
-> //
mysql> delimiter ;
mysql> CALL unsafe_sp();
```

The `CREATE PROCEDURE` and `CALL` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the `DROP DATABASE` statement that drops the `accounting` database. Thus, the `CALL` statement has different effects on the master and slave and is not replication-safe.

The preceding example uses a stored procedure, but similar problems can occur for stored functions that are invoked within statements that are written to the binary log: Function invocation has different effects on the master and slave.

To guard against this danger for servers that have binary logging enabled, MySQL 5.0.6 introduces the requirement that stored procedure and function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER PROCEDURE` or `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_routine_creators variable)
```

If you do not want to require routine creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_routine_creators` system variable to 1. You can also set this variable by using the `--log-bin-trust-routine-creators` option when starting the server. If binary logging is not enabled, `log_bin_trust_routine_creators` does not apply and `SUPER` is not required for routine creation.

- If a routine that performs updates is non-deterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
  - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a routine is refused unless you declare the routine to be deterministic or to not modify data. Two sets of routine characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a routine always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given, so you must specify `DETERMINISTIC` explicitly to declare that a routine is deterministic.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the routine reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a routine does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE PROCEDURE` or `CREATE FUNCTION` statement to be accepted, `DETERMINISTIC` or one of `NO SQL` and `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This routine has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_routine_creators
variable)
```

If you set `log_bin_trust_routine_creators` to 1, the requirement that routines be deterministic or not modify data is dropped.

- A `CALL` statement is written to the binary log if the routine returns no error, but not otherwise. When a routine that modifies data fails, you get this warning:

```
ERROR 1417 (HY000): A routine failed and has neither NO SQL nor
READS SQL DATA in its declaration and binary logging is enabled; if
non-transactional tables were updated, the binary log will miss their
changes
```

This logging behavior has the potential to cause problems. If a routine partly modifies a non-transactional table (such as a `MyISAM` table) and returns an error, the binary log will not reflect these changes. To protect against this, you should use transactional tables in the routine and modify the tables within transactions.

If you use the `IGNORE` keyword with `INSERT`, `DELETE`, or `UPDATE` to ignore errors within a routine, a partial update might occur but no error will result. Such statements are logged and they replicate normally.

- Although statements normally are not written to the binary log if they are rolled back, `CALL` statements are logged even when they occur within a rolled-back transaction. This can result in a `CALL` being rolled back on the master but executed on slaves.
- If a stored function is invoked within a statement such as `SELECT` that does not modify data, execution of the function is not written to the binary log, even if the function itself modifies data. This logging behavior has the potential to cause problems. Suppose that a function `myfunc()` is defined as follows:

```
CREATE FUNCTION myfunc () RETURNS INT DETERMINISTIC
BEGIN
    INSERT INTO t (i) VALUES(1);
    RETURN 0;
END;
```

Given that definition, the following statement is not written to the binary log because it is a `SELECT`. Nevertheless, it modifies the table `t` because `myfunc()` modifies `t`:

```
SELECT myfunc();
```

A workaround for this problem is to invoke functions that do updates only within statements that do updates (and which therefore are written to the binary log). Note that although the `DO` statement sometimes is executed for the side effect of evaluating an expression, `DO` is not a workaround here because it is not written to the binary log.

- On slave servers, `--replicate-*-table` rules do not apply to `CALL` statements or to statements within stored routines. These statements are always replicated. If such statements contain references to tables that do not exist on the slave, they could have undesirable effects when executed on the slave.

**Routine logging changes in MySQL 5.0.12:** The changes in 5.0.12 address several problems that were present in earlier versions:

- Stored function invocations in non-logged statements such as `SELECT` were not being logged, even when a function itself changed data.
- Stored procedure logging at the `CALL` level could cause different effects on a master and slave if a procedure took different execution paths on the two machines.
- `CALL` statements were logged even when they occurred within a rolled-back transaction.

To deal with these issues, MySQL 5.0.12 implements the following changes to function and proced-

ure logging:

- A stored function invocation is logged as a DO statement if the function changes data and occurs within a statement that would not otherwise be logged. This corrects the problem of non-replication of data changes that result from use of stored functions in non-logged statements. For example, SELECT statements are not written to the binary log, but a SELECT might invoke a stored function that makes changes. To handle this, a DO *func\_name*( ) statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1), (2), (3);

SELECT f1(a) FROM t1;
```

When the SELECT statement executes, the function *f1*( ) is invoked three times. Two of those invocations insert a row, and MySQL logs a DO statement for each of them. That is, MySQL writes the following statements to the binary log:

```
DO f1(1);
DO f1(2);
```

The server also logs a DO statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the DO statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

Note: See later in this section for changes made in MySQL 5.0.19: These logged DO *func\_name*( ) statements are logged as SELECT *func\_name*( ) statements instead.

- Stored procedure calls are logged at the statement level rather than at the CALL level. That is, the server does not log the CALL statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This eliminates the problems that could result from a procedure having different execution paths on different machines. For example, the DROP DATABASE problem shown earlier for the *unsafe\_sp*( ) procedure does not occur and the routine is no longer replication-unsafe because it has the same effect on master and slave servers.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in non-procedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

*var\_name* is the local variable name, and *var\_value* is a constant indicating the value that the variable has at the time the statement is logged. NAME\_CONST( ) has a value of *var\_value*, and a “name” of *var\_name*. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST( 'myname' , 14 );
+-----+
| myname |
+-----+
|      14 |
+-----+
```

NAME\_CONST( ) allows a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a SET statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable @my\_var, that statement will be preceded in the binary log by the following statement, where value is the value of @my\_var on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Previously, CALL statements were logged even if they occurred within a rolled-back transaction. As of MySQL 5.0.12, transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs BEGIN, COMMIT, and ROLLBACK statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, BEGIN and COMMIT statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
  - Updates to transactional tables are not logged.
  - Updates to non-transactional tables are logged because rollback does not cancel them.
  - Updates to a mix of transactional and non-transactional tables are logged surrounded by BEGIN and ROLLBACK so that slaves will make the same changes and rollbacks as on the master.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a DO statement (if it occurs within a statement that is not logged). For this reason, care still should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.
- Because procedure logging occurs at the statement level rather than at the CALL level, interpretation of the --replicate-\*-table options is revised to apply only to stored functions. They no longer apply to stored procedures, except those procedures that are invoked from within functions.

**Routine logging changes in MySQL 5.0.16:** In 5.0.12, a change was introduced to log stored procedure calls at the statement level rather than at the CALL level. This change eliminates the requirement that procedures be identified as safe. The requirement now exists only for stored functions, because they still appear in the binary log as function invocations rather than as the statements executed within the function. To reflect the lifting of the restriction on stored procedures, the log\_bin\_trust\_routine\_creators system variable is renamed to log\_bin\_trust\_function\_creators and the --log-bin-trust-routine-creators server option is renamed to --log-bin-trust-function-creators. (For backward compatibility, the old names are re-

cognized but result in a warning.) Error messages that now apply only to functions and not to routines in general are re-worded.

**Routine logging changes in MySQL 5.0.19:** In 5.0.12, a change was introduced to log a stored function invocation as `DO func_name()` if the invocation changes data and occurs within a non-logged statement, or if the function invokes a stored procedure that produces an error. In 5.0.19, these invocations are logged as `SELECT func_name()` instead. The change to `SELECT` was made because use of `DO` was found to yield insufficient control over error code checking.

---

# Chapter 18. Triggers

Support for triggers is included beginning with MySQL 5.0.2. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table. For example, the following statements create a table and an INSERT trigger. The trigger sums the values inserted into one of the table's columns:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

This chapter describes the syntax for creating and dropping triggers, and shows some examples of how to use them. Discussion of restrictions on use of triggers is given in Section I.1, "Restrictions on Stored Routines and Triggers". Remarks regarding binary logging as it applies to triggers are given in Section 17.4, "Binary Logging of Stored Routines and Triggers".

## 18.1. CREATE TRIGGER Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  TRIGGER trigger_name trigger_time trigger_event
  ON tbl_name FOR EACH ROW trigger_stmt
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. CREATE TRIGGER was added in MySQL 5.0.2. Currently, its use requires the SUPER privilege.

The trigger becomes associated with the table named *tbl\_name*, which must refer to a permanent table. You cannot associate a trigger with a TEMPORARY table or a view.

When the trigger is activated, the DEFINER clause determines the privileges that apply, as described later in this section.

*trigger\_time* is the trigger action time. It can be BEFORE or AFTER to indicate that the trigger activates before or after the statement that activated it.

*trigger\_event* indicates the kind of statement that activates the trigger. The *trigger\_event* can be one of the following:

- INSERT: The trigger is activated whenever a new row is inserted into the table; for example, through INSERT, LOAD DATA, and REPLACE statements.
- UPDATE: The trigger is activated whenever a row is modified; for example, through UPDATE statements.
- DELETE: The trigger is activated whenever a row is deleted from the table; for example, through DELETE and REPLACE statements. However, DROP TABLE and TRUNCATE statements on the table do *not* activate this trigger, because they do not use DELETE. See Section 13.2.9, "TRUNCATE Syntax".

It is important to understand that the *trigger\_event* does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an INSERT trigger is activated by not only INSERT statements but also LOAD DATA statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger will activate for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

There cannot be two triggers for a given table that have the same trigger action time and event. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

*trigger\_stmt* is the statement to execute when the trigger activates. If you want to execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are allowable within stored routines. See Section 17.2.5, “`BEGIN ... END` Compound Statement Syntax”. Some statements are not allowed in triggers; see Section I.1, “Restrictions on Stored Routines and Triggers”.

**Note:** Currently, triggers are not activated by cascaded foreign key actions. This limitation will be lifted as soon as possible.

**Note:** Before MySQL 5.0.10, triggers cannot contain direct references to tables by name. Beginning with MySQL 5.0.10, you can write triggers such as the one named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
  a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b4 INT DEFAULT 0
);

DELIMITER |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW BEGIN
  INSERT INTO test2 SET a2 = NEW.a1;
  DELETE FROM test3 WHERE a3 = NEW.a1;
  UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;
|

DELIMITER ;

INSERT INTO test3 (a3) VALUES
  (NULL), (NULL), (NULL), (NULL), (NULL),
  (NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
  (0), (0), (0), (0), (0), (0), (0), (0), (0), (0);
```

Suppose that you insert the following values into table `test1` as shown here:

```
mysql> INSERT INTO test1 VALUES
-> (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8 Duplicates: 0 Warnings: 0
```

As a result, the data in the four tables will be as follows:

```
mysql> SELECT * FROM test1;
+-----+
| a1    |
+-----+
|      1 |
|      3 |
```

```

      1 |
      7 |
      1 |
      8 |
      4 |
      4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+-----+
| a2 |
+-----+
      1 |
      3 |
      1 |
      7 |
      1 |
      8 |
      4 |
      4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+-----+
| a3 |
+-----+
      2 |
      5 |
      6 |
      9 |
     10 |
+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM test4;
+-----+-----+
| a4 | b4 |
+-----+-----+
      1 |    3 |
      2 |    0 |
      3 |    1 |
      4 |    2 |
      5 |    0 |
      6 |    0 |
      7 |    1 |
      8 |    1 |
      9 |    0 |
     10 |    0 |
+-----+-----+
10 rows in set (0.00 sec)

```

You can refer to columns in the subject table (the table associated with the trigger) by using the aliases OLD and NEW. OLD.col\_name refers to a column of an existing row before it is updated or deleted. NEW.col\_name refers to the column of a new row to be inserted or an existing row after it is updated.

The DEFINER clause specifies the MySQL account to be used when checking access privileges at trigger activation time. It was added in MySQL 5.0.17. If a user value is given, it should be a MySQL account in 'user\_name'@'host\_name' format (the same format used in the GRANT statement). The user\_name and host\_name values both are required. CURRENT\_USER also can be given as CURRENT\_USER(). The default DEFINER value is the user who executes the CREATE TRIGGER statement. (This is the same as DEFINER = CURRENT\_USER.)

If you specify the DEFINER clause, you cannot set the value to any account but your own unless you have the SUPER privilege. These rules determine the legal DEFINER user values:

- If you do not have the `SUPER` privilege, the only legal `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

Although it is possible to create triggers with a non-existent `DEFINER` value, it is not a good idea for such triggers to be activated until the definer actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

Note: Because MySQL currently requires the `SUPER` privilege for the use of `CREATE TRIGGER`, only the second of the preceding rules applies. (MySQL 5.1.6 implements the `TRIGGER` privilege and requires that privilege for trigger creation, so at that point both rules come into play and `SUPER` is required only for specifying a `DEFINER` value other than your own account.)

From MySQL 5.0.17 on, MySQL checks trigger privileges like this:

- At `CREATE TRIGGER` time, the user that issues the statement must have the `SUPER` privilege.
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
  - The `SUPER` privilege.
  - The `SELECT` privilege for the subject table if references to table columns occur via `OLD.col_name` or `NEW.col_name` in the trigger definition.
  - The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger definition.
  - Whatever other privileges normally are required for the statements executed by the trigger.

Before MySQL 5.0.17, MySQL checks trigger privileges like this:

- At `CREATE TRIGGER` time, the user that issues the statement must have the `SUPER` privilege.
- At trigger activation time, privileges are checked against the user whose actions cause the trigger to be activated. This user must have whatever privileges normally are required for the statements executed by the trigger.

Note that the introduction of the `DEFINER` clause changes the meaning of `CURRENT_USER()` within trigger definitions: The `CURRENT_USER()` function evaluates to the trigger `DEFINER` value as of MySQL 5.0.17 and to the user whose actions caused the trigger to be activated before 5.0.17.

## 18.2. DROP TRIGGER Syntax

```
DROP TRIGGER [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` was added in MySQL 5.0.2. Its use requires the `SUPER` privilege.

**Note:** Prior to MySQL 5.0.10, the table name was required instead of the schema name (`table_name.trigger_name`). When upgrading from a previous version of MySQL 5.0 to MySQL 5.0.10 or newer, you must drop all triggers *before upgrading* and re-create them afterwards,

or else `DROP TRIGGER` does not work after the upgrade. See Section 2.11.2, “Upgrading from MySQL 4.1 to 5.0”, for a suggested upgrade procedure.

In addition, triggers created in MySQL 5.0.16 or later cannot be dropped following a downgrade to MySQL 5.0.15 or earlier. If you wish to perform such a downgrade, you must also in this case drop all triggers *prior* to the downgrade, and then re-create them afterwards.

(For more information about these two issues, see Bug#15921 [<http://bugs.mysql.com/15921>] and Bug#18588 [<http://bugs.mysql.com/18588>].)

## 18.3. Using Triggers

Support for triggers is included beginning with MySQL 5.0.2. This section discusses how to use triggers and some limitations regarding their use. Additional information about trigger limitations is given in Section I.1, “Restrictions on Stored Routines and Triggers”.

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is associated with a table and is defined to activate when an `INSERT`, `DELETE`, or `UPDATE` statement for the table executes. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is deleted from a table or after each row that is updated.

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement. The syntax for these statements is described in Section 18.1, “`CREATE TRIGGER` Syntax”, and Section 18.2, “`DROP TRIGGER` Syntax”.

Here is a simple example that associates a trigger with a table for `INSERT` statements. It acts as an accumulator to sum the values inserted into one of the columns of the table.

The following statements create a table and a trigger for it:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other allowable keyword here is `AFTER`.
- The keyword `INSERT` indicates the event that activates the trigger. In the example, `INSERT` statements cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` statements.
- The statement following `FOR EACH ROW` defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement. In the example, the triggered statement is a simple `SET` that accumulates the values inserted into the amount column. The statement refers to the column as `NEW.amount` which means “the value of the amount column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
```

```

+-----+
| Total amount inserted |
+-----+
| 1852.48                |
+-----+

```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activation time and activation event. For example, you cannot define two `BEFORE INSERT` triggers or two `AFTER UPDATE` triggers for a table. This should rarely be a significant limitation, because it is possible to define a trigger that executes multiple statements by using the `BEGIN . . . END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

The `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. (`OLD` and `NEW` are not case sensitive.) In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read-only. You can refer to it (if you have the `SELECT` privilege), but not modify it. A column named with `NEW` can be referred to if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

`OLD` and `NEW` are MySQL extensions to triggers.

By using the `BEGIN . . . END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is allowed within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value needs to be checked before it is used to update the row:

```

mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
-> FOR EACH ROW
-> BEGIN
->     IF NEW.amount < 0 THEN
->         SET NEW.amount = 0;
->     ELSEIF NEW.amount > 100 THEN
->         SET NEW.amount = 100;
->     END IF;
-> END;//
mysql> delimiter ;

```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to invoke the same routine from within several triggers.

There are some limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are allowed to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`.
- Prior to MySQL 5.0.10, triggers cannot contain direct references to tables by name.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- An `AFTER` trigger is executed only if the `BEFORE` trigger (if any) and the row operation both execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a trigger (and thus the whole statement) should cause rollback of all changes performed by the statement. For non-transactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

---

# Chapter 19. Views

Views (including updatable views) are implemented in MySQL Server 5.0. Views are available in binary releases from 5.0.1 and up.

This chapter discusses the following topics:

- Creating or altering views with `CREATE VIEW` or `ALTER VIEW`
- Destroying views with `DROP VIEW`

Discussion of restrictions on use of views is given in Section I.4, “Restrictions on Views”.

To use views if you have upgraded to MySQL 5.0.1 from an older release, you should upgrade your grant tables so that they contain the view-related privileges. See Section 5.6.2, “mysql\_upgrade — Check Tables for MySQL Upgrade”.

Metadata about views can be obtained from the `INFORMATION_SCHEMA.VIEWS` table and by using the `SHOW CREATE VIEW` statement. See Section 20.15, “The `INFORMATION_SCHEMA.VIEWS` Table”, and Section 13.5.4.7, “`SHOW CREATE VIEW` Syntax”.

## 19.1. ALTER VIEW Syntax

```
ALTER
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = { user | CURRENT_USER }]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of an existing view. The syntax is similar to that for `CREATE VIEW`. See Section 19.2, “`CREATE VIEW` Syntax”. This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement.

This statement was added in MySQL 5.0.1. The `DEFINER` and `SQL SECURITY` clauses may be used as of MySQL 5.0.16 to specify the security context to be used when checking access privileges at view invocation time. For details, see Section 19.2, “`CREATE VIEW` Syntax”.

## 19.2. CREATE VIEW Syntax

```
CREATE
  [OR REPLACE]
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = { user | CURRENT_USER }]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement creates a new view, or replaces an existing one if the `OR REPLACE` clause is given. The *select\_statement* is a `SELECT` statement that provides the definition of the view. The statement can select from base tables or other views.

This statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement

you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, specify the name as `db_name.view_name` when you create it.

```
mysql> CREATE VIEW test.v AS SELECT * FROM t;
```

Base tables and views share the same namespace within a database, so a database cannot contain a base table and a view that have the same name.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, the optional `column_list` clause can be given as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

Columns retrieved by the `SELECT` statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Unqualified table or view names in the `SELECT` statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
```

qty	price	value
3	50	150

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system or user variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Within a stored routine, the definition cannot refer to routine parameters or local variables.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- The tables named in the view definition must already exist.
- You cannot associate a trigger with a view.

`ORDER BY` is allowed in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK` `IN SHARE MODE`, and `PROCEDURE`.

If you create a view and then change the query processing environment by changing system variables, that may affect the results that you get from the view:

```
mysql> CREATE VIEW v AS SELECT CHARSET(CHAR(65)), COLLATION(CHAR(65));
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SET NAMES 'latin1';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT * FROM v;
+-----+-----+
| CHARSET(CHAR(65)) | COLLATION(CHAR(65)) |
+-----+-----+
| latin1           | latin1_swedish_ci   |
+-----+-----+
1 row in set (0.00 sec)
```

```
mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT * FROM v;
+-----+-----+
| CHARSET(CHAR(65)) | COLLATION(CHAR(65)) |
+-----+-----+
| utf8             | utf8_general_ci     |
+-----+-----+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. They were added in MySQL 5.0.13, but have no effect until MySQL 5.0.16.

`CURRENT_USER` also can be given as `CURRENT_USER()`.

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine creator. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

The default `DEFINER` value is the user who executes the `CREATE VIEW` statement. (This is the same as `DEFINER = CURRENT_USER`.) If a *user* value is given, it should be a MySQL account in '*user\_name*'@'*host\_name*' format (the same format used in the `GRANT` statement). The *user\_name* and *host\_name* values both are required.

If you specify the `DEFINER` clause, you cannot set the value to any user but your own unless you have the `SUPER` privilege. These rules determine the legal `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only legal *user* value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SUPER` privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.

The `SQL SECURITY` characteristic determines which MySQL account to use when checking access privileges for the view when the view is executed. The legal characteristic values are `DEFINER` and `INVOKER`. These indicate that the view must be executable by the user who defined it or in-

voked it, respectively. The default `SQL SECURITY` value is `DEFINER`.

As of MySQL 5.0.16 (when the `DEFINER` and `SQL SECURITY` clauses were implemented), view privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required when the function runs can be checked only as it executes: For different invocations of the function, different execution paths within the function might be taken.
- At view execution time, privileges for objects accessed by the view are checked against the privileges held by the view creator or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.
- If view execution causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function is defined with a `SQL SECURITY` characteristic of `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges of its creator. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Prior to MySQL 5.0.16 (before the `DEFINER` and `SQL SECURITY` clauses were implemented), privileges required for objects used in a view are checked at view creation time.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges need to be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the function `f()` and the view `v`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY INVOKER`.

If you invoke a view that was created before MySQL 5.0.13, it is treated as though it was created with a `SQL SECURITY INVOKER` clause and with a `DEFINER` value that is the same as your account. However, because the actual definer is unknown, MySQL issues a warning. To make the warning go away, it is sufficient to re-create the view so that the view definition includes a `DEFINER` clause.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present. The algorithm affects how MySQL processes the view.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For UNDEFINED, MySQL chooses which algorithm to use. It prefers MERGE over TEMPTABLE if possible, because MERGE is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose TEMPTABLE explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the MERGE algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be UNDEFINED for three reasons:

- No ALGORITHM clause is present in the CREATE VIEW statement.
- The CREATE VIEW statement has an explicit ALGORITHM = UNDEFINED clause.
- ALGORITHM = MERGE is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to UNDEFINED.

As mentioned earlier, MERGE is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the MERGE algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view WHERE clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view WHERE clause is added to the statement WHERE clause using an AND connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a WHERE clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

The MERGE algorithm requires a one-to-one relationship between the rows in the view and the rows in the underlying table. If this relationship does not hold, a temporary table must be used instead. Lack of a one-to-one relationship occurs if the view contains any of a number of constructs:

- Aggregate functions (SUM ( ), MIN ( ), MAX ( ), COUNT ( ), and so forth)
- DISTINCT
- GROUP BY
- HAVING
- UNION or UNION ALL
- Refers only to literal values (in this case, there is no underlying table)

Some views are updatable. That is, you can use them in statements such as UPDATE, DELETE, or INSERT to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (SUM ( ), MIN ( ), MAX ( ), COUNT ( ), and so forth)
- DISTINCT
- GROUP BY
- HAVING
- UNION or UNION ALL
- Subquery in the select list
- Join
- Non-updatable view in the FROM clause
- A subquery in the WHERE clause that refers to a table in the FROM clause
- Refers only to literal values (in this case, there is no underlying table to update)
- ALGORITHM = TEMPTABLE (use of a temporary table always makes a view non-updatable)

With respect to insertability (being updatable with INSERT statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159  
col1 + 3  
UPPER(col2)  
col3 / col4  
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is allowable:

```
UPDATE v SET col1 = 0;
```

This update is not allowable because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the MERGE algorithm. For this to work, the view must use an inner join (not an outer join or a UNION). Also, only a single table in the view definition can be updated, so the SET clause must name only columns from one of the tables in the view. Views that use UNION ALL are disallowed even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, INSERT can work if it inserts into a single table. DELETE is not supported.

The WITH CHECK OPTION clause can be given for an updatable view to prevent inserts or updates to rows except those for which the WHERE clause in the *select\_statement* is true.

In a WITH CHECK OPTION clause for an updatable view, the LOCAL and CASCADED keywords determine the scope of check testing when the view is defined in terms of another view. The LOCAL keyword restricts the CHECK OPTION only to the view being defined. CASCADED causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is CASCADED. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
-> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
-> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
-> WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a LOCAL check option, so inserts are tested only against the `v2` check. `v3` has a CASCADED check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See Section 5.2.2, “Server System Variables”.

The CREATE VIEW statement was added in MySQL 5.0.1. The WITH CHECK OPTION clause was implemented in MySQL 5.0.2.

## 19.3. DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
  view_name [, view_name] ...
  [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each non-existent view. See Section 13.5.4.25, “`SHOW WARNINGS` Syntax”.

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

This statement was added in MySQL 5.0.1.

---

# Chapter 20. The INFORMATION\_SCHEMA Database

INFORMATION\_SCHEMA provides access to database metadata.

*Metadata* is data about the data, such as the name of a database or table, the data type of a column, or access privileges. Other terms that sometimes are used for this information are *data dictionary* and *system catalog*.

INFORMATION\_SCHEMA is the information database, the place that stores information about all the other databases that the MySQL server maintains. Inside INFORMATION\_SCHEMA there are several read-only tables. They are actually views, not base tables, so there are no files associated with them.

In effect, we have a database named INFORMATION\_SCHEMA, although the server does not create a database directory with that name. It is possible to select INFORMATION\_SCHEMA as the default database with a USE statement, but it is possible only to read the contents of tables. You cannot insert into them, update them, or delete from them.

Here is an example of a statement that retrieves information from INFORMATION\_SCHEMA:

```
mysql> SELECT table_name, table_type, engine
-> FROM information_schema.tables
-> WHERE table_schema = 'db5'
-> ORDER BY table_name DESC;
```

table_name	table_type	engine
v56	VIEW	NULL
v3	VIEW	NULL
v2	VIEW	NULL
v	VIEW	NULL
tables	BASE TABLE	MyISAM
t7	BASE TABLE	MyISAM
t3	BASE TABLE	MyISAM
t2	BASE TABLE	MyISAM
t	BASE TABLE	MyISAM
pk	BASE TABLE	InnoDB
loop	BASE TABLE	MyISAM
kurs	BASE TABLE	MyISAM
k	BASE TABLE	MyISAM
into	BASE TABLE	MyISAM
goto	BASE TABLE	MyISAM
fk2	BASE TABLE	InnoDB
fk	BASE TABLE	InnoDB

17 rows in set (0.01 sec)

Explanation: The statement requests a list of all the tables in database db5, in reverse alphabetical order, showing just three pieces of information: the name of the table, its type, and its storage engine.

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges.

The SELECT ... FROM INFORMATION\_SCHEMA statement is intended as a more consistent way to provide access to the information provided by the various SHOW statements that MySQL supports (SHOW DATABASES, SHOW TABLES, and so forth). Using SELECT has these advantages, compared to SHOW:

- It conforms to Codd's rules. That is, all access is done on tables.

- Nobody needs to learn a new statement syntax. Because they already know how `SELECT` works, they only need to learn the object names.
- The implementor need not worry about adding keywords.
- There are millions of possible output variations, instead of just one. This provides more flexibility for applications that have varying requirements about what metadata they need.
- Migration is easier because every other DBMS does it this way.

However, because `SHOW` is popular with MySQL employees and users, and because it might be confusing were it to disappear, the advantages of conventional syntax are not a sufficient reason to eliminate `SHOW`. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as well. These are described in Section 20.18, “Extensions to `SHOW` Statements”.

There is no difference between the privileges required for `SHOW` statements and those required to select information from `INFORMATION_SCHEMA`. In either case, you have to have some privilege on an object in order to see information about it.

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

The following sections describe each of the tables and columns that are in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA` Name” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW` Name” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: <http://www.dbazine.com/gulutzan5.shtml>.

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64.

Each section indicates what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`, if there is such a statement.

**Note:** At present, there are some missing columns and some columns out of order. We are working on this and update the documentation as changes are made.

## 20.1. The INFORMATION\_SCHEMA SCHEMATA

---

## Table

A schema is a database, so the SCHEMATA table provides information about databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CATALOG_NAME		NULL
SCHEMA_NAME		Database
DEFAULT_CHARACTER_SET_NAME		
DEFAULT_COLLATION_NAME		
SQL_PATH		NULL

### Notes:

- DEFAULT\_COLLATION\_NAME was added in MySQL 5.0.6.

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']
```

```
SHOW DATABASES
[LIKE 'wild']
```

## 20.2. The INFORMATION\_SCHEMA TABLES Table

The TABLES table provides information about tables in databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA	Table_...	
TABLE_NAME	Table_...	
TABLE_TYPE		
ENGINE	Engine	MySQL extension
VERSION	Version	MySQL extension
ROW_FORMAT	Row_format	MySQL extension
TABLE_ROWS	Rows	MySQL extension
AVG_ROW_LENGTH	Avg_row_length	MySQL extension
DATA_LENGTH	Data_length	MySQL extension
MAX_DATA_LENGTH	Max_data_length	MySQL extension
INDEX_LENGTH	Index_length	MySQL extension
DATA_FREE	Data_free	MySQL extension
AUTO_INCREMENT	Auto_increment	MySQL extension
CREATE_TIME	Create_time	MySQL extension
UPDATE_TIME	Update_time	MySQL extension
CHECK_TIME	Check_time	MySQL extension
TABLE_COLLATION	Collation	MySQL extension

CHECKSUM	Checksum	MySQL extension
CREATE_OPTIONS	Create_options	MySQL extension
TABLE_COMMENT	Comment	MySQL extension

**Notes:**

- TABLE\_SCHEMA and TABLE\_NAME are a single field in a SHOW display, for example Table\_in\_db1.
- TABLE\_TYPE should be BASE TABLE or VIEW. If table is temporary, then TABLE\_TYPE = TEMPORARY. (There are no temporary views, so this is not ambiguous.)
- The TABLE\_ROWS column is NULL if the table is in the INFORMATION\_SCHEMA database. For InnoDB tables, the row count is only a rough estimate used in SQL optimization.
- We have nothing for the table's default character set. TABLE\_COLLATION is close, because collation names begin with a character set name.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
  [WHERE table_schema = 'db_name']
  [WHERE |AND table_name LIKE 'wild']

SHOW TABLES
  [FROM db_name]
  [LIKE 'wild']
```

## 20.3. The INFORMATION\_SCHEMA COLUMNS Table

The COLUMNS table provides information about columns in tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME	Field	
ORDINAL_POSITION		see notes
COLUMN_DEFAULT	Default	
IS_NULLABLE	Null	
DATA_TYPE	Type	
CHARACTER_MAXIMUM_LENGTH	Type	
CHARACTER_OCTET_LENGTH		
NUMERIC_PRECISION	Type	
NUMERIC_SCALE	Type	
CHARACTER_SET_NAME		
COLLATION_NAME	Collation	
COLUMN_TYPE	Type	MySQL extension
COLUMN_KEY	Key	MySQL extension

EXTRA	Extra	MySQL extension
COLUMN_COMMENT	Comment	MySQL extension

**Notes:**

- In SHOW, the Type display includes values from several different COLUMNS columns.
- ORDINAL\_POSITION is necessary because you might want to say ORDER BY ORDINAL\_POSITION. Unlike SHOW, SELECT does not have automatic ordering.
- CHARACTER\_OCTET\_LENGTH should be the same as CHARACTER\_MAXIMUM\_LENGTH, except for multi-byte character sets.
- CHARACTER\_SET\_NAME can be derived from Collation. For example, if you say SHOW FULL COLUMNS FROM t, and you see in the Collation column a value of latin1\_swedish\_ci, the character set is what's before the first underscore: latin1.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']
```

```
SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

## 20.4. The INFORMATION\_SCHEMA STATISTICS Table

The STATISTICS table provides information about table indexes.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		= Database
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database
INDEX_NAME	Key_name	
SEQ_IN_INDEX	Seq_in_index	
COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension

**Notes:**

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
  [AND table_schema = 'db_name']
```

```
SHOW INDEX
  FROM tbl_name
  [FROM db_name]
```

## 20.5. The INFORMATION\_SCHEMA USER\_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		<i>host_n</i> ' <i>user_name</i> '@' <i>ame</i> ' value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

**Notes:**

- This is a non-standard table. It takes its values from the `mysql.user` table.

## 20.6. The INFORMATION\_SCHEMA SCHEMA\_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		<i>host_n</i> ' <i>user_name</i> '@' <i>ame</i> ' value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
TABLE_SCHEMA		MySQL extension
PRIVILEGE_TYPE		MySQL extension

IS_GRANTABLE		MySQL extension
--------------	--	-----------------

**Notes:**

- This is a non-standard table. It takes its values from the `mysql.db` table.

## 20.7. The INFORMATION\_SCHEMA TABLE\_PRIVILEGES Table

The TABLE\_PRIVILEGES table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		<i>host_n</i> ' <i>user_name</i> '@' <i>ame</i> ' value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

**Notes:**

- PRIVILEGE\_TYPE can contain one (and only one) of these values: SELECT, INSERT, UPDATE, REFERENCES, ALTER, INDEX, DROP, CREATE VIEW.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

## 20.8. The INFORMATION\_SCHEMA COLUMN\_PRIVILEGES Table

The COLUMN\_PRIVILEGES table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		<i>host_n</i> ' <i>user_name</i> '@' <i>ame</i> ' value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		

PRIVILEGE_TYPE		
IS_GRANTABLE		

**Notes:**

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT, INSERT, UPDATE, REFERENCES`.
- If the user has `GRANT OPTION` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES

SHOW GRANTS ...
```

## 20.9. The INFORMATION\_SCHEMA CHARACTER\_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>CHARACTER_SET_NAME</code>	Charset	
<code>DEFAULT_COLLATE_NAME</code>	Default collation	
<code>DESCRIPTION</code>	Description	MySQL extension
<code>MAXLEN</code>	Maxlen	MySQL extension

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE name LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

## 20.10. The INFORMATION\_SCHEMA COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>COLLATION_NAME</code>	Collation	
<code>CHARACTER_SET_NAME</code>	Charset	MySQL extension
<code>ID</code>	Id	MySQL extension

IS_DEFAULT	Default	MySQL extension
IS_COMPILED	Compiled	MySQL extension
SORTLEN	Sortlen	MySQL extension

The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE collation_name LIKE 'wild']
```

```
SHOW COLLATION
  [LIKE 'wild']
```

## 20.11. The INFORMATION\_SCHEMA COLLATION\_CHARACTER\_SET\_APPLICABILITY Table

The COLLATION\_CHARACTER\_SET\_APPLICABILITY table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from SHOW COLLATION.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
COLLATION_NAME	Collation	
CHARACTER_SET_NAME	Charset	

## 20.12. The INFORMATION\_SCHEMA TABLE\_CONSTRAINTS Table

The TABLE\_CONSTRAINTS table describes which tables have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_SCHEMA		
TABLE_NAME		
CONSTRAINT_TYPE		

### Notes:

- The CONSTRAINT\_TYPE value can be UNIQUE, PRIMARY KEY, or FOREIGN KEY.
- The UNIQUE and PRIMARY KEY information is about the same as what you get from the Key\_name field in the output from SHOW INDEX when the Non\_unique field is 0.
- The CONSTRAINT\_TYPE column can contain one of these values: UNIQUE, PRIMARY KEY, FOREIGN KEY, CHECK. This is a CHAR (not ENUM) column. The CHECK value is not available until we support CHECK.

## 20.13. The INFORMATION\_SCHEMA KEY\_COLUMN\_USAGE Table

The KEY\_COLUMN\_USAGE table describes which key columns have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_CATALOG		
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
ORDINAL_POSITION		
POSITION_IN_UNIQUE_CONSTRAINT		
REFERENCED_TABLE_SCHEMA		
REFERENCED_TABLE_NAME		
REFERENCED_COLUMN_NAME		

### Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of ORDINAL\_POSITION is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of POSITION\_IN\_UNIQUE\_CONSTRAINT is NULL for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

For example, suppose that there are two tables name t1 and t3 that have the following definitions:

```
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the KEY\_COLUMN\_USAGE table has two rows:

- One row with CONSTRAINT\_NAME = 'PRIMARY', TABLE\_NAME = 't1',

COLUMN\_NAME = 's3', ORDINAL\_POSITION = 1, POSITION\_IN\_UNIQUE\_CONSTRAINT = NULL.

- One row with CONSTRAINT\_NAME = 'CO', TABLE\_NAME = 't3', COLUMN\_NAME = 's2', ORDINAL\_POSITION = 1, POSITION\_IN\_UNIQUE\_CONSTRAINT = 1.
- REFERENCED\_TABLE\_SCHEMA, REFERENCED\_TABLE\_NAME, and REFERENCED\_COLUMN\_NAME were added in MySQL 5.0.6.

## 20.14. The INFORMATION\_SCHEMA ROUTINES Table

The ROUTINES table provides information about stored routines (both procedures and functions). The ROUTINES table does not include user-defined functions (UDFs) at this time.

The column named “mysql.proc name” indicates the mysql.proc table column that corresponds to the INFORMATION\_SCHEMA.ROUTINES table column, if any.

INFORMATION_SCHEMA Name	mysql.proc Name	Remarks
SPECIFIC_NAME	specific_name	
ROUTINE_CATALOG		NULL
ROUTINE_SCHEMA	db	
ROUTINE_NAME	name	
ROUTINE_TYPE	type	{ PROCEDURE   FUNCTION }
DTD_IDENTIFIER		(data type descriptor)
ROUTINE_BODY		SQL
ROUTINE_DEFINITION	body	
EXTERNAL_NAME		NULL
EXTERNAL_LANGUAGE	language	NULL
PARAMETER_STYLE		SQL
IS_DETERMINISTIC	is_deterministic	
SQL_DATA_ACCESS	sql_data_access	
SQL_PATH		NULL
SECURITY_TYPE	security_type	
CREATED	created	
LAST_ALTERED	modified	
SQL_MODE	sql_mode	MySQL extension
ROUTINE_COMMENT	comment	MySQL extension
DEFINER	definer	MySQL extension

### Notes:

- MySQL calculates EXTERNAL\_LANGUAGE thus:
  - If mysql.proc.language = 'SQL', EXTERNAL\_LANGUAGE is NULL
  - Otherwise, EXTERNAL\_LANGUAGE is what is in mysql.proc.language. However, we do not have external languages yet, so it is always NULL.

## 20.15. The INFORMATION\_SCHEMA VIEWS Table

The VIEWS table provides information about views in databases. You must have the SHOW VIEW privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
VIEW_DEFINITION		
CHECK_OPTION		
IS_UPDATABLE		
DEFINER		
SECURITY_TYPE		

### Notes:

- The VIEW\_DEFINITION column has most of what you see in the Create Table field that SHOW CREATE VIEW produces. Skip the words before SELECT and skip the words WITH CHECK OPTION. Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The CHECK\_OPTION column always has a value of NONE.
- The IS\_UPDATABLE column is YES if the view is updatable, NO if the view is not updatable.
- The DEFINER and SECURITY\_TYPE columns were added in MySQL 5.0.14. DEFINER indicates who defined the view. SECURITY\_TYPE has a value of DEFINER or INVOKER.

## 20.16. The INFORMATION\_SCHEMA TRIGGERS Table

The TRIGGERS table provides information about triggers. You must have the SUPER privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TRIGGER_CATALOG		NULL
TRIGGER_SCHEMA		
TRIGGER_NAME	Trigger	
EVENT_MANIPULATION	Event	

EVENT_OBJECT_CATALOG		NULL
EVENT_OBJECT_SCHEMA		
EVENT_OBJECT_TABLE	Table	
ACTION_ORDER		0
ACTION_CONDITION		NULL
ACTION_STATEMENT	Statement	
ACTION_ORIENTATION		ROW
ACTION_TIMING	Timing	
ACTION_REFERENCE_OLD_TABLE		NULL
ACTION_REFERENCE_NEW_TABLE		NULL
ACTION_REFERENCE_OLD_ROW		OLD
ACTION_REFERENCE_NEW_ROW		NEW
CREATED		NULL (0)
SQL_MODE		MySQL extension
DEFINER		MySQL extension

**Notes:**

- The TRIGGERS table was added in MySQL 5.0.10.
- The TRIGGER\_SCHEMA and TRIGGER\_NAME columns contain the name of the database in which the trigger occurs and the trigger name, respectively.
- The EVENT\_MANIPULATION column contains one of the values 'INSERT', 'DELETE', or 'UPDATE'.
- As noted in Chapter 18, *Triggers*, every trigger is associated with exactly one table. The EVENT\_OBJECT\_SCHEMA and EVENT\_OBJECT\_TABLE columns contain the database in which this table occurs, and the table's name.
- The ACTION\_ORDER statement contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always 0, because it is not possible to have more than one trigger with the same EVENT\_MANIPULATION and ACTION\_TIMING on the same table.
- The ACTION\_STATEMENT column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the Statement column of the output from SHOW TRIGGERS. Note that this text uses UTF-8 encoding.
- The ACTION\_ORIENTATION column always contains the value 'ROW'.
- The ACTION\_TIMING column contains one of the two values 'BEFORE' or 'AFTER'.
- The columns ACTION\_REFERENCE\_OLD\_ROW and ACTION\_REFERENCE\_NEW\_ROW contain the old and new column identifiers, respectively. This means that ACTION\_REFERENCE\_OLD\_ROW always contains the value 'OLD' and ACTION\_REFERENCE\_NEW\_ROW always contains the value 'NEW'.
- The SQL\_MODE column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the sql\_mode system variable. See Section 5.2.5, “The Server SQL Mode”.
- The DEFINER column was added in MySQL 5.0.17. DEFINER indicates who defined the trigger.

- The following columns currently always contain NULL: TRIGGER\_CATALOG, EVENT\_OBJECT\_CATALOG, ACTION\_CONDITION, ACTION\_REFERENCE\_OLD\_TABLE, ACTION\_REFERENCE\_NEW\_TABLE, and CREATED.

Example, using the ins\_sum trigger defined in Section 18.3, “Using Triggers”:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
***** 1. row *****
      TRIGGER_CATALOG: NULL
      TRIGGER_SCHEMA: test
      TRIGGER_NAME: ins_sum
      EVENT_MANIPULATION: INSERT
      EVENT_OBJECT_CATALOG: NULL
      EVENT_OBJECT_SCHEMA: test
      EVENT_OBJECT_TABLE: account
      ACTION_ORDER: 0
      ACTION_CONDITION: NULL
      ACTION_STATEMENT: SET @sum = @sum + NEW.amount
      ACTION_ORIENTATION: ROW
      ACTION_TIMING: BEFORE
      ACTION_REFERENCE_OLD_TABLE: NULL
      ACTION_REFERENCE_NEW_TABLE: NULL
      ACTION_REFERENCE_OLD_ROW: OLD
      ACTION_REFERENCE_NEW_ROW: NEW
      CREATED: NULL
      SQL_MODE:
      DEFINER: me@localhost
```

See also Section 13.5.4.23, “SHOW TRIGGERS Syntax”.

## 20.17. Other INFORMATION\_SCHEMA Tables

We intend to implement additional INFORMATION\_SCHEMA tables. In particular, we acknowledge the need for the PARAMETERS and REFERENTIAL\_CONSTRAINTS tables.

## 20.18. Extensions to SHOW Statements

Some extensions to SHOW statements accompany the implementation of INFORMATION\_SCHEMA:

- SHOW can be used to get information about the structure of INFORMATION\_SCHEMA itself.
- Several SHOW statements accept a WHERE clause that provides more flexibility in specifying which rows to display.

These extensions are available beginning with MySQL 5.0.3.

INFORMATION\_SCHEMA is an information database, so its name is included in the output from SHOW DATABASES. Similarly, SHOW TABLES can be used with INFORMATION\_SCHEMA to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_information_schema |
+-----+
| CHARACTER_SETS               |
| COLLATIONS                   |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                     |
| COLUMN_PRIVILEGES            |
| KEY_COLUMN_USAGE             |
+-----+
```

```

ROUTINES
SCHEMATA
SCHEMA_PRIVILEGES
STATISTICS
TABLES
TABLE_CONSTRAINTS
TABLE_PRIVILEGES
TRIGGERS
USER_PRIVILEGES
VIEWS
+-----+
16 rows in set (0.00 sec)

```

SHOW COLUMNS and DESCRIBE can display information about the columns in individual INFORMATION\_SCHEMA tables.

Several SHOW statement have been extended to allow a WHERE clause:

```

SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW KEYS
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW VARIABLES

```

The WHERE clause, if present, is evaluated against the column names displayed by the SHOW statement. For example, the SHOW CHARACTER SET statement produces these output columns:

```

mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| dec8    | DEC West European | dec8_swedish_ci | 1 |
| cp850   | DOS West European | cp850_general_ci | 1 |
| hp8     | HP West European | hp8_english_ci | 1 |
| koi8r   | KOI8-R Relcom Russian | koi8r_general_ci | 1 |
| latin1  | cp1252 West European | latin1_swedish_ci | 1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1 |
...

```

To use a WHERE clause with SHOW CHARACTER SET, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string 'japanese':

```

mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| ujis    | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |
+-----+-----+-----+-----+

```

This statement displays the multi-byte character sets:

```

mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+-----+-----+-----+-----+

```

The INFORMATION\_SCHEMA Database

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
euckr	EUC-KR Korean	euckr_korean_ci	2
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
utf8	UTF-8 Unicode	utf8_general_ci	3
ucs2	UCS-2 Unicode	ucs2_general_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3

---

# Chapter 21. Precision Math

MySQL 5.0 introduces precision math: numeric value handling that results in more accurate results and more control over invalid values than in earlier versions of MySQL. Precision math is based on two implementation changes:

- The introduction of SQL modes in MySQL 5.0 that control how strict the server is about accepting or rejecting invalid data.
- The introduction in MySQL 5.0.3 of a library for fixed-point arithmetic.

These changes have several implications for numeric operations:

- **More precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, a number such as `.0001` is treated as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly 1, not a value that merely “close” to 1.
- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND ( )` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Improved platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the `sql_mode` system variable.

An important result of these changes is that MySQL provides improved compliance with standard SQL.

The following discussion covers several aspects of how precision math works (including possible incompatibilities with older applications). At the end, some examples are given that demonstrate how MySQL 5.0 handles numeric operations precisely. For information about using the `sql_mode` system variable to control the SQL mode, see Section 5.2.5, “The Server SQL Mode”.

## 21.1. Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (`DECIMAL` and integer types) and exact-value numeric literals. Approximate-value data types and numeric literals still are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar need not be both exact-value or both approximate-value. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

## 21.2. DECIMAL Data Type Changes

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms) as of MySQL 5.0.3, with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The non-standard MySQL extension to the upper range of `DECIMAL` columns

Some of these changes result in possible incompatibilities for applications that are written for older versions of MySQL. These incompatibilities are noted throughout this section.

The declaration syntax for a `DECIMAL` column remains `DECIMAL(M,D)`, although the range of values for the arguments has changed somewhat:

- *M* is the maximum number of digits (the precision). It has a range of 1 to 65. This introduces a possible incompatibility for older applications, because previous versions of MySQL allow a range of 1 to 254.

The precision of 65 digits actually applies as of MySQL 5.0.6. From 5.0.3 to 5.0.5, the precision is 64 digits.

- *D* is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than *M*.

The maximum value of 65 for *M* means that calculations on `DECIMAL` values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals is different from before. (Prior to MySQL 5.0.3, decimal values could have up to 254 digits. However, calculations were done using floating-point and thus were approximate, not exact.) This change in the range of literal values is another possible source of incompatibility for older applications.

Values for `DECIMAL` columns no longer are represented as strings that require one byte per digit or sign character. Instead, a binary format is used that packs nine decimal digits into four bytes. This change to `DECIMAL` storage format changes the storage requirements as well. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the "leftover" digits require some fraction of four bytes. For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require four bytes. A `DECIMAL(20,10)` column has ten digits on either side of the decimal point. Each part requires four bytes for nine of the digits, and one byte for the remaining digit.

The storage required for leftover digits is given by the following table:

Leftover Digits	Number of Bytes
0	0
1	1
2	1
3	2

4	2
5	3
6	3
7	4
8	4
9	4

As a result of the change from string to numeric format for DECIMAL storage, DECIMAL columns no longer store a leading + character or leading 0 digits. Before MySQL 5.0.3, if you inserted +0003.1 into a DECIMAL(5,1) column, it was stored as +0003.1. As of MySQL 5.0.3, it is stored as 3.1. Applications that rely on the older behavior must be modified to account for this change.

The change of storage format also means that DECIMAL columns no longer support the non-standard extension that allowed values larger than the range implied by the column definition. Formerly, one byte was allocated for storing the sign character. For positive values that needed no sign byte, MySQL allowed an extra digit to be stored instead. For example, a DECIMAL(3,0) column must support a range of at least -999 to 999, but MySQL would allow storing values from 1000 to 9999 as well, by using the sign byte to store an extra digit. This extension to the upper range of DECIMAL columns no longer is allowed. In MySQL 5.0.3 and up, a DECIMAL(M,D) column allows at most M#D digits to the left of the decimal point. This can result in an incompatibility if an application has a reliance on MySQL allowing "too-large" values.

The SQL standard requires that the precision of NUMERIC(M,D) be *exactly* M digits. For DECIMAL(M,D), the standard requires a precision of at least M digits but allows more. In MySQL, DECIMAL(M,D) and NUMERIC(M,D) are the same, and both have a precision of exactly M digits.

Summary of incompatibilities:

The following list summarizes the incompatibilities that result from changes to DECIMAL column and value handling. You can use it as guide when porting older applications for use with MySQL 5.0.3 and up.

- For DECIMAL(M,D), the maximum M is 65, not 254.
- Calculations involving exact-value decimal numbers are accurate to 65 digits. This is fewer than the maximum number of digits allowed before MySQL 5.0.3 (254 digits), but the exact-value precision is greater. Calculations formerly were done with double-precision floating-point, which has a precision of 52 bits (about 15 decimal digits).
- The non-standard MySQL extension to the upper range of DECIMAL columns no longer is supported.
- Leading '+' and '0' characters are not stored.

The behavior used by the server for DECIMAL columns in a table depends on the version of MySQL used to create the table. If your server is from MySQL 5.0.3 or higher, but you have DECIMAL columns in tables that were created before 5.0.3, the old behavior still applies to those columns. To convert the tables to the newer DECIMAL format, dump them with `mysqldump` and reload them.

## 21.3. Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for INSERT into a column with an exact data type (DECIMAL or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (Without strict mode, truncation for INSERT is allowable.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using DECIMAL exact arithmetic and has a precision of 65 digits. (The term “exact” is subject to the limits of what can be represented in binary. For example,  $1.0/3.0$  can be approximated in decimal notation as  $.333\dots$ , but not written as an exact number, so  $(1.0/3.0)*3.0$  does not evaluate to exactly  $1.0$ .)
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as BIGINT (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See Section 5.2.5, “The Server SQL Mode”.) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
mysql> SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (DECIMAL or integer), it is inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in *Rounding Behavior*.

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

By default, division by zero produces a result of NULL and no warning. With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes:

<code>sql_mode</code> Value	Result
' ' (Default)	No warning, no error; <code>i</code> is set to NULL.
strict	No warning, no error; <code>i</code> is set to NULL.
<code>ERROR_FOR_DIVISION_BY_ZERO</code>	Warning, no error; <code>i</code> is set to NULL.
strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code>	Error condition; no row is inserted.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has non-numeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. *This includes the empty string.*
- A string that begins with a number can be converted, but the trailing non-numeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

## 21.4. Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into `DECIMAL` columns.

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For inserts into a `DECIMAL` column, the target is an exact data type, so rounding uses "round half up," regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SELECT d FROM t;
+-----+
```

```

| d |
+---+
| 3 |
| 3 |
+---+

```

## 21.5. Precision Math Examples

This section provides some examples that show how precision math improves query results in MySQL 5 compared to older versions.

**Example 1.** Numbers are used with their exact value as given when possible.

Before MySQL 5.0.3, numbers that are treated as floating-point values produce inexact results:

```

mysql> SELECT .1 + .2 = .3;
+-----+
| .1 + .2 = .3 |
+-----+
|                0 |
+-----+

```

As of MySQL 5.0.3, numbers are used as given when possible:

```

mysql> SELECT .1 + .2 = .3;
+-----+
| .1 + .2 = .3 |
+-----+
|                1 |
+-----+

```

For floating-point values, results are inexact:

```

mysql> SELECT .1E0 + .2E0 = .3E0;
+-----+
| .1E0 + .2E0 = .3E0 |
+-----+
|                0 |
+-----+

```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds .0001 to a variable 1,000 times.

```

CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;

```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```

+-----+-----+
| d | f |

```

```
+-----+-----+
| 1.0000 | 0.999999999999991 |
+-----+-----+
```

**Example 2.** Multiplication is performed with the scale required by standard SQL. That is, for two numbers  $X1$  and  $X2$  that have scale  $S1$  and  $S2$ , the scale of the result is  $S1 + S2$ :

Before MySQL 5.0.3, this is what happens:

```
mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
|          0.00 |
+-----+
```

The displayed value is incorrect. The value was calculated correctly in this case, but not displayed to the required scale. To see that the calculated value actually was .0001, try this:

```
mysql> SELECT .01 * .01 + .0000;
+-----+
| .01 * .01 + .0000 |
+-----+
|                0.0001 |
+-----+
```

As of MySQL 5.0.3, the displayed scale is correct:

```
mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001 |
+-----+
```

**Example 3.** Rounding behavior is well-defined.

Before MySQL 5.0.3, rounding behavior (for example, with the `ROUND()` function) is dependent on the implementation of the underlying C library. This results in inconsistencies from platform to platform. For example, you might get a different value on Windows than on Linux, or a different value on x86 machines than on PowerPC machines.

As of MySQL 5.0.3, rounding happens like this:

Rounding for `DECIMAL` columns and exact-valued numbers uses the “round half up” rule. Values with a fractional part of .5 or greater are rounded away from zero to the nearest integer, as shown here:

```
mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+-----+
| 3          | -3          |
+-----+-----+
```

However, rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. Values with any fractional part on such systems are rounded to the nearest even integer:

```
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+-----+
```

```
+-----+
|          2 |          -2 |
+-----+
```

**Example 4.** In strict mode, inserting a value that is too large results in overflow and causes an error, rather than truncation to a legal value.

Before MySQL 5.0.2 (or in 5.0.2 and later, without strict mode), truncation to a legal value occurs:

```
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
|  127 |
+-----+
1 row in set (0.00 sec)
```

As of MySQL 5.0.2, overflow occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

**Example 5:** In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, and not a result of `NULL`.

Before MySQL 5.0.2 (or when not using strict mode in 5.0.2 or a later version), division by zero has a result of `NULL`:

```
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| NULL |
+-----+
1 row in set (0.00 sec)
```

As of MySQL 5.0.2, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0
```

```
mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

**Example 6.** Prior to MySQL 5.0.3 (before precision math was introduced), exact-value and approximate-value literals both are converted to double-precision floating-point values:

```
mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 4.1.18-log |
+-----+
1 row in set (0.01 sec)
```

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.07 sec)
Records: 1 Duplicates: 0 Warnings: 0
```

```
mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | double(3,1)  |      |     | 0.0     |      |
| b     | double       |      |     | 0       |      |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.04 sec)
```

As of MySQL 5.0.3, the approximate-value literal still is converted to floating-point, but the exact-value literal is handled as DECIMAL:

```
mysql> SELECT VERSION();
+-----+
| VERSION() |
+-----+
| 5.0.19-log |
+-----+
1 row in set (0.17 sec)
```

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.19 sec)
Records: 1 Duplicates: 0 Warnings: 0
```

```
mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | decimal(2,1) unsigned | NO  |     | 0.0     |      |
| b     | double       | NO  |     | 0       |      |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.02 sec)
```

**Example 7.** If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

Result before MySQL 5.0.3 (prior to the introduction of precision math in MySQL):

```
mysql> DESCRIBE y;
```

Field	Type	Null	Key	Default	Extra
AVG(i)	double(17,4)	YES		NULL	
AVG(d)	double(17,4)	YES		NULL	
AVG(f)	double	YES		NULL	

The result is a double no matter the argument type.

Result as of MySQL 5.0.3:

```
mysql> DESCRIBE y;
```

Field	Type	Null	Key	Default	Extra
AVG(i)	decimal(14,4)	YES		NULL	
AVG(d)	decimal(14,4)	YES		NULL	
AVG(f)	double	YES		NULL	

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type. (From MySQL 5.0.3 to 5.0.6, the first two columns are `DECIMAL(64,0)`.)

---

# Chapter 22. APIs and Libraries

This chapter describes the APIs available for MySQL, where to get them, and how to use them. The C API is the most extensively covered, because it was developed by the MySQL team, and is the basis for most of the other APIs. This chapter also covers the `libmysqld` library (the embedded server), as well as some programs that are useful for application developers.

## 22.1. libmysqld, the Embedded MySQL Server Library

### 22.1.1. Overview of the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change an old threaded application to use the embedded library, you normally only have to add calls to the following functions:

Function	When to Call
<code>mysql_server_init()</code>	Should be called before any other MySQL function is called, preferably early in the <code>main()</code> function.
<code>mysql_server_end()</code>	Should be called before your program exits.
<code>mysql_thread_init()</code>	Should be called in each thread you create that accesses MySQL.
<code>mysql_thread_end()</code>	Should be called before calling <code>pthread_exit()</code>

Then you must link your code with `libmysqld.a` instead of `libmysqlclient.a`.

The `mysql_server_xxx()` functions are also included in `libmysqlclient.a` to allow you to change between the embedded and the client/server version by just linking your application with the right library. See Section 22.2.12.1, “`mysql_server_init()`”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default. To use authentication for the embedded server, specify the `--with-embedded-privilege-control` option when you invoke `configure` to configure your MySQL distribution.

### 22.1.2. Compiling Programs with libmysqld

To get a `libmysqld` library you should configure MySQL with the `--with-embedded-server` option. See Section 2.9.2, “Typical configure Options”.

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into a compiled version of a program, use the GNU C compiler (`gcc`). The compiler will need to know where to find various files and need instructions on how to compile the program. The following example shows how a program could be compiled from the command line:

```
gcc mysql_test.c -o mysql_test -lz \  
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Immediately following the `gcc` command is the name of the uncompiled C program file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it's compiled. Because of a problem with `mysql_config`, the option `-lz` (for compression) is added here. The `mysql_config` piece is contained in backticks, not single quotes.

### 22.1.3. Restrictions when using the Embedded MySQL Server

The embedded server has the following limitations:

- No support for ISAM tables. (This is mainly done to make the library smaller.)
- No user-defined functions (UDFs).
- No stack trace on core dump.
- No internal RAID support. (This is not normally needed as most current operating systems support big files.)
- You cannot set this up as a master or a slave (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

### 22.1.4. Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_server_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` option as one of the elements of the second argument of the `mysql_server_init()` function. See Section 22.2.12.1, “`mysql_server_init()`”, for more information on the `mysql_server_init()` function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the `[server]` group. These are read by both MySQL versions. Client/server-specific options should go under the `[mysqld]` section. Put options specific to the embedded MySQL server library in the `[embedded]` section. Options specific to applications go under section labeled `[ApplicationName_SERVER]`. See Section 4.3.2, “Using Option Files”.

## 22.1.5. Things left to do in Embedded Server (TODO)

- We are going to provide options to leave out some parts of MySQL to make the library smaller.
- There is still a lot of speed optimization to do.
- Errors are written to `stderr`. We will add an option to specify a filename for these.
- We have to change InnoDB not to be so verbose when using the embedded version. If your database does not contain InnoDB tables, to suppress related messages you can add the `-skip-innodb` option to the options file under the group `[libmysqld_server]`, or when initializing the server with `mysql_server_init()`.

## 22.1.6. Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

### Example 1

```
test1_libmysqld.c

#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;

static char *server_options[] = { "mysql_test", "--defaults-file=my.cnf" };
int num_elements = sizeof(server_options)/ sizeof(char *);

static char *server_groups[] = { "libmysqld_server", "libmysqld_client" };

int main(void)
{
    mysql_server_init(num_elements, server_options, server_groups);
    mysql = mysql_init(NULL);
    mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
    mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);

    mysql_real_connect(mysql, NULL,NULL,NULL, "database1", 0,NULL,0);

    mysql_query(mysql, "SELECT column1, column2 FROM table1");

    results = mysql_store_result(mysql);

    while((record = mysql_fetch_row(results))) {
        printf("%s - %s \n", record[0], record[1]);
    }

    mysql_free_result(results);
    mysql_close(mysql);
    mysql_server_end();

    return 0;
}
```

Here is the command line for compiling the above program:

```
gcc test1_libmysqld.c -o test1_libmysqld -lz \  
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

### Example 2

To try out the example, create an `test2_libmysqld` directory at the same level as the MySQL source directory. Save the `test2_libmysqld.c` source and the GNUmakefile in the directory, and run GNU make from inside the `test2_libmysqld` directory.

```
test2_libmysqld.c  
  
/*  
 * A simple example client, using the embedded MySQL server library  
 */  
  
#include <mysql.h>  
#include <stdarg.h>  
#include <stdio.h>  
#include <stdlib.h>  
  
MYSQL *db_connect(const char *dbname);  
void db_disconnect(MYSQL *db);  
void db_do_query(MYSQL *db, const char *query);  
  
const char *server_groups[] = {  
    "test2_libmysqld_SERVER", "embedded", "server", NULL  
};  
  
int  
main(int argc, char **argv)  
{  
    MYSQL *one, *two;  
  
    /* mysql_server_init() must be called before any other mysql  
     * functions.  
     *  
     * You can use mysql_server_init(0, NULL, NULL), and it  
     * initializes the server using groups = {  
     *   "server", "embedded", NULL  
     * }.  
     *  
     * In your $HOME/.my.cnf file, you probably want to put:  
  
[test2_libmysqld_SERVER]  
language = /path/to/source/of/mysql/sql/share/english  
  
     * You could, of course, modify argc and argv before passing  
     * them to this function. Or you could create new ones in any  
     * way you like. But all of the arguments in argv (except for  
     * argv[0], which is the program name) should be valid options  
     * for the MySQL server.  
     *  
     * If you link this client against the normal mysqlclient  
     * library, this function is just a stub that does nothing.  
     */  
    mysql_server_init(argc, argv, (char **)server_groups);  
  
    one = db_connect("test");  
    two = db_connect(NULL);  
  
    db_do_query(one, "SHOW TABLE STATUS");  
    db_do_query(two, "SHOW DATABASES");
```

---

```

mysql_close(two);
mysql_close(one);

/* This must be called after all other mysql functions */
mysql_server_end();

exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
    va_list ap;
    va_start(ap, fmt);
    vfprintf(stderr, fmt, ap);
    va_end(ap);
    (void)putc('\n', stderr);
    if (db)
        db_disconnect(db);
    exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
    MYSQL *db = mysql_init(NULL);
    if (!db)
        die(db, "mysql_init failed: no memory");
    /*
     * Notice that the client and server use separate group names.
     * This is critical, because the server does not accept the
     * client's options, and vice versa.
     */
    mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
    if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
        die(db, "mysql_real_connect failed: %s", mysql_error(db));

    return db;
}

void
db_disconnect(MYSQL *db)
{
    mysql_close(db);
}

void
db_do_query(MYSQL *db, const char *query)
{
    if (mysql_query(db, query) != 0)
        goto err;

    if (mysql_field_count(db) > 0)
    {
        MYSQL_RES *res;
        MYSQL_ROW row, end_row;
        int num_fields;

        if (!(res = mysql_store_result(db)))
            goto err;
        num_fields = mysql_num_fields(res);
        while ((row = mysql_fetch_row(res)))
        {
            (void)fputs(">> ", stdout);
            for (end_row = row + num_fields; row < end_row; ++row)
                (void)printf("%s\t", row ? (char*)*row : "NULL");
            (void)fputc('\n', stdout);
        }
        (void)fputc('\n', stdout);
    }
}

```

---

```
    mysql_free_result(res);
}
else
    (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));

return;

err:
    die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);
}
```

GNUmakefile

```
# This assumes the MySQL software is installed in /usr/local/mysql
inc      := /usr/local/mysql/include/mysql
lib      := /usr/local/mysql/lib

# If you have not installed the MySQL software yet, try this instead
#inc     := $(HOME)/mysql-5.0/include
#lib     := $(HOME)/mysql-5.0/libmysqld

CC       := gcc
CPPFLAGS := -I$(inc) -D_THREAD_SAFE -D_REENTRANT
CFLAGS  := -g -W -Wall
LDFLAGS := -static
# You can change -lmysqld to -mysqlclient to use the
# client/server library
LDLIBS  = -L$(lib) -lmysqld -lz -lm -lcrypt

ifneq (,$(shell grep FreeBSD /COPYRIGHT 2>/dev/null))
# FreeBSD

else
# Assume Linux
LDLIBS += -lpthread
endif

# This works for simple one-file test programs
sources := $(wildcard *.c)
objects := $(patsubst %c,%o,$(sources))
targets := $(basename $(sources))

all: $(targets)

clean:
    rm -f $(targets) $(objects) *.core
```

## 22.1.7. Licensing the Embedded Server

We encourage everyone to promote free software by releasing code under the GPL or a compatible license. For those who are not able to do this, another option is to purchase a commercial license for the MySQL code from MySQL AB. For details, please see <http://www.mysql.com/company/legal/licensing/>.

## 22.2. MySQL C API

The C API code is distributed with MySQL. It is included in the `mysqlclient` library and allows C programs to access a database.

Many of the clients in the MySQL source distribution are written in C. If you are looking for examples that demonstrate how to use the C API, take a look at these clients. You can find these in the `clients` directory in the MySQL source distribution.

Most of the other client APIs (all except Connector/J and Connector/NET) use the `mysqlclient` library to communicate with the MySQL server. This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs, because they are referenced from the library. See Chapter 8, *Client and Utility Programs*, for a list of these variables.

The client has a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (the maximum is 16MB). Because buffer sizes are increased only as demand warrants, simply increasing the default maximum limit does not in itself cause more resources to be used. This size check is mostly a check for erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each thread's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have BLOB values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The client's default maximum is 16MB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter when the server is started. See Section 7.5.2, "Tuning Server Parameters".

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

For programming with threads, see Section 22.2.15, "How to Make a Threaded Client". For creating a standalone application which includes the "server" and "client" in the same program (and does not communicate with an external MySQL server), see Section 22.1, "libmysqld, the Embedded MySQL Server Library".

## 22.2.1. C API Data types

- `MYSQL`

This structure represents a handle to one database connection. It is used for almost all MySQL functions. You should not try to make a copy of a `MYSQL` structure. There is no guarantee that such a copy will be usable.

- `MYSQL_RES`

This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- `MYSQL_ROW`

This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- `MYSQL_FIELD`

This structure contains information about a field, such as the field's name, type, and size. Its members are described in more detail here. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- `MYSQL_FIELD_OFFSET`

This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- `my_ulonglong`

The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of 0 to 1.84e19.

On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

```
printf ("Number of rows: %lu\n", (unsigned long) mysql_num_rows(result));
```

The `MYSQL_FIELD` structure contains the members listed here:

- `char * name`

The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias.

- `char * org_name`

The name of the field, as a null-terminated string. Aliases are ignored.

- `char * table`

The name of the table containing this field, if it isn't a calculated field. For calculated fields, the `table` value is an empty string. If the table was given an alias with an `AS` clause, the value of `table` is the alias.

- `char * org_table`

The name of the table, as a null-terminated string. Aliases are ignored.

- `char * db`

The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string.

- `char * catalog`

The catalog name. This value is always "def".

- `char * def`

The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `unsigned long length`

The width of the field, as specified in the table definition.

- `unsigned long max_length`

The maximum width of the field for the result set (the length of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

- `unsigned int name_length`

The length of name.

- `unsigned int org_name_length`

The length of `org_name`.

- unsigned int `table_length`

The length of `table`.

- unsigned int `org_table_length`

The length of `org_table`.

- unsigned int `db_length`

The length of `db`.

- unsigned int `catalog_length`

The length of `catalog`.

- unsigned int `def_length`

The length of `def`.

- unsigned int `flags`

Different bit-flags for the field. The `flags` value may have zero or more of the following bits set:

Flag Value	Flag Description
NOT_NULL_FLAG	Field can't be NULL
PRI_KEY_FLAG	Field is part of a primary key
UNIQUE_KEY_FLAG	Field is part of a unique key
MULTIPLE_KEY_FLAG	Field is part of a non-unique key
UNSIGNED_FLAG	Field has the UNSIGNED attribute
ZEROFILL_FLAG	Field has the ZEROFILL attribute
BINARY_FLAG	Field has the BINARY attribute
AUTO_INCREMENT_FLAG	Field has the AUTO_INCREMENT attribute
ENUM_FLAG	Field is an ENUM (deprecated)
SET_FLAG	Field is a SET (deprecated)
BLOB_FLAG	Field is a BLOB or TEXT (deprecated)
TIMESTAMP_FLAG	Field is a TIMESTAMP (deprecated)

Use of the `BLOB_FLAG`, `ENUM_FLAG`, `SET_FLAG`, and `TIMESTAMP_FLAG` flags is deprecated because they indicate the type of a field rather than an attribute of its type. It is preferable to test `field->type` against `MYSQL_TYPE_BLOB`, `MYSQL_TYPE_ENUM`, `MYSQL_TYPE_SET`, or `MYSQL_TYPE_TIMESTAMP` instead.

The following example illustrates a typical use of the `flags` value:

```
if (field->flags & NOT_NULL_FLAG)
    printf("Field can't be null\n");
```

You may use the following convenience macros to determine the boolean status of the `flags` value:

Flag Status	Description
<code>IS_NOT_NULL(flags)</code>	True if this field is defined as NOT NULL

IS_PRI_KEY(flags)	True if this field is a primary key
IS_BLOB(flags)	True if this field is a BLOB or TEXT (deprecated; test field->type instead)

- unsigned int decimals  
The number of decimals for numeric fields.
- unsigned int charsetnr  
The character set number for the field.
- enum enum\_field\_types type  
The type of the field. The type value may be one of the MYSQL\_TYPE\_ symbols shown in the following table.

Type Value	Type Description
MYSQL_TYPE_TINY	TINYINT field
MYSQL_TYPE_SHORT	SMALLINT field
MYSQL_TYPE_LONG	INTEGER field
MYSQL_TYPE_INT24	MEDIUMINT field
MYSQL_TYPE_LONGLONG	BIGINT field
MYSQL_TYPE_DECIMAL	DECIMAL or NUMERIC field
MYSQL_TYPE_NEWDECIMAL	Precision math DECIMAL or NUMERIC field (MySQL 5.0.3 and up)
MYSQL_TYPE_FLOAT	FLOAT field
MYSQL_TYPE_DOUBLE	DOUBLE or REAL field
MYSQL_TYPE_BIT	BIT field (MySQL 5.0.3 and up)
MYSQL_TYPE_TIMESTAMP	TIMESTAMP field
MYSQL_TYPE_DATE	DATE field
MYSQL_TYPE_TIME	TIME field
MYSQL_TYPE_DATETIME	DATETIME field
MYSQL_TYPE_YEAR	YEAR field
MYSQL_TYPE_STRING	CHAR or BINARY field
MYSQL_TYPE_VAR_STRING	VARCHAR or VARBINARY field
MYSQL_TYPE_BLOB	BLOB or TEXT field (use max_length to determine the maximum length)
MYSQL_TYPE_SET	SET field
MYSQL_TYPE_ENUM	ENUM field
MYSQL_TYPE_GEOMETRY	Spatial field
MYSQL_TYPE_NULL	NULL-type field
MYSQL_TYPE_CHAR	Deprecated; use MYSQL_TYPE_TINY instead

You can use the IS\_NUM() macro to test whether a field has a numeric type. Pass the type value to IS\_NUM() and it evaluates to TRUE if the field is numeric:

```
if (IS_NUM(field->type))
    printf("Field is numeric\n");
```

To distinguish between binary and non-binary data for string data types, check whether the `charsetnr` value is 63. If so, the character set is `binary`, which indicates binary rather than non-binary data. This is how to distinguish between `BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, and `BLOB` and `TEXT`.

## 22.2.2. C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See Section 22.2.3, “C API Function Descriptions”.

Function	Description
<code>mysql_affected_rows()</code>	Returns the number of rows changed/deleted/inserted by the last <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> query.
<code>mysql_autocommit()</code>	Toggles autocommit mode on/off.
<code>mysql_change_user()</code>	Changes user and database on an open connection.
<code>mysql_close()</code>	Closes a server connection.
<code>mysql_commit()</code>	Commits the transaction.
<code>mysql_connect()</code>	Connects to a MySQL server. This function is deprecated; use <code>mysql_real_connect()</code> instead.
<code>mysql_create_db()</code>	Creates a database. This function is deprecated; use the SQL statement <code>CREATE DATABASE</code> instead.
<code>mysql_data_seek()</code>	Seeks to an arbitrary row number in a query result set.
<code>mysql_debug()</code>	Does a <code>DEBUG_PUSH</code> with the given string.
<code>mysql_drop_db()</code>	Drops a database. This function is deprecated; use the SQL statement <code>DROP DATABASE</code> instead.
<code>mysql_dump_debug_info()</code>	Makes the server write debug information to the log.
<code>mysql_eof()</code>	Determines whether the last row of a result set has been read. This function is deprecated; <code>mysql_errno()</code> or <code>mysql_error()</code> may be used instead.
<code>mysql_errno()</code>	Returns the error number for the most recently invoked MySQL function.
<code>mysql_error()</code>	Returns the error message for the most recently invoked MySQL function.
<code>mysql_escape_string()</code>	Escapes special characters in a string for use in an SQL statement.
<code>mysql_fetch_field()</code>	Returns the type of the next table field.
<code>mysql_fetch_field_direct()</code>	Returns the type of a table field, given a field number.
<code>mysql_fetch_fields()</code>	Returns an array of all field structures.
<code>mysql_fetch_lengths()</code>	Returns the lengths of all columns in the current row.
<code>mysql_fetch_row()</code>	Fetches the next row from the result set.
<code>mysql_field_seek()</code>	Puts the column cursor on a specified column.
<code>mysql_field_count()</code>	Returns the number of result columns for the most recent statement.
<code>mysql_field_tell()</code>	Returns the position of the field cursor used for the last <code>mysql_fetch_field()</code> .
<code>mysql_free_result()</code>	Frees memory used by a result set.
<code>mysql_get_client_info()</code>	Returns client version information as a string.
<code>mysql_get_client_version()</code>	Returns client version information as an integer.
<code>mysql_get_host_info()</code>	Returns a string describing the connection.
<code>mysql_get_server_version()</code>	Returns version number of server as an integer.

<b>mysql_get_proto_info()</b>	Returns the protocol version used by the connection.
<b>mysql_get_server_info()</b>	Returns the server version number.
<b>mysql_info()</b>	Returns information about the most recently executed query.
<b>mysql_init()</b>	Gets or initializes a MYSQL structure.
<b>mysql_insert_id()</b>	Returns the ID generated for an AUTO_INCREMENT column by the previous query.
<b>mysql_kill()</b>	Kills a given thread.
<b>mysql_library_end()</b>	Finalize MySQL C API library.
<b>mysql_library_init()</b>	Initialize MySQL C API library.
<b>mysql_list_dbs()</b>	Returns database names matching a simple regular expression.
<b>mysql_list_fields()</b>	Returns field names matching a simple regular expression.
<b>mysql_list_processes()</b>	Returns a list of the current server threads.
<b>mysql_list_tables()</b>	Returns table names matching a simple regular expression.
<b>mysql_more_results()</b>	Checks whether any more results exist.
<b>mysql_next_result()</b>	Returns/initiates the next result in multiple-statement executions.
<b>mysql_num_fields()</b>	Returns the number of columns in a result set.
<b>mysql_num_rows()</b>	Returns the number of rows in a result set.
<b>mysql_options()</b>	Sets connect options for <code>mysql_connect()</code> .
<b>mysql_ping()</b>	Checks whether the connection to the server is working, reconnecting as necessary.
<b>mysql_query()</b>	Executes an SQL query specified as a null-terminated string.
<b>mysql_real_connect()</b>	Connects to a MySQL server.
<b>mysql_real_escape_string()</b>	Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection.
<b>mysql_real_query()</b>	Executes an SQL query specified as a counted string.
<b>mysql_refresh()</b>	Flush or reset tables and caches.
<b>mysql_reload()</b>	Tells the server to reload the grant tables.
<b>mysql_rollback()</b>	Rolls back the transaction.
<b>mysql_row_seek()</b>	Seeks to a row offset in a result set, using value returned from <code>mysql_row_tell()</code> .
<b>mysql_row_tell()</b>	Returns the row cursor position.
<b>mysql_select_db()</b>	Selects a database.
<b>mysql_server_end()</b>	Finalize embedded server library.
<b>mysql_server_init()</b>	Initialize embedded server library.
<b>mysql_set_local_infile_default()</b>	Set the LOAD DATA LOCAL INFILE handler callbacks to their default values.
<b>mysql_set_local_infile_handler()</b>	Install application-specific LOAD DATA LOCAL INFILE handler callbacks.
<b>mysql_set_server_option()</b>	Sets an option for the connection (like <code>multi-statements</code> ).
<b>mysql_sqlstate()</b>	Returns the SQLSTATE error code for the last error.
<b>mysql_shutdown()</b>	Shuts down the database server.
<b>mysql_stat()</b>	Returns the server status as a string.
<b>mysql_store_result()</b>	Retrieves a complete result set to the client.
<b>mysql_thread_id()</b>	Returns the current thread ID.
<b>mysql_thread_safe()</b>	Returns 1 if the clients are compiled as thread-safe.
<b>mysql_use_result()</b>	Initiates a row-by-row result set retrieval.

<code>mysql_warning_count()</code>	Returns the warning count for the previous SQL statement.
------------------------------------	---

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. The library can be either the `mysqlclient` C client library or the `mysqld` embedded server library, depending on whether the application was linked with the `-libmysqlclient` or `-libmysqld` flag.
2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.
3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)
4. Close the connection to the MySQL server by calling `mysql_close()`.
5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you don't call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

`mysql_library_init()` and `mysql_library_end()` are available as of MySQL 5.0.3. These actually are `#define` symbols that make them equivalent to `mysql_server_init()` and `mysql_server_end()`, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL library no matter whether the application uses the `mysqlclient` or `mysqld` library. For older versions of MySQL, you can call `mysql_server_init()` and `mysql_server_end()` instead.

In a non-multi-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, a race condition is possible if `mysql_library_init()` is invoked by `mysql_init()` in a multi-threaded environment: `mysql_library_init()` is not thread-safe, so it should be called prior to any other client library call.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the hostname, username, and password). Upon connection, `mysql_real_connect()` sets the reconnect flag (part of the `MYSQL` structure) to a value of 1 in versions of the API older than 5.0.3, or 0 in newer versions. A value of 1 for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. As of MySQL 5.0.13, you can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior. When you are done with the connection, call `mysql_close()` to terminate it.

While a connection is active, the client may send SQL statements to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-`SELECT` query (for example, `INSERT`, `UPDATE`, `DELETE`), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For `SELECT` queries, you retrieve the selected rows as a result set. (Note that some statements are `SELECT`-like in that they return rows. These include `SHOW`, `DESCRIBE`, and `EXPLAIN`. They should be treated the same way as `SELECT` statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Client programs should choose the approach that is most appropriate for their requirements. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you don't have random access to rows within the result set (you can only access rows sequentially), and you don't know how many rows are in the result set until you have retrieved them all. Furthermore, you **must** retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a `SELECT`. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the statement was a `SELECT` and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the statement returned no data (indicating that it was an `INSERT`, `UPDATE`, `DELETE`, and so forth), and was not expected to return rows. If `mysql_field_count()` is non-zero, the statement should have returned rows, but didn't. This indicates that the statement was a `SELECT` that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` allow you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, allowing you to determine when an error occurred and what it was.

## 22.2.3. C API Function Descriptions

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-NULL value to indicate success or a NULL value to indicate an error, and functions returning an integer return zero to indicate success or non-zero to indicate an error. Note that “non-zero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```
if (result)                /* correct */
    ... error ...

if (result < 0)            /* incorrect */
    ... error ...

if (result == -1)         /* incorrect */
    ... error ...
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

### 22.2.3.1. `mysql_affected_rows()`

```
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

#### Description

Returns the number of rows changed by the last UPDATE, deleted by the last DELETE or inserted by the last INSERT statement. May be called immediately after `mysql_query()` for UPDATE, DELETE, or INSERT statements. For SELECT statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

#### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an UPDATE statement, no rows matched the WHERE clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a SELECT query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`. Because `mysql_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

#### Errors

None.

#### Example

```
mysql_query(&mysql, "UPDATE products SET cost=cost*1.25 WHERE group=10");
printf("%ld products updated", (long) mysql_affected_rows(&mysql));
```

If you specify the flag `CLIENT_FOUND_ROWS` when connecting to `mysqld`, `mysql_affected_rows()` returns the number of rows matched by the WHERE statement for UPDATE statements. Otherwise, it returns the number of rows actually changed.

Note that when you use a REPLACE command, `mysql_affected_rows()` returns 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

If you use `INSERT ... ON DUPLICATE KEY UPDATE` to insert a row, `mysql_affected_rows()` returns 1 if the row is inserted as a new row and 2 if an existing row is updated.

### 22.2.3.2. `mysql_autocommit()`

```
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

**Description**

Sets autocommit mode on if mode is 1, off if mode is 0.

**Return Values**

Zero if successful. Non-zero if an error occurred.

**Errors**

None.

### 22.2.3.3. `mysql_change_user()`

```
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char *password, const char *db)
```

**Description**

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_change_user()` fails if the connected user cannot be authenticated or doesn't have permission to use the database. In this case, the user and database are not changed

The `db` parameter may be set to `NULL` if you don't want to have a default database.

This command always performs a `ROLLBACK` of any active transactions, closes all temporary tables, unlocks all locked tables and resets the state as if one had done a new connect. This happens even if the user didn't change.

**Return Values**

Zero for success. Non-zero if an error occurred.

**Errors**

The same that you can get from `mysql_real_connect()`.

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.
- `ER_UNKNOWN_COM_ERROR`  
The MySQL server doesn't implement this command (probably an old server).
- `ER_ACCESS_DENIED_ERROR`

The user or password was wrong.

- ER\_BAD\_DB\_ERROR

The database didn't exist.

- ER\_DBACCESS\_DENIED\_ERROR

The user did not have access rights to the database.

- ER\_WRONG\_DB\_NAME

The database name was too long.

#### **Example**

```
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
    fprintf(stderr, "Failed to change user. Error: %s\n",
            mysql_error(&mysql));
}
```

### **22.2.3.4. mysql\_character\_set\_name()**

```
const char *mysql_character_set_name(MYSQL *mysql)
```

#### **Description**

Returns the default character set for the current connection.

#### **Return Values**

The default character set

#### **Errors**

None.

### **22.2.3.5. mysql\_close()**

```
void mysql_close(MYSQL *mysql)
```

#### **Description**

Closes a previously opened connection. `mysql_close()` also deallocates the connection handle pointed to by `mysql` if the handle was allocated automatically by `mysql_init()` or `mysql_connect()`.

#### **Return Values**

None.

#### **Errors**

None.

### **22.2.3.6. mysql\_commit()**

```
my_bool mysql_commit(MYSQL *mysql)
```

#### **Description**

Commits the current transaction.

As of MySQL 5.0.3, the action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

#### Return Values

Zero if successful. Non-zero if an error occurred.

#### Errors

None.

### 22.2.3.7. `mysql_connect()`

```
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char
*user, const char *passwd)
```

#### Description

This function is deprecated. It is preferable to use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case, the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you can't retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

#### Return Values

Same as for `mysql_real_connect()`.

#### Errors

Same as for `mysql_real_connect()`.

### 22.2.3.8. `mysql_create_db()`

```
int mysql_create_db(MYSQL *mysql, const char *db)
```

#### Description

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

#### Return Values

Zero if the database was created successfully. Non-zero if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- CR\_SERVER\_GONE\_ERROR

The MySQL server has gone away.

- CR\_SERVER\_LOST

The connection to the server was lost during the query.

- CR\_UNKNOWN\_ERROR

An unknown error occurred.

#### **Example**

```
if(mysql_create_db(&mysql, "my_database"))
{
    fprintf(stderr, "Failed to create new database. Error: %s\n",
            mysql_error(&mysql));
}
```

### **22.2.3.9. mysql\_data\_seek()**

```
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

#### **Description**

Seeks to an arbitrary row in a query result set. The offset value is a row number and should be in the range from 0 to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

#### **Return Values**

None.

#### **Errors**

None.

### **22.2.3.10. mysql\_debug()**

```
void mysql_debug(const char *debug)
```

#### **Description**

Does a `DEBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See Section E.1, “Debugging a MySQL Server”, and Section E.2, “Debugging a MySQL Client”.

#### **Return Values**

None.

#### **Errors**

None.

**Example**

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```
mysql_debug("d:t:0,/tmp/client.trace");
```

**22.2.3.11. mysql\_drop\_db()**

```
int mysql_drop_db(MYSQL *mysql, const char *db)
```

**Description**

Drops the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL DROP DATABASE statement instead.

**Return Values**

Zero if the database was dropped successfully. Non-zero if an error occurred.

**Errors**

- CR\_COMMANDS\_OUT\_OF\_SYNC  
Commands were executed in an improper order.
- CR\_SERVER\_GONE\_ERROR  
The MySQL server has gone away.
- CR\_SERVER\_LOST  
The connection to the server was lost during the query.
- CR\_UNKNOWN\_ERROR  
An unknown error occurred.

**Example**

```
if(mysql_drop_db(&mysql, "my_database"))  
    fprintf(stderr, "Failed to drop the database: Error: %s\n",  
            mysql_error(&mysql));
```

**22.2.3.12. mysql\_dump\_debug\_info()**

```
int mysql_dump_debug_info(MYSQL *mysql)
```

**Description**

Instructs the server to write some debug information to the log. For this to work, the connected user must have the SUPER privilege.

**Return Values**

Zero if the command was successful. Non-zero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 22.2.3.13. `mysql_eof()`

```
mysql_bool mysql_eof(MYSQL_RES *result)
```

#### Description

This function is deprecated. `mysql_errno()` or `mysql_error()` may be used instead.

`mysql_eof()` determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to `mysql_store_result()`, the client receives the entire set in one operation. In this case, a NULL return from `mysql_fetch_row()` always means the end of the result set has been reached and it is unnecessary to call `mysql_eof()`. When used with `mysql_store_result()`, `mysql_eof()` always returns true.

On the other hand, if you use `mysql_use_result()` to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call `mysql_fetch_row()` repeatedly. Because an error may occur on the connection during this process, a NULL return value from `mysql_fetch_row()` does not necessarily mean the end of the result set was reached normally. In this case, you can use `mysql_eof()` to determine what happened. `mysql_eof()` returns a non-zero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

#### Return Values

Zero if no error occurred. Non-zero if the end of the result set has been reached.

#### Errors

None.

#### Example

The following example shows how you might use `mysql_eof()`:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result)) // mysql_fetch_row() failed due to an error
```

```
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

### 22.2.3.14. `mysql_errno()`

```
unsigned int mysql_errno(MYSQL *mysql)
```

#### Description

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at Appendix B, *Error Codes and Messages*.

Note that some functions like `mysql_fetch_row()` don't set `mysql_errno()` if they succeed.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

#### Return Values

An error code value for the last `mysql_XXX()` call, if it failed. zero means no error occurred.

#### Errors

None.

### 22.2.3.15. `mysql_error()`

```
const char *mysql_error(MYSQL *mysql)
```

#### Description

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function didn't fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_errno()`, the following two tests are equivalent:

```
if(mysql_errno(&mysql))
{
    // an error occurred
}
```

```
if(mysql_error(&mysql)[0] != '\0')
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages. See Section 5.11.2, “Setting the Error Message Language”.

#### **Return Values**

A null-terminated character string that describes the error. An empty string if no error occurred.

#### **Errors**

None.

### **22.2.3.16. `mysql_escape_string()`**

You should use `mysql_real_escape_string()` instead!

This function is identical to `mysql_real_escape_string()` except that `mysql_real_escape_string()` takes a connection handler as its first argument and escapes the string according to the current character set. `mysql_escape_string()` does not take a connection argument and does not respect the current character set.

### **22.2.3.17. `mysql_fetch_field()`**

```
MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)
```

#### **Description**

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to `mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a BLOB field. (The 8KB size is chosen because MySQL doesn't know the maximum length for the BLOB. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

#### **Return Values**

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

#### **Errors**

None.

#### **Example**

```
MYSQL_FIELD *field;

while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}
```

```
}
```

### 22.2.3.18. `mysql_fetch_field_direct()`

```
MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned  
int fieldnr)
```

#### Description

Given a field number `fieldnr` for a column within a result set, returns that column's field definition as a `MYSQL_FIELD` structure. You may use this function to retrieve the definition for an arbitrary column. The value of `fieldnr` should be in the range from 0 to `mysql_num_fields(result)-1`.

#### Return Values

The `MYSQL_FIELD` structure for the specified column.

#### Errors

None.

#### Example

```
unsigned int num_fields;  
unsigned int i;  
MYSQL_FIELD *field;  
  
num_fields = mysql_num_fields(result);  
for(i = 0; i < num_fields; i++)  
{  
    field = mysql_fetch_field_direct(result, i);  
    printf("Field %u is %s\n", i, field->name);  
}
```

### 22.2.3.19. `mysql_fetch_fields()`

```
MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)
```

#### Description

Returns an array of all `MYSQL_FIELD` structures for a result set. Each structure provides the field definition for one column of the result set.

#### Return Values

An array of `MYSQL_FIELD` structures for all columns of a result set.

#### Errors

None.

#### Example

```
unsigned int num_fields;  
unsigned int i;  
MYSQL_FIELD *fields;  
  
num_fields = mysql_num_fields(result);  
fields = mysql_fetch_fields(result);  
for(i = 0; i < num_fields; i++)  
{  
    printf("Field %u is %s\n", i, fields[i].name);  
}
```

}

### 22.2.3.20. `mysql_fetch_lengths()`

```
unsigned long *mysql_fetch_lengths(MYSQL_RES *result)
```

#### Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling `strlen()`. In addition, if the result set contains binary data, you **must** use this function to determine the size of the data, because `strlen()` returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing NULL values is zero. To see how to distinguish these two cases, see the description for `mysql_fetch_row()`.

#### Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null characters). NULL if an error occurred.

#### Errors

`mysql_fetch_lengths()` is valid only for the current row of the result set. It returns NULL if you call it before calling `mysql_fetch_row()` or after retrieving all rows in the result.

#### Example

```
MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("Column %u is %lu bytes in length.\n", i, lengths[i]);
    }
}
```

### 22.2.3.21. `mysql_fetch_row()`

```
MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)
```

#### Description

Retrieves the next row of a result set. When used after `mysql_store_result()`, `mysql_fetch_row()` returns NULL when there are no more rows to retrieve. When used after `mysql_use_result()`, `mysql_fetch_row()` returns NULL when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by `mysql_num_fields(result)`. If `row` holds the return value from a call to `mysql_fetch_row()`, pointers to the values are accessed as `row[0]` to `row[mysql_num_fields(result)-1]`. NULL values in the row are indicated by NULL pointers.

The lengths of the field values in the row may be obtained by calling

`mysql_fetch_lengths()`. Empty fields and fields containing NULL both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is NULL, the field is NULL; otherwise, the field is empty.

### Return Values

A `MYSQL_ROW` structure for the next row. NULL if there are no more rows to retrieve or if an error occurred.

### Errors

Note that error is not reset between calls to `mysql_fetch_row()`

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### Example

```
MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;

num_fields = mysql_num_fields(result);
while ((row = mysql_fetch_row(result)))
{
    unsigned long *lengths;
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("[%.*s] ", (int) lengths[i], row[i] ? row[i] : "NULL");
    }
    printf("\n");
}
```

## 22.2.3.22. `mysql_field_count()`

```
unsigned int mysql_field_count(MYSQL *mysql)
```

### Description

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned NULL (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether the query was a SELECT (or SELECT-like) statement. The example shown here illustrates how this may be done.

See Section 22.2.13.1, “Why `mysql_store_result()` Sometimes Returns NULL After `mysql_query()` Returns Success”.

### Return Values

An unsigned integer representing the number of columns in a result set.

### Errors

None.

**Example**

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if(mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
        else // mysql_store_result() should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    }
}
}
```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a SELECT.

**22.2.3.23. mysql\_field\_seek()**

```
MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result,
MYSQL_FIELD_OFFSET offset)
```

**Description**

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an offset value of zero.

**Return Values**

The previous value of the field cursor.

**Errors**

None.

**22.2.3.24. mysql\_field\_tell()**

```
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

**Description**

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can

be used as an argument to `mysql_field_seek()`.

**Return Values**

The current offset of the field cursor.

**Errors**

None.

### 22.2.3.25. `mysql_free_result()`

```
void mysql_free_result(MYSQL_RES *result)
```

**Description**

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, and so forth. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

**Return Values**

None.

**Errors**

None.

### 22.2.3.26. `mysql_get_character_set_info()`

```
void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO *cs)
```

**Description**

This function provides information about the default client character set. The default character set may be changed with the `mysql_set_character_set()` function.

This function was added in MySQL 5.0.10.

**Example**

```
if (!mysql_set_character_set(&mysql, "utf8"))
{
    MY_CHARSET_INFO cs;
    mysql_get_character_set_info(&mysql, &cs);
    printf("character set information:\n");
    printf("character set name: %s\n", cs.name);
    printf("collation name: %s\n", cs.csname);
    printf("comment: %s\n", cs.comment);
    printf("directory: %s\n", cs.dir);
    printf("multi byte character min. length: %d\n", cs.mbminlen);
    printf("multi byte character max. length: %d\n", cs.mbmaxlen);
}
```

### 22.2.3.27. `mysql_get_client_info()`

```
char *mysql_get_client_info(void)
```

**Description**

Returns a string that represents the client library version.

**Return Values**

A character string that represents the MySQL client library version.

**Errors**

None.

**22.2.3.28. `mysql_get_client_version()`**

```
unsigned long mysql_get_client_version(void)
```

**Description**

Returns an integer that represents the client library version. The value has the format `XYZZ` where `X` is the major version, `YY` is the release level, and `ZZ` is the version number within the release level. For example, a value of `40102` represents a client library version of `4.1.2`.

**Return Values**

An integer that represents the MySQL client library version.

**Errors**

None.

**22.2.3.29. `mysql_get_host_info()`**

```
char *mysql_get_host_info(MYSQL *mysql)
```

**Description**

Returns a string describing the type of connection in use, including the server hostname.

**Return Values**

A character string representing the server hostname and the connection type.

**Errors**

None.

**22.2.3.30. `mysql_get_proto_info()`**

```
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

**Description**

Returns the protocol version used by current connection.

**Return Values**

An unsigned integer representing the protocol version used by the current connection.

**Errors**

None.

**22.2.3.31. `mysql_get_server_info()`**

```
char *mysql_get_server_info(MYSQL *mysql)
```

**Description**

---

Returns a string that represents the server version number.

**Return Values**

A character string that represents the server version number.

**Errors**

None.

### 22.2.3.32. `mysql_get_server_version()`

```
unsigned long mysql_get_server_version(MYSQL *mysql)
```

**Description**

Returns the version number of the server as an integer.

**Return Values**

A number that represents the MySQL server version in this format:

```
major_version*10000 + minor_version *100 + sub_version
```

For example, 5.0.12 is returned as 50012.

This function is useful in client programs for quickly determining whether some version-specific server capability exists.

**Errors**

None.

### 22.2.3.33. `mysql_hex_string()`

```
unsigned long mysql_hex_string(char *to, const char *from, unsigned long length)
```

**Description**

This function is used to create a legal SQL string that you can use in an SQL statement. See Section 9.1.1, “Strings”.

The string in `from` is encoded to hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in `to` and a terminating null byte is appended.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. When `mysql_hex_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

The return value can be placed into an SQL statement using either `0xvalue` or `X'value'` format. However, the return value does not include the `0x` or `X' . . . '`. The caller must supply whichever of those is desired.

**Example**

```
char query[1000], *end;

end = strmov(query, "INSERT INTO test_table values(");
end = strmov(end, "0x");
end += mysql_hex_string(end, "What's this", 11);
end = strmov(end, ", 0x");
```

```
end += mysql_hex_string(end, "binary data: \0\r\n", 16);
*end++ = ')';

if (mysql_real_query(&mysql, query, (unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

### Return Values

The length of the value placed into `to`, not including the terminating null character.

### Errors

None.

## 22.2.3.34. `mysql_info()`

```
char *mysql_info(MYSQL *mysql)
```

### Description

Retrieves a string providing information about the most recently executed query, but only for the statements listed here. For other statements, `mysql_info()` returns `NULL`. The format of the string varies depending on the type of query, as described here. The numbers are illustrative only; the string contains values appropriate for the query.

- `INSERT INTO ... SELECT ...`  
String format: Records: 100 Duplicates: 0 Warnings: 0
- `INSERT INTO ... VALUES (...),(...),(...)...`  
String format: Records: 3 Duplicates: 0 Warnings: 0
- `LOAD DATA INFILE ...`  
String format: Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
- `ALTER TABLE`  
String format: Records: 3 Duplicates: 0 Warnings: 0
- `UPDATE`  
String format: Rows matched: 40 Changed: 40 Warnings: 0

Note that `mysql_info()` returns a non-`NULL` value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

### Return Values

A character string representing additional information about the most recently executed query. `NULL` if no information is available for the query.

### Errors

None.

### 22.2.3.35. `mysql_init()`

```
MYSQL *mysql_init(MYSQL *mysql)
```

#### Description

Allocates or initializes a MYSQL object suitable for `mysql_real_connect()`. If `mysql` is a NULL pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

#### Return Values

An initialized MYSQL\* handle. NULL if there was insufficient memory to allocate a new object.

#### Errors

In case of insufficient memory, NULL is returned.

### 22.2.3.36. `mysql_insert_id()`

```
my_ulonglong mysql_insert_id(MYSQL *mysql)
```

#### Description

Returns the value generated for an AUTO\_INCREMENT column by the previous INSERT or UPDATE statement. Use this function after you have performed an INSERT statement into a table that contains an AUTO\_INCREMENT field.

More precisely, `mysql_insert_id()` is updated under these conditions:

- INSERT statements that store a value into an AUTO\_INCREMENT column. This is true whether the value is automatically generated by storing the special values NULL or 0 into the column, or is an explicit non-special value.
- In the case of a multiple-row INSERT statement, `mysql_insert_id()` returns the **first** automatically generated AUTO\_INCREMENT value; if no such value is generated, it returns the last **last** explicit value inserted into the AUTO\_INCREMENT column.
- INSERT statements that generate an AUTO\_INCREMENT value by inserting `LAST_INSERT_ID(expr)` into any column.
- INSERT statements that generate an AUTO\_INCREMENT value by updating any column to `LAST_INSERT_ID(expr)`.
- The value of `mysql_insert_id()` is not affected by statements such as SELECT that return a result set.
- If the previous statement returned an error, the value of `mysql_insert_id()` is undefined.

Note that `mysql_insert_id()` returns 0 if the previous statement does not use an AUTO\_INCREMENT value. If you need to save the value for later, be sure to call `mysql_insert_id()` immediately after the statement that generates the value.

The value of `mysql_insert_id()` is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

See Section 12.9.3, “Information Functions”.

Also note that the value of the SQL `LAST_INSERT_ID()` function always contains the most recently generated AUTO\_INCREMENT value, and is not reset between statements because the value

of that function is maintained in the server. Another difference is that `LAST_INSERT_ID()` is not updated if you set an `AUTO_INCREMENT` column to a specific non-special value.

The reason for the difference between `LAST_INSERT_ID()` and `mysql_insert_id()` is that `LAST_INSERT_ID()` is made easy to use in scripts while `mysql_insert_id()` tries to provide a little more exact information of what happens to the `AUTO_INCREMENT` column.

#### **Return Values**

Described in the preceding discussion.

#### **Errors**

None.

### **22.2.3.37. `mysql_kill()`**

```
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

#### **Description**

Asks the server to kill the thread specified by `pid`.

#### **Return Values**

Zero for success. Non-zero if an error occurred.

#### **Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### **22.2.3.38. `mysql_library_end()`**

```
void mysql_library_end(void)
```

#### **Description**

This is a synonym for the `mysql_server_end()` function. It was added in MySQL 5.0.3.

See Section 22.2.2, “C API Function Overview”, for usage information.

### **22.2.3.39. `mysql_library_init()`**

```
int mysql_library_init(int argc, char **argv, char **groups)
```

#### **Description**

This is a synonym for the `mysql_server_init()` function. It was added in MySQL 5.0.3. See

Section 22.2.12.1, “mysql\_server\_init()”.

See Section 22.2.2, “C API Function Overview” for usage information.

### 22.2.3.40. mysql\_list\_dbs()

```
MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)
```

#### Description

Returns a result set consisting of database names on the server that match the simple regular expression specified by the *wild* parameter. *wild* may contain the wildcard characters ‘%’ or ‘\_’, or may be a NULL pointer to match all databases. Calling `mysql_list_dbs()` is similar to executing the query `SHOW databases [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

#### Return Values

A `MYSQL_RES` result set for success. NULL if an error occurred.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 22.2.3.41. mysql\_list\_fields()

```
MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const char *wild)
```

#### Description

Returns a result set consisting of field names in the given table that match the simple regular expression specified by the *wild* parameter. *wild* may contain the wildcard characters ‘%’ or ‘\_’, or may be a NULL pointer to match all fields. Calling `mysql_list_fields()` is similar to executing the query `SHOW COLUMNS FROM tbl_name [LIKE wild]`.

Note that it's recommended that you use `SHOW COLUMNS FROM tbl_name` instead of `mysql_list_fields()`.

You must free the result set with `mysql_free_result()`.

#### Return Values

A `MYSQL_RES` result set for success. NULL if an error occurred.

**Errors**

- CR\_COMMANDS\_OUT\_OF\_SYNC  
Commands were executed in an improper order.
- CR\_SERVER\_GONE\_ERROR  
The MySQL server has gone away.
- CR\_SERVER\_LOST  
The connection to the server was lost during the query.
- CR\_UNKNOWN\_ERROR  
An unknown error occurred.

**22.2.3.42. `mysql_list_processes()`**

```
MYSQL_RES *mysql_list_processes(MYSQL *mysql)
```

**Description**

Returns a result set describing the current server threads. This is the same kind of information as that reported by `mysqladmin processlist` or a `SHOW PROCESSLIST` query.

You must free the result set with `mysql_free_result()`.

**Return Values**

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

**Errors**

- CR\_COMMANDS\_OUT\_OF\_SYNC  
Commands were executed in an improper order.
- CR\_SERVER\_GONE\_ERROR  
The MySQL server has gone away.
- CR\_SERVER\_LOST  
The connection to the server was lost during the query.
- CR\_UNKNOWN\_ERROR  
An unknown error occurred.

**22.2.3.43. `mysql_list_tables()`**

```
MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)
```

**Description**

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters `'%'` or `'_'`, or may be a `NULL` pointer to match all tables. Calling `mysql_list_tables()` is similar to ex-

cuting the query `SHOW tables [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

## 22.2.3.44. `mysql_more_results()`

```
my_bool mysql_more_results(MYSQL *mysql)
```

### Description

Returns true if more results exist from the currently executed query, and the application must call `mysql_next_result()` to fetch the results.

### Return Values

`TRUE` (1) if more results exist. `FALSE` (0) if no more results exist.

In most cases, you can call `mysql_next_result()` instead to test whether more results exist and initiate retrieval if so.

See Section 22.2.9, “C API Handling of Multiple Query Execution”, and Section 22.2.3.45, “`mysql_next_result()`”.

### Errors

None.

## 22.2.3.45. `mysql_next_result()`

```
int mysql_next_result(MYSQL *mysql)
```

### Description

If more query results exist, `mysql_next_result()` reads the next query results and returns the status back to application.

You must call `mysql_free_result()` for the preceding query if it returned a result set.

After calling `mysql_next_result()` the state of the connection is as if you had called `mysql_real_query()` or `mysql_query()` for the next query. This means that you can call `mysql_store_result()`, `mysql_warning_count()`, `mysql_affected_rows()`, and

so forth.

If `mysql_next_result()` returns an error, no other statements are executed and there are no more results to fetch.

See Section 22.2.9, “C API Handling of Multiple Query Execution”.

### Return Values

Return Value	Description
0	Successful and there are more results
-1	Successful and there are no more results
>0	An error occurred

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order. For example if you didn't call `mysql_use_result()` for a previous result set.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

## 22.2.3.46. `mysql_num_fields()`

```
unsigned int mysql_num_fields(MYSQL_RES *result)
```

To pass a `MYSQL*` argument instead, use `unsigned int mysql_field_count(MYSQL *mysql)`.

### Description

Returns the number of columns in a result set.

Note that you can get the number of columns either from a pointer to a result set or to a connection handle. You would use the connection handle if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See Section 22.2.13.1, “Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success”.

### Return Values

An unsigned integer representing the number of columns in a result set.

### Errors

None.

**Example**

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if (mysql_errno(&mysql))
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
        else if (mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
    }
}
```

An alternative (if you know that your query should have returned a result set) is to replace the `mysql_errno(&mysql)` call with a check whether `mysql_field_count(&mysql)` is = 0. This happens only if something went wrong.

**22.2.3.47. `mysql_num_rows()`**

```
my_ulonglong mysql_num_rows(MYSQL_RES *result)
```

**Description**

Returns the number of rows in the result set.

The use of `mysql_num_rows()` depends on whether you use `mysql_store_result()` or `mysql_use_result()` to return the result set. If you use `mysql_store_result()`, `mysql_num_rows()` may be called immediately. If you use `mysql_use_result()`, `mysql_num_rows()` does not return the correct value until all the rows in the result set have been retrieved.

**Return Values**

The number of rows in the result set.

**Errors**

None.

**22.2.3.48. `mysql_options()`**

```
int mysql_options(MYSQL *mysql, enum mysql_option option, const
```

char \*arg)

**Description**

Can be used to set extra connect options and affect behavior for a connection. This function may be called multiple times to set several options.

mysql\_options() should be called after mysql\_init() and before mysql\_connect() or mysql\_real\_connect().

The option argument is the option that you want to set; the arg argument is the value for the option. If the option is an integer, then arg should point to the value of the integer.

Possible option values:

Option	Argument Type	Function
MYSQL_INIT_COMMAND	char *	Command to execute when connecting to the MySQL server. Will automatically be re-executed when re-connecting.
MYSQL_OPT_COMPRESS	Not used	Use the compressed client/server protocol.
MYSQL_OPT_CONNECT_TIMEOUT	unsigned int *	Connect timeout in seconds.
MYSQL_OPT_GUESS_CONNECTION	Not used	For an application linked against libmysqld, this allows the library to guess whether to use the embedded server or a remote server. "Guess" means that if the hostname is set and is not localhost, it uses a remote server. This behavior is the default. MYSQL_OPT_USE_EMBEDDED_CONNECTION and MYSQL_OPT_USE_REMOTE_CONNECTION can be used to override it. This option is ignored for applications linked against libmysqlclient.
MYSQL_OPT_LOCAL_INFILE	optional pointer to uint	If no pointer is given or if pointer points to an unsigned int != 0 the command LOAD LOCAL INFILE is enabled.
MYSQL_OPT_NAMED_PIPE	Not used	Use named pipes to connect to a MySQL server on NT.
MYSQL_OPT_PROTOCOL	unsigned int *	Type of protocol to use. Should be one of the enum values of mysql_protocol_type defined in mysql.h.
MYSQL_OPT_READ_TIMEOUT	unsigned int *	Timeout for reads from server (works currently only on Windows on TCP/IP connections).
MYSQL_OPT_RECONNECT	my_bool *	Enable or disable automatic reconnection to the server if the connection is found to have been lost. Reconnect has been off by default since MySQL 5.0.3; this option is new in 5.0.13 and provides a way to set reconnection behavior explicitly.
MYSQL_OPT_SET_CLIENT_IP	char *	For an application linked against

		linked against libmysqld (with libmysqld compiled with authentication support), this means that the user is considered to have connected from the specified IP address (specified as a string) for authentication purposes. This option is ignored for applications linked against libmysqlclient.
MYSQL_OPT_USE_EMBEDDED_CONNECTION	Not used	For an application linked against libmysqld, this forces the use of the embedded server for the connection. This option is ignored for applications linked against libmysqlclient.
MYSQL_OPT_USE_REMOTE_CONNECTION	Not used	For an application linked against libmysqld, this forces the use of a remote server for the connection. This option is ignored for applications linked against libmysqlclient.
MYSQL_OPT_USE_RESULT	Not used	This option is unused.
MYSQL_OPT_WRITE_TIMEOUT	unsigned int *	Timeout for writes to server (works currently only on Windows on TCP/IP connections).
MYSQL_READ_DEFAULT_FILE	char *	Read options from the named option file instead of from my.cnf.
MYSQL_READ_DEFAULT_GROUP	char *	Read options from the named group from my.cnf or the file specified with MYSQL_READ_DEFAULT_FILE.
MYSQL_REPORT_DATA_TRUNCATION	my_bool *	Enable or disable reporting of data truncation errors for prepared statements via MYSQL_BIND.error. (Default: enabled) Added in 5.0.3.
MYSQL_SECURE_AUTH	my_bool*	Whether to connect to a server that does not support the password hashing used in MySQL 4.1.1 and later.
MYSQL_SET_CHARSET_DIR	char*	The pathname to the directory that contains character set definition files.
MYSQL_SET_CHARSET_NAME	char*	The name of the character set to use as the default character set.
MYSQL_SHARED_MEMORY_BASE_NAME	char*	Named of shared-memory object for communication to server. Should be same as the option --shared-memory-base-name used for the mysqld server you want to connect to.

Note that the client group is always read if you use MYSQL\_READ\_DEFAULT\_FILE or MYSQL\_READ\_DEFAULT\_GROUP.

The specified group in the option file may contain the following options:

Option	Description
--------	-------------

<code>connect-timeout</code>	Connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.
<code>compress</code>	Use the compressed client/server protocol.
<code>database</code>	Connect to this database if no database was specified in the connect command.
<code>debug</code>	Debug options.
<code>disable-local-infile</code>	Disable use of <code>LOAD DATA LOCAL</code> .
<code>host</code>	Default hostname.
<code>init-command</code>	Command to execute when connecting to MySQL server. Will automatically be re-executed when reconnecting.
<code>interactive-timeout</code>	Same as specifying <code>CLIENT_INTERACTIVE</code> to <code>mysql_real_connect()</code> . See Section 22.2.3.51, “ <code>mysql_real_connect()</code> ”.
<code>local-infile[=(0 1)]</code>	If no argument or argument <code>!= 0</code> then enable use of <code>LOAD DATA LOCAL</code> .
<code>max_allowed_packet</code>	Max size of packet client can read from server.
<code>multi-results</code>	Allow multiple result sets from multiple-statement executions or stored procedures.
<code>multi-statements</code>	Allow the client to send multiple statements in a single string (separated by ‘;’).
<code>password</code>	Default password.
<code>pipe</code>	Use named pipes to connect to a MySQL server on NT.
<code>protocol={TCP SOCKET PIPE MEMORY}</code>	The protocol to use when connecting to the server.
<code>port</code>	Default port number.
<code>return-found-rows</code>	Tell <code>mysql_info()</code> to return found rows instead of updated rows when using <code>UPDATE</code> .
<code>shared-memory-base-name=me</code>	Shared-memory name to use to connect to server (default is “MYSQL”).
<code>socket</code>	Default socket file.
<code>user</code>	Default user.

Note that `timeout` has been replaced by `connect-timeout`, but `timeout` is still supported in MySQL 5.0.22 for backward compatibility.

For more information about option files, see Section 4.3.2, “Using Option Files”.

### Return Values

Zero for success. Non-zero if you used an unknown option.

### Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql, MYSQL_OPT_COMPRESS, 0);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "odbc");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

```
}
```

This code requests the client to use the compressed client/server protocol and read the additional options from the `odbc` section in the `my.cnf` file.

### 22.2.3.49. `mysql_ping()`

```
int mysql_ping(MYSQL *mysql)
```

#### Description

Checks whether the connection to the server is working. If the connection has gone down, an automatic reconnection is attempted.

This function can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

#### Return Values

Zero if the connection to the server is alive. Non-zero if an error occurred. A non-zero return does not indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

#### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 22.2.3.50. `mysql_query()`

```
int mysql_query(MYSQL *mysql, const char *query)
```

#### Description

Executes the SQL query pointed to by the null-terminated string `query`. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (`;`) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 22.2.9, “C API Handling of Multiple Query Execution”.

`mysql_query()` cannot be used for queries that contain binary data; you should use `mysql_real_query()` instead. (Binary data may contain the `‘\0’` character, which `mysql_query()` interprets as the end of the query string.)

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See Section 22.2.3.22, “`mysql_field_count()`”.

#### Return Values

Zero if the query was successful. Non-zero if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 22.2.3.51. `mysql_real_connect()`

```
MYSQL *mysql_real_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd, const char *db, unsigned int port, const char *unix_socket, unsigned long client_flag)
```

#### Description

`mysql_real_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_real_connect()` must complete successfully before you can execute any other API functions that require a valid MySQL connection handle structure.

The parameters are specified as follows:

- The first parameter should be the address of an existing MySQL structure. Before calling `mysql_real_connect()` you must call `mysql_init()` to initialize the MySQL structure. You can change a lot of connect options with the `mysql_options()` call. See Section 22.2.3.48, “`mysql_options()`”.
- The value of `host` may be either a hostname or an IP address. If `host` is NULL or the string “localhost”, a connection to the local host is assumed. If the OS supports sockets (Unix) or named pipes (Windows), they are used instead of TCP/IP to connect to the server.
- The `user` parameter contains the user's MySQL login ID. If `user` is NULL or the empty string “”, the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current username must be specified explicitly. See Section 23.1.9.2, “Configuring a MyODBC DSN on Windows”.
- The `passwd` parameter contains the password for `user`. If `passwd` is NULL, only entries in the `user` table for the user that have a blank (empty) password field are checked for a match. This allows the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether they have specified a password.

**Note:** Do not attempt to encrypt the password before calling `mysql_real_connect()`; password encryption is handled automatically by the client API.

- `db` is the database name. If `db` is not NULL, the connection sets the default database to this value.
- If `port` is not 0, the value is used as the port number for the TCP/IP connection. Note that the `host` parameter determines the type of the connection.
- If `unix_socket` is not NULL, the string specifies the socket or named pipe that should be

used. Note that the `host` parameter determines the type of the connection.

- The value of `client_flag` is usually 0, but can be set to a combination of the following flags to enable certain features:

Flag Name	Flag Description
CLIENT_COMPRESS	Use compression protocol.
CLIENT_FOUND_ROWS	Return the number of found (matched) rows, not the number of changed rows.
CLIENT_IGNORE_SPACE	Allow spaces after function names. Makes all functions names reserved words.
CLIENT_INTERACTIVE	Allow <code>interactive_timeout</code> seconds (instead of <code>wait_timeout</code> seconds) of inactivity before closing the connection. The client's session <code>wait_timeout</code> variable is set to the value of the session <code>interactive_timeout</code> variable.
CLIENT_LOCAL_FILES	Enable LOAD DATA LOCAL handling.
CLIENT_MULTI_STATEMENTS	Tell the server that the client may send multiple statements in a single string (separated by ';'). If this flag is not set, multiple-statement execution is disabled.
CLIENT_MULTI_RESULTS	Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This is automatically set if <code>CLIENT_MULTI_STATEMENTS</code> is set.
CLIENT_NO_SCHEMA	Don't allow the <code>db_name.tbl_name.col_name</code> syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs.
CLIENT_ODBC	The client is an ODBC client. This changes <code>mysqld</code> to be more ODBC-friendly.
CLIENT_SSL	Use SSL (encrypted protocol). This option should not be set by application programs; it is set internally in the client library. Instead, use <code>mysql_ssl_set()</code> before calling <code>mysql_real_connect()</code> .

For some parameters, it is possible to have the value taken from an option file rather than from an explicit value in the `mysql_real_connect()` call. To do this, call `mysql_options()` with the `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP` option before calling `mysql_real_connect()`. Then, in the `mysql_real_connect()` call, specify the "no-value" value for each parameter to be read from an option file:

- For `host`, specify a value of `NULL` or the empty string ("").
- For `user`, specify a value of `NULL` or the empty string.
- For `passwd`, specify a value of `NULL`. (For the password, a value of the empty string in the `mysql_real_connect()` call cannot be overridden in an option file, because the empty string indicates explicitly that the MySQL account must have an empty password.)
- For `db`, specify a value of `NULL` or the empty string.
- For `port`, specify a value of 0.
- For `unix_socket`, specify a value of `NULL`.

If no value is found in an option file for a parameter, its default value is used as indicated in the descriptions given earlier in this section.

**Return Values**

A `MYSQL*` connection handle if the connection was successful, `NULL` if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

**Errors**

- `CR_CONN_HOST_ERROR`

Failed to connect to the MySQL server.

- `CR_CONNECTION_ERROR`

Failed to connect to the local MySQL server.

- `CR_IPSOCK_ERROR`

Failed to create an IP socket.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_SOCKET_CREATE_ERROR`

Failed to create a Unix socket.

- `CR_UNKNOWN_HOST`

Failed to find the IP address for the hostname.

- `CR_VERSION_ERROR`

A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version. This can happen if you use a very old client library to connect to a new server that wasn't started with the `--old-protocol` option.

- `CR_NAMEDPIPEOPEN_ERROR`

Failed to create a named pipe on Windows.

- `CR_NAMEDPIPEWAIT_ERROR`

Failed to wait for a named pipe on Windows.

- `CR_NAMEDPIPESETSTATE_ERROR`

Failed to get a pipe handler on Windows.

- `CR_SERVER_LOST`

If `connect_timeout > 0` and it took longer than `connect_timeout` seconds to connect to the server or if the server died while executing the `init-command`.

**Example**

```
MYSQL mysql;
```

```
mysql_init(&mysql);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "your_prog_name");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
```

```
        mysql_error(&mysql));
    }
```

By using `mysql_options()` the MySQL library reads the `[client]` and `[your_prog_name]` sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some non-standard way.

Note that upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the MySQL structure) to a value of 1 in versions of the API older than 5.0.3, or 0 in newer versions. A value of 1 for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. As of MySQL 5.0.13, you can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior.

### 22.2.3.52. `mysql_real_escape_string()`

```
unsigned long mysql_real_escape_string(MYSQL *mysql, char *to,
const char *from, unsigned long length)
```

Note that `mysql` must be a valid, open connection. This is needed because the escaping depends on the character set in use by the server.

#### Description

This function is used to create a legal SQL string that you can use in an SQL statement. See Section 9.1.1, “Strings”.

The string in `from` is encoded to an escaped SQL string, taking into account the current character set of the connection. The result is placed in `to` and a terminating null byte is appended. Characters encoded are NUL (ASCII 0), `'\n'`, `'\r'`, `'\'`, `'\''`, `'\"'`, and Control-Z (see Section 9.1, “Literal Values”). (Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. This function quotes the other characters to make them easier to read in log files.)

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and you need room for the terminating null byte.) When `mysql_real_escape_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

If you need to change the character set of the connection, you should use the `mysql_set_character_set()` function rather than executing a `SET NAMES` (or `SET CHARACTER SET`) statement. `mysql_set_character_set()` works like `SET NAMES` but also affects the character set used by `mysql_real_escape_string()`, which `SET NAMES` does not.

#### Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
*end++ = '\\';
end += mysql_real_escape_string(&mysql, end,"What's this",11);
*end++ = '\\';
*end++ = ',';
*end++ = '\\';
end += mysql_real_escape_string(&mysql, end,"binary data: \\0\\r\\n",16);
*end++ = '\\';
*end++ = ')';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

**Return Values**

The length of the value placed into `to`, not including the terminating null character.

**Errors**

None.

### 22.2.3.53. `mysql_real_query()`

```
int mysql_real_query(MYSQL *mysql, const char *query, unsigned long length)
```

**Description**

Executes the SQL query pointed to by `query`, which should be a string `length` bytes long. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (`;`) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 22.2.9, “C API Handling of Multiple Query Execution”.

You **must** use `mysql_real_query()` rather than `mysql_query()` for queries that contain binary data, because binary data may contain the `\0` character. In addition, `mysql_real_query()` is faster than `mysql_query()` because it does not call `strlen()` on the query string.

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See Section 22.2.3.22, “`mysql_field_count()`”.

**Return Values**

Zero if the query was successful. Non-zero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 22.2.3.54. `mysql_refresh()`

```
int mysql_refresh(MYSQL *mysql, unsigned int options)
```

**Description**

This functions flushes tables or caches, or resets replication server information. The connected user must have the RELOAD privilege.

The `options` argument is a bit mask composed from any combination of the following values. Multiple values can be OR'ed together to perform multiple operations with a single call.

- `REFRESH_GRANT`  
Refresh the grant tables, like `FLUSH PRIVILEGES`.
- `REFRESH_LOG`  
Flush the logs, like `FLUSH LOGS`.
- `REFRESH_TABLES`  
Flush the table cache, like `FLUSH TABLES`.
- `REFRESH_HOSTS`  
Flush the host cache, like `FLUSH HOSTS`.
- `REFRESH_STATUS`  
Reset status variables, like `FLUSH STATUS`.
- `REFRESH_THREADS`  
Flush the thread cache.
- `REFRESH_SLAVE`  
On a slave replication server, reset the master server information and restart the slave, like `RESET SLAVE`.
- `REFRESH_MASTER`  
On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like `RESET MASTER`.

### **Return Values**

Zero for success. Non-zero if an error occurred.

### **Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 22.2.3.55. `mysql_reload()`

```
int mysql_reload(MYSQL *mysql)
```

#### Description

Asks the MySQL server to reload the grant tables. The connected user must have the RELOAD privilege.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL FLUSH PRIVILEGES statement instead.

#### Return Values

Zero for success. Non-zero if an error occurred.

#### Errors

- CR\_COMMANDS\_OUT\_OF\_SYNC  
Commands were executed in an improper order.
- CR\_SERVER\_GONE\_ERROR  
The MySQL server has gone away.
- CR\_SERVER\_LOST  
The connection to the server was lost during the query.
- CR\_UNKNOWN\_ERROR  
An unknown error occurred.

### 22.2.3.56. `mysql_rollback()`

```
my_bool mysql_rollback(MYSQL *mysql)
```

#### Description

Rolls back the current transaction.

As of MySQL 5.0.3, the action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

#### Return Values

Zero if successful. Non-zero if an error occurred.

#### Errors

None.

### 22.2.3.57. `mysql_row_seek()`

```
MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET offset)
```

#### Description

Sets the row cursor to an arbitrary row in a query result set. The `offset` value is a row offset that should be a value returned from `mysql_row_tell()` or from `mysql_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_row_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

**Return Values**

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_row_seek()`.

**Errors**

None.

### 22.2.3.58. `mysql_row_tell()`

```
MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)
```

**Description**

Returns the current position of the row cursor for the last `mysql_fetch_row()`. This value can be used as an argument to `mysql_row_seek()`.

You should use `mysql_row_tell()` only after `mysql_store_result()`, not after `mysql_use_result()`.

**Return Values**

The current offset of the row cursor.

**Errors**

None.

### 22.2.3.59. `mysql_select_db()`

```
int mysql_select_db(MYSQL *mysql, const char *db)
```

**Description**

Causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_select_db()` fails unless the connected user can be authenticated as having permission to use the database.

**Return Values**

Zero for success. Non-zero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- CR\_SERVER\_LOST

The connection to the server was lost during the query.

- CR\_UNKNOWN\_ERROR

An unknown error occurred.

### 22.2.3.60. `mysql_set_character_set()`

```
int mysql_set_character_set(MYSQL *mysql, char *csname)
```

#### Description

This function is used to set the default character set for the current connection. The string `csname` specifies a valid character set name. The connection collation becomes the default collation of the character set. This function works like the `SET NAMES` statement, but also sets the value of `mysql->charset`, and thus affects the character set used by `mysql_real_escape_string()`

This function was added in MySQL 5.0.7.

#### Return Values

Zero for success. Non-zero if an error occurred.

#### Example

```
MYSQL mysql;

mysql_init(&mysql);
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}

if (!mysql_set_charset_name(&mysql, "utf8"))
{
    printf("New client character set: %s\n", mysql_character_set_name(&mysql));
}
```

### 22.2.3.61. `mysql_set_local_infile_default()`

```
void
mysql_set_local_infile_default(MYSQL *mysql);
```

#### Description

Sets the `LOAD LOCAL DATA INFILE` handler callback functions to the defaults used internally by the C client library. The library calls this function automatically if `mysql_set_local_infile_handler()` has not been called or does not supply valid functions for each of its callbacks.

The `mysql_set_local_infile_default()` function was added in MySQL 4.1.2.

#### Return Values

None.

**Errors**

None.

**22.2.3.62. `mysql_set_local_infile_handler()`**

```
void
mysql_set_local_infile_handler(MYSQL *mysql,
                              int (*local_infile_init)(void **, const char *, void *),
                              int (*local_infile_read)(void *, char *, unsigned int),
                              void (*local_infile_end)(void *),
                              int (*local_infile_error)(void *, char*, unsigned int),
                              void *userdata);
```

**Description**

This function installs callbacks to be used during the execution of `LOAD DATA LOCAL INFILE` statements. It enables application programs to exert control over local (client-side) datafile reading. The arguments are the connection handler, a set of pointers to callback functions, and a pointer to a data area that the callbacks can use to share information.

To use `mysql_set_local_infile_handler()`, you must write the following callback functions:

```
int
local_infile_init(void **ptr, const char *filename, void *userdata);
```

The initialization function. This is called once to do any setup necessary, open the datafile, allocate data structures, and so forth. The first `void**` argument is a pointer to a pointer. You can set the pointer (that is, `*ptr`) to a value that will be passed to each of the other callbacks (as a `void*`). The callbacks can use this pointed-to value to maintain state information. The `userdata` argument is the same value that is passed to `mysql_set_local_infile_handler()`.

The initialization function should return zero for success, non-zero for an error.

```
int
local_infile_read(void *ptr, char *buf, unsigned int buf_len);
```

The data-reading function. This is called repeatedly to read the data file. `buf` points to the buffer where the read data should be stored, and `buf_len` is the maximum number of bytes that the callback can read and store in the buffer. (It can read fewer bytes, but should not read more.)

The return value is the number of bytes read, or zero when no more data could be read (this indicates EOF). Return a value less than zero if an error occurs.

```
void
local_infile_end(void *ptr)
```

The termination function. This is called once after `local_infile_read()` has returned zero (EOF) or an error. This function should deallocate any memory allocated by `local_infile_init()` and perform any other cleanup necessary. It is invoked even if the initialization function returns an error.

```
int
local_infile_error(void *ptr, char *error_msg, unsigned int error_msg_len);
```

The error-handling function. This is called to get a textual error message to return to the user in case any of your other functions returns an error. `error_msg` points to the buffer into which the message should be written, and `error_msg_len` is the length of the buffer. The message should be written as a null-terminated string, so the message can be at most `error_msg_len-1` bytes long.

The return value is the error number.

Typically, the other callbacks store the error message in the data structure pointed to by `ptr`, so that `local_infile_error()` can copy the message from there into `error_msg`.

After calling `mysql_set_local_infile_handler()` in your C code and passing pointers to your callback functions, you can then issue a `LOAD DATA LOCAL INFILE` statement (for example, by using `mysql_query()`). The client library automatically invokes your callbacks. The filename specified in `LOAD DATA LOCAL INFILE` will be passed as the second parameter to the `local_infile_init()` callback.

The `mysql_set_local_infile_handler()` function was added in MySQL 4.1.2.

**Return Values**

None.

**Errors**

None.

**22.2.3.63. `mysql_set_server_option()`**

```
int          mysql_set_server_option(MYSQL          *mysql,          enum
enum_mysql_set_option option)
```

**Description**

Enables or disables an option for the connection. `option` can have one of the following values:

<code>MYSQL_OPTION_MULTI_STATEMENTS_ON</code>	Enable multi statement support.
<code>MYSQL_OPTION_MULTI_STATEMENTS_OFF</code>	Disable multi statement support.

**Return Values**

Zero for success. Non-zero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `ER_UNKNOWN_COM_ERROR`  
The server didn't support `mysql_set_server_option()` (which is the case that the server is older than 4.1.1) or the server didn't support the option one tried to set.

**22.2.3.64. `mysql_shutdown()`**

```
int mysql_shutdown(MYSQL *mysql, enum enum_shutdown_level shutdown_level)
```

**Description**

Asks the database server to shut down. The connected user must have SHUTDOWN privileges. The `shutdown_level` argument was added in MySQL 5.0.1. MySQL 5.0 servers support only one type of shutdown; `shutdown_level` must be equal to SHUTDOWN\_DEFAULT. Additional shutdown levels are planned to make it possible to choose the desired level. Dynamically linked executables which have been compiled with older versions of the `libmysqlclient` headers and call `mysql_shutdown()` need to be used with the old `libmysqlclient` dynamic library.

The shutdown process is described in Section 5.2.6, “The MySQL Server Shutdown Process”.

**Return Values**

Zero for success. Non-zero if an error occurred.

**Errors**

- CR\_COMMANDS\_OUT\_OF\_SYNC  
Commands were executed in an improper order.
- CR\_SERVER\_GONE\_ERROR  
The MySQL server has gone away.
- CR\_SERVER\_LOST  
The connection to the server was lost during the query.
- CR\_UNKNOWN\_ERROR  
An unknown error occurred.

### 22.2.3.65. `mysql_sqlstate()`

```
const char *mysql_sqlstate(MYSQL *mysql)
```

**Description**

Returns a null-terminated string containing the SQLSTATE error code for the last error. The error code consists of five characters. '00000' means “no error.” The values are specified by ANSI SQL and ODBC. For a list of possible values, see Appendix B, *Error Codes and Messages*.

Note that not all MySQL errors are mapped to SQLSTATE error codes. The value 'HY000' (general error) is used for unmapped errors.

**Return Values**

A null-terminated character string containing the SQLSTATE error code.

**See Also**

See Section 22.2.3.14, “`mysql_errno()`”, Section 22.2.3.15, “`mysql_error()`”, and Section 22.2.7.26, “`mysql_stmt_sqlstate()`”.

### 22.2.3.66. `mysql_ssl_set()`

```
int mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert,
```

---

```
const char *ca, const char *capath, const char *cipher)
```

**Description**

`mysql_ssl_set()` is used for establishing secure connections using SSL. It must be called before `mysql_real_connect()`.

`mysql_ssl_set()` does nothing unless OpenSSL support is enabled in the client library.

`mysql` is the connection handler returned from `mysql_init()`. The other parameters are specified as follows:

- `key` is the pathname to the key file.
- `cert` is the pathname to the certificate file.
- `ca` is the pathname to the certificate authority file.
- `capath` is the pathname to a directory that contains trusted SSL CA certificates in pem format.
- `cipher` is a list of allowable ciphers to use for SSL encryption.

Any unused SSL parameters may be given as `NULL`.

**Return Values**

This function always returns 0. If SSL setup is incorrect, `mysql_real_connect()` returns an error when you attempt to connect.

### 22.2.3.67. `mysql_stat()`

```
char *mysql_stat(MYSQL *mysql)
```

**Description**

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

**Return Values**

A character string describing the server status. `NULL` if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

## 22.2.3.68. `mysql_store_result()`

`MYSQL_RES *mysql_store_result(MYSQL *mysql)`

### Description

You must call `mysql_store_result()` or `mysql_use_result()` for every query that successfully retrieves data (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth).

You don't have to call `mysql_store_result()` or `mysql_use_result()` for other queries, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect if the query didn't have a result set by checking if `mysql_store_result()` returns 0 (more about this later on).

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See Section 22.2.3.22, “`mysql_field_count()`”.

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns a null pointer if the query didn't return a result set (if the query was, for example, an `INSERT` statement).

`mysql_store_result()` also returns a null pointer if reading of the result set failed. You can check whether an error occurred by checking if `mysql_error()` returns a non-empty string, if `mysql_errno()` returns non-zero, or if `mysql_field_count()` returns zero.

An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

Once you have called `mysql_store_result()` and got a result back that isn't a null pointer, you may call `mysql_num_rows()` to find out how many rows are in the result set.

You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

You must call `mysql_free_result()` once you are done with the result set.

See Section 22.2.13.1, “Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success”.

### Return Values

A `MYSQL_RES` result structure with the results. `NULL` if an error occurred.

### Errors

`mysql_store_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- CR\_UNKNOWN\_ERROR

An unknown error occurred.

### 22.2.3.69. `mysql_thread_id()`

```
unsigned long mysql_thread_id(MYSQL *mysql)
```

#### Description

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

#### Return Values

The thread ID of the current connection.

#### Errors

None.

### 22.2.3.70. `mysql_use_result()`

```
MYSQL_RES *mysql_use_result(MYSQL *mysql)
```

#### Description

You must call `mysql_store_result()` or `mysql_use_result()` for every query that successfully retrieves data (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`).

`mysql_use_result()` initiates a result set retrieval but does not actually read the result set into the client like `mysql_store_result()` does. Instead, each row must be retrieved individually by making calls to `mysql_fetch_row()`. This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than `mysql_store_result()`. The client allocates memory only for the current row and a communication buffer that may grow up to `max_allowed_packet` bytes.

On the other hand, you shouldn't use `mysql_use_result()` if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a `^S` (stop scroll). This ties up the server and prevent other threads from updating any tables from which the data is being fetched.

When using `mysql_use_result()`, you must execute `mysql_fetch_row()` until a `NULL` value is returned, otherwise, the unfetched rows are returned as part of the result set for your next query. The C API gives the error `Commands out of sync; you can't run this command now if you forget to do this!`

You may not use `mysql_data_seek()`, `mysql_row_seek()`, `mysql_row_tell()`, `mysql_num_rows()`, or `mysql_affected_rows()` with a result returned from `mysql_use_result()`, nor may you issue other queries until `mysql_use_result()` has finished. (However, after you have fetched all the rows, `mysql_num_rows()` accurately returns the number of rows fetched.)

You must call `mysql_free_result()` once you are done with the result set.

When using the `libmysqld` embedded server, the memory benefits are essentially lost because

memory usage incrementally increases with each row retrieved until `mysql_free_result()` is called.

**Return Values**

A `MYSQL_RES` result structure. `NULL` if an error occurred.

**Errors**

`mysql_use_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 22.2.3.71. `mysql_warning_count()`

```
unsigned int mysql_warning_count(MYSQL *mysql)
```

**Description**

Returns the number of warnings generated during execution of the previous SQL statement.

**Return Values**

The warning count.

**Errors**

None.

## 22.2.4. C API Prepared Statements

The MySQL client/server protocol provides for the use of prepared statements. This capability uses the `MYSQL_STMT` statement handler data structure returned by the `mysql_stmt_init()` initialization function. Prepared execution is an efficient way to execute a statement more than once. The statement is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the statement handle returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Prepared statements might not provide a performance increase in some situations. For best results, test your application both with prepared and non-prepared statements and choose whichever yields

best performance.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

The following statements can be used as prepared statements: `CREATE TABLE`, `DELETE`, `DO`, `INSERT`, `REPLACE`, `SELECT`, `SET`, `UPDATE`, and most `SHOW` statements. Other statements are not supported in MySQL 5.0.

## 22.2.5. C API Prepared Statement Data types

Prepared statements mainly use the `MYSQL_STMT` and `MYSQL_BIND` data structures. A third structure, `MYSQL_TIME`, is used to transfer temporal data.

- `MYSQL_STMT`

This structure represents a prepared statement. A statement is created by calling `mysql_stmt_init()`, which returns a statement handle (that is, a pointer to a `MYSQL_STMT`). The handle is used for all subsequent statement-related functions until you close it with `mysql_stmt_close()`.

The `MYSQL_STMT` structure has no members that are for application use. Also, you should not try to make a copy of a `MYSQL_STMT` structure. There is no guarantee that such a copy will be usable.

Multiple statement handles can be associated with a single connection. The limit on the number of handles depends on the available system resources.

- `MYSQL_BIND`

This structure is used both for statement input (data values sent to the server) and output (result values returned from the server). For input, it is used with `mysql_stmt_bind_param()` to bind parameter data values to buffers for use by `mysql_stmt_execute()`. For output, it is used with `mysql_stmt_bind_result()` to bind result set buffers for use in fetching rows with `mysql_stmt_fetch()`.

To use a `MYSQL_BIND` structure, you should zero its contents to initialize it, and then set its members appropriately. For example, to declare and initialize an array of three `MYSQL_BIND` structures, use this code:

```
MYSQL_BIND    bind[3];
memset(bind, 0, sizeof(bind));
```

The `MYSQL_BIND` structure contains the following members for use by application programs. Each is used both for input and for output, although sometimes for different purposes depending on the direction of data transfer.

- `enum enum_field_types buffer_type`

The type of the buffer. The allowable `buffer_type` values are listed later in this section. For input, `buffer_type` indicates what type of value you are binding to a statement parameter. For output, it indicates what type of value you expect to receive in a result buffer.

- `void *buffer`

For input, this is a pointer to the buffer in which a statement parameter's data value is stored. For output, it is a pointer to the buffer in which to return a result set column value. For numeric data types, `buffer` should point to a variable of the proper C type. (If you are associating the variable with a column that has the `UNSIGNED` attribute, the variable should be an unsigned C type. Indicate whether the variable is signed or unsigned by using the `is_unsigned` member, described later in this list.) For date and time data types, `buffer`

should point to a `MYSQL_TIME` structure. For character and binary string data types, `buffer` should point to a character buffer.

- `unsigned long buffer_length`

The actual size of `*buffer` in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the `buffer_length` value specifies the length of `*buffer` when used with `mysql_stmt_bind_param()`, or the maximum number of data bytes that can be fetched into the buffer when used with `mysql_stmt_bind_result()`.

- `unsigned long *length`

A pointer to an `unsigned long` variable that indicates the actual number of bytes of data stored in `*buffer`. `length` is used for character or binary C data. For input parameter data binding, `length` points to an `unsigned long` variable that indicates the length of the parameter value stored in `*buffer`; this is used by `mysql_stmt_execute()`. For output value binding, the return value of `mysql_stmt_fetch()` determines the interpretation of the length. If `mysql_stmt_fetch()` returns 0, `*length` indicates the actual length of the parameter value. If `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED`, `*length` indicates the non-truncated length of the parameter value. In this case, the minimum of `*length` and `buffer_length` indicates the actual length of the value.

`length` is ignored for numeric and temporal data types because the length of the data value is determined by the `buffer_type` value.

- `my_bool *is_null`

This member points to a `my_bool` variable that is true if a value is NULL, false if it is not NULL. For input, set `*is_null` to true to indicate that you are passing a NULL value as a statement parameter. For output, this value is set to true after you fetch a row if the result set column value returned from the statement is NULL.

`is_null` is a pointer to a boolean rather than a boolean scalar so that it can be used in the following way:

- If your data values are always NULL, use `MYSQL_TYPE_NULL` to bind the column.
- If your data values are always NOT NULL, set `is_null = (my_bool*) 0`.
- In all other cases, you should set `is_null` to the address of a `my_bool` variable and change that variable's value appropriately between executions to indicate whether data values are NULL or NOT NULL.

- `my_bool is_unsigned`

This member is used for integer types. (These correspond to the `MYSQL_TYPE_TINY`, `MYSQL_TYPE_SHORT`, `MYSQL_TYPE_LONG`, and `MYSQL_TYPE_LONGLONG` type codes.) `is_unsigned` should be set to true for unsigned types and false for signed types.

- `my_bool *error`

For output, set this member to point to a `my_bool` variable to have truncation information for the parameter stored there after a row fetching operation. (Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.) When truncation reporting is enabled, `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED` and `*error` is true in the `MYSQL_BIND` structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column. The `error` member was added in MySQL 5.0.3.

- `MYSQL_TIME`

This structure is used to send and receive `DATE`, `TIME`, `DATETIME`, and `TIMESTAMP` data directly to and from the server. This is done by setting the `buffer_type` member of a `MYSQL_BIND` structure to one of the temporal types, and setting the `buffer` member to point to a `MYSQL_TIME` structure.

The `MYSQL_TIME` structure contains the following members:

- `unsigned int year`  
The year.
- `unsigned int month`  
The month of the year.
- `unsigned int day`  
The day of the month.
- `unsigned int hour`  
The hour of the day.
- `unsigned int minute`  
The minute of the hour.
- `unsigned int second`  
The second of the minute.
- `my_bool neg`  
A boolean flag to indicate whether the time is negative.
- `unsigned long second_part`  
The fractional part of the second. This member currently is unused.

Only those parts of a `MYSQL_TIME` structure that apply to a given type of temporal value are used: The `year`, `month`, and `day` elements are used for `DATE`, `DATETIME`, and `TIMESTAMP` values. The `hour`, `minute`, and `second` elements are used for `TIME`, `DATETIME`, and `TIMESTAMP` values. See Section 22.2.10, “C API Handling of Date and Time Values”.

The following table shows the allowable values that may be specified in the `buffer_type` member of `MYSQL_BIND` structures. The table also shows those `SQL` types that correspond most closely to each `buffer_type` value, and, for numeric and temporal types, the corresponding recommended C type.

The types are “recommended” because implicit type conversion may be performed in both directions. The `buffer_type` value controls the conversion that will be performed. For example, to fetch a `SQL MEDIUMINT` column value, you can specify a `buffer_type` value of `MYSQL_TYPE_LONG` and use a C variable of type `int` as the destination buffer. If you fetch a numeric column with a value of 255 into a `char[4]` character array, specify a `buffer_type` value of `MYSQL_TYPE_STRING` and the resulting value in the array will be a 4-byte string containing `'255\0'`.

To distinguish between binary and non-binary data for string data types, check whether the `charsetnr` value of the result set metadata is 63. If so, the character set is `binary`, which indicates binary rather than non-binary data. This is how to distinguish between `BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, and `BLOB` and `TEXT`.

buffer_type Value	SQL Type	Recommended C Type
MYSQL_TYPE_BIT	BIT	unsigned long long int
MYSQL_TYPE_TINY	TINYINT	unsigned char
MYSQL_TYPE_SHORT	SMALLINT	short int
MYSQL_TYPE_LONG	INT	int
MYSQL_TYPE_LONGLONG	BIGINT	long long int
MYSQL_TYPE_FLOAT	FLOAT	float
MYSQL_TYPE_DOUBLE	DOUBLE	double
MYSQL_TYPE_NEWDECIMAL	DECIMAL	char[ ]
MYSQL_TYPE_TIME	TIME	MYSQL_TIME
MYSQL_TYPE_DATE	DATE	MYSQL_TIME
MYSQL_TYPE_DATETIME	DATETIME	MYSQL_TIME
MYSQL_TYPE_TIMESTAMP	TIMESTAMP	MYSQL_TIME
MYSQL_TYPE_STRING	CHAR/BINARY	char[ ]
MYSQL_TYPE_VAR_STRING	VARCHAR/VARBINARY	char[ ]
MYSQL_TYPE_TINY_BLOB	TINYBLOB/TINYTEXT	char[ ]
MYSQL_TYPE_BLOB	BLOB/TEXT	char[ ]
MYSQL_TYPE_MEDIUM_BLOB	MEDIUMBLOB/MEDIUMTEXT	char[ ]
MYSQL_TYPE_LONG_BLOB	LOB/TEXT	char[ ]

## 22.2.6. C API Prepared Statement Function Overview

The functions available for prepared statement processing are summarized here and described in greater detail in a later section. See Section 22.2.7, “C API Prepared Statement Function Descriptions”.

Function	Description
<b>mysql_stmt_affected_rows()</b>	Returns the number of rows changes, deleted, or inserted by prepared UPDATE, DELETE, or INSERT statement.
<b>mysql_stmt_attr_get()</b>	Get value of an attribute for a prepared statement.
<b>mysql_stmt_attr_set()</b>	Sets an attribute for a prepared statement.
<b>mysql_stmt_bind_param()</b>	Associates application data buffers with the parameter markers in a prepared SQL statement.
<b>mysql_stmt_bind_result()</b>	Associates application data buffers with columns in the result set.
<b>mysql_stmt_close()</b>	Frees memory used by prepared statement.
<b>mysql_stmt_data_seek()</b>	Seeks to an arbitrary row number in a statement result set.
<b>mysql_stmt_errno()</b>	Returns the error number for the last statement execution.
<b>mysql_stmt_error()</b>	Returns the error message for the last statement execution.
<b>mysql_stmt_execute()</b>	Executes the prepared statement.
<b>mysql_stmt_fetch()</b>	Fetches the next row of data from the result set and returns data for all bound columns.
<b>mysql_stmt_fetch_column()</b>	Fetch data for one column of the current row of the result set.
<b>mysql_stmt_field_count()</b>	Returns the number of result columns for the most recent statement.
<b>mysql_stmt_free_result()</b>	Free the resources allocated to the statement handle.

<b>mysql_stmt_init()</b>	Allocates memory for MYSQL_STMT structure and initializes it.
<b>mysql_stmt_insert_id()</b>	Returns the ID generated for an AUTO_INCREMENT column by prepared statement.
<b>mysql_stmt_num_rows()</b>	Returns total rows from the statement buffered result set.
<b>mysql_stmt_param_count()</b>	Returns the number of parameters in a prepared SQL statement.
<b>mysql_stmt_param_metadata()</b>	(Return parameter metadata in the form of a result set.) Currently, this function does nothing.
<b>mysql_stmt_prepare()</b>	Prepares an SQL string for execution.
<b>mysql_stmt_reset()</b>	Reset the statement buffers in the server.
<b>mysql_stmt_result_metadata()</b>	Returns prepared statement metadata in the form of a result set.
<b>mysql_stmt_row_seek()</b>	Seeks to a row offset in a statement result set, using value returned from <code>mysql_stmt_row_tell()</code> .
<b>mysql_stmt_row_tell()</b>	Returns the statement row cursor position.
<b>mysql_stmt_send_long_data()</b>	Sends long data in chunks to server.
<b>mysql_stmt_sqlstate()</b>	Returns the SQLSTATE error code for the last statement execution.
<b>mysql_stmt_store_result()</b>	Retrieves the complete result set to the client.

Call `mysql_stmt_init()` to create a statement handle, then `mysql_stmt_prepare` to prepare it, `mysql_stmt_bind_param()` to supply the parameter data, and `mysql_stmt_execute()` to execute the statement. You can repeat the `mysql_stmt_execute()` by changing parameter values in the respective buffers supplied through `mysql_stmt_bind_param()`.

If the statement is a `SELECT` or any other statement that produces a result set, `mysql_stmt_prepare()` also returns the result set metadata information in the form of a `MYSQL_RES` result set through `mysql_stmt_result_metadata()`.

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

You can also send the text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See Section 22.2.7.25, “`mysql_stmt_send_long_data()`”.

When statement execution has been completed, the statement handle must be closed using `mysql_stmt_close()` so that all resources associated with it can be freed.

If you obtained a `SELECT` statement's result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

### Execution Steps

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handle with `mysql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.
2. If the statement produces a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of result set, albeit a separate one from the one that contains the rows returned by the query. The metadata result set indicates how many columns are in the result and contains information about each column.

3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.
4. Call `mysql_stmt_execute()` to execute the statement.
5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.
6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.
7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:

- The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.
- The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

- The client uses the statement handle and sends the parameter data to the server.
- The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set, the server sends the data back to the client. Otherwise, it sends an okay status and total number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

- The client reads the data from the packet row by row and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error code, error message, and `SQLSTATE` value using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, respectively.

### **Prepared Statement Logging**

For prepared statements that are executed with the `mysql_stmt_prepare()` and `mysql_stmt_execute()` C API functions, the server writes `Prepare` and `Execute` lines to the general query log so that you can tell when statements are prepared and executed.

Suppose that you prepare and execute a statement as follows:

1. Call `mysql_stmt_prepare()` to prepare the statement string "SELECT ?".

2. Call `mysql_stmt_bind_param()` to bind the value 3 to the parameter in the prepared statement.
3. Call `mysql_stmt_execute()` to execute the prepared statement.

As a result of the preceding calls, the server writes the following lines to the general query log:

```
Prepare [1] SELECT ?
Execute [1] SELECT 3
```

Each `Prepare` and `Execute` line in the log is tagged with a `[N]` statement identifier so that you can keep track of which prepared statement is being logged. `N` is a positive integer. If there are multiple prepared statements active simultaneously for the client, `N` may be greater than 1. Each `Execute` line shows a prepared statement after substitution of data values for `?` parameters.

Version notes: `Prepare` lines are displayed without `[N]` before MySQL 4.1.10. `Execute` lines are not displayed at all before MySQL 4.1.10.

## 22.2.7. C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions described in detail in the following sections.

Note that all functions operating with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

To create a `MYSQL_STMT` handle, use the `mysql_stmt_init()` function.

### 22.2.7.1. `mysql_stmt_affected_rows()`

```
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```

#### Description

Returns the total number of rows changed, deleted, or inserted by the last executed statement. May be called immediately after `mysql_stmt_execute()` for `UPDATE`, `DELETE`, or `INSERT` statements. For `SELECT` statements, `mysql_stmt_affected_rows()` works like `mysql_num_rows()`.

#### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query, or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_stmt_affected_rows()` was called prior to calling `mysql_stmt_store_result()`. Because `mysql_stmt_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

See Section 22.2.3.1, “`mysql_affected_rows()`”, for additional information on the return value.

#### Errors

None.

#### Example

For the usage of `mysql_stmt_affected_rows()`, refer to the Example from Section 22.2.7.10, “`mysql_stmt_execute()`”.

### 22.2.7.2. `mysql_stmt_attr_get()`

```
int mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type
option, void *arg)
```

**Description**

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that should contain the option value. If the option is an integer, then `arg` should point to the value of the integer.

See Section 22.2.7.3, “`mysql_stmt_attr_set()`”, for a list of options and option types.

**Note:** In MySQL 5.0, `mysql_stmt_attr_get()` uses `unsigned int *`, not `my_bool *`, for `STMT_ATTR_UPDATE_MAX_LENGTH`. This is corrected in MySQL 5.1.7.

**Return Values**

0 if okay. Non-zero if `option` is unknown.

**Errors**

None.

### 22.2.7.3. `mysql_stmt_attr_set()`

```
int mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type
option, const void *arg)
```

**Description**

Can be used to affect behavior for a prepared statement. This function may be called multiple times to set several options.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, then `arg` should point to the value of the integer.

Possible option values:

Option	Argument Type	Function
STMT_ATTR_UPDATE_MAX_LENGTH	<code>my_bool *</code>	If set to 1: Update metadata <code>MYSQL_FIELD-&gt;max_length</code> in <code>mysql_stmt_store_result()</code> .
STMT_ATTR_CURSOR_TYPE	<code>unsigned long *</code>	Type of cursor to open for statement when <code>mysql_stmt_execute()</code> is invoked. <code>*arg</code> can be <code>CURSOR_TYPE_NO_CURSOR</code> (the default) or <code>CURSOR_TYPE_READ_ONLY</code> .
STMT_ATTR_PREFETCH_ROWS	<code>unsigned long *</code>	Number of rows to fetch from server at a time when using a cursor. <code>*arg</code> can be in the range from 1 to the maximum value of <code>unsigned long</code> . The default is 1.

**Note:** In MySQL 5.0, `mysql_stmt_attr_get()` uses `unsigned int *`, not `my_bool *`, for `STMT_ATTR_UPDATE_MAX_LENGTH`. This is corrected in MySQL 5.1.7.

If you use the `STMT_ATTR_CURSOR_TYPE` option with `CURSOR_TYPE_READ_ONLY`, a cursor is opened for the statement when you invoke `mysql_stmt_execute()`. If there is already an open cursor from a previous `mysql_stmt_execute()` call, it closes the cursor before opening a new one. `mysql_stmt_reset()` also closes any open cursor before preparing the statement for re-execution. `mysql_stmt_free_result()` closes any open cursor.

If you open a cursor for a prepared statement, `mysql_stmt_store_result()` is unnecessary, because that function causes the result set to be buffered on the client side.

The `STMT_ATTR_CURSOR_TYPE` option was added in MySQL 5.0.2. The `STMT_ATTR_PREFETCH_ROWS` option was added in MySQL 5.0.6.

### Return Values

0 if okay. Non-zero if option is unknown.

### Errors

None.

### Example

The following example opens a cursor for a prepared statement and sets the number of rows to fetch at a time to 5:

```
MYSQL_STMT *stmt;
int rc;
unsigned long type;
unsigned long prefetch_rows = 5;

stmt = mysql_stmt_init(mysql);
type = (unsigned long) CURSOR_TYPE_READ_ONLY;
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_CURSOR_TYPE, (void*) &type);
/* ... check return value ... */
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_PREFETCH_ROWS,
                        (void*) &prefetch_rows);
/* ... check return value ... */
```

## 22.2.7.4. `mysql_stmt_bind_param()`

```
my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

### Description

`mysql_stmt_bind_param()` is used to bind data for the parameter markers in the SQL statement that was passed to `mysql_stmt_prepare()`. It uses `MYSQL_BIND` structures to supply the data. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain an element for each ‘?’ parameter marker that is present in the query.

Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?,?,?)
```

When you bind the parameters, the array of `MYSQL_BIND` structures must contain three elements, and can be declared like this:

```
MYSQL_BIND bind[3];
```

The members of each `MYSQL_BIND` element that should be set are described in Section 22.2.5, “C API Prepared Statement Data types”.

### Return Values

Zero if the bind was successful. Non-zero if an error occurred.

### Errors

- `CR_INVALID_BUFFER_USE`

Indicates if the bind is to supply the long data in chunks and if the buffer type is non string or binary.

- `CR_UNSUPPORTED_PARAM_TYPE`

The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### Example

For the usage of `mysql_stmt_bind_param()`, refer to the Example from Section 22.2.7.10, “`mysql_stmt_execute()`”.

## 22.2.7.5. `mysql_stmt_bind_result()`

```
my_bool mysql_stmt_bind_result(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

### Description

`mysql_stmt_bind_result()` is used to associate (bind) columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain an element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol doesn't return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol does not place data into the newly bound buffers until the next call to `mysql_stmt_fetch()` occurs.

To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and the address of the length buffer. The members of each `MYSQL_BIND` element that should be set are described in Section 22.2.5, “C API Prepared Statement Data types”.

### Return Values

Zero if the bind was successful. Non-zero if an error occurred.

### Errors

- `CR_UNSUPPORTED_PARAM_TYPE`

The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### Example

For the usage of `mysql_stmt_bind_result()`, refer to the Example from Section 22.2.7.11, “`mysql_stmt_fetch()`”.

## 22.2.7.6. `mysql_stmt_close()`

```
my_bool mysql_stmt_close(MYSQL_STMT *)
```

### Description

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handle pointed to by `stmt`.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

### Return Values

Zero if the statement was freed successfully. Non-zero if an error occurred.

### Errors

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### Example

For the usage of `mysql_stmt_close()`, refer to the Example from Section 22.2.7.10, “`mysql_stmt_execute()`”.

## 22.2.7.7. `mysql_stmt_data_seek()`

```
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

### Description

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from 0 to `mysql_stmt_num_rows(stmt)-1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

**Return Values**

None.

**Errors**

None.

**22.2.7.8. `mysql_stmt_errno()`**

```
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

**Description**

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at Appendix B, *Error Codes and Messages*.

**Return Values**

An error code value. Zero if no error occurred.

**Errors**

None.

**22.2.7.9. `mysql_stmt_error()`**

```
const char *mysql_stmt_error(MYSQL_STMT *stmt)
```

**Description**

For the statement specified by `stmt`, `mysql_stmt_error()` returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string (" ") is returned if no error occurred. This means the following two tests are equivalent:

```
if (mysql_stmt_errno(stmt))
{
    // an error occurred
}

if (mysql_stmt_error(stmt)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages.

**Return Values**

A character string that describes the error. An empty string if no error occurred.

**Errors**

None.

**22.2.7.10. `mysql_stmt_execute()`**

```
int mysql_stmt_execute(MYSQL_STMT *stmt)
```

### Description

`mysql_stmt_execute()` executes the prepared query associated with the statement handle. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

If the statement is an UPDATE, DELETE, or INSERT, the total number of changed, deleted, or inserted rows can be found by calling `mysql_stmt_affected_rows()`. If this is a statement such as SELECT that generates a result set, you must call `mysql_stmt_fetch()` to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to Section 22.2.7.11, “`mysql_stmt_fetch()`”.

For statements that generate a result set, you can request that `mysql_stmt_execute()` open a cursor for the statement by calling `mysql_stmt_attr_set()` before executing the statement. If you execute a statement multiple times, `mysql_stmt_execute()` closes any open cursor before opening a new one.

### Return Values

Zero if execution was successful. Non-zero if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### Example

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(col1 INT,\
                                                    col2 VARCHAR(40),\
                                                    col3 SMALLINT,\
                                                    col4 TIMESTAMP)"
#define INSERT_SAMPLE "INSERT INTO test_table(col1,col2,col3) VALUES(?,?,?)"

MYSQL_STMT      *stmt;
```

---

```

MYSQL_BIND    bind[3];
my_ulonglong  affected_rows;
int           param_count;
short        small_data;
int          int_data;
char         str_data[STRING_SIZE];
unsigned long str_length;
my_bool      is_null;

if (mysql_query(mysql, DROP_SAMPLE_TABLE))
{
    fprintf(stderr, " DROP TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

if (mysql_query(mysql, CREATE_SAMPLE_TABLE))
{
    fprintf(stderr, " CREATE TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

/* Prepare an INSERT query with 3 parameters */
/* (the TIMESTAMP column is not named; the server */
/* sets it to the current date and time) */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_SAMPLE, strlen(INSERT_SAMPLE)))
{
    fprintf(stderr, " mysql_stmt_prepare(), INSERT failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
fprintf(stdout, " prepare, INSERT successful\n");

/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in INSERT: %d\n", param_count);

if (param_count != 3) /* validate parameter count */
{
    fprintf(stderr, " invalid parameter count returned by MySQL\n");
    exit(0);
}

/* Bind the data for all 3 parameters */

memset(bind, 0, sizeof(bind));

/* INTEGER PARAM */
/* This is a number type, so there is no need to specify buffer_length */

strncpy(str_data, "MySQL", STRING_SIZE); /* string */
str_length= strlen(str_data);

/* INSERT SMALLINT data as NULL */
is_null= 1;

/* Execute the INSERT statement - 1*/
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute(), 1 failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the total number of affected rows */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 1): %lu\n",
        (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}

/* Specify data values for second row, then re-execute the statement */
int_data= 1000;
strncpy(str_data, "The most popular Open Source database", STRING_SIZE);
str_length= strlen(str_data);
small_data= 1000; /* smallint */
is_null= 0; /* reset */

/* Execute the INSERT statement - 2*/
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute, 2 failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the total rows affected */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 2): %lu\n",
        (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}

/* Close the statement */
if (mysql_stmt_close(stmt))
{
```

```

    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

```

**Note:** For complete examples on the use of prepared statement functions, refer to the file `tests/mysql_client_test.c`. This file can be obtained from a MySQL source distribution or from the BitKeeper source repository.

## 22.2.7.11. `mysql_stmt_fetch()`

```
int mysql_stmt_fetch(MYSQL_STMT *stmt)
```

### Description

`mysql_stmt_fetch()` returns the next row in the result set. It can be called only while the result set exists; that is, after a call to `mysql_stmt_execute()` that creates a result set or after `mysql_stmt_store_result()`, which is called after `mysql_stmt_execute()` to buffer the entire result set.

`mysql_stmt_fetch()` returns row data using the buffers bound by `mysql_stmt_bind_result()`. It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the `length` pointer.

All columns must be bound by the application before calling `mysql_stmt_fetch()`.

If a fetched data value is a NULL value, the `*is_null` value of the corresponding `MYSQL_BIND` structure contains TRUE (1). Otherwise, the data and its length are returned in the `*buffer` and `*length` elements based on the buffer type specified by the application. Each numeric and temporal type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by `data_length`.

Type	Length
<code>MYSQL_TYPE_TINY</code>	1
<code>MYSQL_TYPE_SHORT</code>	2
<code>MYSQL_TYPE_LONG</code>	4
<code>MYSQL_TYPE_LONGLONG</code>	8
<code>MYSQL_TYPE_FLOAT</code>	4
<code>MYSQL_TYPE_DOUBLE</code>	8
<code>MYSQL_TYPE_TIME</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_DATE</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_DATETIME</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_STRING</code>	<code>data_length</code>
<code>MYSQL_TYPE_BLOB</code>	<code>data_length</code>

### Return Values

Return Value	Description
0	Successful, the data has been fetched to application data buffers.
1	Error occurred. Error code and message can be obtained by calling <code>mysql_stmt_errno()</code> and <code>mysql_stmt_error()</code> .
<code>MYSQL_NO_DATA</code>	No more rows/data exists
<code>MYSQL_DATA_TRUNCATED</code>	Data truncation occurred

`MYSQL_DATA_TRUNCATED` is returned when truncation reporting is enabled. (Reporting is enabled by default, but can be controlled with `mysql_options()`.) To determine which parameters were truncated when this value is returned, check the error members of the `MYSQL_BIND` parameter structures.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.
- `CR_UNSUPPORTED_PARAM_TYPE`  
The buffer type is `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, but the data type is not `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP`.
- All other unsupported conversion errors are returned from `mysql_stmt_bind_result()`.

### Example

The following example demonstrates how to fetch data from a table using `mysql_stmt_result_metadata()`, `mysql_stmt_bind_result()`, and `mysql_stmt_fetch()`. (This example expects to retrieve the two rows inserted by the example shown in Section 22.2.7.10, “`mysql_stmt_execute()`”). The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 FROM test_table"

MYSQL_STMT      *stmt;
MYSQL_BIND      bind[4];
MYSQL_RES       *prepare_meta_result;
MYSQL_TIME      ts;
unsigned long   length[4];
int             param_count, column_count, row_count;
short          small_data;
int            int_data;
char           str_data[STRING_SIZE];
my_bool        is_null[4];
my_bool        error[4];

/* Prepare a SELECT query to fetch data from test_table */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
```

---

```

    exit(0);
}
if (mysql_stmt_prepare(stmt, SELECT_SAMPLE, strlen(SELECT_SAMPLE)))
{
    fprintf(stderr, " mysql_stmt_prepare(), SELECT failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
fprintf(stdout, " prepare, SELECT successful\n");

/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in SELECT: %d\n", param_count);

if (param_count != 0) /* validate parameter count */
{
    fprintf(stderr, " invalid parameter count returned by MySQL\n");
    exit(0);
}

/* Fetch result set meta information */
prepare_meta_result = mysql_stmt_result_metadata(stmt);
if (!prepare_meta_result)
{
    fprintf(stderr,
            " mysql_stmt_result_metadata(), returned no meta information\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get total columns in the query */
column_count= mysql_num_fields(prepare_meta_result);
fprintf(stdout, " total columns in SELECT statement: %d\n", column_count);

if (column_count != 4) /* validate column count */
{
    fprintf(stderr, " invalid column count returned by MySQL\n");
    exit(0);
}

/* Execute the SELECT query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute(), failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Bind the result buffers for all 4 columns before fetching them */
memset(bind, 0, sizeof(bind));

/* INTEGER COLUMN */
bind[0].buffer_type= MYSQL_TYPE_LONG;
bind[0].buffer= (char *)&int_data;
bind[0].is_null= &is_null[0];
bind[0].length= &length[0];
bind[0].error= &error[0];

/* STRING COLUMN */
bind[1].buffer_type= MYSQL_TYPE_STRING;
bind[1].buffer= (char *)str_data;
bind[1].buffer_length= STRING_SIZE;
bind[1].is_null= &is_null[1];
bind[1].length= &length[1];
bind[1].error= &error[1];

/* SMALLINT COLUMN */
bind[2].buffer_type= MYSQL_TYPE_SHORT;

```

---

```

bind[2].buffer= (char *)&small_data;
bind[2].is_null= &is_null[2];
bind[2].length= &length[2];
bind[2].error= &error[2];

/* TIMESTAMP COLUMN */
bind[3].buffer_type= MYSQL_TYPE_TIMESTAMP;
bind[3].buffer= (char *)&ts;
bind[3].is_null= &is_null[3];
bind[3].length= &length[3];
bind[3].error= &error[3];

/* Bind the result buffers */
if (mysql_stmt_bind_result(stmt, bind))
{
    fprintf(stderr, "mysql_stmt_bind_result() failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Now buffer all results to client */
if (mysql_stmt_store_result(stmt))
{
    fprintf(stderr, "mysql_stmt_store_result() failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Fetch all rows */
row_count= 0;
fprintf(stdout, "Fetching results ...\n");
while (!mysql_stmt_fetch(stmt))
{
    row_count++;
    fprintf(stdout, " row %d\n", row_count);

    /* column 1 */
    fprintf(stdout, " column1 (integer) : ");
    if (is_null[0])
        fprintf(stdout, " NULL\n");
    else
        fprintf(stdout, " %d(%ld)\n", int_data, length[0]);

    /* column 2 */
    fprintf(stdout, " column2 (string) : ");
    if (is_null[1])
        fprintf(stdout, " NULL\n");
    else
        fprintf(stdout, " %s(%ld)\n", str_data, length[1]);

    /* column 3 */
    fprintf(stdout, " column3 (smallint) : ");
    if (is_null[2])
        fprintf(stdout, " NULL\n");
    else
        fprintf(stdout, " %d(%ld)\n", small_data, length[2]);

    /* column 4 */
    fprintf(stdout, " column4 (timestamp): ");
    if (is_null[3])
        fprintf(stdout, " NULL\n");
    else
        fprintf(stdout, " %04d-%02d-%02d %02d:%02d:%02d (%ld)\n",
            ts.year, ts.month, ts.day,
            ts.hour, ts.minute, ts.second,
            length[3]);
    fprintf(stdout, "\n");
}

```

```
/* Validate rows fetched */
fprintf(stdout, " total rows fetched: %d\n", row_count);
if (row_count != 2)
{
    fprintf(stderr, " MySQL failed to return all rows\n");
    exit(0);
}

/* Free the prepared result metadata */
mysql_free_result(prepare_meta_result);

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
```

### 22.2.7.12. `mysql_stmt_fetch_column()`

```
int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, unsigned int column, unsigned long offset)
```

#### Description

Fetch one column from the current result set row. `bind` provides the buffer where data should be placed. It should be set up the same way as for `mysql_stmt_bind_result()`. `column` indicates which column to fetch. The first column is numbered 0. `offset` is the offset within the data value at which to begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is offset 0.

#### Return Values

Zero if the value was fetched successfully. Non-zero if an error occurred.

#### Errors

- `CR_INVALID_PARAMETER_NO`  
Invalid column number.
- `CR_NO_DATA`  
The end of the result set has already been reached.

### 22.2.7.13. `mysql_stmt_field_count()`

```
unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)
```

#### Description

Returns the number of columns for the most recent statement for the statement handler. This value is zero for statements such as `INSERT` or `DELETE` that do not produce result sets.

`mysql_stmt_field_count()` can be called after you have prepared a statement by invoking `mysql_stmt_prepare()`.

#### Return Values

An unsigned integer representing the number of columns in a result set.

**Errors**

None.

**22.2.7.14. `mysql_stmt_free_result()`**

```
my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)
```

**Description**

Releases memory associated with the result set produced by execution of the prepared statement. If there is a cursor open for the statement, `mysql_stmt_free_result()` closes it.

**Return Values**

Zero if the result set was freed successfully. Non-zero if an error occurred.

**Errors****22.2.7.15. `mysql_stmt_init()`**

```
MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)
```

**Description**

Create a `MYSQL_STMT` handle. The handle should be freed with `mysql_stmt_close(MYSQL_STMT *)`.

**Return values**

A pointer to a `MYSQL_STMT` structure in case of success. `NULL` if out of memory.

**Errors**

- `CR_OUT_OF_MEMORY`  
Out of memory.

**22.2.7.16. `mysql_stmt_insert_id()`**

```
my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)
```

**Description**

Returns the value generated for an `AUTO_INCREMENT` column by the prepared `INSERT` or `UPDATE` statement. Use this function after you have executed a prepared `INSERT` statement on a table which contains an `AUTO_INCREMENT` field.

See Section 22.2.3.36, “`mysql_insert_id()`”, for more information.

**Return Values**

Value for `AUTO_INCREMENT` column which was automatically generated or explicitly set during execution of prepared statement, or value generated by `LAST_INSERT_ID(expr)` function. Return value is undefined if statement does not set `AUTO_INCREMENT` value.

**Errors**

None.

**22.2.7.17. `mysql_stmt_num_rows()`**

```
my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)
```

**Description**

Returns the number of rows in the result set.

The use of `mysql_stmt_num_rows()` depends on whether you used `mysql_stmt_store_result()` to buffer the entire result set in the statement handle.

If you use `mysql_stmt_store_result()`, `mysql_stmt_num_rows()` may be called immediately.

**Return Values**

The number of rows in the result set.

**Errors**

None.

### 22.2.7.18. `mysql_stmt_param_count()`

```
unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)
```

**Description**

Returns the number of parameter markers present in the prepared statement.

**Return Values**

An unsigned long integer representing the number of parameters in a statement.

**Errors**

None.

**Example**

For the usage of `mysql_stmt_param_count()`, refer to the Example from Section 22.2.7.10, “`mysql_stmt_execute()`”.

### 22.2.7.19. `mysql_stmt_param_metadata()`

```
MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)
```

This function currently does nothing.

**Description****Return Values****Errors**

### 22.2.7.20. `mysql_stmt_prepare()`

```
int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *query, unsigned long length)
```

**Description**

Given the statement handle returned by `mysql_stmt_init()`, prepares the SQL statement pointed to by the string `query` and returns a status value. The string length should be given by the `length` argument. The string must consist of a single SQL statement. You should not add a termin-

ating semicolon (;) or \g to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark (?) characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are allowed in the VALUES() list of an INSERT statement (to specify column values for a row), or in a comparison with a column in a WHERE clause to specify a comparison value. However, they are not allowed for identifiers (such as table or column names), or to specify both operands of a binary operator such as the = equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using `mysql_stmt_bind_param()` before executing the statement.

### Return Values

Zero if the statement was prepared successfully. Non-zero if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

If the prepare operation was unsuccessful (that is, `mysql_stmt_prepare()` returns non-zero), the error message can be obtained by calling `mysql_stmt_error()`.

### Example

For the usage of `mysql_stmt_prepare()`, refer to the Example from Section 22.2.7.10, “`mysql_stmt_execute()`”.

## 22.2.7.21. `mysql_stmt_reset()`

```
my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
```

### Description

Reset the prepared statement on the client and server to state after prepare. This is mainly used to reset data sent with `mysql_stmt_send_long_data()`. Any open cursor for the statement is closed.

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

### Return Values

Zero if the statement was reset successfully. Non-zero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 22.2.7.22. `mysql_stmt_result_metadata()`

```
MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)
```

**Description**

If a statement passed to `mysql_stmt_prepare()` is one that produces a result set, `mysql_stmt_result_metadata()` returns the result set metadata in the form of a pointer to a `MYSQL_RES` structure that can be used to process the meta information such as total number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- `mysql_num_fields()`
- `mysql_fetch_field()`
- `mysql_fetch_field_direct()`
- `mysql_fetch_fields()`
- `mysql_field_count()`
- `mysql_field_seek()`
- `mysql_field_tell()`
- `mysql_free_result()`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysql_free_result()`. This is similar to the way you free a result set obtained from a call to `mysql_store_result()`.

The result set returned by `mysql_stmt_result_metadata()` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysql_stmt_fetch()`.

**Return Values**

A `MYSQL_RES` result structure. `NULL` if no meta information exists for the prepared query.

**Errors**

- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

**Example**

For the usage of `mysql_stmt_result_metadata()`, refer to the Example from Section 22.2.7.11, “`mysql_stmt_fetch()`”.

**22.2.7.23. `mysql_stmt_row_seek()`**

```
MYSQL_ROW_OFFSET mysql_stmt_row_seek(MYSQL_STMT *stmt,  
MYSQL_ROW_OFFSET offset)
```

**Description**

Sets the row cursor to an arbitrary row in a statement result set. The `offset` value is a row offset that should be a value returned from `mysql_stmt_row_tell()` or from `mysql_stmt_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_stmt_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_stmt_row_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

**Return Values**

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_stmt_row_seek()`.

**Errors**

None.

**22.2.7.24. `mysql_stmt_row_tell()`**

```
MYSQL_ROW_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)
```

**Description**

Returns the current position of the row cursor for the last `mysql_stmt_fetch()`. This value can be used as an argument to `mysql_stmt_row_seek()`.

You should use `mysql_stmt_row_tell()` only after `mysql_stmt_store_result()`.

**Return Values**

The current offset of the row cursor.

**Errors**

None.

**22.2.7.25. `mysql_stmt_send_long_data()`**

```
my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int
parameter_number, const char *data, unsigned long length)
```

### Description

Allows an application to send parameter data to the server in pieces (or “chunks”). This function can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the TEXT or BLOB data types.

`parameter_number` indicates which parameter to associate the data with. Parameters are numbered beginning with 0. `data` is a pointer to a buffer containing data to be sent, and `length` indicates the number of bytes in the buffer.

**Note:** The next `mysql_stmt_execute()` call ignores the bind buffer for all parameters that have been used with `mysql_stmt_send_long_data()` since last `mysql_stmt_execute()` or `mysql_stmt_reset()`.

If you want to reset/forget the sent data, you can do it with `mysql_stmt_reset()`. See Section 22.2.7.21, “`mysql_stmt_reset()`”.

### Return Values

Zero if the data is sent successfully to server. Non-zero if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### Example

The following example demonstrates how to send the data for a TEXT column in chunks. It inserts the data value 'MySQL - The most popular Open Source database' into the `text_column` column. The `mysql` variable is assumed to be a valid connection handle.

```
#define INSERT_QUERY "INSERT INTO test_long_data(text_column) VALUES(?)"

MYSQL_BIND bind[1];
long      length;

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY)))
{
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
}
```

```
    exit(0);
}
memset(bind, 0, sizeof(bind));
bind[0].buffer_type= MYSQL_TYPE_STRING;
bind[0].length= &length;
bind[0].is_null= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
    fprintf(stderr, "\n param bind failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply data in chunks to server */
if (!mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply the next piece of data */
if (mysql_stmt_send_long_data(stmt,0," - The most popular Open Source database")
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Now, execute the query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, "\n mysql_stmt_execute failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}
```

### 22.2.7.26. `mysql_stmt_sqlstate()`

```
const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)
```

#### Description

For the statement specified by `stmt`, `mysql_stmt_sqlstate()` returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. "00000" means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see Appendix B, *Error Codes and Messages*.

Note that not all MySQL errors are yet mapped to SQLSTATE codes. The value "HY000" (general error) is used for unmapped errors.

#### Return Values

A null-terminated character string containing the SQLSTATE error code.

### 22.2.7.27. `mysql_stmt_store_result()`

```
int mysql_stmt_store_result(MYSQL_STMT *stmt)
```

#### Description

You must call `mysql_stmt_store_result()` for every statement that successfully produces a

result set (SELECT, SHOW, DESCRIBE, EXPLAIN), and only if you want to buffer the complete result set by the client, so that the subsequent `mysql_stmt_fetch()` call returns buffered data.

It is unnecessary to call `mysql_stmt_store_result()` for other statements, but if you do, it does not harm or cause any notable performance problem. You can detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns NULL. For more information, refer to Section 22.2.7.22, “`mysql_stmt_result_metadata()`”.

**Note:** MySQL doesn't by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications doesn't need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STMT_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See Section 22.2.7.3, “`mysql_stmt_attr_set()`”.

### Return Values

Zero if the results are buffered successfully. Non-zero if an error occurred.

### Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

## 22.2.8. C API Prepared statement problems

Here follows a list of the currently known problems with prepared statements:

- `TIME`, `TIMESTAMP`, and `DATETIME` do not support parts of seconds (for example from `DATE_FORMAT()`).
- When converting an integer to string, `ZEROFILL` is honored with prepared statements in some cases where the MySQL server doesn't print the leading zeros. (For example, with `MIN(number-with-zerofill)`).
- When converting a floating point number to a string in the client, the rightmost digits of the converted value may differ slightly from those of the original value.
- *Prepared statements do not use the Query Cache, even in cases where a query does not contain any placeholders.* See Section 5.14.1, “How the Query Cache Operates”.
- Prepared statements do not support multi-statements (that is, multiple statements within a single string separated by ‘;’ characters). This also means that prepared statements cannot invoke stored procedures that return result sets, because prepared statements do not support multiple

result sets.

## 22.2.9. C API Handling of Multiple Query Execution

MySQL 5.0 supports the execution of multiple statements specified in a single query string. To use this capability with a given connection, you must specify the `CLIENT_MULTI_STATEMENTS` option in the `flags` parameter to `mysql_real_connect()` when opening the connection. You can also set this for an existing connection by calling `mysql_set_server_option(MYSQL_OPTION_MULTI_STATEMENTS_ON)`.

By default, `mysql_query()` and `mysql_real_query()` return only the first query status and the subsequent queries status can be processed using `mysql_more_results()` and `mysql_next_result()`.

```
/* Connect to server with option CLIENT_MULTI_STATEMENTS */
mysql_real_connect(..., CLIENT_MULTI_STATEMENTS);

/* Now execute multiple queries */
mysql_query(mysql, "DROP TABLE IF EXISTS test_table;\
CREATE TABLE test_table(id INT);\
INSERT INTO test_table VALUES(10);\
UPDATE test_table SET id=20 WHERE id=10;\
SELECT * FROM test_table;\
DROP TABLE test_table");

do
{
    /* Process all results */
    ...
    printf("total affected rows: %lld", mysql_affected_rows(mysql));
    ...
    if (!(result= mysql_store_result(mysql)))
    {
        printf(stderr, "Got fatal error processing query\n");
        exit(1);
    }
    process_result_set(result); /* client function */
    mysql_free_result(result);
} while (!mysql_next_result(mysql));
```

The multiple-statement capability can be used with `mysql_query()` or `mysql_real_query()`. It cannot be used with the prepared statement interface. Prepared statement handles are defined to work only with strings that contain a single statement.

## 22.2.10. C API Handling of Date and Time Values

The binary protocol allows you to send and receive date and time values (`DATE`, `TIME`, `DATETIME`, and `TIMESTAMP`), using the `MYSQL_TIME` structure. The members of this structure are described in Section 22.2.5, “C API Prepared Statement Data types”.

To send temporal data values, create a prepared statement using `mysql_stmt_prepare()`. Then, before calling `mysql_stmt_execute()` to execute the statement, use the following procedure to set up each temporal parameter:

1. In the `MYSQL_BIND` structure associated with the data value, set the `buffer_type` member to the type that indicates what kind of temporal value you're sending. For `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` values, set `buffer_type` to `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, respectively.
2. Set the `buffer` member of the `MYSQL_BIND` structure to the address of the `MYSQL_TIME` structure in which you pass the temporal value.

3. Fill in the members of the `MYSQL_TIME` structure that are appropriate for the type of temporal value to be passed.

Use `mysql_stmt_bind_param()` to bind the parameter data to the statement. Then you can call `mysql_stmt_execute()`.

To retrieve temporal values, the procedure is similar, except that you set the `buffer_type` member to the type of value you expect to receive, and the `buffer` member to the address of a `MYSQL_TIME` structure into which the returned value should be placed. Use `mysql_bind_results()` to bind the buffers to the statement after calling `mysql_stmt_execute()` and before fetching the results.

Here is a simple example that inserts `DATE`, `TIME`, and `TIMESTAMP` data. The `mysql` variable is assumed to be a valid connection handle.

```
MYSQL_TIME  ts;
MYSQL_BIND  bind[3];
MYSQL_STMT  *stmt;

strmov(query, "INSERT INTO test_table(date_field, time_field,
                                     timestamp_field) VALUES(?,?,?");

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, "mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(mysql, query, strlen(query)))
{
    fprintf(stderr, "\nmysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* set up input buffers for all 3 parameters */
bind[0].buffer_type= MYSQL_TYPE_DATE;
bind[0].buffer= (char *)&ts;
bind[0].is_null= 0;
bind[0].length= 0;
...
bind[1]= bind[2]= bind[0];
...

mysql_stmt_bind_param(stmt, bind);

/* supply the data to be sent in the ts structure */
ts.year= 2002;
ts.month= 02;
ts.day= 03;

ts.hour= 10;
ts.minute= 45;
ts.second= 20;

mysql_stmt_execute(stmt);
..
```

## 22.2.11. C API Threaded Function Descriptions

You need to use the following functions when you want to create a threaded client. See Section 22.2.15, “How to Make a Threaded Client”.

### 22.2.11.1. `my_init()`

```
void my_init(void)
```

#### Description

This function needs to be called once in the program before calling any MySQL function. This initializes some global variables that MySQL needs. If you are using a thread-safe client library, this also calls `mysql_thread_init()` for this thread.

This is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()` and `mysql_connect()`.

#### Return Values

None.

### 22.2.11.2. `mysql_thread_init()`

```
my_bool mysql_thread_init(void)
```

#### Description

This function needs to be called for each created thread to initialize thread-specific variables.

This is automatically called by `my_init()` and `mysql_connect()`.

#### Return Values

Zero if successful. Non-zero if an error occurred.

### 22.2.11.3. `mysql_thread_end()`

```
void mysql_thread_end(void)
```

#### Description

This function needs to be called before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

Note that this function *is not invoked automatically by the client library*. It must be called explicitly to avoid a memory leak.

#### Return Values

None.

### 22.2.11.4. `mysql_thread_safe()`

```
unsigned int mysql_thread_safe(void)
```

#### Description

This function indicates whether the client is compiled as thread-safe.

#### Return Values

1 if the client is thread-safe, 0 otherwise.

## 22.2.12. C API Embedded Server Function Descriptions

If you want to allow your application to be linked against the embedded MySQL server library, you must use the `mysql_server_init()` and `mysql_server_end()` functions. See Section 22.1, “libmysqld, the Embedded MySQL Server Library”.

However, to provide improved memory management, even programs that are linked with `-lmysqlclient` rather than `-lmysqld` should include calls to begin and end use of the library. As of MySQL 5.0.3, the `mysql_library_init()` and `mysql_library_end()` functions can be used to do this. These actually are `#define` symbols that make them equivalent to `mysql_server_init()` and `mysql_server_end()`, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL C API library no matter whether the application uses `libmysqlclient` or `libmysqld`. For more information, see Section 22.2.2, “C API Function Overview”.

### 22.2.12.1. `mysql_server_init()`

```
int mysql_server_init(int argc, char **argv, char **groups)
```

#### Description

This function **must** be called once in the program using the embedded server before calling any other MySQL function. It starts the server and initializes any subsystems (`mysys`, `InnoDB`, and so forth) that the server uses. If this function is not called, the next call to `mysql_init()` executes `mysql_server_init()`.

In a non-multi-threaded environment, the call to `mysql_server_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, a race condition is possible if `mysql_server_init()` is invoked by `mysql_init()` in a multi-threaded environment: `mysql_server_init()` is not thread-safe, so it should be called prior to any other client library call.

If you are using the `DEBUG` package that comes with MySQL, you should call `mysql_server_init()` after you have called `my_init()`.

The `argc` and `argv` arguments are analogous to the arguments to `main()`. The first element of `argv` is ignored (it typically contains the program name). For convenience, `argc` may be 0 (zero) if there are no command-line arguments for the server. `mysql_server_init()` makes a copy of the arguments so it's safe to destroy `argv` or `groups` after the call.

If you want to connect to an external server without starting the embedded server, you have to specify a negative value for `argc`.

The NULL-terminated list of strings in `groups` selects which groups in the option files are active. See Section 4.3.2, “Using Option Files”. For convenience, `groups` may be NULL, in which case the `[server]` and `[embedded]` groups are active.

#### Example

```
#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
    "this_program",          /* this string is not used */
    "--datadir=.",
    "--key_buffer_size=32M"
};

static char *server_groups[] = {
    "embedded",
    "server",
    "this_program_SERVER",
    (char *)NULL
};

int main(void) {
    if (mysql_server_init(sizeof(server_args) / sizeof(char *),
```

```
        server_args, server_groups))
    exit(1);
/* Use any MySQL API functions here */
mysql_server_end();
return EXIT_SUCCESS;
}
```

**Return Values**

0 if okay, 1 if an error occurred.

### 22.2.12.2. `mysql_server_end()`

```
void mysql_server_end(void)
```

**Description**

This function **must** be called once in the program after all other MySQL functions. It shuts down the embedded server.

**Return Values**

None.

## 22.2.13. Common questions and problems when using the C API

### 22.2.13.1. Why `mysql_store_result()` Sometimes Returns NULL After `mysql_query()` Returns Success

It is possible for `mysql_store_result()` to return NULL following a successful call to `mysql_query()`. When this happens, it means one of the following conditions occurred:

- There was a `malloc()` failure (for example, if the result set was too large).
- The data couldn't be read (an error occurred on the connection).
- The query returned no data (for example, it was an INSERT, UPDATE, or DELETE).

You can always check whether the statement should have produced a non-empty result by calling `mysql_field_count()`. If `mysql_field_count()` returns zero, the result is empty and the last query was a statement that does not return values (for example, an INSERT or a DELETE). If `mysql_field_count()` returns a non-zero value, the statement should have produced a non-empty result. See the description of the `mysql_field_count()` function for an example.

You can test for an error by calling `mysql_error()` or `mysql_errno()`.

### 22.2.13.2. What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- `mysql_affected_rows()` returns the number of rows affected by the last query when doing an INSERT, UPDATE, or DELETE.

For a fast re-create, use `TRUNCATE TABLE`.

- `mysql_num_rows()` returns the number of rows in a result set. With `mysql_store_result()`, `mysql_num_rows()` may be called as soon as `mysql_store_result()` returns. With `mysql_use_result()`, `mysql_num_rows()` may be called only after you have fetched all the rows with `mysql_fetch_row()`.
- `mysql_insert_id()` returns the ID generated by the last query that inserted a row into a table with an `AUTO_INCREMENT` index. See Section 22.2.3.36, “`mysql_insert_id()`”.
- Some queries (`LOAD DATA INFILE ...`, `INSERT INTO ... SELECT ...`, `UPDATE`) return additional information. The result is returned by `mysql_info()`. See the description for `mysql_info()` for the format of the string that it returns. `mysql_info()` returns a `NULL` pointer if there is no additional information.

### 22.2.13.3. How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an `AUTO_INCREMENT` column, you can obtain the value stored into that column by calling the `mysql_insert_id()` function.

You can check from your C applications whether a value was stored in an `AUTO_INCREMENT` column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an `INSERT` with an `AUTO_INCREMENT` index:

```
if ((result = mysql_store_result(&mysql)) == 0 &&
    mysql_field_count(&mysql) == 0 &&
    mysql_insert_id(&mysql) != 0)
{
    used_id = mysql_insert_id(&mysql);
}
```

For more information, see Section 22.2.3.36, “`mysql_insert_id()`”.

When a new `AUTO_INCREMENT` value has been generated, you can also obtain it by executing a `SELECT LAST_INSERT_ID()` statement with `mysql_query()` and retrieving the value from the result set returned by the statement.

For `LAST_INSERT_ID()`, the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another `AUTO_INCREMENT` column with a non-magic value (that is, a value that is not `NULL` and not 0).

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```
INSERT INTO foo (auto,text)
    VALUES(NULL,'text');           # generate ID by inserting NULL
INSERT INTO foo2 (id,text)
    VALUES(LAST_INSERT_ID(),'text'); # use ID in second table
```

Note that `mysql_insert_id()` returns the value stored into an `AUTO_INCREMENT` column, whether that value is automatically generated by storing `NULL` or 0 or was specified as an explicit value. `LAST_INSERT_ID()` returns only automatically generated `AUTO_INCREMENT` values. If you store an explicit value other than `NULL` or 0, it does not affect the value returned by `LAST_INSERT_ID()`.

### 22.2.13.4. Problems Linking with the C API

When linking with the C API, the following errors may occur on some systems:

```
gcc -g -o client test.o -L/usr/local/lib/mysql -lmysqlclient -lsocket -lnsl
Undefined      first referenced
symbol         in file
```

```
floor          /usr/local/lib/mysql/libmysqlclient.a(password.o)
ld: fatal: Symbol referencing errors. No output written to client
```

If this happens on your system, you must include the math library by adding `-lm` to the end of the compile/link line.

## 22.2.14. Building Client Programs

If you compile MySQL clients that you've written yourself or that you obtain from a third-party, they must be linked using the `-lmysqlclient -lz` options in the link command. You may also need to specify a `-L` option to tell the linker where to find the library. For example, if the library is installed in `/usr/local/mysql/lib`, use `-L/usr/local/mysql/lib -lmysqlclient -lz` in the link command.

For clients that use MySQL header files, you may need to specify an `-I` option when you compile them (for example, `-I/usr/local/mysql/include`), so that the compiler can find the header files.

To make it simpler to compile MySQL programs on Unix, we have provided the `mysql_config` script for you. See Section 22.9.2, “`mysql_config` — Get Compile Options for Compiling Clients”.

You can use it to compile a MySQL client as follows:

```
CFG=/usr/local/mysql/bin/mysql_config
sh -c "gcc -o progname ` $CFG --cflags ` progname.c ` $CFG --libs `"
```

The `sh -c` is needed to get the shell not to treat the output from `mysql_config` as one word.

## 22.2.15. How to Make a Threaded Client

The client library is almost thread-safe. The biggest problem is that the subroutines in `net.c` that read from sockets are not interrupt safe. This was done with the thought that you might want to have your own alarm that can break a long read to a server. If you install interrupt handlers for the `SIGPIPE` interrupt, the socket handling should be thread-safe.

To avoid aborting the program when a connection terminates, MySQL blocks `SIGPIPE` on the first call to `mysql_server_init()`, `mysql_init()`, or `mysql_connect()`. If you want to use your own `SIGPIPE` handler, you should first call `mysql_server_init()` and then install your handler.

In the older binaries we distribute on our Web site (<http://www.mysql.com/>), the client libraries are not normally compiled with the thread-safe option (the Windows binaries are by default compiled to be thread-safe). Newer binary distributions should have both a normal and a thread-safe client library.

To get a threaded client where you can interrupt the client from other threads and set timeouts when talking with the MySQL server, you should use the `-lmysys`, `-lmystrings`, and `-ldbbug` libraries and the `net_serv.o` code that the server uses.

If you don't need interrupts or timeouts, you can just compile a thread-safe client library (`mysqlclient_r`) and use this. See Section 22.2, “MySQL C API”. In this case, you don't have to worry about the `net_serv.o` object file or the other MySQL libraries.

When using a threaded client and you want to use timeouts and interrupts, you can make great use of the routines in the `thr_alarm.c` file. If you are using routines from the `mysys` library, the only thing you must remember is to call `my_init()` first! See Section 22.2.11, “C API Threaded Function Descriptions”.

All functions except `mysql_real_connect()` are by default thread-safe. The following notes

describe how to compile a thread-safe client library and use it in a thread-safe manner. (The notes below for `mysql_real_connect()` actually apply to `mysql_connect()` as well, but because `mysql_connect()` is deprecated, you should be using `mysql_real_connect()` anyway.)

To make `mysql_real_connect()` thread-safe, you must recompile the client library with this command:

```
shell> ./configure --enable-thread-safe-client
```

This creates a thread-safe client library `libmysqlclient_r`. (Assuming that your OS has a thread-safe `gethostbyname_r()` function.) This library is thread-safe per connection. You can let two threads share the same connection with the following caveats:

- Two threads can't send a query to the MySQL server at the same time on the same connection. In particular, you have to ensure that between a `mysql_query()` and `mysql_store_result()` no other thread is using the same connection.
- Many threads can access different result sets that are retrieved with `mysql_store_result()`.
- If you use `mysql_use_result`, you have to ensure that no other thread is using the same connection until the result set is closed. However, it really is best for threaded clients that share the same connection to use `mysql_store_result()`.
- If you want to use multiple threads on the same connection, you must have a mutex lock around your `mysql_query()` and `mysql_store_result()` call combination. Once `mysql_store_result()` is ready, the lock can be released and other threads may query the same connection.
- If you program with POSIX threads, you can use `pthread_mutex_lock()` and `pthread_mutex_unlock()` to establish and release a mutex lock.

You need to know the following if you have a thread that is calling MySQL functions which did not create the connection to the MySQL database:

When you call `mysql_init()` or `mysql_connect()`, MySQL creates a thread-specific variable for the thread that is used by the debug library (among other things).

If you call a MySQL function, before the thread has called `mysql_init()` or `mysql_connect()`, the thread does not have the necessary thread-specific variables in place and you are likely to end up with a core dump sooner or later.

To get things to work smoothly you have to do the following:

1. Call `my_init()` at the start of your program if it calls any other MySQL function before calling `mysql_real_connect()`.
2. Call `mysql_thread_init()` in the thread handler before calling any MySQL function.
3. In the thread, call `mysql_thread_end()` before calling `pthread_exit()`. This frees the memory used by MySQL thread-specific variables.

You may get some errors because of undefined symbols when linking your client with `libmysqlclient_r`. In most cases this is because you haven't included the thread libraries on the link/compile line.

## 22.3. MySQL PHP API

PHP is a server-side, HTML-embedded scripting language that may be used to create dynamic Web pages. It is available for most operating systems and Web servers, and can access most common databases, including MySQL. PHP may be run as a separate program or compiled as a module for use with the Apache Web server.

PHP actually provides two different MySQL API extensions:

- `mysql`: Available for PHP versions 4 and 5, this extension is intended for use with MySQL versions prior to MySQL 4.1. This extension does not support the improved authentication protocol used in MySQL 5.0, nor does it support prepared statements or multiple statements. If you wish to use this extension with MySQL 5.0, you will likely want to configure the MySQL server to use the `--old-passwords` option (see Section A.2.3, “Client does not support authentication protocol”). This extension is documented on the PHP Web site at <http://php.net/mysql>.
- `mysqli` - Stands for “MySQL, Improved”; this extension is available only in PHP 5. It is intended for use with MySQL 4.1.1 and later. This extension fully supports the authentication protocol used in MySQL 5.0, as well as the Prepared Statements and Multiple Statements APIs. In addition, this extension provides an advanced, object-oriented programming interface. You can read the documentation for the `mysqli` extension at <http://php.net/mysqli>. A helpful article can be found at <http://www.zend.com/php5/articles/php5-mysqli.php>.

If you're experiencing problems with enabling both the `mysql` and the `mysqli` extension when building PHP on Linux yourself, see Section 22.3.2, “Enabling Both `mysql` and `mysqli` in PHP”.

The PHP distribution and documentation are available from the PHP Web site [<http://www.php.net/>]. MySQL provides the `mysql` and `mysqli` extensions for the Windows operating system for MySQL versions as of 5.0.18 on <http://dev.mysql.com/downloads/connector/php/>. You can find information why you should preferably use the extensions provided by MySQL on that page.

## 22.3.1. Common Problems with MySQL and PHP

- `Error: Maximum Execution Time Exceeded`: This is a PHP limit; go into the `php.ini` file and set the maximum execution time up from 30 seconds to something higher, as needed. It is also not a bad idea to double the RAM allowed per script to 16MB instead of 8MB.
- `Fatal error: Call to unsupported or undefined function mysql_connect() in ...`: This means that your PHP version isn't compiled with MySQL support. You can either compile a dynamic MySQL module and load it into PHP or recompile PHP with built-in MySQL support. This process is described in detail in the PHP manual.
- `Error: Undefined reference to 'uncompress'`: This means that the client library is compiled with support for a compressed client/server protocol. The fix is to add `-lz` last when linking with `-lmysqlclient`.
- `Error: Client does not support authentication protocol`: This is most often encountered when trying to use the older `mysql` extension with MySQL 4.1.1 and later. Possible solutions are: downgrade to MySQL 4.0; switch to PHP 5 and the newer `mysqli` extension; or configure the MySQL server with `--old-passwords`. (See Section A.2.3, “Client does not support authentication protocol”, for more information.)

Those with PHP4 legacy code can make use of a compatibility layer for the old and new MySQL libraries, such as this one: <http://www.coggeshall.org/oss/mysql2i>.

## 22.3.2. Enabling Both `mysql` and `mysqli` in PHP

If you're experiencing problems with enabling both the `mysql` and the `mysqli` extension when

building PHP on Linux yourself, you should try the following procedure.

1. Configure PHP like this:

```
./configure --with-mysqli=/usr/bin/mysql_config --with-mysql=/usr
```

2. Edit the `Makefile` and search for a line that starts with `EXTRA_LIBS`. It might look like this (all on one line):

```
EXTRA_LIBS = -lcrypt -lcrypt -lmysqlclient -lz -lresolv -lm -ldl -lnsl  
-lxml2 -lz -lm -lxml2 -lz -lm -lmysqlclient -lz -lcrypt -lnsl -lm  
-lxml2 -lz -lm -lcrypt -lxml2 -lz -lm -lcrypt
```

Remove all duplicates, so that the line looks like this (all on one line):

```
EXTRA_LIBS = -lcrypt -lcrypt -lmysqlclient -lz -lresolv -lm -ldl -lnsl  
-lxml2
```

3. Build and install PHP:

```
make  
make install
```

## 22.4. MySQL Perl API

The Perl DBI module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI, you must install the DBI module, as well as a DataBase Driver (DBD) module for each type of server you want to access. For MySQL, this driver is the `DBD::mysql` module.

Perl DBI is the recommended Perl interface. It replaces an older interface called `mysqlperl`, which should be considered obsolete.

Installation instructions for Perl DBI support are given in Section 2.14, “Perl Installation Notes”.

DBI information is available at the command line, online, or in printed form:

- Once you have the DBI and `DBD::mysql` modules installed, you can get information about them at the command line with the `perldoc` command:

```
shell> perldoc DBI  
shell> perldoc DBI::FAQ  
shell> perldoc DBD::mysql
```

You can also use `pod2man`, `pod2html`, and so forth to translate this information into other formats.

- For online information about Perl DBI, visit the DBI Web site, <http://dbi.perl.org/>. That site hosts a general DBI mailing list. MySQL AB hosts a list specifically about `DBD::mysql`; see Section 1.7.1, “MySQL Mailing Lists”.
- For printed information, the official DBI book is *Programming the Perl DBI* (Alligator Descartes and Tim Bunce, O'Reilly & Associates, 2000). Information about the book is available at the DBI Web site, <http://dbi.perl.org/>.

For information that focuses specifically on using DBI with MySQL, see *MySQL and Perl for the Web* (Paul DuBois, New Riders, 2001). This book's Web site is <http://www.kitebird.com/mysql-perl/>.

## 22.5. MySQL C++ API

MySQL++ is a MySQL API for C++. Warren Young has taken over this project. More information can be found at <http://www.mysql.com/products/mysql++/>.

### 22.5.1. Borland C++

You can compile the MySQL Windows source with Borland C++ 5.02. (The Windows source includes only projects for Microsoft VC++, for Borland C++ you have to do the project files yourself.)

One known problem with Borland C++ is that it uses a different structure alignment than VC++. This means that you run into problems if you try to use the default `libmysql.dll` libraries (that were compiled using VC++) with Borland C++. To avoid this problem, only call `mysql_init()` with `NULL` as an argument, not a pre-allocated `MYSQL` structure.

## 22.6. MySQL Python API

MySQLdb provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at <http://sourceforge.net/projects/mysql-python/>.

## 22.7. MySQL Tcl API

MySQLtcl is a simple API for accessing a MySQL database server from the Tcl programming language. It can be found at <http://www.xdobry.de/mysqltcl/>.

## 22.8. MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the Eiffel programming language, written by Michael Ravits. It can be found at <http://efsa.sourceforge.net/archive/ravits/mysql.htm>.

## 22.9. MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

- `msql2mysql`

A shell script that converts mSQL programs to MySQL. It doesn't handle every case, but it gives a good start when converting.

- `mysql_config`

A shell script that produces the option values needed when compiling MySQL programs.

### 22.9.1. `msql2mysql` — Convert mSQL Programs for Use with MySQL

Initially, the MySQL C API was developed to be very similar to that for the mSQL database system. Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The `msql2mysql` utility performs the conversion of mSQL C API function calls to their MySQL equivalents. `msql2mysql` converts the input file in place, so make a copy of the original before converting it. For example, use `msql2mysql` like this:

```
shell> cp client-prog.c client-prog.c.orig
```

```
shell> mysql2mysql client-prog.c  
client-prog.c converted
```

Then examine `client-prog.c` and make any post-conversion revisions that may be necessary.

`mysql2mysql` uses the `replace` utility to make the function name substitutions. See Section 8.17, “`replace` — A String-Replacement Utility”.

## 22.9.2. `mysql_config` — Get Compile Options for Compiling Clients

`mysql_config` provides you with useful information for compiling your MySQL client and connecting it to MySQL.

`mysql_config` supports the following options:

- `--cflags`

Compiler flags to find include files and critical compiler flags and defines used when compiling the `libmysqlclient` library.

- `--include`

Compiler options to find MySQL include files. (Note that normally you would use `--cflags` instead of this option.)

- `--libmysqld-libs, --embedded`

Libraries and options required to link with the MySQL embedded server.

- `--libs`

Libraries and options required to link with the MySQL client library.

- `--libs_r`

Libraries and options required to link with the thread-safe MySQL client library.

- `--port`

The default TCP/IP port number, defined when configuring MySQL.

- `--socket`

The default Unix socket file, defined when configuring MySQL.

- `--version`

Version number for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config  
Usage: /usr/local/mysql/bin/mysql_config [options]  
Options:  
--cflags          [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]  
--include        [-I/usr/local/mysql/include/mysql]  
--libs           [-L/usr/local/mysql/lib/mysql -lmysqlclient -lz  
                -lcrypt -lnsl -lm -L/usr/lib -lssl -lcrypto]  
--libs_r        [-L/usr/local/mysql/lib/mysql -lmysqlclient_r  
                -lpthread -lz -lcrypt -lnsl -lm -lpthread]
```

```
--socket      [/tmp/mysql.sock]
--port        [3306]
--version     [4.0.16]
--libmysqld-libs [-L/usr/local/mysql/lib/mysql -lmysqld -lpthread -lz
                -lcrypt -lnsl -lm -lpthread -lrt]
```

You can use `mysql_config` within a command line to include the value that it displays for a particular option. For example, to compile a MySQL client program, use `mysql_config` as follows:

```
shell> CFG=/usr/local/mysql/bin/mysql_config
shell> sh -c "gcc -o progname ` $CFG --cflags ` progname.c ` $CFG --libs `"
```

When you use `mysql_config` this way, be sure to invoke it within backtick (``) characters. That tells the shell to execute it and substitute its output into the surrounding command.

---

# Chapter 23. Connectors

This chapter describes MySQL Connectors, drivers that provide connectivity to the MySQL server for client programs. There are currently five MySQL Connectors:

- Connector/ODBC provides driver support for connecting to a MySQL server using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix and Mac OS X platforms.
- Connector/NET enables developers to create .NET applications that use data stored in a MySQL database. Connector/NET implement a fully-functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that want to use Connector/NET can be written in any of the supported .NET languages.
- Connector/J provides driver support for connecting to MySQL from a Java application using the standard Java Database Connectivity (JDBC) API.
- Connector/MXJ is a tool that enables easy deployment and management of MySQL server and database through your Java application.
- Connector/PHP is a Windows-only connector for PHP that provides the `mysql` and `mysqli` extensions for use with MySQL 5.0.18 and later.

For information on connecting to a MySQL server using other languages and interfaces than those detailed above, including Perl, Python and PHP for other platforms and environments, please refer to the Chapter 22, *APIs and Libraries* chapter.

## 23.1. MySQL Connector/ODBC

MySQL provides support for ODBC by means of MySQL Connector/ODBC, the family of MyODBC drivers. This is the reference for the Connector/ODBC product family of MyODBC drivers that provide ODBC 3.5x compliant access to the MySQL Database System. It teaches you how to install MyODBC and how to use it. There is also information about common programs that are known to work with MyODBC and answers to some of the most frequently asked questions about MyODBC.

This reference applies to MyODBC 3.51. You can find a manual for an older version of MyODBC in the binary or source distribution for that version.

This is a reference to the MySQL ODBC drivers, not a general ODBC reference. For more information about ODBC, refer to <http://www.microsoft.com/data/>.

The application development part of this reference assumes a good working knowledge of C, general DBMS knowledge, and finally, but not least, familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to <http://dev.mysql.com/doc/>.

If you have questions that are not answered in this document, please send a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com).

### 23.1.1. Introduction to MyODBC

#### 23.1.1.1. What is ODBC?

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that allows connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to <http://www.microsoft.com/data/>.

### **23.1.1.2. What is Connector/ODBC?**

Connector/ODBC is the term designating the MySQL AB product family of MySQL ODBC drivers. These are known as the MyODBC drivers.

### **23.1.1.3. What is MyODBC 2.50?**

MyODBC 2.50 is a 32-bit ODBC driver from MySQL AB that is based on ODBC 2.50 specification level 0 (with level 1 and 2 features). This is one of the most popular ODBC drivers in the Open Source market, used by many users to access the MySQL functionality.

### **23.1.1.4. What is MyODBC 3.51?**

MyODBC 3.51 is a 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. This version is enhanced compared to the existing MyODBC 2.50 driver. It has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) in order to continue to provide all functionality of ODBC for accessing MySQL.

### **23.1.1.5. Where to Get MyODBC**

MySQL AB distributes all its products under the General Public License (GPL). You can get a copy of the latest version of MyODBC binaries and sources from the MySQL AB Web site <http://dev.mysql.com/downloads/>.

For more information about MyODBC, visit <http://www.mysql.com/products/myodbc/>.

For more information about licensing, visit <http://www.mysql.com/company/legal/licensing/>.

### **23.1.1.6. Supported Platforms**

MyODBC can be used on all major platforms supported by MySQL, such as:

- Windows 95, 98, Me, NT, 2000, XP, and 2003
- All Unix Operating Systems
  - AIX
  - Amiga
  - BSDI
  - DEC
  - FreeBSD
  - HP-UX 10, 11
  - Linux
  - Mac OS X Server
  - Mac OS X
  - NetBSD
  - OpenBSD
  - OS/2

- SGI Irix
- Solaris
- SunOS
- SCO OpenServer
- SCO UnixWare
- Tru64 Unix

If a binary distribution is not available for downloading for a particular platform, you can build the driver yourself by downloading the driver sources. You can contribute the binaries to MySQL by sending a mail message to `<myodbc@lists.mysql.com>`, so that it becomes available for other users.

### 23.1.1.7. MyODBC Mailing List

MySQL AB provides assistance to the user community by means of its mailing lists. For MyODBC-related issues, you can get help from experienced users by using the `<myodbc@lists.mysql.com>` mailing list.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>. See Section 1.7.1, “MySQL Mailing Lists”.

Of particular interest is the ODBC forum in the MySQL Connectors section of the forums.

### 23.1.1.8. MyODBC Forum

Community support from experienced users is available through the MySQL Forums, located at <http://forums.mysql.com>. See Section 1.7.2, “MySQL Community Support at the MySQL Forums”.

### 23.1.1.9. How to Report MyODBC Problems or Bugs

If you encounter difficulties or problems with MyODBC, you should start by making a log file from the ODBC Manager (the log you get when requesting logs from ODBC ADMIN) and MyODBC. The procedure for doing this is described in Section 23.1.9.7, “Getting an ODBC Trace File”.

Check the MyODBC trace file to find out what could be wrong. You should be able to determine what statements were issued by searching for the string `>mysql_real_query` in the `myodbc.log` file.

You should also try issuing the statements from the `mysql` client program or from `admindemo`. This helps you determine whether the error is in MyODBC or MySQL.

If you find out something is wrong, please only send the relevant rows (maximum 40 rows) to the `myodbc` mailing list. See Section 1.7.1, “MySQL Mailing Lists”. Please never send the whole MyODBC or ODBC log file!

If you are unable to find out what's wrong, the last option is to create an archive in `tar` or `Zip` format that contains a MyODBC trace file, the ODBC log file, and a `README` file that explains the problem. You can send this to <ftp://ftp.mysql.com/pub/mysql/upload/>. Only we at MySQL AB has access to the files you upload, and we are very discreet with the data.

If you can create a program that also demonstrates the problem, please include it in the archive as well.

If the program works with some other SQL server, you should include an ODBC log file where you do exactly the same thing in the other SQL server.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

### 23.1.1.10. How to Submit a MyODBC Patch

You can send a patch or suggest a better solution for any existing code or problems by sending a mail message to <myodbc@lists.mysql.com>.

## 23.1.2. General Information About ODBC and MyODBC

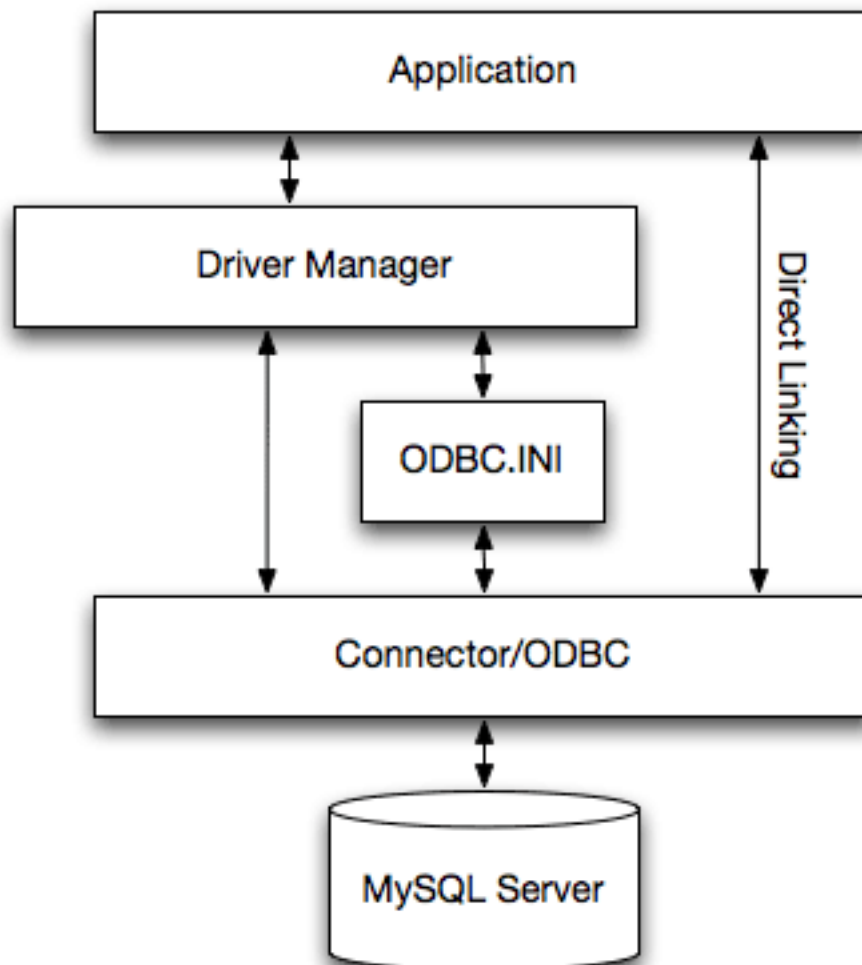

### 23.1.2.1. Introduction to ODBC

Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by MyODBC is given at Section 23.1.16, “MyODBC API Reference”. For general information about ODBC, see <http://www.microsoft.com/data/>.

### 23.1.2.2. MyODBC Architecture

The MyODBC architecture is based on five components, as shown in the following diagram:

- **Application:**

An application is a program that calls the ODBC API to access the data from the MySQL server. The Application communicates with the Driver Manager using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

- Selecting the MySQL server and connecting to it
- Submitting SQL statements for execution
- Retrieving results (if any)
- Processing errors
- Committing or rolling back the transaction enclosing the SQL statement
- Disconnecting from the MySQL server

Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

- Resolves Data Source Names (DSN)
- Driver loading and unloading
- Processes ODBC function calls or passes them to the driver

- **MyODBC Driver:**

The MyODBC driver is a library that implements the functions in the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by the MySQL.

- **ODBC.INI:**

ODBC.INI is the ODBC configuration file that stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded using the Data Source Name. The driver uses this to read connection parameters based on the DSN specified. For more information, Section 23.1.9, "MyODBC Configuration".

- **MySQL Server:**

The MySQL server is the source of data. MySQL is:

- A database management system (DBMS)
- A relational database management system (RDBMS)
- Open Source Software

### 23.1.2.3. ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC-aware ap-

plication and any drivers. Its main functionality includes:

- Resolving Data Source Names (DSN)
- Driver loading and unloading
- Processing ODBC function calls or passing them to the driver

The following driver managers are commonly used:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), <http://www.microsoft.com/data/>
- unixODBC Driver Manager for Unix (`libodbc.so`), <http://www.unixodbc.org>.
- iODBC ODBC Driver Manager for Unix (`libiodbc.so`), <http://www.iodbc.org>

MyODBC 3.51 also is shipped with UnixODBC beginning with version 2.1.2.

### 23.1.2.4. Types of MySQL ODBC Drivers

MySQL AB supports two Open Source ODBC drivers for accessing MySQL functionality through the ODBC API: MyODBC (MyODBC 2.50) and MySQL ODBC 3.51 Driver (MyODBC 3.51).

Note: From this section onward, we refer both the drivers generically as MyODBC. Whenever there is a difference, we use the original names.

### 23.1.3. How to Install MyODBC

MyODBC works on Windows 9x, Me, NT, 2000, XP, and 2003, and on most Unix platforms.

MyODBC is Open Source. You can find the newest version at <http://dev.mysql.com/downloads/connector/odbc/>. Please note that the 2.50.x versions are LGPL licensed, whereas the 3.51.x versions are GPL licensed.

If you have problem with MyODBC and your program also works with OLEDB, you should try the OLEDB driver.

Normally, you need to install MyODBC only on Windows machines. You need MyODBC for Unix only if you have a program like ColdFusion that is running on a Unix machine and uses ODBC to connect for database access.

If you want to install MyODBC on a Unix box, you also need an ODBC manager. MyODBC is known to work with most Unix ODBC managers.

- To make a connection to a Unix box from a Windows box with an ODBC application (one that doesn't support MySQL natively), you must first install MyODBC on the Windows machine.
- The user and Windows machine must have access privileges for the MySQL server on the Unix machine. This is set up with the `GRANT` command. See Section 13.5.1.3, "GRANT Syntax".
- You must create an ODBC DSN entry as follows:
  1. Open the Control Panel on the Windows machine.
  2. Double-click the ODBC Data Sources 32-bit icon.
  3. Click the tab `User DSN`.

4. Click the Add button.
  5. Select MySQL in the screen Create New Data Source and click the Finish button.
  6. The MySQL Driver default configuration screen is shown. See Section 23.1.9.2, “Configuring a MyODBC DSN on Windows”.
- Start your application and select the ODBC driver with the DSN that you specified in the ODBC administrator.

Notice that other configuration options are shown on the MySQL screen that you can try if you run into problems (options such as trace, don't prompt on connect, and so forth).

## 23.1.4. Installing MyODBC from a Binary Distribution on Windows

To install MyODBC on Windows, you should download the appropriate distribution file from <http://dev.mysql.com/downloads/connector/odbc/>, unpack it, and execute the `MyODBC-VERSION.exe` file.

On Windows, you may get the following error when trying to install the older MyODBC 2.50 driver:

```
An error occurred while copying C:\WINDOWS\SYSTEM\MFC30.DLL. Restart Windows and try installing again (before running any applications which use ODBC)
```

The problem is that some other program is using ODBC. Because of how Windows is designed, you may not be able in this case to install new ODBC drivers with Microsoft's ODBC setup program. In most cases, you can continue by pressing Ignore to copy the rest of the MyODBC files and the final installation should still work. If it doesn't, the solution is to re-boot your computer in “safe mode.” Choose safe mode by pressing F8 just before your machine starts Windows during re-booting, install MyODBC, and re-boot to normal mode.

## 23.1.5. Installing MyODBC from a Binary Distribution on Unix

### 23.1.5.1. Installing MyODBC from an RPM Distribution

To install or upgrade MyODBC from an RPM distribution on Linux, simply download the RPM distribution of the latest version of MyODBC and follow the instructions below. Use `su root` to become root, then install the RPM file.

If you are installing for the first time:

```
shell> su root
shell> rpm -ivh MyODBC-3.51.01.i386-1.rpm
```

If the driver exists, upgrade it like this:

```
shell> su root
shell> rpm -Uvh MyODBC-3.51.01.i386-1.rpm
```

If there is any dependency error for MySQL client library, `libmysqlclient`, simply ignore it by supplying the `--nodeps` option, and then make sure the MySQL client shared library is in the path

or set through `LD_LIBRARY_PATH`.

This installs the driver libraries and related documents to `/usr/local/lib` and `/usr/share/doc/MyODBC` respectively. Proceed onto Section 23.1.9.3, “Configuring a MyODBC DSN on Unix”.

To **uninstall** the driver, become `root` and execute an `rpm` command:

```
shell> su root
shell> rpm -e MyODBC
```

## 23.1.5.2. Installing MyODBC from a Binary Tarball Distribution

To install the driver from a tarball distribution (`.tar.gz` file), download the latest version of the driver for your operating system and follow these steps:

```
shell> su root
shell> gunzip MyODBC-3.51.01-i686-pc-linux.tar.gz
shell> tar xvf MyODBC-3.51.01-i686-pc-linux.tar
shell> cd MyODBC-3.51.01-i686-pc-linux
```

Read the installation instructions in the `INSTALL-BINARY` file and execute these commands.

```
shell> cp libmyodbc* /usr/local/lib
shell> cp odbc.ini /usr/local/etc
shell> export ODBCINI=/usr/local/etc/odbc.ini
```

Then proceed on to Section 23.1.9.3, “Configuring a MyODBC DSN on Unix”, to configure the DSN for MyODBC. For more information, refer to the `INSTALL-BINARY` file that comes with your distribution.

## 23.1.6. Installing MyODBC from a Source Distribution on Windows

### 23.1.6.1. Requirements

- MDAC, Microsoft Data Access SDK from <http://www.microsoft.com/data/>.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because MyODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

### 23.1.6.2. Building MyODBC 3.51

MyODBC 3.51 source distributions include `Makefiles` that uses `nmake`. In the distribution, you can find `Makefile` for building the release version and `Makefile_debug` for building debugging versions of the driver libraries and DLLs.

To build the driver, use this procedure:

1. Download and extract the sources to a folder, then change location into that folder. The following command assumes the folder is named `myodbc3-src`:

```
C:\> cd myodbc3-src
```

2. Edit `Makefile` to specify the correct path for the MySQL client libraries and header files. Then use the following commands to build and install the release version:

```
C:\> nmake -f Makefile
C:\> nmake -f Makefile install
```

`nmake -f Makefile` builds the release version of the driver and places the binaries in subdirectory called `Release`.

`nmake -f Makefile install` installs (copies) the driver DLLs and libraries(`myodbc3.dll`, `myodbc3.lib`) to your system directory.

3. To build the debug version, use `Makefile_Debug` rather than `Makefile`, as shown below:

```
C:\> nmake -f Makefile_debug
C:\> nmake -f Makefile_debug install
```

4. You can clean and rebuild the driver by using:

```
C:\> nmake -f Makefile clean
C:\> nmake -f Makefile install
```

**Note:**

- Make sure to specify the correct MySQL client libraries and header files path in the Makefiles (set the `MYSQL_LIB_PATH` and `MYSQL_INCLUDE_PATH` variables). The default header file path is assumed to be `C:\mysql\include`. The default library path is assumed to be `C:\mysql\lib\opt` for release DLLs and `C:\mysql\lib\debug` for debug versions.
- For the complete usage of `nmake`, visit [http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv\\_vcce4/html/evgrfRunningNMAKE.asp](http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv_vcce4/html/evgrfRunningNMAKE.asp).
- If you are using the BitKeeper tree for compiling, All Windows-specific Makefiles are named as `Win_Makefile*`.

### 23.1.6.3. Testing

After the driver libraries are copied/installed to the system directory, you can test whether the libraries are properly built by using the samples provided in the `samples` subdirectory:

```
C:\> cd samples
C:\> nmake -f Makefile all
```

### 23.1.6.4. Building MyODBC 2.50

The MyODBC 2.50 source distribution includes VC workspace files. You can build the driver using these files (`.dsp` and `.dsw`) directly by loading them from Microsoft Visual Studio 6.0 or higher.

## 23.1.7. Installing MyODBC from a Source Distribution on Unix

### 23.1.7.1. Requirements

- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because MyODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.
- The MySQL library must be configured with the `--enable-thread-safe-client` option. `libmysqlclient` installed as a shared library.
- One of the following Unix ODBC driver managers must be installed:
  - `iodbc` 3.0 or later (<http://www.iodbc.org>)
  - `unixodbc` Alpha 3 or later (<http://www.unixodbc.org>)
- If using a **character set** that isn't compiled into the MySQL client library (the defaults are: `latin1` `big5` `czech` `eur_kr` `gb2312` `gbk` `sjis` `tis620` `ujis`) then you need to install the `mysql` character definitions from the `charsets` directory into `SHAREDIR` (by default, `/usr/local/mysql/share/mysql/charsets`). These should be in place if you have installed the MySQL server on the same machine.

Once you have all the required files, unpack the source files to a separate directory and follow the instructions as given below:

### 23.1.7.2. Typical configure Options

The `configure` script gives you a great deal of control over how you configure your MyODBC build. Typically you do this using options on the `configure` command line. You can also affect `configure` using certain environment variables. For a list of options and environment variables supported by `configure`, run this command:

```
shell> ./configure --help
```

Some of the more commonly used `configure` options are described here:

1. To compile MyODBC, you need to supply the MySQL client include and library files path using the `--with-mysql-path=DIR` option, where `DIR` is the directory where the MySQL is installed.

MySQL compile options can be determined by running `DIR/bin/mysql_config`.

2. Supply the standard header and library files path for your ODBC Driver Manager(`iodbc` or `unixodbc`).

- If you are using `iodbc` and `iodbc` is not installed in its default location (`/usr/local`), you might have to use the `--with-iodbc=DIR` option, where `DIR` is the directory where `iodbc` is installed.

If the `iodbc` headers do not reside in `DIR/include`, you can use the `--with-iodbc-includes=INCDIR` option to specify their location.

The applies to libraries. If they are not in `DIR/lib`, you can use the `--with-iodbc-libs=LIBDIR` option.

- If you are using `unixODBC`, use the `--with-unixODBC=DIR` option (case sensitive) to make `configure` look for `unixODBC` instead of `iodbc` by default, `DIR` is the directory where `unixODBC` is installed.

If the `unixODBC` headers and libraries aren't located in `DIR/include` and `DIR/lib`, use the `--with-unixODBC-includes=INCDIR` and `--with-unixODBC-libs=LIBDIR` options.

3. You might want to specify an installation prefix other than `/usr/local`. For example, to install the MyODBC drivers in `/usr/local/odbc/lib`, use the `--prefix=/usr/local/odbc` option.

The final configuration command looks something like this:

```
shell> ./configure --prefix=/usr/local \  
          --with-iodbc=/usr/local \  
          --with-mysql-path=/usr/local/mysql
```

### 23.1.7.3. Thread-Safe Client

To link the driver with MySQL thread safe client libraries `libmysqlclient_r.so` or `libmysqlclient_r.a`, you must specify the following `configure` option:

```
--enable-thread-safe
```

and can be disabled(default) using

```
--disable-thread-safe
```

This option enables the building of driver thread-safe library `libmyodbc3_r.so` from by linking with mysql thread-safe client library `libmysqlclient_r.so` (The extensions are OS dependent).

In case while configuring with thread-safe option, and gotten into a configure error, look at the `config.log` and determine whether the error is due to the lack of thread-libraries in the system; and supply one with LIBS options i.e.

```
LIBS="-lpthread" ./configure ..
```

### 23.1.7.4. Shared or Static Options

You can enable or disable the shared and static versions using these options:

```
--enable-shared[=yes/no]  
--disable-shared  
--enable-static[=yes/no]  
--disable-static
```

### 23.1.7.5. Enabling Debugging Information

By default, all the binary distributions are built as non-debugging versions (configured with `--without-debug`).

To enable debugging information, build the driver from source distribution and use the `--with-debug` when you run `configure`.

### 23.1.7.6. Enabling the Documentation

This option is available only for BK clone trees; not for normal source distributions.

By default, the driver is built with (`--without-docs`); And in case if you want the documentation to be taken care in the normal build, then configure with:

```
--with-docs
```

### 23.1.7.7. Building and Compilation

To build the driver libraries, you have to just execute `make`, which takes care of everything.

```
shell> make
```

If any errors occur, correct them and continue the build process. If you aren't able to build, then send a detailed email to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com) for further assistance.

### 23.1.7.8. Building Shared Libraries

On most platforms, MySQL doesn't build or support `.so` (shared) client libraries by default, because building with shared libraries has caused us problems in the past.

In cases like this, you have to download the MySQL distribution and configure it with these options:

```
--without-server --enable-shared
```

To build shared driver libraries, you must specify the `--enable-shared` option for configure. By default, configure does not enable this option.

If you have configured with the `--disable-shared` option, you can build the `.so` file from the static libraries using the following commands:

```
shell> cd MyODBC-3.51.01
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error \
        -o .libs/libmyodbc3-3.51.01.so \
        catalog.o connect.o cursor.o dll.o error.o execute.o \
        handle.o info.o misc.o myodbc3.o options.o prepare.o \
        results.o transact.o utility.o \
        -L/usr/local/mysql/lib/mysql/ \
        -L/usr/local/iodbc/lib/ \
        -lz -lc -lmysqlclient -liodbcinst
```

Make sure to change `-liodbcinst` to `-lodbcinst` if you are using `unixODBC` instead of `iODBC`, and configure the library paths accordingly.

This builds and places the `libmyodbc3-3.51.01.so` file in the `.libs` directory. Copy this file to MyODBC library directory (`/usr/local/lib` (or the `lib` directory under the installation directory that you supplied with the `--prefix`).

```
shell> cd .libs
shell> cp libmyodbc3-3.51.01.so /usr/local/lib
shell> cd /usr/local/lib
shell> ln -s libmyodbc3-3.51.01.so libmyodbc3.so
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error \
        -o .libs/libmyodbc3_r-3.51.01.so \
        catalog.o connect.o cursor.o dll.o error.o execute.o \
        handle.o info.o misc.o myodbc3.o options.o prepare.o \
        results.o transact.o utility.o \
        -L/usr/local/mysql/lib/mysql/ \
        -L/usr/local/iodbc/lib/ \
        -lz -lc -lmysqlclient_r -liodbcinst
```

### 23.1.7.9. Installing Driver Libraries

To install the driver libraries, execute the following command:

```
shell> make install
```

That command installs one of the following sets of libraries:

For MyODBC 3.51:

- `libmyodbc3.so`
- `libmyodbc3-3.51.01.so`, where 3.51.01 is the version of the driver
- `libmyodbc3.a`

For thread-safe MyODBC 3.51:

- `libmyodbc3_r.so`
- `libmyodbc3-3_r.51.01.so`
- `libmyodbc3_r.a`

For MyODBC 2.5.0:

- `libmyodbc.so`
- `libmyodbc-2.50.39.so`, where 2.50.39 is the version of the driver
- `libmyodbc.a`

For more information on build process, refer to the `INSTALL` file that comes with the source distribution. Note that if you are trying to use the `make` from Sun, you may end up with errors. On the other hand, GNU `gmake` should work fine on all platforms.

### 23.1.7.10. Testing MyODBC on Unix

To run the basic samples provided in the distribution with the libraries that you built, just execute:

```
shell> make test
```

Make sure the DSN 'myodbc3' is configured first in `odbc.ini` and environment variable `ODBCINI` is pointing to the right `odbc.ini` file; and MySQL server is running. You can find a sample `odbc.ini` with the driver distribution.

You can even modify the `samples/run-samples` script to pass the desired DSN, UID, and PASSWORD values as the command line arguments to each sample.

### 23.1.7.11. Mac OS X Notes

To build the driver on Mac OS X (Darwin), make use of the following configure example:

```
shell> ./configure --prefix=/usr/local
                --with-unixODBC=/usr/local
                --with-mysql-path=/usr/local/mysql
```

```
--disable-shared
--enable-gui=no
--host=powerpc-apple
```

The command assumes that the unixODBC and MySQL are installed in the default locations. If not, configure accordingly.

On Mac OS X, `--enable-shared` builds `.dylib` files by default. You can build `.so` files like this:

```
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error
    -o .libs/libmyodbc3-3.51.01.so *.o
    -L/usr/local/mysql/lib/
    -L/usr/local/iodbc/lib
    -liodbcinst -lmysqlclient -lz -lc
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error
    -o .libs/libmyodbc3-3.51.01.so *.o
    -L/usr/local/mysql/lib/
    -L/usr/local/iodbc/lib
    -liodbcinst -lmysqlclienti_r -lz -lc -lpthread
```

Make sure to change the `-liodbcinst` to `-lodbcinst` in case of using unixODBC instead of iODBC and configure the libraries path accordingly.

In Apple's version of GCC, both `cc` and `gcc` are actually symbolic links to `gcc3`.

Copy this library to the `$prefix/lib` directory and symlink to `libmyodbc3.so`.

You can cross-check the output shared-library properties using this command:

```
shell> otool -LD .libs/libmyodbc3-3.51.01.so
```

## 23.1.7.12. HP-UX Notes

To build the driver on HP-UX 10.x or 11.x, make use of the following configure example:

If using `cc`:

```
shell> CC="cc" \
    CFLAGS="+z" \
    LDFLAGS="-Wl,+b:-Wl,+s" \
    ./configure --prefix=/usr/local
    --with-unixodbc=/usr/local
    --with-mysql-path=/usr/local/mysql/lib/mysql
    --enable-shared
    --enable-thread-safe
```

If using `gcc`:

```
shell> CC="gcc" \
    LDFLAGS="-Wl,+b:-Wl,+s" \
    ./configure --prefix=/usr/local
    --with-unixodbc=/usr/local
    --with-mysql-path=/usr/local/mysql
    --enable-shared
    --enable-thread-safe
```

Once the driver is built, cross-check its attributes using `chatr .libs/libmyodbc3.sl` to determine whether you need to have the MySQL client libraries path using the `SHLIB_PATH` environment variable. For static versions, ignore all shared-library options and run `configure` with the `--disable-shared` option.

### 23.1.7.13. AIX Notes:

To build the driver on AIX, make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
          --with-unixodbc=/usr/local
          --with-mysql-path=/usr/local/mysql
          --disable-shared
          --enable-thread-safe
```

**NOTE:** For more information about how to build and set up the static and shared libraries across the different platforms refer to 'Using static and shared libraries across platforms [<http://www.fortran-2000.com/ArnaudRecipes/sharedlib.html>]'

## 23.1.8. Installing MyODBC from the Development Source Tree

Note: You should read this section only if you are interested in helping us test our new code.

The most recent development source tree is available from our public Subversion trees at <http://dev.mysql.com/tech-resources/sources.html>.

To be able to access these trees, you must have Subversion installed. Subversion is freely available from <http://subversion.tigris.org/>.

After obtaining the development source tree, use these instructions:

1. You need GNU `autoconf` 2.52 (or newer), `automake` 1.4, `libtool` 1.4, and `m4` to run the next set of commands. (The example assumes that you are using the source tree in a directory named `myodbc-3.51/`.)

```
shell> cd myodbc-3.51
shell> bk -r edit
shell> aclocal; autoheader; autoconf; automake;
shell> ./configure # Add your favorite options here
shell> make
```

For more information on how to build, refer to `INSTALL` file located in the same directory. On Windows, make use of Windows Makefiles `WIN-Makefile` and `WIN-Makefile_debug` in building the driver, for more information, see Section 23.1.6, "Installing MyODBC from a Source Distribution on Windows".

2. When the build is done, run `make install` to install the MyODBC 3.51 driver on your system.
3. If you have gotten to the `make` stage and the distribution does not compile, please report it to [myodbc@lists.mysql.com](mailto:myodbc@lists.mysql.com).
4. After the initial checkout operation to get the source tree, you should run `svn update` periodically to get updates.

## 23.1.9. MyODBC Configuration

This section describes how to configure MyODBC, including DSN creation and the different arguments that the driver takes as an input arguments in the connection string. It also describes how to create an ODBC trace file.

### 23.1.9.1. What is a Data Source Name?

A *data source* is a place where data comes from. The data source must have a persistent identifier, the Data Source Name. Using the Data Source Name, MySQL can access initialization information. With the initialization information, MySQL knows where to access the database and what settings to use when the access starts.

In effect, the data source is the *path* to the data. In different contexts this might mean different things, but typically it identifies a running MySQL server (for example via a network address or service name), plus the default database for that server at connection time, plus necessary connection information such as the port. The MySQL drivers (and, on Windows systems, the ODBC Driver Manager) use the data source for connecting. An administrative utility called the Microsoft ODBC Data Source Administrator may be useful for this purpose.

There are two places where the initialization information might be: in the Windows registry (on a Windows system), or in a DSN file (on any system).

If the information is in the Windows registry, it is called a *Machine data source*. It might be a *User data source*, in which case only one user can see it. Or it might be a *System data source* in which case it is accessible to all users on the computer, or indeed to all users connected to the computer, if the users are connected by Microsoft Windows NT services. When you run the ODBC Data Administration program, you have a choice whether to use "User" or "System" -- there are separate tabs.

If the information is in a DSN file, it is called a "File data source". This is a text file. Its advantages are: (a) it is an option for any kind of computer, not just a computer with a Windows operating system; (b) its contents can be transmitted or copied relatively easily.

### 23.1.9.2. Configuring a MyODBC DSN on Windows

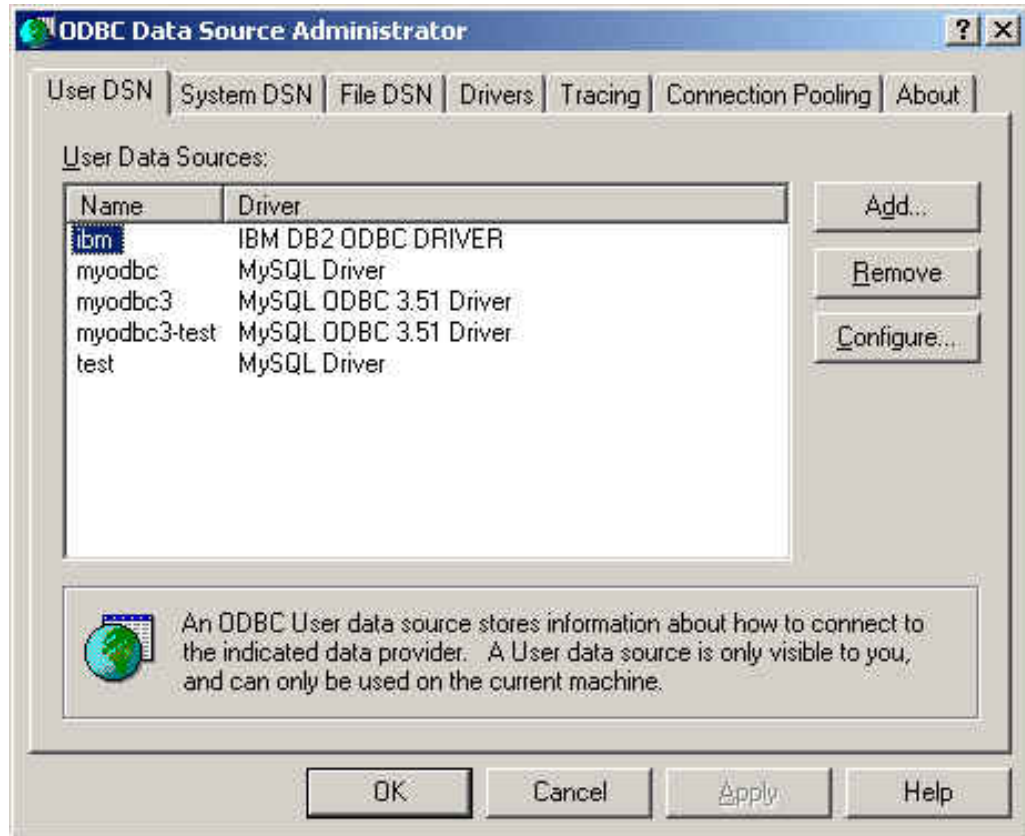

To add and configure a new MyODBC data source on Windows, use the ODBC Data Source Administrator. The ODBC Administrator updates your data source connection information. As you add data sources, the ODBC Administrator updates the registry information for you.

To open the ODBC Administrator from the Control Panel:

1. Click Start, point to Settings, and then click Control Panel.
2. On computers running Microsoft Windows 2000 or newer, double-click Administrative Tools, and then double-click Data Sources (ODBC). On computers running older versions of Windows, double-click 32-bit ODBC or ODBC.

The ODBC Data Source Administrator dialog box appears, as shown here:

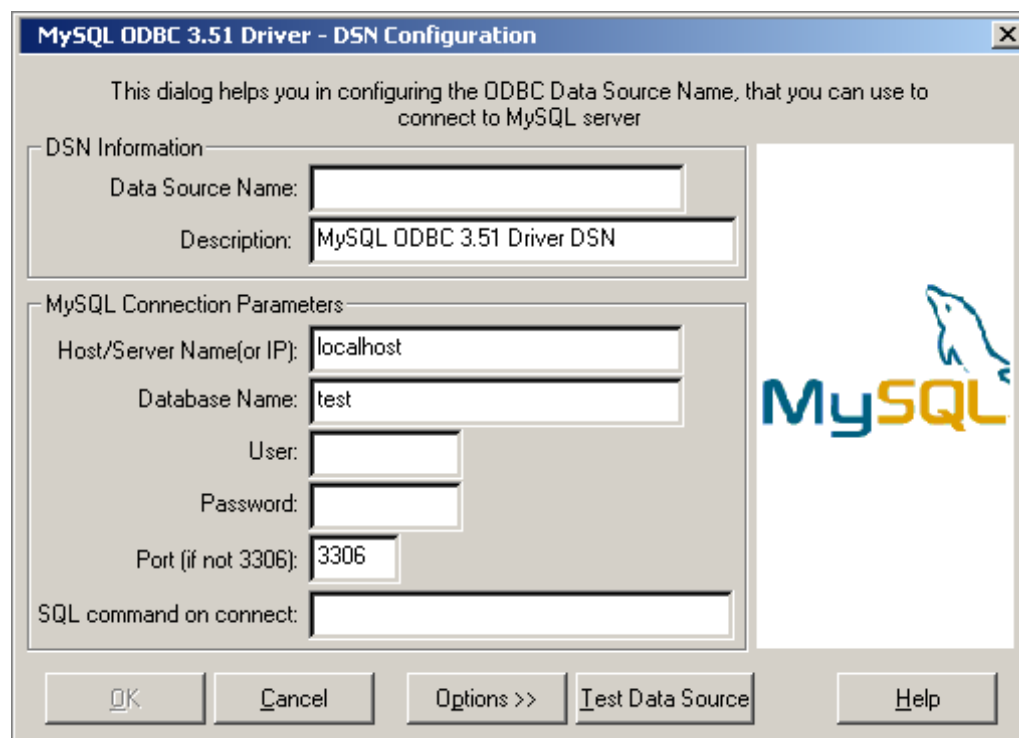

Click Help for detailed information about each tab of the ODBC Data Source Administrator dialog box.

To add a data source on Windows:

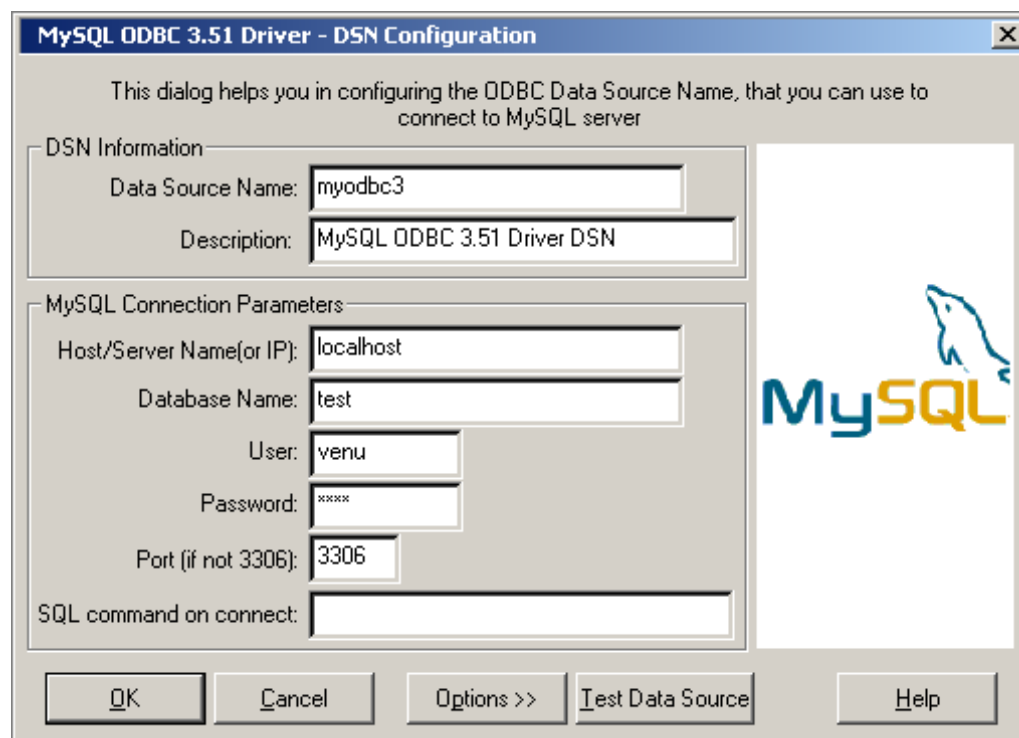

1. Open the ODBC Data Source Administrator.
2. In the ODBC Data Source Administrator dialog box, click Add. The Create New Data Source dialog box appears.
3. Select MySQL ODBC 3.51 Driver, and then click Finish. The MySQL ODBC 3.51 Driver - DSN Configuration dialog box appears, as shown here:

4. In the Data Source Name box, enter the name of the data source you want to access. It can be any valid name that you choose.
5. In the Description box, enter the description needed for the DSN.
6. For Host or Server Name (or IP) box, enter the name of the MySQL server host that you want to access. By default, it is localhost.
7. In the Database Name box, enter the name of the MySQL database that you want to use as the default database.
8. In the User box, enter your MySQL username (your database user ID).
9. In the Password box, enter your password.
10. In the Port box, enter the port number if it is not the default (3306).
11. In the SQL Command box, you can enter an optional SQL statement that you want to issue automatically after the connection has been established.

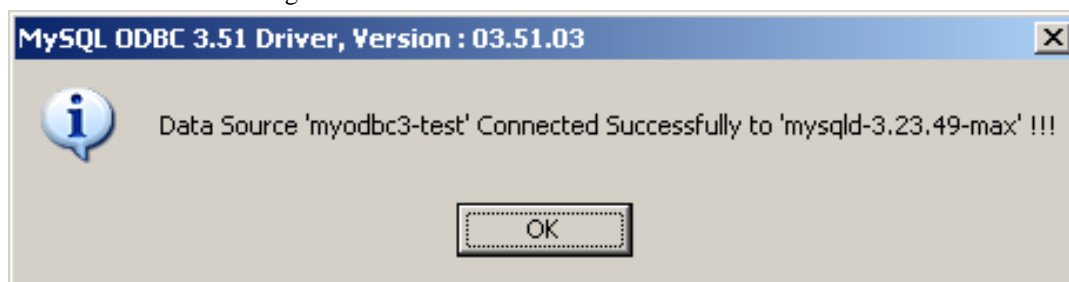

The final dialog looks like this:

Click OK to add this data source.

**Note:** Upon clicking OK, the Data Sources dialog box appears, and the ODBC Administrator updates the registry information. The username and connect string that you entered become the default connection values for this data source when you connect to it.

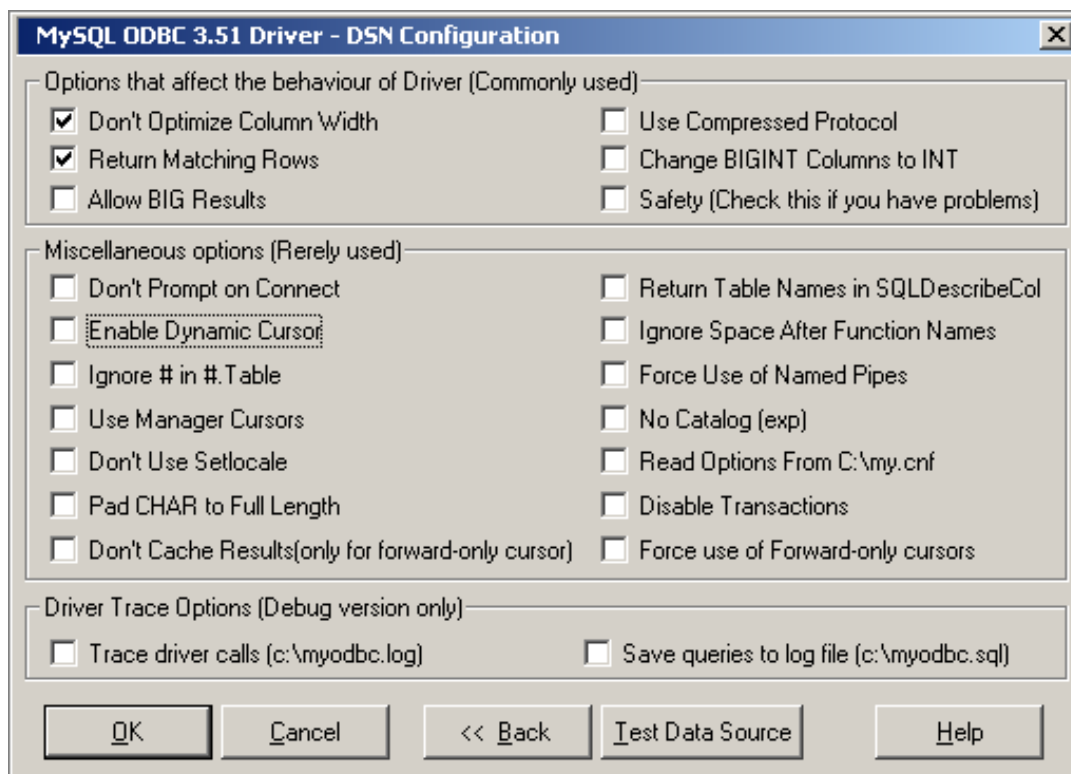

You can also test whether your settings are suitable for connecting to the server using the button Test Data Source. This feature is available only for the MyODBC 3.51 driver. A successful test results in the following window:

A failed test results in an error:

The DSN configuration dialog also has an Options button. If you select it, the following options dialog appears displaying that control driver behavior. Refer to Section 23.1.9.4, “Connection Parameters”, for information about the meaning of these options.

**Note:** The options listed under Driver Trace Options are disabled (grayed out) unless you are using the debugging version of the driver DLL.

To modify a data source on Windows:

1. Open the ODBC Data Source Administrator. Click the appropriate DSN tab.
2. Select the MySQL data source that you want to modify and then click Configure. The MySQL ODBC 3.51 Driver - DSN Configuration dialog box appears.
3. Modify the applicable data source fields, and then click OK.

When you have finished modifying the information in this dialog box, the ODBC Administrator updates the registry information.

### 23.1.9.3. Configuring a MyODBC DSN on Unix

On Unix, you configure DSN entries directly in the `odbc.ini` file. Here is a typical `odbc.ini` file that configures `myodbc` and `myodbc3` as the DSN names for MyODBC 2.50 and MyODBC 3.51, respectively:

```

;
; odbc.ini configuration for MyODBC and MyODBC 3.51 drivers
;

[ODBC Data Sources]
myodbc      = MyODBC 2.50 Driver DSN
myodbc3    = MyODBC 3.51 Driver DSN

[myodbc]
Driver      = /usr/local/lib/libmyodbc.so
Description = MyODBC 2.50 Driver DSN
SERVER     = localhost
PORT      =
USER      = root

```

```

Password      =
Database      = test
OPTION        = 3
SOCKET        =

[myodbc3]
Driver        = /usr/local/lib/libmyodbc3.so
Description   = MyODBC 3.51 Driver DSN
SERVER        = localhost
PORT          =
USER          = root
Password      =
Database      = test
OPTION        = 3
SOCKET        =

[Default]
Driver        = /usr/local/lib/libmyodbc3.so
Description   = MyODBC 3.51 Driver DSN
SERVER        = localhost
PORT          =
USER          = root
Password      =
Database      = test
OPTION        = 3
SOCKET        =

```

Refer to the Section 23.1.9.4, “Connection Parameters”, for the list of connection parameters that can be supplied.

**Note:** If you are using unixODBC, you can use the following tools to set up the DSN:

- ODBCConfig GUI tool(HOWTO: ODBCConfig [<http://www.unixodbc.org/config.html>])
- odbcinst

In some cases when using unixODBC, you might get this error:

```
Data source name not found and no default driver specified
```

If this happens, make sure the ODBCINI and ODBCSYSINI environment variables are pointing to the right `odbc.ini` file. For example, if your `odbc.ini` file is located in `/usr/local/etc`, set the environment variables like this:

```
export ODBCINI=/usr/local/etc/odbc.ini
export ODBCSYSINI=/usr/local/etc
```

### 23.1.9.4. Connection Parameters

You can specify the following parameters for MyODBC in the [Data Source Name] section of an `ODBC.INI` file or through the `InConnectionString` argument in the `SQLDriverConnect()` call.

Parameter	Default Value	Comment
<code>user</code>	ODBC (on Windows)	The username used to connect to MySQL.
<code>server</code>	localhost	The hostname of the MySQL server.
<code>database</code>		The default database.
<code>option</code>	0	Options that specify how MyODBC should work. See below.

port	3306	The TCP/IP port to use if server is not localhost.
stmt		A statement to execute when connecting to MySQL.
password		The password for the user account on server.
socket		The Unix socket file or Windows named pipe to connect to if server is localhost.

The `option` argument is used to tell MyODBC that the client isn't 100% ODBC compliant. On Windows, you normally select options by toggling the checkboxes in the connection screen, but you can also select them in the `option` argument. The following options are listed in the order in which they appear in the MyODBC connect screen:

Value	Description
1	The client can't handle that MyODBC returns the real width of a column.
2	The client can't handle that MySQL returns the true value of affected rows. If this flag is set, MySQL returns "found rows" instead. You must have MySQL 3.21.14 or newer to get this to work.
4	Make a debug log in <code>c:\myodbc.log</code> . This is the same as putting <code>MYSQL_DEBUG=d:t:O,c::\myodbc.log</code> in <code>AUTOEXEC.BAT</code> . (On Unix, the file is <code>/tmp/myodbc.log</code> .)
8	Don't set any packet limit for results and parameters.
16	Don't prompt for questions even if driver would like to prompt.
32	Enable or disable the dynamic cursor support. (Not allowed in MyODBC 2.50.)
64	Ignore use of database name in <code>db_name.tbl_name.col_name</code> .
128	Force use of ODBC manager cursors (experimental).
256	Disable the use of extended fetch (experimental).
512	Pad CHAR columns to full column length.
1024	<code>SQLDescribeCol()</code> returns fully qualified column names.
2048	Use the compressed client/server protocol.
4096	Tell server to ignore space after function name and before '(' (needed by PowerBuilder). This makes all function names keywords.
8192	Connect with named pipes to a <code>mysqld</code> server running on NT.
16384	Change LONGLONG columns to INT columns (some applications can't handle LONGLONG).
32768	Return 'user' as <code>Table_qualifier</code> and <code>Table_owner</code> from <code>SQLTables</code> (experimental).
65536	Read parameters from the <code>[client]</code> and <code>[odbc]</code> groups from <code>my.cnf</code> .
131072	Add some extra safety checks (should not be needed but...).
262144	Disable transactions.
524288	Enable query logging to <code>c:\myodbc.sql(/tmp/myodbc.sql)</code> file. (Enabled only in debug mode.)
1048576	Do not cache the results locally in the driver, instead read from server ( <code>mysql_use_result()</code> ). This works only for forward-only cursors. This option is very important in dealing with large tables when you don't want the driver to cache the entire result set.
2097152	Force the use of Forward-only cursor type. In case of applications setting the default static/dynamic cursor type, and one wants the driver to use non-cache result sets, then this option ensures the forward-only cursor behavior.

To select multiple options, add together their values. For example, setting `option` to 12 (4+8) gives you debugging without packet limits.

The default `myodbc3.dll` is compiled for optimal performance. If you want to debug MyODBC 3.51 (for example, to enable tracing), you should instead use `myodbc3d.dll`. To install this file, copy `myodbc3d.dll` over the installed `myodbc3.dll` file. Make sure to revert back to the release version of the driver DLL once you are done with the debugging because the debug version may cause performance issues. Note that the `myodbc3d.dll` isn't included in MyODBC 3.51.07 through 3.51.11. If you are using one of these versions, you should copy that DLL from a previous version (for example, 3.51.06).

For MyODBC 2.50, `myodbc.dll` and `myodbcd.dll` are used instead.

The following table shows some recommended `option` values for various configurations:

Configuration	Option Value
Microsoft Access	3
Microsoft Visual Basic	3
Large tables with too many rows	2049
Driver trace generation (Debug mode)	4
Query log generation (Debug mode)	524288
Generate driver trace as well as query log (Debug mode)	524292
Large tables with no-cache results	3145731

### 23.1.9.5. Connecting Without a Predefined DSN

Yes. You can connect to the MySQL server using `SQLDriverConnect`, by specifying the `DRIVER` name field. Here are the connection strings for MyODBC using DSN-Less connection:

#### For MyODBC 2.50:

```
ConnectionString = "DRIVER={MySQL};\
SERVER=localhost;\
DATABASE=test;\
USER=venu;\
PASSWORD=venu;\
OPTION=3;"
```

#### For MyODBC 3.51:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};\
SERVER=localhost;\
DATABASE=test;\
USER=venu;\
PASSWORD=venu;\
OPTION=3;"
```

If your programming language converts backslash followed by whitespace to a space, it is preferable to specify the connection string as a single long string, or to use a concatenation of multiple strings that does not add spaces in between. For example:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"
"SERVER=localhost;"
"DATABASE=test;"
"USER=venu;"
"PASSWORD=venu;"
"OPTION=3;"
```

Refer to the Section 23.1.9.4, "Connection Parameters", for the list of connection parameters that can be supplied.

### 23.1.9.6. Establishing a Remote Connection to System A from System B

If you want to connect to system A from system B with a username and password of `myuser` and `mypassword`, here is a simple procedure.

On system A, follow these steps:

1. Start the MySQL server.
2. Use `GRANT` to set up an account with a username of `myuser` that can connect from system B using a password of `myuser`:

```
GRANT ALL ON *.* to 'myuser'@'B' IDENTIFIED BY 'mypassword';
```

3. The `GRANT` statement grants all privileges to user `myuser` for connecting from system B using the password `mypassword`. To execute this statement, you should be either `root` on system A (or another user who has appropriate privileges). For more information about MySQL privileges, refer to Section 5.9, “MySQL User Account Management”.

On system B, follow these steps:

1. Configure a MyODBC DSN using the following connection parameters:

```
DSN           = remote_test
SERVER or HOST = A (or IP address of system A)
DATABASE      = test (The default database or an appropriate one)
USER         = myuser
PASSWORD     = mypassword
```

To set up a DSN-less connection, refer to Section 23.1.9.5, “Connecting Without a Predefined DSN”.

2. Check whether you are able to access system A from system B by using ping or other means. If you are not able to reach system A, check your network or Internet connections or contact your system administrator.
3. Try to connect using `DSN=remote_test`. If it fails, trace the MyODBC log, and take the further steps based on the error message from the log. If you need further assistance, send a detailed mail message to `<myodbc@lists.mysql.com>`.

You can also find a simple HOWTO at <http://www.phphelp.com/tutorial/using-myodbc-to-connect-to-a-remote-database.html>.

### 23.1.9.7. Getting an ODBC Trace File

If you encounter difficulties or problems with MyODBC, you should start by making a log file from the ODBC Manager (the log you get when requesting logs from ODBC ADMIN) and MyODBC.

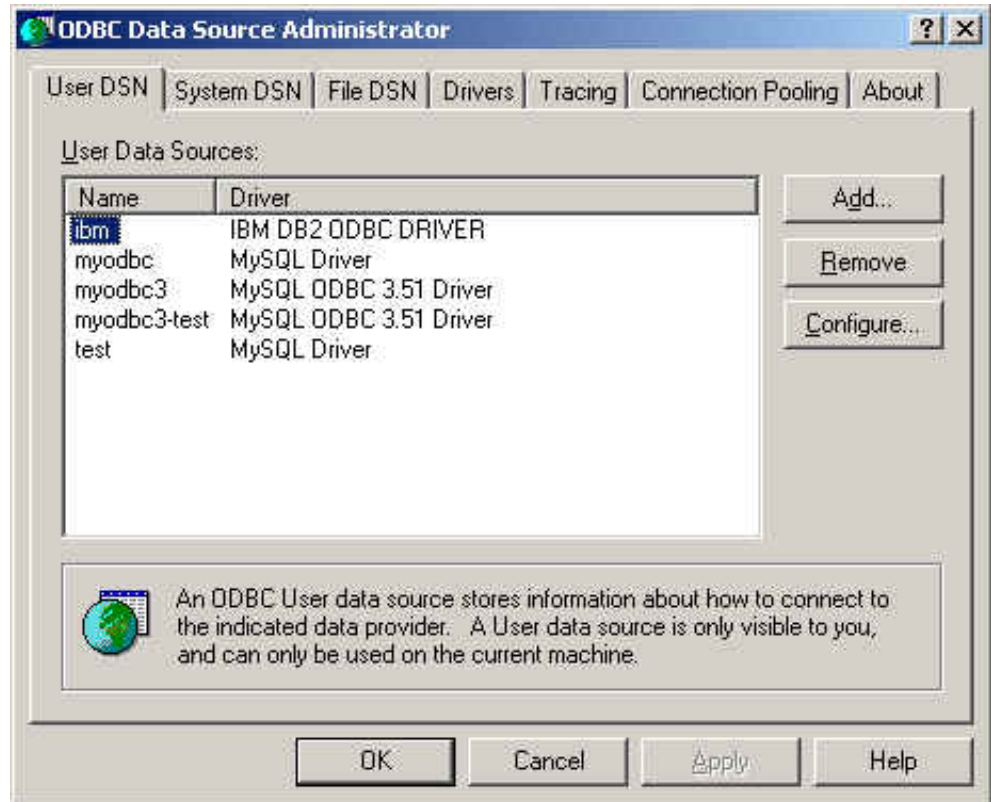

To get an ODBC trace through Driver Manager, do the following:

- Open ODBC Data source administrator:
  1. Click `Start`, point to `Settings`, and then click `Control Panel`.
  2. On computers running Microsoft Windows 2000, XP, or 2003, double-click `Administrative Tools`, and then double-click `Data Sources (ODBC)`, as shown below.

On computers running an earlier version of Microsoft Windows, double-click 32-bit ODBC or ODBC in the Control Panel.

- The ODBC Data Source Administrator dialog box appears, as shown below:

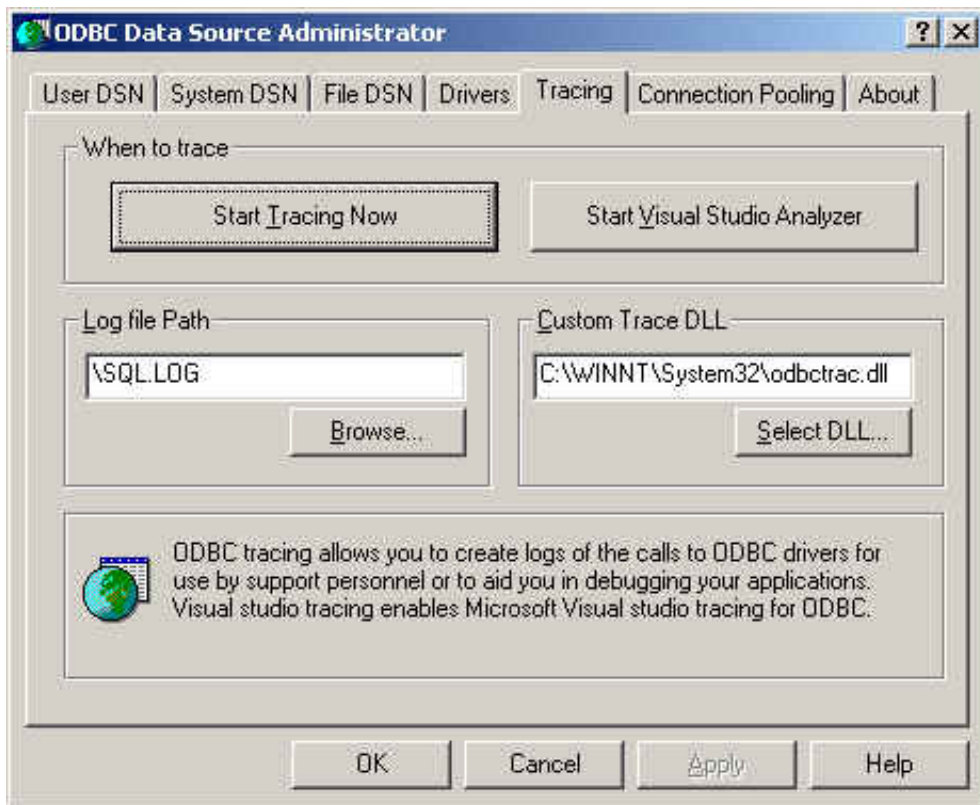

- Click Help for detailed information about each tab of the ODBC Data Source Administrator dialog box.
- Enable the trace option. The procedure for this differs for Windows and Unix.

To enable the trace option on Windows:

- The Tracing tab of the ODBC Data Source Administrator dialog box enables you to configure the way ODBC function calls are traced.
- When you activate tracing from the Tracing tab, the Driver Manager logs all ODBC function calls for all subsequently run applications.
- ODBC function calls from applications running before tracing is activated are not logged. ODBC function calls are recorded in a log file you specify.
- Tracing ceases only after you click Stop Tracing Now. Remember that while tracing is on, the log file continues to increase in size and that tracing affects the performance of all your ODBC applications.

To enable the trace option on Unix:

1. On Unix, you need to explicitly set the Trace option in the ODBC.INI file.

Set the tracing ON or OFF by using TraceFile and Trace parameters in odbc.ini as shown below:

```
TraceFile = /tmp/odbc.trace
Trace     = 1
```

TraceFile specifies the name and full path of the trace file and Trace is set to ON or OFF. You can also use 1 or YES for ON and 0 or NO for OFF. If you are using ODBCConfig from unixODBC, then follow the instructions for tracing unixODBC calls at HOWTO-ODBCConfig [<http://www.unixodbc.org/config.html>].

To generate a MyODBC log, do the following:

1. Ensure that you are using the driver debug DLL (that is, myodbc3d.dll and not myodbc3.dll for MyODBC 3.51, and myodbcd.dll for MyODBC 2.50).

The easiest way to do this is to get myodbc3d.dll (or myodbcd.dll) from the MyODBC 3.51 distribution and copy it over the myodbc3.dll (or myodbc.dll), which is probably in your C:\\windows\\system32 or C:\\winnt\\system32 directory. Note that you probably want to restore the old myodbc.dll file when you have finished testing, as this is a lot faster than myodbc3d.dll (or myodbcd.dll), so do keep a backup copy of original DLLs.

2. Enable the Trace MyODBC option flag in the MyODBC connect/configure screen. The log is written to file C:\\myodbc.log. If the trace option is not remembered when you are going back to the above screen, it means that you are not using the myodbcd.dll driver (see above). On Linux or if you are using DSN-Less connection, then you need to supply OPTION=4 in the connection string.

3. Start your application and try to get it to fail. Then check the MyODBC trace file to find out what could be wrong.

If you find out something is wrong, please send a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com) (or to [<support@mysql.com>](mailto:support@mysql.com) if you have a support contract from MySQL AB) with a brief description of the problem, with the following additional information:

- MyODBC version
- ODBC Driver Manager type and version
- MySQL server version
- ODBC trace from Driver Manager
- MyODBC log file from MyODBC driver
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem!

Also, before posting the bug, check the MyODBC mailing list archive at <http://lists.mysql.com/>.

### **23.1.9.8. Applications Tested with MyODBC**

MyODBC has been tested with the following applications:

- MS Access 95, 97, 2000, and 2002
- C++-Builder, Borland Builder 4
- Centura Team Developer (formerly Gupta SQL/Windows)
- ColdFusion (on Solaris and NT with service pack 5), How-to: MySQL and Coldfusion [<http://www.njwtech.net/addons/coldfusion/mysql.html>]. Troubleshooting Data Sources and Database Connectivity for UnixPlatforms [<http://www.macromedia.com/v1/handlers/index.cfm?ID=11328&Method=Full&PageCall=/support/index.cfm>].
- Crystal Reports
- DataJunction
- Delphi
- ERwin
- MS Excel
- iHTML
- FileMaker Pro
- FoxPro
- Notes 4.5/4.6
- MS Visio Enterprise 2000

- Vision
- Visual Objects
- Visual Interdev
- SBSS
- Perl DBD-ODBC
- Paradox
- Powerbuilder
- Powerdesigner 32-bit
- MS Visual C++
- Visual Basic
- ODBC.NET through CSharp(C#), VB and C++
- Data Architect(<http://thekompany.com/products/dataarchitect/>)
- SQLEXPRESS for Xbase++(<http://www.SQLEXPRESS.net>)
- Open Office (<http://www.openoffice.org>) How-to: MySQL + OpenOffice [[http://dba.openoffice.org/proposals/MySQL\\_OOo.html](http://dba.openoffice.org/proposals/MySQL_OOo.html)]. How-to: OpenOffice + MyODBC + unixODBC [<http://www.unixodbc.org/doc/OOoMySQL.pdf>].
- Star Office (<http://www.sun.com/software/star/staroffice/6.0/index.html>)
- G2-ODBC bridge (<http://www.gensym.com>)
- Sambar Server (<http://www.sambarserver.info>) How-to: MyODBC + SambarServer + MySQL [<http://www.sambarserver.info/article.php?sid=66>].

If you know of any other applications that work with MyODBC, please send mail to [myodbc@lists.mysql.com](mailto:myodbc@lists.mysql.com) about them.

### 23.1.9.9. Programs Known to Work With MyODBC

Most programs should work with MyODBC, but for each of those listed here, we have tested it ourselves or received confirmation from some user that it works. Many of the descriptions provide workarounds for problems that you might encounter.

- **Program**

- **Comment**

- Access

To make Access work:

- If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC (Microsoft Data Access Components) from <http://www.microsoft.com/data/>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified. Another way to work around this bug is to upgrade to MyODBC 2.50.33 and MySQL 3.23.x, which together provide a work-around for the problem.

You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be

found at <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114>. This fixes some cases where columns are marked as #DELETED# in Access.

Note: If you are using MySQL 3.22, you must apply the MDAC patch and use MyODBC 2.50.32 or 2.50.34 and up to work around this problem.

- For all versions of Access, you should enable the MyODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a timestamp in all tables that you want to be able to update. For maximum portability, don't use a length specification in the column declaration. That is, use `TIMESTAMP`, not `TIMESTAMP(N)`,  $N < 14$ .
- You should have a primary key in the table. If not, new or updated rows may show up as #DELETED#.
- Use only `DOUBLE` float fields. Access fails when comparing with single floats. The symptom usually is that new or updated rows may show up as #DELETED# or that you can't find or update rows.
- If you are using MyODBC to link to a table that has a `BIGINT` column, the results are displayed as #DELETED#. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

Old records still display as #DELETED#, but newly added/updated records are displayed properly.

- If you still get the error `Another user has changed your data` after adding a `TIMESTAMP` column, the following trick may help you:

Don't use a table data sheet view. Instead, create a form with the fields you want, and use that form data sheet view. You should set the `DefaultValue` property for the `TIMESTAMP` column to `NOW()`. It may be a good idea to hide the `TIMESTAMP` column from view so your users are not confused.

- In some cases, Access may generate illegal SQL statements that MySQL can't understand. You can fix this by selecting `"Query|SQLSpecific|Pass-Through"` from the Access menu.
  - On NT, Access reports `BLOB` columns as `OLE OBJECTS`. If you want to have `MEMO` columns instead, you should change `BLOB` columns to `TEXT` with `ALTER TABLE`.
  - Access can't always handle `DATE` columns properly. If you have a problem with these, change the columns to `DATETIME`.
  - If you have in Access a column defined as `BYTE`, Access tries to export this as `TINYINT` instead of `TINYINT UNSIGNED`. This gives you problems if you have values larger than 127 in the column.
- ADO

When you are coding with the ADO API and MyODBC, you need to pay attention to some default properties that aren't supported by the MySQL server. For example, using the `CursorLocation` Property as `adUseServer` returns a result of -1 for the `RecordCount` Property. To have the right value, you need to set this property to `adUseClient`, as shown in the VB code here:

```
Dim myconn As New ADODB.Connection
Dim myrs As New Recordset
Dim mySQL As String
Dim myrows As Long

myconn.Open "DSN=MyODBCsample"
mySQL = "SELECT * from user"
myrs.Source = mySQL
Set myrs.ActiveConnection = myconn
myrs.CursorLocation = adUseClient
myrs.Open
myrows = myrs.RecordCount

myrs.Close
myconn.Close
```

Another workaround is to use a `SELECT COUNT( *)` statement for a similar query to get the correct row count.

- Active server pages (ASP)

You should select the `Return matching rows` option.

- BDE applications

To get these to work, you should select the `Don't optimize column widths` and `Return matching rows` options.

- Borland Builder 4

When you start a query, you can use the `Active` property or the `Open` method. Note that `Active` starts by automatically issuing a `SELECT * FROM ...` query. That may not be a good thing if your tables are large.

- ColdFusion (On Unix)

The following information is taken from the ColdFusion documentation:

Use the following information to configure ColdFusion Server for Linux to use the unixODBC driver with MyODBC for MySQL data sources. Allaire has verified that MyODBC 2.50.26 works with MySQL 3.22.27 and ColdFusion for Linux. (Any newer version should also work.) You can download MyODBC at <http://dev.mysql.com/downloads/connector/odbc/>.

ColdFusion version 4.5.1 allows you to use the ColdFusion Administrator to add the MySQL data source. However, the driver is not included with ColdFusion version 4.5.1. Before the MySQL driver appears in the ODBC datasources drop-down list, you must build and copy the MyODBC driver to `/opt/coldfusion/lib/libmyodbc.so`.

The `Contrib` directory contains the program `mydsn-xxx.zip` which allows you to build and remove the DSN registry file for the MyODBC driver on Coldfusion applications.

- DataJunction

You have to change it to output `VARCHAR` rather than `ENUM`, as it exports the latter in a manner that causes MySQL problems.

- Excel

Works. A few tips:

- If you have problems with dates, try to select them as strings using the `CONCAT( )` function. For example:

```
SELECT CONCAT(rise_time), CONCAT(set_time)
FROM sunrise_sunset;
```

Values retrieved as strings this way should be correctly recognized as time values by Excel97.

The purpose of `CONCAT()` in this example is to fool ODBC into thinking the column is of "string type." Without the `CONCAT()`, ODBC knows the column is of time type, and Excel does not understand that.

Note that this is a bug in Excel, because it automatically converts a string to a time. This would be great if the source was a text file, but is unfortunate when the source is an ODBC connection that reports exact types for each column.

- Word

To retrieve data from MySQL to Word/Excel documents, you need to use the MyODBC driver and the Add-in Microsoft Query help.

For example, create a database with a table containing two columns of text:

- Insert rows using the `mysql` client command-line tool.
- Create a DSN file using the ODBC manager, for example, `my` for the database that was just created.
- Open the Word application.
- Create a blank new document.
- In the Database tool bar, press the `Insert Database` button.
- Press the `Get Data` button.
- At the right hand of the `Get Data` screen, press the `Ms Query` button.
- In `Ms Query`, create a new data source using the `my` DSN file.
- Select the new query.
- Select the columns that you want.
- Make a filter if you want.
- Make a Sort if you want.
- Select `Return Data to Microsoft Word`.
- Click `Finish`.
- Click `Insert Data` and select the records.
- Click `OK` and you see the rows in your Word document.

- odbcdadmin

Test program for ODBC.

- Delphi

You must use BDE 3.2 or newer. Select the `Don't optimize column width` option when connecting to MySQL.

Also, here is some potentially useful Delphi code that sets up both an ODBC entry and a BDE entry for MyODBC. The BDE entry requires a BDE Alias Editor that is free at a Delphi Super Page near you. (Thanks to Bryan Brunton <bryan@flesherfab.com> for this):

```
fReg:= TRegistry.Create;
fReg.OpenKey('\Software\ODBC\ODBC.INI\DocumentsFab', True);
fReg.WriteString('Database', 'Documents');
fReg.WriteString('Description', ' ');
fReg.WriteString('Driver', 'C:\WINNT\System32\myodbc.dll');
fReg.WriteString('Flag', '1');
fReg.WriteString('Password', '');
fReg.WriteString('Port', ' ');
fReg.WriteString('Server', 'xmark');
fReg.WriteString('User', 'winuser');
fReg.OpenKey('\Software\ODBC\ODBC.INI\ODBC Data Sources', True);
fReg.WriteString('DocumentsFab', 'MySQL');
fReg.CloseKey;
fReg.Free;

Mem1.Lines.Add('DATABASE NAME=');
Mem1.Lines.Add('USER NAME=');
Mem1.Lines.Add('ODBC DSN=DocumentsFab');
Mem1.Lines.Add('OPEN MODE=READ/WRITE');
Mem1.Lines.Add('BATCH COUNT=200');
Mem1.Lines.Add('LANGDRIVER=');
Mem1.Lines.Add('MAX ROWS=-1');
Mem1.Lines.Add('SCHEMA CACHE DIR=');
Mem1.Lines.Add('SCHEMA CACHE SIZE=8');
Mem1.Lines.Add('SCHEMA CACHE TIME=-1');
Mem1.Lines.Add('SQLPASSTHRU MODE=SHARED AUTOCOMMIT');
Mem1.Lines.Add('SQLQRYMODE=');
Mem1.Lines.Add('ENABLE SCHEMA CACHE=FALSE');
Mem1.Lines.Add('ENABLE BCD=FALSE');
Mem1.Lines.Add('ROWSET SIZE=20');
Mem1.Lines.Add('BLOBS TO CACHE=64');
Mem1.Lines.Add('BLOB SIZE=32');

AliasEditor.Add('DocumentsFab', 'MySQL', Mem1.Lines);
```

- **C++ Builder**

Tested with BDE 3.0. The only known problem is that when the table schema changes, query fields are not updated. BDE, however, does not seem to recognize primary keys, only the index named PRIMARY, although this has not been a problem.

- **Vision**

You should select the Return matching rows option.

- **Visual Basic**

To be able to update a table, you must define a primary key for the table.

Visual Basic with ADO can't handle big integers. This means that some queries like SHOW PROCESSLIST do not work properly. The fix is to use OPTION=16384 in the ODBC connect string or to select the Change BIGINT columns to INT option in the MyODBC connect screen. You may also want to select the Return matching rows option.

- **VisualInterDev**

If you have a BIGINT in your result, you may get the error [Microsoft][ODBC Driver Manager] Driver does not support this parameter Try selecting the Change BIGINT columns to INT option in the MyODBC connect screen.

- **Visual Objects**

You should select the `Don't optimize column widths` option.

- MS Visio Enterprise 2000

We made database model diagram by connecting from MS Visio Enterprise 2000 to MySQL via MyODBC (2.50.37 or greater) and using Visio's reverse engineer function to retrieve information about the DB (Visio shows all the column definitions, primary keys, indexes and so on). Also, we tested by designing new tables in Visio and exported them to MySQL via MyODBC.

## 23.1.10. MyODBC Connection-Related Issues

This section answers MyODBC connection-related questions.

### 23.1.10.1. While Configuring a MyODBC DSN, a Could Not Load Translator or Setup Library Error Occurs

For more information, refer to MS KnowledgeBase Article(Q260558) [<http://support.microsoft.com/default.aspx?scid=kb;EN-US;q260558>]. Also, make sure you have the latest valid `ct13d32.dll` in your system directory.

### 23.1.10.2. While Connecting, an Access denied Error Occurs

Refer to Section 5.8.8, "Causes of Access denied Errors".

### 23.1.10.3. INFO: About ODBC Connection Pooling

Refer to this document about connection pooling: <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q169470>.

## 23.1.11. MyODBC and Microsoft Access

This section of the document answers questions related to MyODBC with Microsoft Access.

### 23.1.11.1. How to Set Up Microsoft Access to Work with MySQL using MyODBC?

The following must be done on your client PC to make Microsoft Access work with MyODBC.

1. If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC (Microsoft Data Access Components) from <http://www.microsoft.com/data/>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified. Another way to work around this bug is to upgrade to MyODBC 2.50.33 and MySQL 3.23.x, which together provide a workaround for the problem.

You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be found at <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114>. This fixes some cases where columns are marked as `#DELETED#` in Access.

Note: If you are using MySQL 3.22, you must apply the MDAC patch and use MyODBC 2.50.32 or 2.50.34 and up to work around this problem.

2. Install the latest version of MySQL from <http://dev.mysql.com/downloads/>.
3. Install the latest version of MyODBC 3.51 or 2.50 from <http://dev.mysql.com/downloads/connector/odbc/>.

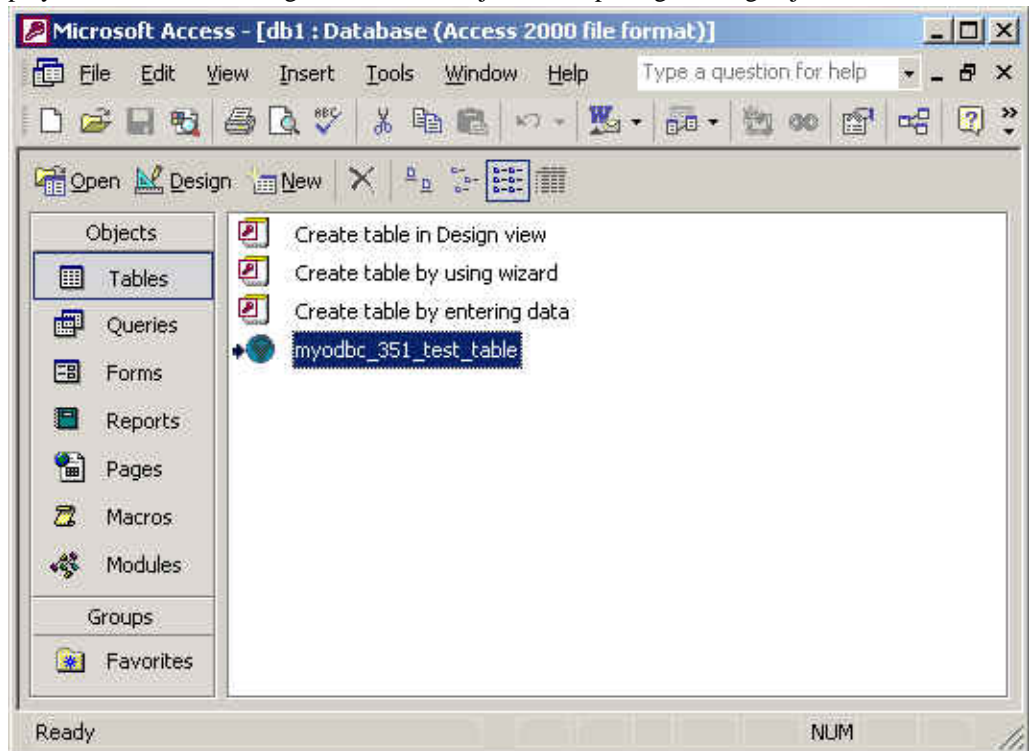

4. For all Access versions, you should enable the `Return matching rows` option.
5. Start working with Access as the front end for MySQL Server through MyODBC.

### 23.1.11.2. How to Export a Table or Query from Access to MySQL?

You cannot export a table or query to MySQL unless you have installed MyODBC.

To export a table from Access to MySQL, follow these instructions:

1. When you open an Access database or an Access project, a Database window appears. It displays shortcuts for creating new database objects and opening existing objects.

2. Click the name of the table or query you want to export, and then in the File menu, select Export.
3. In the Export Object Type *Object name* To dialog box, in the Save As Type box, select ODBC Databases ( ) as shown here:

4. In the Export dialog box, enter a name for the file (or use the suggested name), and then select OK.

5. The Select Data Source dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the File Data Source or Machine Data Source tab, and then double-click the MyODBC or MyODBC 3.51 data source that you want to export to. To define a new data source for MyODBC, please Section 23.1.9.2, “Configuring a MyODBC DSN on Windows”.

Microsoft Access connects to the MySQL Server through this data source and exports new tables and or data.

### **23.1.11.3. How to Import or Link MySQL Database Tables to Access?**

You cannot export a table or query to MySQL database unless you have installed the MyODBC.

**To import or link a table or tables from MySQL to Access, follow the instructions:**

1. Open a database, or switch to the Database window for the open database.
2. To import tables, on the File menu, point to Get External Data, and then click Import. To link tables, on the File menu, point to Get External Data, and then click Link Tables.
3. In the Import (or Link) dialog box, in the Files Of Type box, select ODBC Databases (.). The Select Data Source dialog box lists the defined data sources The Select Data Source dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the File Data Source or Machine Data Source tab, and then double-click the MyODBC or MyODBC 3.51 data source that you want to export to. To define a new data source for the MyODBC or MyODBC 3.51 driver, please Section 23.1.9.2, “Configuring a MyODBC DSN on Windows”.
4. If the ODBC data source that you selected requires you to log on, enter your login ID and password (additional information might also be required), and then click OK.
5. Microsoft Access connects to the MySQL server through ODBC data source and displays the list of tables that you can import or link.
6. Click each table that you want to import or link, and then click OK. If you're linking a table and it doesn't have an index that uniquely identifies each record, Microsoft Access displays a list of the fields in the linked table. Click a field or a combination of fields that uniquely identifies each record, and then click OK.

### **23.1.11.4. The Structure or Location of a Linked Table has been Changed. Can I See Those Changes Locally in Linked Tables?**

Yes. Use the following procedure to view or to refresh links when the structure or location of a linked table has changed. The Linked Table Manager lists the paths to all currently linked tables.

**To view or refresh links:**

1. Open the database that contains links to tables.
2. On the Tools menu, point to Add-ins (Database Utilities in Access 2000 or newer), and then click Linked Table Manager.
3. Select the check box for the tables whose links you want to refresh.
4. Click OK to refresh the links.

Microsoft Access confirms a successful refresh or, if the table wasn't found, displays the `Select New Location of <table name>` dialog box in which you can specify its the table's new location. If several selected tables have moved to the new location that you specify, the `Linked Table Manager` searches that location for all selected tables, and updates all links in one step.

**To change the path for a set of linked tables:**

1. Open the database that contains links to tables.
2. On the `Tools` menu, point to `Add-ins (Database Utilities in Access 2000 or newer)`, and then click `Linked Table Manager`.
3. Select the `Always Prompt For A New Location` check box.
4. Select the check box for the tables whose links you want to change, and then click `OK`.
5. In the `Select New Location of <table name>` dialog box, specify the new location, click `Open`, and then click `OK`.

### 23.1.11.5. When I Insert or Update a Record in Linked Tables, I Get #DELETED#

If the inserted or updated records are shown as `#DELETED#` in the access, then:

- If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC (Microsoft Data Access Components) from <http://www.microsoft.com/data/>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified. Another way to work around this bug is to upgrade to MyODBC 2.50.33 and MySQL 3.23.x, which together provide a workaround for the problem.

You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be found at <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114>. This fixes some cases where columns are marked as `#DELETED#` in Access.

Note: If you are using MySQL 3.22, you must apply the MDAC patch and use MyODBC 2.50.32 or 2.50.34 and up to work around this problem.

- For all versions of Access, you should enable the `MyODBC Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a timestamp in all tables that you want to be able to update. For maximum portability, don't use a length specification in the column declaration. That is, use `TIMESTAMP`, not `TIMESTAMP (N)`,  $N < 14$ .
- You should have a primary key in the table. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you can't find or update rows.
- If you are using MyODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in `ODBC DSN Administrator`.
  - Delete the table link from Access and re-create it.

Old records still display as #DELETED#, but newly added/updated records are displayed properly.

### 23.1.11.6. How Do I Handle Write Conflicts or Row Location Errors?

If you see the following errors, select the `Return Matching Rows` option in the DSN configuration dialog, or specify `OPTION=2`, as the connection parameter:

`Write Conflict. Another user has changed your data.`

`Row cannot be located for updating. Some values may have been changed since it was last read.`

### 23.1.11.7. Whenever I Export a Table from Access 97, a Strange Syntax Error Occurs

This is a strange issue from Access 97, and doesn't appear with Access 2000 or 2002. You can overcome this by upgrading the MyODBC driver to at least MyODBC 3.51.02.

### 23.1.11.8. Access Returns Another user has modified the record that you have modified While Editing Records

With some programs, this error may occur: `Another user has modified the record that you have modified`. In most cases, this can be solved by doing one of the following things:

- Add a primary key for the table if one doesn't exist.
- Add a timestamp column if one doesn't exist.
- Only use double float fields. Some programs may fail when they compare single floats.

If these strategies don't help, you should start by making a log file from the ODBC manager (the log you get when requesting logs from ODBCADMIN) and a MyODBC log to help you figure out why things go wrong. For instructions, see Section 23.1.9.7, "Getting an ODBC Trace File".

### 23.1.11.9. How to Trap ODBC Login Error Messages in Access?

Read "How to Trap ODBC Login Error Messages in Access" at <http://support.microsoft.com/support/kb/articles/Q124/9/01.asp?LN=EN-US&SD=gn&FR=0%3CP%3E>.

### 23.1.11.10. How Do I Optimize Access for Performance with MyODBC?

- Optimizing for Client/Server Performance  
[<http://support.microsoft.com/default.aspx?scid=kb;en-us;128808>]
- Tips for Converting Applications to Using ODBCDirect  
[<http://support.microsoft.com/default.aspx?scid=kb;en-us;164481>]
- Tips for Optimizing Queries on Attached SQL Tables  
[<http://support.microsoft.com/default.aspx?scid=kb;EN-US;q99321>]

### 23.1.11.11. I Have Very Long Tables. What is the Best Configuration for MyODBC to Access These Tables?

If you have very large (long) tables in Access, it might take a very long time to open them. Or you might run low on virtual memory and eventually get an ODBC Query Failed error and the table cannot open. To deal with this, select the following options:

- Return Matching Rows (2)
- Allow BIG Results (8).

These add up to a value of 10 (OPTION=10).

### 23.1.11.12. How to Set the QueryTimeout Value for ODBC Connections?

Read “Set the QueryTimeout Value for ODBC Connections” at <http://support.microsoft.com/default.aspx?scid=kb%3Ben-us%3B153756>.

### 23.1.11.13. INFO: Tools to Export/Import from/to Access to/from MySQL

Refer to converters [<http://www.mysql.com/portal/software/convertors/>] section for list of available tools.

## 23.1.12. MyODBC and Microsoft VBA and ASP

This section answers questions related to using MyODBC with Microsoft Visual Basic(ADO, DAO & RDO) and ASP.

### 23.1.12.1. Why Does `SELECT COUNT(*) FROM tbl_name` Return an Error?

It's because the `COUNT(*)` expression is returning a `BIGINT`, and ADO can't make sense of a number this big. Select the `Change BIGINT columns to INT` option (option value 16384).

### 23.1.12.2. Whenever I Use the `AppendChunk()` or `GetChunk()` ADO Methods, I Get an Error Multiple-step operation generated errors. Check each status value.

The `GetChunk()` and `AppendChunk()` methods from ADO doesn't work as expected when the cursor location is specified as `adUseServer`. On the other hand, you can overcome this error by using `adUseClient`.

A simple example can be found from, [http://www.dwam.net/iishelp/ado/docs/adomth02\\_4.htm](http://www.dwam.net/iishelp/ado/docs/adomth02_4.htm)

### 23.1.12.3. How to Find the Total Number of Rows Affected by a Particular SQL Statement in ADO?

You can make use of `RecordsAffected` property in the ADO execute method. For more information on the usage of execute method, refer to <http://msdn.microsoft.com/library/default.asp?url=/library/en-us/ado270/html/mdmthcnexecute.asp>.

### 23.1.12.4. How Do I Handle Blob Data in Visual Basic?

Here is an excellent article from Mike Hillyer (<m.hillyer@telusplanet.net>); explaining how to insert or fetch data from blob columns through MyODBC from ADO: MySQL BLOB columns and Visual Basic 6 [<http://www.dynamergy.com/mike/articles/blobaccessvb.html>].

### **23.1.12.5. How Do I Map Visual Basic Data Types to MySQL Types?**

Here is yet another good article from Mike Hillyer (<m.hillyer@telusplanet.net>): How to map Visual basic data type to MySQL types [<http://www.dynamergy.com/mike/articles/vbmysqldatatype.php>].

### **23.1.12.6. SAMPLES: VB with ADO, DAO and RDO**

A simple examples for the usage of ADO, DAO and RDO with VB can be found here:

- ADO sample: Section 23.1.19, "MyODBC With VB: ADO, DAO and RDO"
- DAO sample: Section 23.1.19, "MyODBC With VB: ADO, DAO and RDO"
- RDO sample: Section 23.1.19, "MyODBC With VB: ADO, DAO and RDO"

If you find any other good example or HOW-TO on ADO/DAO/RDO, please send the details to <[myodbc@lists.mysql.com](mailto:myodbc@lists.mysql.com)>

### **23.1.12.7. ASP and MySQL with MyODBC**

For more information about how to access MySQL via ASP using MyODBC, refer to the following articles:

- Using MyODBC To Access Your MySQL Database Via ASP [<http://www.devarticles.com/c/a/ASP/Using-MyODBC-To-Access-Your-MySQL-Database-Via-ASP/>]
- ASP and MySQL at DWAM.NT [[http://www.dwam.net/mysql/asp\\_myodbc.asp](http://www.dwam.net/mysql/asp_myodbc.asp)]

A Frequently Asked Questions list for ASP can be found at <http://support.microsoft.com/default.aspx?scid=/Support/ActiveServer/faq/data/adofaq.asp>.

### **23.1.12.8. INFO: Frequently Asked Questions on ActiveX Data Objects (ADO)**

For information, see ActiveX Data Objects(ADO) Frequently Asked Questions [<http://support.microsoft.com/default.aspx?scid=kb;EN-US;q183606>].

## **23.1.13. MyODBC and Third-Party ODBC Tools**

This section answers questions related to MyODBC with various ODBC-related tools; such as Microsoft Word, Excel and ColdFusion.

### **23.1.13.1. How to Retrieve Data from MySQL into MS-Word/Excel Documents?**

To retrieve data from MySQL to Word/Excel documents, you need to use the MyODBC driver and the Add-in Microsoft Query help.

For example, create a database with a table containing two columns of text:

- Insert rows using the `mysql` client command-line tool.
- Create a DSN file using the ODBC manager, for example, `my` for the database that was just created.
- Open the Word application.
- Create a blank new document.
- In the Database tool bar, press the `Insert Database` button.
- Press the `Get Data` button.
- At the right hand of the `Get Data` screen, press the `Ms Query` button.
- In `Ms Query`, create a new data source using the `my` DSN file.
- Select the new query.
- Select the columns that you want.
- Make a filter if you want.
- Make a Sort if you want.
- Select `Return Data to Microsoft Word`.
- Click `Finish`.
- Click `Insert Data` and select the records.
- Click `OK` and you see the rows in your Word document.

### 23.1.13.2. Exporting Tables from MS DTS to MySQL Using MyODBC Results in a Syntax Error

This is an issue similar to that of Access 97 when your table consists of `TEXT` or `VARCHAR` data types. You can fix this error by upgrading your MyODBC driver to version 3.51.02 or higher.

### 23.1.13.3. HOWTO: Configure MySQL+MyODBC+unixODBC+ColdFusion on Solaris

Refer to `MySQL ColdFusion unixODBC MyODBC and Solaris - how to succeed` [<http://dbforums.com/showthread.php?threadid=174934>]

## 23.1.14. MyODBC General Functionality

This section of the document answers questions related to MyODBC general functionality.

### 23.1.14.1. How to Get the Value of an `AUTO_INCREMENT` Column in ODBC

A common problem is how to get the value of an automatically generated ID from an `INSERT` statement. With ODBC, you can do something like this (assuming that `auto` is an `AUTO_INCREMENT` field):

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
SELECT LAST_INSERT_ID();
```

Or, if you are just going to insert the ID into another table, you can do this:

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
INSERT INTO tbl2 (id,text) VALUES(LAST_INSERT_ID(),'text');
```

See Section 22.2.13.3, “How to Get the Unique ID for the Last Inserted Row”.

For the benefit of some ODBC applications (at least Delphi and Access), the following query can be used to find a newly inserted row:

```
SELECT * FROM tbl WHERE auto IS NULL;
```

### 23.1.14.2. Does MyODBC Support Dynamic Cursor Type?

Yes. MyODBC 3.51 supports `Dynamic` cursor type along with `Forward-only` and `static`.

Due to the performance issues, the driver does not support this feature by default. You can enable this by specifying the connection option flag as `OPTION=32` or by checking the `Enable Dynamic Cursor` option from the DSN configuration.

### 23.1.14.3. What Causes Transactions are not enabled Errors?

The driver returns this error when an application issues any transactional call but the underlying MySQL server either does not support transactions or they are not enabled.

To avoid this problem, you must use a server that has either or both of the `InnoDB` or `BDB` storage engines enabled, and use tables of those types. MySQL servers from version 4.0 and up support `InnoDB` by default. MySQL-Max servers also support `BDB` on platforms where `BDB` is available.

Also, if your server supports transactional storage engines (`InnoDB` and `BDB`) make sure the `disable transactions` option is not set from the DSN configuration.

### 23.1.14.4. What Causes Cursor not found Errors?

This occurs because the application is using old MyODBC 2.50 version, and it did not set the cursor name explicitly through `SQLSetCursorName`. The fix is to upgrade to MyODBC 3.51 version.

### 23.1.14.5. Can I Use MyODBC 2.50 Applications with MyODBC 3.51?

Yes. If you find something is not working with MyODBC 3.51 that works with MyODBC 2.50, then send a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com)

### 23.1.14.6. Can I Access MySQL from .NET Environment Using MyODBC?

Yes. You can make use of `odbc.net` to connect to MySQL through MyODBC. Here are the few basic samples to connect to MySQL from VC.NET and VB.NET.

- See Section 23.1.20.1, “ODBC.NET: CSHARP(C#)”.
- See Section 23.1.20.2, “ODBC.NET: VB”.

Here is yet another excellent article "Exploring MySQL on .NET environment [<http://www.mysql.com/newsletter/2002-07/a0000000035.html>]" by **Venu** (MyODBC developer) that covers about all MySQL .NET interfaces along with some useful examples.

**Caution:** Using ODBC.NET with MyODBC, while fetching empty string (0 length), it starts giving the SQL\_NO\_DATA exception. You can get the patch for this from <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q319243>.

### 23.1.14.7. Why Does MyODBC Perform Poorly, and Also Make a Lot of Disk Activity for Relatively Small Queries?

MyODBC is a lot faster than any other ODBC driver. Slowness might be due to not using the following options.

- The **ODBC Tracing** option is turned on. You can cross-check whether this option is not turned on by following the instructions from here [<http://support.microsoft.com/default.aspx?scid=kb;EN-US;268591>].

As shown in the above image, the 'When to trace' option from the ODBC Data Source Administrator 'Tracing' tab should always point to 'Start Tracing Now', instead of 'Stop Tracing Now'.

- The **Debug version** of the driver is used. If you are using the debug version of the driver DLL, it can also relatively slow down the query processing time. You can cross-check whether you are using the debug or release version of the DLL from the 'Comments' section of the driver DLL properties (from the system directory, right click on the driver DLL and click on properties) as shown below:

- The **Driver trace and query logs** are enabled. Even if you intent to use the debug version of the driver (you should always use the release version in the production environment), make sure the driver trace and query log options(OPTION=4,524288 respectively) are not enabled as shown below:

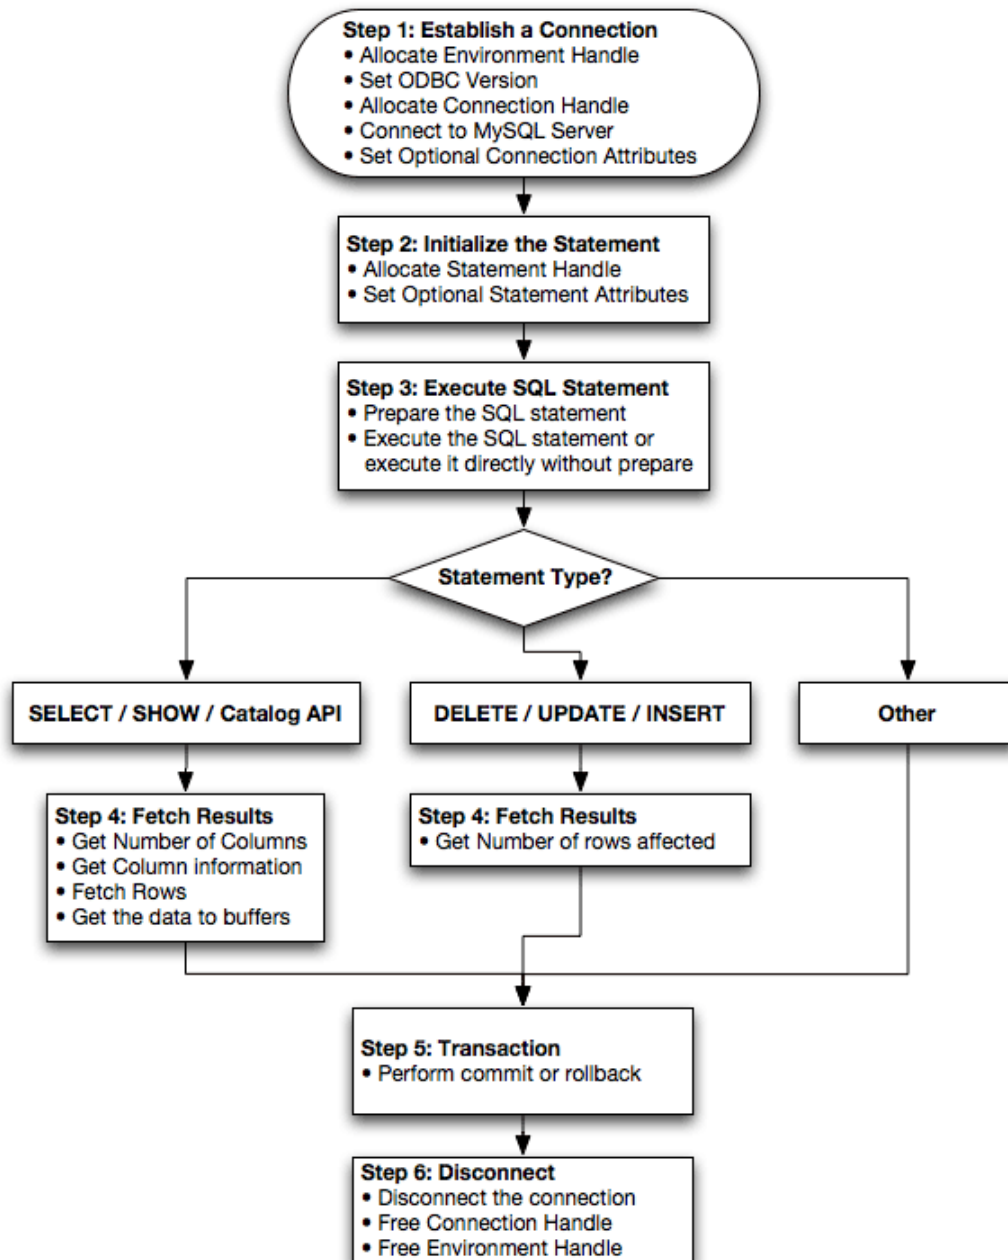

## 23.1.15. Basic MyODBC Application Steps

Interacting with a MySQL server from MyODBC applications involves the following operations:

- Configure the MyODBC DSN
- Connect to MySQL server
- Initialization operations
- Execute SQL statements
- Retrieve results
- Perform Transactions
- Disconnect from the server

Most applications use some variation of these steps. The basic application steps are shown in the following diagram:

## 23.1.16. MyODBC API Reference

This section summarizes ODBC routines, categorized by functionality.

For the complete ODBC API reference, please refer to the ODBC Programmer's Reference at [http://msdn.microsoft.com/library/en-us/odbc/html/odbcabout\\_this\\_manual.asp](http://msdn.microsoft.com/library/en-us/odbc/html/odbcabout_this_manual.asp).

An application can call `SQLGetInfo` function to obtain conformance information about MyODBC. To obtain information about support for a specific function in the driver, an application can call `SQLGetFunctions`.

Note: For backward compatibility, the MyODBC 3.51 driver supports all deprecated functions.

The following tables list MyODBC API calls grouped by task:

### Connecting to a data source:

Function name	MyODBC 2.50	MyODBC 3.51	Conformance	Purpose
SQLAllocHandle	No	Yes	ISO 92	Obtains an environment, connection, statement, or descriptor handle.
SQLConnect	Yes	Yes	ISO 92	Connects to a specific driver by data source name, user ID, and password.
SQLDriverConnect	Yes	Yes	ODBC	Connects to a specific driver by connection string or requests that the Driver Manager and driver display connection dialog boxes for the user.
SQLAllocEnv	Yes	Yes	Deprecated	Obtains an environment handle allocated from driver.
SQLAllocConnect	Yes	Yes	Deprecated	Obtains a connection handle

#### Obtaining information about a driver and data source:

Function name	MyODBC 2.50	MyODBC 3.51	Conformance	Purpose
SQLDataSources	No	No	ISO 92	Returns the list of available data sources, handled by the Driver Manager
SQLDrivers	No	No	ODBC	Returns the list of installed drivers and their attributes, handles by Driver Manager
SQLGetInfo	Yes	Yes	ISO 92	Returns information about a specific driver and data source.
SQLGetFunctions	Yes	Yes	ISO 92	Returns supported driver functions.
SQLGetTypeInfo	Yes	Yes	ISO 92	Returns information about supported data types.

#### Setting and retrieving driver attributes:

Function name	MyODBC 2.50	MyODBC 3.51	Conformance	Purpose
SQLSetConnectAttr	No	Yes	ISO 92	Sets a connection attribute.
SQLGetConnectAttr	No	Yes	ISO 92	Returns the value of a connection attribute.
SQLSetConnectOption	Yes	Yes	Deprecated	Sets a connection option
SQLGetConnectOption	Yes	Yes	Deprecated	Returns the value of a connection option
SQLSetEnvAttr	No	Yes	ISO 92	Sets an environment attribute.
SQLGetEnvAttr	No	Yes	ISO 92	Returns the value of an environment attribute.
SQLSetStmtAttr	No	Yes	ISO 92	Sets a statement attribute.

SQLGetStmtAttr	No	Yes	ISO 92	Returns the value of a statement attribute.
SQLSetStmtOption	Yes	Yes	Deprecated	Sets a statement option
SQLGetStmtOption	Yes	Yes	Deprecated	Returns the value of a statement option

**Preparing SQL requests:**

Function name	MyODBC	MyODBC	Conformance	Purpose
	<b>2.50</b>	<b>3.51</b>		
SQLAllocStmt	Yes	Yes	Deprecated	Allocates a statement handle
SQLPrepare	Yes	Yes	ISO 92	Prepares an SQL statement for later execution.
SQLBindParameter	Yes	Yes	ODBC	Assigns storage for a parameter in an SQL statement.
SQLGetCursorName	Yes	Yes	ISO 92	Returns the cursor name associated with a statement handle.
SQLSetCursorName	Yes	Yes	ISO 92	Specifies a cursor name.
SQLSetScrollOptions	Yes	Yes	ODBC	Sets options that control cursor behavior.

**Submitting requests:**

Function name	MyODBC	MyODBC	Conformance	Purpose
	<b>2.50</b>	<b>3.51</b>		
SQLExecute	Yes	Yes	ISO 92	Executes a prepared statement.
SQLExecDirect	Yes	Yes	ISO 92	Executes a statement
SQLNativeSql	Yes	Yes	ODBC	Returns the text of an SQL statement as translated by the driver.
SQLDescribeParam	Yes	Yes	ODBC	Returns the description for a specific parameter in a statement.
SQLNumParams	Yes	Yes	ISO 92	Returns the number of parameters in a statement.
SQLParamData	Yes	Yes	ISO 92	Used in conjunction with SQLPutData to supply parameter data at execution time. (Useful for long data values.)
SQLPutData	Yes	Yes	ISO 92	Sends part or all of a data value for a parameter. (Useful for long data values.)

**Retrieving results and information about results:**

Function name	MyODBC	MyODBC	Conformance	Purpose
	<b>2.50</b>	<b>3.51</b>		
SQLRowCount	Yes	Yes	ISO 92	Returns the number of rows affected by an insert, update, or delete request.
SQLNumResult-	Yes	Yes	ISO 92	Returns the number of columns in

Cols				the result set.
SQLDescribeCol	Yes	Yes	ISO 92	Describes a column in the result set.
SQLColAttribute	No	Yes	ISO 92	Describes attributes of a column in the result set.
SQLColAttributes	Yes	Yes	Deprecated	Describes attributes of a column in the result set.
SQLFetch	Yes	Yes	ISO 92	Returns multiple result rows.
SQLFetchScroll	No	Yes	ISO 92	Returns scrollable result rows.
SQLExtendedFetch	Yes	Yes	Deprecated	Returns scrollable result rows.
SQLSetPos	Yes	Yes	ODBC	Positions a cursor within a fetched block of data and allows an application to refresh data in the rowset or to update or delete data in the result set.
SQLBulkOperations	No	Yes	ODBC	Performs bulk insertions and bulk bookmark operations, including update, delete, and fetch by bookmark.

**Retrieving error or diagnostic information:**

Function name	MyODBC	MyODBC	Conformance	Purpose
	<b>2.50</b>	<b>3.51</b>		
SQLError	Yes	Yes	Deprecated	Returns additional error or status information
SQLGetDiagField	Yes	Yes	ISO 92	Returns additional diagnostic information (a single field of the diagnostic data structure).
SQLGetDiagRec	Yes	Yes	ISO 92	Returns additional diagnostic information (multiple fields of the diagnostic data structure).

**Obtaining information about the data source's system tables (catalog functions) item:**

Function name	MyODBC	MyODBC	Conformance	Purpose
	<b>2.50</b>	<b>3.51</b>		
SQLColumnPrivileges	Yes	Yes	ODBC	Returns a list of columns and associated privileges for one or more tables.
SQLColumns	Yes	Yes	X/Open	Returns the list of column names in specified tables.
SQLForeignKeys	Yes	Yes	ODBC	Returns a list of column names that make up foreign keys, if they exist for a specified table.
SQLPrimaryKeys	Yes	Yes	ODBC	Returns the list of column names that make up the primary key for a table.
SQLSpecialColumns	Yes	Yes	X/Open	Returns information about the optimal set of columns that uniquely identifies a row in a specified table, or the columns that are auto-

				atically updated when any value in the row is updated by a transaction.
SQLStatistics	Yes	Yes	ISO 92	Returns statistics about a single table and the list of indexes associated with the table.
SQLTablePrivileges	Yes	Yes	ODBC	Returns a list of tables and the privileges associated with each table.
SQLTables	Yes	Yes	X/Open	Returns the list of table names stored in a specific data source.

**Performing transactions:**

Function name	MyODBC	MyODBC	Conformance	Purpose
	<b>2.50</b>	<b>3.51</b>		
SQLTransact	Yes	Yes	Deprecated	Commits or rolls back a transaction
SQLEndTran	No	Yes	ISO 92	Commits or rolls back a transaction.

**Terminating a statement:**

Function name	MyODBC	MyODBC	Conformance	Purpose
	<b>2.50</b>	<b>3.51</b>		
SQLFreeStmt	Yes	Yes	ISO 92	Ends statement processing, discards pending results, and, optionally, frees all resources associated with the statement handle.
SQLCloseCursor	Yes	Yes	ISO 92	Closes a cursor that has been opened on a statement handle.
SQLCancel	Yes	Yes	ISO 92	Cancels an SQL statement.

**Terminating a connection:**

Function name	MyODBC	MyODBC	Conformance	Purpose
	<b>2.50</b>	<b>3.51</b>		
SQLDisconnect	Yes	Yes	ISO 92	Closes the connection.
SQLFreeHandle	No	Yes	ISO 92	Releases an environment, connection, statement, or descriptor handle.
SQLFreeConnect	Yes	Yes	Deprecated	Releases connection handle
SQLFreeEnv	Yes	Yes	Deprecated	Releases an environment handle

## 23.1.17. MyODBC Data Types

The following table illustrates how driver maps the server data types to default SQL and C data types:

Native Value	SQL Type	C Type
--------------	----------	--------

bit	SQL_BIT	SQL_C_BIT
tinyint	SQL_TINYINT	SQL_C_STINYINT
tinyint unsigned	SQL_TINYINT	SQL_C_UTINYINT
bigint	SQL_BIGINT	SQL_C_SBIGINT
bigint unsigned	SQL_BIGINT	SQL_C_UBIGINT
long varbinary	SQL_LONGVARBINARY	SQL_C_BINARY
blob	SQL_LONGVARBINARY	SQL_C_BINARY
longblob	SQL_LONGVARBINARY	SQL_C_BINARY
tinyblob	SQL_LONGVARBINARY	SQL_C_BINARY
mediumblob	SQL_LONGVARBINARY	SQL_C_BINARY
long varchar	SQL_LONGVARCHAR	SQL_C_CHAR
text	SQL_LONGVARCHAR	SQL_C_CHAR
mediumtext	SQL_LONGVARCHAR	SQL_C_CHAR
char	SQL_CHAR	SQL_C_CHAR
numeric	SQL_NUMERIC	SQL_C_CHAR
decimal	SQL_DECIMAL	SQL_C_CHAR
integer	SQL_INTEGER	SQL_C_SLONG
integer unsigned	SQL_INTEGER	SQL_C_ULONG
int	SQL_INTEGER	SQL_C_SLONG
int unsigned	SQL_INTEGER	SQL_C_ULONG
mediumint	SQL_INTEGER	SQL_C_SLONG
mediumint unsigned	SQL_INTEGER	SQL_C_ULONG
smallint	SQL_SMALLINT	SQL_C_SSHORT
smallint unsigned	SQL_SMALLINT	SQL_C_USHORT
real	SQL_FLOAT	SQL_C_DOUBLE
double	SQL_FLOAT	SQL_C_DOUBLE
float	SQL_REAL	SQL_C_FLOAT
double precision	SQL_DOUBLE	SQL_C_DOUBLE
date	SQL_DATE	SQL_C_DATE
time	SQL_TIME	SQL_C_TIME
year	SQL_SMALLINT	SQL_C_SHORT
datetime	SQL_TIMESTAMP	SQL_C_TIMESTAMP
timestamp	SQL_TIMESTAMP	SQL_C_TIMESTAMP
text	SQL_VARCHAR	SQL_C_CHAR
varchar	SQL_VARCHAR	SQL_C_CHAR
enum	SQL_VARCHAR	SQL_C_CHAR
set	SQL_VARCHAR	SQL_C_CHAR
bit	SQL_CHAR	SQL_C_CHAR
bool	SQL_CHAR	SQL_C_CHAR

## 23.1.18. MyODBC Error Codes

The following tables lists the error codes returned by the driver apart from the server errors.

Native Code	SQLSTATE 2	SQLSTATE 3	Error Message
-------------	------------	------------	---------------

## Connectors

500	01000	01000	General warning
501	01004	01004	String data, right truncated
502	01S02	01S02	Option value changed
503	01S03	01S03	No rows updated/deleted
504	01S04	01S04	More than one row updated/deleted
505	01S06	01S06	Attempt to fetch before the result set returned the first row set
506	07001	07002	SQLBindParameter not used for all parameters
507	07005	07005	Prepared statement not a cursor-specification
508	07009	07009	Invalid descriptor index
509	08002	08002	Connection name in use
510	08003	08003	Connection does not exist
511	24000	24000	Invalid cursor state
512	25000	25000	Invalid transaction state
513	25S01	25S01	Transaction state unknown
514	34000	34000	Invalid cursor name
515	S1000	HY000	General driver defined error
516	S1001	HY001	Memory allocation error
517	S1002	HY002	Invalid column number
518	S1003	HY003	Invalid application buffer type
519	S1004	HY004	Invalid SQL data type
520	S1009	HY009	Invalid use of null pointer
521	S1010	HY010	Function sequence error
522	S1011	HY011	Attribute can not be set now
523	S1012	HY012	Invalid transaction operation code
524	S1013	HY013	Memory management error
525	S1015	HY015	No cursor name available
526	S1024	HY024	Invalid attribute value
527	S1090	HY090	Invalid string or buffer length
528	S1091	HY091	Invalid descriptor field identifier
529	S1092	HY092	Invalid attribute/option identifier
530	S1093	HY093	Invalid parameter number
531	S1095	HY095	Function type out of range
532	S1106	HY106	Fetch type out of range
533	S1117	HY117	Row value out of range
534	S1109	HY109	Invalid cursor position
535	S1C00	HYC00	Optional feature not implemented
0	21S01	21S01	Column count does not match value count
0	23000	23000	Integrity constraint violation
0	42000	42000	Syntax error or access violation
0	42S02	42S02	Base table or view not found
0	42S12	42S12	Index not found
0	42S21	42S21	Column already exists
0	42S22	42S22	Column not found

0	08S01	08S01	Communication link failure
---	-------	-------	----------------------------

## 23.1.19. MyODBC With VB: ADO, DAO and RDO

This section contains simple examples of the use of MySQL ODBC 3.51 Driver with ADO, DAO and RDO.

### 23.1.19.1. ADO: rs.addNew, rs.delete, and rs.update

The following ADO (ActiveX Data Objects) example creates a table my\_ado and demonstrates the use of rs.addNew, rs.delete, and rs.update.

```
Private Sub myodbc_ado_Click()

Dim conn As ADODB.Connection
Dim rs As ADODB.Recordset
Dim fld As ADODB.Field
Dim sql As String

'connect to MySQL server using MySQL ODBC 3.51 Driver
Set conn = New ADODB.Connection
conn.ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"_
    & "SERVER=localhost;"_
    & " DATABASE=test;"_
    & "UID=venu;PWD=venu; OPTION=3"

conn.Open

'create table
conn.Execute "DROP TABLE IF EXISTS my_ado"
conn.Execute "CREATE TABLE my_ado(id int not null primary key, name varchar(20)
    & "txt text, dt date, tm time, ts timestamp)"

'direct insert
conn.Execute "INSERT INTO my_ado(id,name,txt) values(1,100,'venu')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(2,200,'MySQL')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(3,300,'Delete')"

Set rs = New ADODB.Recordset
rs.CursorLocation = adUseServer

'fetch the initial table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Initial my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
    Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close

'rs insert
rs.Open "select * from my_ado", conn, adOpenDynamic, adLockOptimistic
rs.AddNew
rs!Name = "Monty"
rs!txt = "Insert row"
```

```

rs.Update
rs.Close

'rs update
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-row"
rs.Update
rs.Close

'rs update second time..
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-second-time"
rs.Update
rs.Close

'rs delete
rs.Open "SELECT * FROM my_ado"
rs.MoveNext
rs.MoveNext
rs.Delete
rs.Close

'fetch the updated table ..
rs.Open "SELECT * FROM my_ado", conn
  Debug.Print rs.RecordCount
  rs.MoveFirst
  Debug.Print String(50, "-") & "Updated my_ado Result Set " & String(50, "-")
  For Each fld In rs.Fields
    Debug.Print fld.Name,
    Next
    Debug.Print

    Do Until rs.EOF
      For Each fld In rs.Fields
        Debug.Print fld.Value,
        Next
      rs.MoveNext
      Debug.Print
    Loop
  rs.Close
conn.Close
End Sub

```

### 23.1.19.2. DAO: rs.addNew, rs.update, and Scrolling

The following DAO (Data Access Objects) example creates a table my\_dao and demonstrates the use of rs.addNew, rs.update, and result set scrolling.

```

Private Sub myodbc_dao_Click()

Dim ws As Workspace
Dim conn As Connection
Dim queryDef As queryDef
Dim str As String

'connect to MySQL using MySQL ODBC 3.51 Driver
Set ws = DBEngine.CreateWorkspace("", "venu", "venu", dbUseODBC)
str = "odbc;DRIVER={MySQL ODBC 3.51 Driver};"_
      & "SERVER=localhost;"_
      & " DATABASE=test;"_
      & "UID=venu;PWD=venu; OPTION=3"
Set conn = ws.OpenConnection("test", dbDriverNoPrompt, False, str)

'Create table my_dao
Set queryDef = conn.CreateQueryDef("", "drop table if exists my_dao")

```

```

queryDef.Execute

Set queryDef = conn.CreateQueryDef("", "create table my_dao(Id INT AUTO_INCREMENT PRIMARY KEY, Name VARCHAR(255), Ts TIMESTAMP(14) NOT NULL)")
queryDef.Execute

'Insert new records using rs.addNew
Set rs = conn.OpenRecordset("my_dao")
Dim i As Integer

    For i = 10 To 15
        rs.AddNew
        rs!Name = "insert record" & i
        rs!Id2 = i
        rs.Update
    Next i
        rs.Close

'rs update..
Set rs = conn.OpenRecordset("my_dao")
rs.Edit
rs!Name = "updated-string"
rs.Update
rs.Close

'fetch the table back...
Set rs = conn.OpenRecordset("my_dao", dbOpenDynamic)
str = "Results:"
rs.MoveFirst
While Not rs.EOF
str = " " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print "DATA:" & str
rs.MoveNext
Wend

'rs Scrolling
rs.MoveFirst
str = " FIRST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MoveLast
str = " LAST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MovePrevious
str = " LAST-1 ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

'free all resources
rs.Close
queryDef.Close
conn.Close
ws.Close

End Sub

```

### 23.1.19.3. RDO: rs.addNew and rs.update

The following RDO (Remote Data Objects) example creates a table my\_rdo and demonstrates the use of rs.addNew and rs.update.

```

Dim rs As rdoResultset
Dim cn As New rdoConnection
Dim cl As rdoColumn
Dim SQL As String

'cn.Connect = "DSN=test;"

```

```
cn.Connect = "DRIVER={MySQL ODBC 3.51 Driver};"_
             & "SERVER=localhost;"_
             & " DATABASE=test;"_
             & "UID=venu;PWD=venu; OPTION=3"

cn.CursorDriver = rdUseOdbc
cn.EstablishConnection rdDriverPrompt

'drop table my_rdo
SQL = "drop table if exists my_rdo"
cn.Execute SQL, rdExecDirect

'create table my_rdo
SQL = "create table my_rdo(id int, name varchar(20))"
cn.Execute SQL, rdExecDirect

'insert - direct
SQL = "insert into my_rdo values (100,'venu')"
cn.Execute SQL, rdExecDirect

SQL = "insert into my_rdo values (200,'MySQL')"
cn.Execute SQL, rdExecDirect

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 300
rs!Name = "Insert1"
rs.Update
rs.Close

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 400
rs!Name = "Insert 2"
rs.Update
rs.Close

'rs update
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.Edit
rs!id = 999
rs!Name = "updated"
rs.Update
rs.Close

'fetch back...
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
Do Until rs.EOF
For Each cl In rs.rdoColumns
    Debug.Print cl.Value,
Next
rs.MoveNext
Debug.Print
Loop
Debug.Print "Row count="; rs.RowCount

'close
rs.Close
cn.Close

End Sub
```

## 23.1.20. MyODBC with Microsoft .NET

This section contains simple examples that demonstrate the use of MyODBC drivers with ODBC.NET.

### 23.1.20.1. ODBC.NET: CSHARP(C#)

The following sample creates a table `my_odbc_net` and demonstrates the use in C#.

```

/**
 * @sample      : mycon.cs
 * @purpose     : Demo sample for ODBC.NET using MyODBC
 * @author      : Venu, <venu@mysql.com>
 *
 * (C) Copyright MySQL AB, 1995-2006
 *
 **/

/* build command
 *
 * csc /t:exe
 *      /out:mycon.exe mycon.cs
 *      /r:Microsoft.Data.Odbc.dll
 */

using Console = System.Console;
using Microsoft.Data.Odbc;

namespace myodbc3
{
class mycon
{
    static void Main(string[] args)
    {
        try
        {
            //Connection string for MyODBC 2.50
            /*string MyConString = "DRIVER={MySQL};" +
                "SERVER=localhost;" +
                "DATABASE=test;" +
                "UID=venu;" +
                "PASSWORD=venu;" +
                "OPTION=3";

            */
            //Connection string for MyODBC 3.51
            string MyConString = "DRIVER={MySQL ODBC 3.51 Driver};" +
                "SERVER=localhost;" +
                "DATABASE=test;" +
                "UID=venu;" +
                "PASSWORD=venu;" +
                "OPTION=3";

- Peter Harvey

## 23.2. MySQL Connector/NET

### 23.2.1. Introduction

MySQL Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/NET is a fully managed ADO.NET driver written in 100% pure C#.

MySQL Connector/NET includes full support for:

- MySQL 5.0 features (such as stored procedures)
- MySQL 4.1 features (server-side prepared statements, Unicode, and shared memory access, and so forth)
- Large-packet support for sending and receiving rows and BLOBs up to 2 gigabytes in size.

- Protocol compression which allows for compressing the data stream between the client and server.
- Support for connecting using TCP/IP sockets, named pipes, or shared memory on Windows.
- Support for connecting using TCP/IP sockets or Unix sockets on Unix.
- Support for the Open Source Mono framework developed by Novell.
- Fully managed, does not utilize the MySQL client library.

The developers of MySQL Connector/NET greatly value the input of our users in the software development process. If you find MySQL Connector/NET lacking some feature important to you, or if you discover a bug and need to file a bug report, please use the instructions in Section 1.8, “How to Report Bugs or Problems”.

#### Additional resources

- Community support for MySQL Connector/NET can be found through the forums at <http://forums.mysql.com>.
- Community support for MySQL Connector/NET can also be found through the mailing lists at <http://lists.mysql.com>.
- Paid support is available from MySQL AB. Additional information is available at <http://www.mysql.com/support/>.

This document is intended as a user's guide to MySQL Connector/NET and not as a syntax reference. If you need detailed syntax information you should read the `Documentation.chm` file included with the MySQL Connector/NET distribution.

## 23.2.2. Downloading and Installing MySQL Connector/NET

MySQL Connector/NET runs on any platform that supports the .NET framework. The .NET framework is primarily supported on recent versions of Microsoft Windows, and is supported on Linux through the Open Source Mono framework developed by Novell (see <http://www.mono-project.com>).

MySQL Connector/NET is installed through the use of a Windows Installer (.msi) installation package, which can be used to install MySQL Connector/NET on all Windows operating systems. The MSI package is contained within a ZIP archive named `mysql-connector-net-version.zip`, where *version* indicates the MySQL Connector/NET version.

MySQL Connector/NET is available for download from <http://dev.mysql.com/downloads/connector/net/1.0.html>.

The Windows Installer engine was updated with the release of Windows XP; those using an older version can reference this Microsoft Knowledge Base article [<http://support.microsoft.com/default.aspx?scid=kb;EN-US;292539>] for information on upgrading to the latest version.

To install MySQL Connector/NET, right-click on the MSI file and select Install. The installation will begin automatically after the installer prompts you for your installation preferences. The Typical installation is recommended for most users.

If you are having problems running the installer, you can download a ZIP file without an installer as an alternative. That file is called `mysql-connector-net-version-noinstall.zip`. Us-

ing a ZIP program, unpack it to a directory of your choice.

Unless you choose otherwise, MySQL Connector/NET is installed in `C:\Program Files\MySQL\MySQL Connector Net X.X.X`, where `X.X.X` is replaced with the version of MySQL Connector/NET you are installing. New installations do not overwrite existing versions of MySQL Connector/NET.

## 23.2.3. Connector/NET Architecture

MySQL Connector/NET comprises several classes that are used to connect to the database, execute queries and statements, and manage query results.

The following are the major classes of MySQL Connector/NET:

- `MySqlCommand`: Represents an SQL statement to execute against a MySQL database.
- `MySqlCommandBuilder`: Automatically generates single-table commands used to reconcile changes made to a `DataSet` with the associated MySQL database.
- `MySqlConnection`: Represents an open connection to a MySQL Server database.
- `MySqlDataAdapter`: Represents a set of data commands and a database connection that are used to fill a dataset and update a MySQL database.
- `MySqlDataReader`: Provides a means of reading a forward-only stream of rows from a MySQL database.
- `MySqlException`: The exception that is thrown when MySQL returns an error.
- `MySqlHelper`: Helper class that makes it easier to work with the provider.
- `MySqlTransaction`: Represents an SQL transaction to be made in a MySQL database.

Each of these objects will be described in the upcoming sections. These sections are intended to be an overview of the major classes of MySQL Connector/NET, and not a syntax reference. If you need more detailed information you should read the `Documentation.chm` file included with the MySQL Connector/NET distribution.

### 23.2.3.1. The MySqlCommand Class

The `MySqlCommand` class represents an SQL statement to execute against a MySQL database.

*Note:* Prior versions of the provider used the '@' symbol to mark parameters in SQL. This is incompatible with MySQL user variables, so the provider now uses the '?' symbol to locate parameters in SQL. To support older code, you can set `'old syntax=yes'` in your connection string. If you do this, please be aware that an exception will not be thrown if you fail to define a parameter that you intended to use in your SQL.

#### 23.2.3.1.1. Properties

The following properties are available:

- `CommandText`: Gets or sets the SQL statement to execute at the data source.
- `CommandTimeout`: Gets or sets the wait time before terminating the attempt to execute a command and generating an error.
- `CommandType`: Gets or sets a value indicating how the `CommandText` property is to be interpreted. Possible types are `StoredProcedure`, `TableDirect`, and `Text`.
- `Connection`: Gets or sets the `MySqlConnection` used by this instance of the `MySqlCommand`.

- `IsPrepared`: Is true if this command has been prepared, false otherwise.
- `Parameters`: Gets the `MySqlParameterCollection`.
- `Transaction`: Gets or sets the `MySqlConnection` within which the `MySqlCommand` executes.
- `UpdatedRowSource`: Gets or sets how command results are applied to the `DataRow` when used by the `Update` method of the `DbDataAdapter`.

### 23.2.3.1.2. Methods

The following methods are available:

- `Cancel`: Attempts to cancel the execution of a `MySqlCommand`. *This operation is not supported.*
- `Clone`: Creates a clone of this `MySqlCommand` object. `CommandText`, `Connection`, and `Transaction` properties are included as well as the entire parameter list.
- `CreateParameter`: Creates a new instance of a `MySqlParameter` object.
- `Dispose`: Disposes of this instance of `MySqlCommand`.
- `ExecuteNonQuery`: Executes an SQL statement against the connection and returns the number of rows affected.
- `ExecuteReader`: Sends the `CommandText` to the `Connection` and builds a `MySqlDataReader`.
- `ExecuteScalar`: Executes the query, and returns the first column of the first row in the result set returned by the query. Extra columns or rows are ignored.
- `Prepare`: Creates a prepared version of the command on an instance of MySQL Server.

### 23.2.3.1.3. Usage

The following example creates a `MySqlCommand` and a `MySqlConnection`. The `MySqlConnection` is opened and set as the `Connection` for the `MySqlCommand`. The example then calls `ExecuteNonQuery`, and closes the connection. To accomplish this, the `ExecuteNonQuery` is passed a connection string and a query string that is an SQL INSERT statement.

#### 23.2.3.1.3.1. VB.NET

The following example show how to use the `MySqlCommand` class with VB.NET:

```
Public Sub InsertRow(myConnectionString As String)
    ' If the connection string is null, use a default.
    If myConnectionString = "" Then
        myConnectionString = "Database=Test;Data Source=localhost;User Id=userName"
    End If
    Dim myConnection As New MySqlConnection(myConnectionString)
    Dim myInsertQuery As String = "INSERT INTO Orders (id, customerId, amount) VALUES (1001, 1, 100)"
    Dim myCommand As New MySqlCommand(myInsertQuery)
    myCommand.Connection = myConnection
    myConnection.Open()
    myCommand.ExecuteNonQuery()
    myCommand.Connection.Close()
End Sub
```

#### 23.2.3.1.3.2. C#

The following example show how to use the MySqlCommand class with C#:

```
public void InsertRow(string myConnectionString)
{
    // If the connection string is null, use a default.
    if(myConnectionString == "")
    {
        myConnectionString = "Database=Test;Data Source=localhost;User Id=usern
    }
    MySqlConnection myConnection = new MySqlConnection(myConnectionString);
    string myInsertQuery = "INSERT INTO Orders (id, customerId, amount) Values(
    MySqlCommand myCommand = new MySqlCommand(myInsertQuery);
    myCommand.Connection = myConnection;
    myConnection.Open();
    myCommand.ExecuteNonQuery();
    myCommand.Connection.Close();
}
```

### 23.2.3.2. The MySqlCommandBuilder Class

The MySqlDataAdapter does not automatically generate the SQL statements required to reconcile changes made to a DataSet with the associated instance of MySQL. However, you can create a MySqlCommandBuilder object to automatically generate SQL statements for single-table updates if you set the SelectCommand property of the MySqlDataAdapter. Then, any additional SQL statements that you do not set are generated by the MySqlCommandBuilder.

The MySqlCommandBuilder registers itself as a listener for OnRowUpdating events whenever you set the DataAdapter property. You can only associate one MySqlDataAdapter or MySqlCommandBuilder object with each other at one time.

To generate INSERT, UPDATE, or DELETE statements, the MySqlCommandBuilder uses the SelectCommand property to retrieve a required set of metadata automatically. If you change the SelectCommand after the metadata has is retrieved (for example, after the first update), you should call the RefreshSchema method to update the metadata.

The SelectCommand must also return at least one primary key or unique column. If none are present, an InvalidOperationException exception is generated, and the commands are not generated.

The MySqlCommandBuilder also uses the Connection, CommandTimeout, and Transaction properties referenced by the SelectCommand. The user should call RefreshSchema if any of these properties are modified, or if the SelectCommand itself is replaced. Otherwise the InsertCommand, UpdateCommand, and DeleteCommand properties retain their previous values.

If you call Dispose, the MySqlCommandBuilder is disassociated from the MySqlDataAdapter, and the generated commands are no longer used.

#### 23.2.3.2.1. Properties

The following properties are available:

- **DataAdapter:** The MySqlCommandBuilder registers itself as a listener for RowUpdating events that are generated by the MySqlDataAdapter specified in this property. When you create a new instance MySqlCommandBuilder, any existing MySqlCommandBuilder associated with this MySqlDataAdapter is released.
- **QuotePrefix, QuoteSuffix:** Database objects in MySQL can contain special characters such as spaces that would make normal SQL strings impossible to correctly parse. Use of the QuotePrefix and the QuoteSuffix properties allows the MySqlCommandBuilder to build SQL commands that handle this situation.

#### 23.2.3.2.2. Methods

The following methods are available:

- `DeriveParameters`: Retrieves parameter information from the stored procedure specified in the `MySQLCommand` and populates the `Parameters` collection of the specified `MySQLCommand` object. This method is not currently supported because stored procedures are not available in `MySQL`.
- `GetDeleteCommand`: Gets the automatically generated `MySQLCommand` object required to perform deletions on the database.
- `GetInsertCommand`: Gets the automatically generated `MySQLCommand` object required to perform insertions on the database.
- `GetUpdateCommand`: Gets the automatically generated `MySQLCommand` object required to perform updates on the database.
- `RefreshSchema`: Refreshes the database schema information used to generate `INSERT`, `UPDATE`, or `DELETE` statements.

### 23.2.3.2.3. Usage

The following example uses the `MySQLCommand`, along `MySQLDataAdapter` and `MySQLConnection`, to select rows from a data source. The example is passed an initialized `DataSet`, a connection string, a query string that is an SQL `SELECT` statement, and a string that is the name of the database table. The example then creates a `MySQLCommandBuilder`.

#### 23.2.3.2.3.1. VB.NET

The following example shows how to use the `MySQLCommandBuilder` class with VB.NET:

```
Public Shared Function SelectRows(myConnection As String, mySelectQuery As String) As DataSet
    Dim myConn As New MySqlConnection(myConnection)
    Dim myDataAdapter As New MySQLDataAdapter()
    myDataAdapter.SelectCommand = New MySQLCommand(mySelectQuery, myConn)
    Dim cb As SqlCommandBuilder = New MySQLCommandBuilder(myDataAdapter)

    myConn.Open()

    Dim ds As DataSet = New DataSet
    myDataAdapter.Fill(ds, myTableName)

    ' Code to modify data in DataSet here

    ' Without the MySQLCommandBuilder this line would fail.
    myDataAdapter.Update(ds, myTableName)

    myConn.Close()
End Function 'SelectRows
```

#### 23.2.3.2.3.2. C#

The following example shows how to use the `MySQLCommandBuilder` class with C#:

```
public static DataSet SelectRows(string myConnection, string mySelectQuery,
{
    MySqlConnection myConn = new MySqlConnection(myConnection);
    MySQLDataAdapter myDataAdapter = new MySQLDataAdapter();
    myDataAdapter.SelectCommand = new MySQLCommand(mySelectQuery, myConn);
    MySQLCommandBuilder cb = new MySQLCommandBuilder(myDataAdapter);

    myConn.Open();
```

```
DataSet ds = new DataSet();
myDataAdapter.Fill(ds, myTableName);

//code to modify data in DataSet here

//Without the MySqlCommandBuilder this line would fail
myDataAdapter.Update(ds, myTableName);

myConn.Close();
return ds;
}
```

### 23.2.3.3. The MySqlConnection Class

A MySqlConnection object represents a session to a MySQL Server data source. When you create an instance of MySqlConnection, all properties are set to their initial values. For a list of these values, see the MySqlConnection constructor.

If the MySqlConnection goes out of scope, it is not closed. Therefore, you must explicitly close the connection by calling Close or Dispose.

#### 23.2.3.3.1. Properties

The following properties are available:

- **ConnectionString**: Gets or sets the string used to connect to a MySQL Server database.
- **ConnectionTimeout**: Gets the time to wait while trying to establish a connection before terminating the attempt and generating an error.
- **Database**: Gets the name of the current database or the database to be used after a connection is opened.
- **DataSource**: Gets the name of the MySQL server to which to connect.
- **ServerThread**: Returns the id of the server thread this connection is executing on.
- **ServerVersion**: Gets a string containing the version of the MySQL server to which the client is connected.
- **State**: Gets the current state of the connection.
- **UseConnection**: Indicates if this connection should use compression when communicating with the server.

#### 23.2.3.3.2. Methods

The following methods are available:

- **BeginTransaction**: Begins a database transaction.
- **ChangeDatabase**: Changes the current database for an open MySqlConnection.
- **Close**: Closes the connection to the database. This is the preferred method of closing any open connection.
- **CreateCommand**: Creates and returns a MySqlCommand object associated with the MySqlConnection.

- `Dispose`: Releases the resources used by the `MySqlConnection`.
- `Open`: Opens a database connection with the property settings specified by the `ConnectionString`.
- `Ping`: Pings the MySQL server.

### 23.2.3.3.3. Usage

The following example creates a `MySqlCommand` and a `MySqlConnection`. The `MySqlConnection` is opened and set as the `Connection` for the `MySqlCommand`. The example then calls `ExecuteNonQuery`, and closes the connection. To accomplish this, the `ExecuteNonQuery` is passed a connection string and a query string that is an SQL `INSERT` statement.

#### 23.2.3.3.3.1. VB.NET

The following example shows how to use the `MySqlConnection` class with VB.NET:

```
Public Sub InsertRow(myConnectionString As String)
    ' If the connection string is null, use a default.
    If myConnectionString = "" Then
        myConnectionString = "Database=Test;Data Source=localhost;User Id=usern
    End If
    Dim myConnection As New MySqlConnection(myConnectionString)
    Dim myInsertQuery As String = "INSERT INTO Orders (id, customerId, amount)
    Dim myCommand As New MySqlCommand(myInsertQuery)
    myCommand.Connection = myConnection
    myConnection.Open()
    myCommand.ExecuteNonQuery()
    myCommand.Connection.Close()
End Sub
```

#### 23.2.3.3.3.2. C#

The following example shows how to use the `MySqlConnection` class with C#:

```
public void InsertRow(string myConnectionString)
{
    // If the connection string is null, use a default.
    if(myConnectionString == "")
    {
        myConnectionString = "Database=Test;Data Source=localhost;User Id=usern
    }
    MySqlConnection myConnection = new MySqlConnection(myConnectionString);
    string myInsertQuery = "INSERT INTO Orders (id, customerId, amount) Values(
    MySqlCommand myCommand = new MySqlCommand(myInsertQuery);
    myCommand.Connection = myConnection;
    myConnection.Open();
    myCommand.ExecuteNonQuery();
    myCommand.Connection.Close();
}
```

### 23.2.3.4. The `MySqlDataAdapter` Class

The `MySqlDataAdapter` serves as a bridge between a `DataSet` and MySQL for retrieving and saving data. The `MySqlDataAdapter` provides this bridge by mapping `Fill`, which changes the data in the `DataSet` to match the data in the data source, and `Update`, which changes the data in the data source to match the data in the `DataSet`, using the appropriate SQL statements against the data source.

When the `MySQLDataAdapter` fills a `DataSet`, it will create the necessary tables and columns for the returned data if they do not already exist. However, primary key information will not be included in the implicitly created schema unless the `MissingSchemaAction` property is set to `AddWithKey`. You may also have the `MySQLDataAdapter` create the schema of the `DataSet`, including primary key information, before filling it with data using `FillSchema`.

`MySQLDataAdapter` is used in conjunction with `SqlConnection` and `SqlCommand` to increase performance when connecting to a MySQL database.

The `MySQLDataAdapter` also includes the `SelectCommand`, `InsertCommand`, `DeleteCommand`, `UpdateCommand`, and `TableMappings` properties to facilitate the loading and updating of data.

#### 23.2.3.4.1. Properties

The following properties are available:

- `AcceptChangesDuringFill`: Gets or sets a value indicating whether `AcceptChanges` is called on a `DataRow` after it is added to the `DataTable` during any of the `Fill` operations.
- `ContinueUpdateOnError`: Gets or sets a value that specifies whether to generate an exception when an error is encountered during a row update.
- `DeleteCommand`: Gets or sets an SQL statement or stored procedure used to delete records from the data set.
- `InsertCommand`: Gets or sets an SQL statement or stored procedure used to insert records into the data set.
- `MissingMappingAction`: Determines the action to take when incoming data does not have a matching table or column.
- `MissingSchemaAction`: Determines the action to take when existing `DataSet` schema does not match incoming data.
- `SelectCommand`: Gets or sets an SQL statement or stored procedure used to select records in the data source.
- `TableMappings`: Gets a collection that provides the master mapping between a source table and a `DataTable`.
- `UpdateCommand`: Gets or sets an SQL statement or stored procedure used to updated records in the data source.

#### 23.2.3.4.2. Methods

The following methods are available:

- `Fill`: Adds or refreshes rows in the `DataSet` to match those in the data source using the `DataSet` name, and creates a `DataTable` named "Table".
- `FillSchema`: Adds a `DataTable` named "Table" to the specified `DataSet` and configures the schema to match that in the data source based on the specified `SchemaType`.
- `GetFillParameters`: Gets the parameters set by the user when executing an SQL `SELECT` statement.
- `Update`: Calls the respective `INSERT`, `UPDATE`, or `DELETE` statements for each inserted, updated, or deleted row in the specified `DataSet`.

### 23.2.3.4.3. Usage

The following example creates a MySqlCommand and a MySqlConnection. The MySqlConnection is opened and set as the Connection for the MySqlCommand. The example then calls ExecuteNonQuery, and closes the connection. To accomplish this, the ExecuteNonQuery is passed a connection string and a query string that is an SQL INSERT statement.

#### 23.2.3.4.3.1. VB.NET

The following example shows how to use the MySqlDataAdapter class with VB.NET:

```
Public Function SelectRows(dataSet As DataSet, connection As String, query As S
    Dim conn As New MySqlConnection(connection)
    Dim adapter As New MySqlDataAdapter()
    adapter.SelectCommand = new MySqlCommand(query, conn)
    adapter.Fill(dataset)
    Return dataset
End Function
```

#### 23.2.3.4.3.2. C#

The following example shows how to use the MySqlDataAdapter class with C#:

```
public DataSet SelectRows(DataSet dataset, string connection, string query)
{
    MySqlConnection conn = new MySqlConnection(connection);
    MySqlDataAdapter adapter = new MySqlDataAdapter();
    adapter.SelectCommand = new MySqlCommand(query, conn);
    adapter.Fill(dataset);
    return dataset;
}
```

## 23.2.3.5. The MySqlDataReader Class

The MySqlDataReader class provides a means of reading a forward-only stream of rows from a MySQL database.

To create a MySQLDataReader, you must call the ExecuteReader method of the MySqlCommand object, rather than directly using a constructor.

While the MySqlDataReader is in use, the associated MySqlConnection is busy serving the MySqlDataReader, and no other operations can be performed on the MySqlConnection other than closing it. This is the case until the Close method of the MySqlDataReader is called.

IsClosed and RecordsAffected are the only properties that you can call after the MySqlDataReader is closed. Though the RecordsAffected property may be accessed at any time while the MySqlDataReader exists, always call Close before returning the value of RecordsAffected to ensure an accurate return value.

For optimal performance, MySqlDataReader avoids creating unnecessary objects or making unnecessary copies of data. As a result, multiple calls to methods such as GetValue return a reference to the same object. Use caution if you are modifying the underlying value of the objects returned by methods such as GetValue.

### 23.2.3.5.1. Properties

The following properties are available:

- **Depth:** Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.

- `FieldCount`: Gets the number of columns in the current row.
- `HasRows`: Gets a value indicating whether the `MySqlDataReader` contains one or more rows.
- `IsClosed`: Gets a value indicating whether the data reader is closed.
- `Item`: Gets the value of a column in its native format. In C#, this property is the indexer for the `MySqlDataReader` class.
- `RecordsAffected`: Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

### 23.2.3.5.2. Methods

The following methods are available:

- `Close`: Closes the `MySqlDataReader` object.
- `GetBoolean`: Gets the value of the specified column as a Boolean.
- `GetByte`: Gets the value of the specified column as a byte.
- `GetBytes`: Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.
- `GetChar`: Gets the value of the specified column as a single character.
- `GetChars`: Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.
- `GetDataTypeName`: Gets the name of the source data type.
- `GetDateTime`: Gets the value of the specified column as a `DateTime` object.
- `GetDecimal`: Gets the value of the specified column as a `Decimal` object.
- `GetDouble`: Gets the value of the specified column as a double-precision floating point number.
- `GetFieldType`: Gets the `Type` that is the data type of the object.
- `GetFloat`: Gets the value of the specified column as a single-precision floating point number.
- `GetGuid`: Gets the value of the specified column as a GUID.
- `GetInt16`: Gets the value of the specified column as a 16-bit signed integer.
- `GetInt32`: Gets the value of the specified column as a 32-bit signed integer.
- `GetInt64`: Gets the value of the specified column as a 64-bit signed integer.
- `GetMySqlDateTime`: Gets the value of the specified column as a `MySqlDateTime` object.
- `GetName`: Gets the name of the specified column.
- `GetOrdinal`: Gets the column ordinal, given the name of the column.
- `GetSchemaTable`: Returns a `DataTable` that describes the column metadata of the `MySqlDataReader`.
- `GetString`: Gets the value of the specified column as a `String` object.

- `GetTimeSpan`: Gets the value of the specified column as a `TimeSpan` object.
- `GetUInt16`: Gets the value of the specified column as a 16-bit unsigned integer.
- `GetUInt32`: Gets the value of the specified column as a 32-bit unsigned integer.
- `GetUInt64`: Gets the value of the specified column as a 64-bit unsigned integer.
- `GetValue`: Gets the value of the specified column in its native format.
- `GetValues`: Gets all attribute columns in the collection for the current row.
- `IsDBNull`: Gets a value indicating whether the column contains non-existent or missing values.
- `NextResult`: Advances the data reader to the next result, when reading the results of batch SQL statements.
- `Read`: Advances the `MySqlDataReader` to the next record.

### 23.2.3.5.3. Usage

The following example creates a `MySqlConnection`, a `MySqlCommand`, and a `MySqlDataReader`. The example reads through the data, writing it out to the console. Finally, the example closes the `MySqlDataReader`, then the `MySqlConnection`

#### 23.2.3.5.3.1. VB.NET

The following example shows how to use the `MySqlDataReader` class with VB.NET:

```
Public Sub ReadMyData(myConnString As String)
    Dim mySelectQuery As String = "SELECT OrderID, CustomerID FROM Orders"
    Dim myConnection As New MySqlConnection(myConnString)
    Dim myCommand As New MySqlCommand(mySelectQuery, myConnection)
    myConnection.Open()
    Dim myReader As MySqlDataReader
    myReader = myCommand.ExecuteReader()
    ' Always call Read before accessing data.
    While myReader.Read()
        Console.WriteLine((myReader.GetInt32(0) & ", " & myReader.GetString(1)))
    End While
    ' always call Close when done reading.
    myReader.Close()
    ' Close the connection when done with it.
    myConnection.Close()
End Sub 'ReadMyData
```

#### 23.2.3.5.3.2. C#

The following example shows how to use the `MySqlDataReader` class with C#:

```
public void ReadMyData(string myConnString) {
    string mySelectQuery = "SELECT OrderID, CustomerID FROM Orders";
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    MySqlCommand myCommand = new MySqlCommand(mySelectQuery, myConnection);
    myConnection.Open();
    MySqlDataReader myReader;
    myReader = myCommand.ExecuteReader();
    // Always call Read before accessing data.
    while (myReader.Read()) {
        Console.WriteLine(myReader.GetInt32(0) + ", " + myReader.GetString(1));
    }
    // always call Close when done reading.
```

```
myReader.Close();  
// Close the connection when done with it.  
myConnection.Close();  
}
```

### 23.2.3.6. The MySqlConnection Class

This class is created whenever the MySQL Data Provider encounters an error generated from the server.

Any open connections are not automatically closed when an exception is thrown. If the client application determines that the exception is fatal, it should close any open `MySqlDataReader` objects or `MySqlConnection` objects.

#### 23.2.3.6.1. Properties

The following properties are available:

- `HelpLink`: Gets or sets a link to the help file associated with this exception.
- `InnerException`: Gets the Exception instance that caused the current exception.
- `IsFatal`: True if this exception was fatal and cause the closing of the connection, false otherwise.
- `Message`: Gets a message that describes the current exception.
- `Number`: Gets a number that identifies the type of error.
- `Source`: Gets or sets the name of the application or the object that causes the error.
- `StackTrace`: Gets a string representation of the frames on the call stack at the time the current exception was thrown.
- `TargetSite`: Gets the method that throws the current exception.

#### 23.2.3.6.2. Methods

The `MySqlConnection` class has no methods.

#### 23.2.3.6.3. Usage

The following example generates a `MySqlConnection` due to a missing server, and then displays the exception.

##### 23.2.3.6.3.1. VB.NET

This example demonstrates how to use the `MySqlConnection` class with VB.NET:

```
Public Sub ShowException()  
    Dim mySelectQuery As String = "SELECT column1 FROM table1"  
    Dim myConnection As New MySqlConnection ("Data Source=localhost;Database=S  
    Dim myCommand As New MySqlCommand(mySelectQuery, myConnection)  
  
    Try  
        myCommand.Connection.Open()  
    Catch e As MySqlConnection  
        MessageBox.Show( e.Message )  
    End Try  
End Sub
```

### 23.2.3.6.3.2. C#

This example demonstrates how to use the `MySqlConnection` class with C#:

```
public void ShowException()
{
    string mySelectQuery = "SELECT column1 FROM table1";
    MySqlConnection myConnection =
        new MySqlConnection("Data Source=localhost;Database=Sample;");
    MySqlCommand myCommand = new MySqlCommand(mySelectQuery, myConnection);

    try
    {
        myCommand.Connection.Open();
    }
    catch (MySqlConnection e)
    {
        MessageBox.Show( e.Message );
    }
}
```

## 23.2.3.7. The MySqlConnection Helper Class

Helper class that makes it easier to work with the provider. Developers can use the methods of this class to automatically perform common tasks.

### 23.2.3.7.1. Properties

The `MySqlConnection` class has no properties.

### 23.2.3.7.2. Methods

The following methods are available:

- `ExecuteDataRow`: Executes a single SQL command and returns the first row of the resultset. A new `MySqlConnection` object is created, opened, and closed during this method.
- `ExecuteDataset`: Executes a single SQL command and returns the resultset in a `DataSet`. A new `MySqlConnection` object is created, opened, and closed during this method.
- `ExecuteNonQuery`: Executes a single command against a MySQL database. The `MySqlConnection` is assumed to be open when the method is called and remains open after the method completes.
- `ExecuteReader`: Overloaded. Executes a single command against a MySQL database.
- `ExecuteScalar`: Execute a single command against a MySQL database.
- `UpdateDataSet`: Updates the given table with data from the given `DataSet`.

## 23.2.3.8. The MySqlConnection Transaction Class

Represents an SQL transaction to be made in a MySQL database.

### 23.2.3.8.1. Properties

The following properties are available:

- `Connection`: Gets the `MySqlConnection` object associated with the transaction, or a null ref-

erence (Nothing in Visual Basic) if the transaction is no longer valid.

- `IsolationLevel`: Specifies the `IsolationLevel` for this transaction.

### 23.2.3.8.2. Methods

The following methods are available:

- `Commit`: Commits the database transaction.
- `Rollback`: Rolls back a transaction from a pending state.

### 23.2.3.8.3. Usage

The following example creates a `MySqlConnection` and a `MySqlTransaction`. It also demonstrates how to use the `BeginTransaction`, `Commit`, and `Rollback` methods.

#### 23.2.3.8.3.1. VB.NET

The following example shows how to use the `MySqlTransaction` class with VB.NET:

```
Public Sub RunTransaction(myConnString As String)
    Dim myConnection As New MySqlConnection(myConnString)
    myConnection.Open()

    Dim myCommand As MySqlCommand = myConnection.CreateCommand()
    Dim myTrans As MySqlTransaction

    ' Start a local transaction
    myTrans = myConnection.BeginTransaction()
    ' Must assign both transaction object and connection
    ' to Command object for a pending local transaction
    myCommand.Connection = myConnection
    myCommand.Transaction = myTrans

    Try
        myCommand.CommandText = "Insert into Region (RegionID, RegionDescription)
        myCommand.ExecuteNonQuery()
        myCommand.CommandText = "Insert into Region (RegionID, RegionDescription)
        myCommand.ExecuteNonQuery()
        myTrans.Commit()
        Console.WriteLine("Both records are written to database.")
    Catch e As Exception
        Try
            myTrans.Rollback()
        Catch ex As MySqlException
            If Not myTrans.Connection Is Nothing Then
                Console.WriteLine("An exception of type " & ex.GetType().ToString() & _
                    " was encountered while attempting to roll back the")
            End If
        End Try

        Console.WriteLine("An exception of type " & e.GetType().ToString() & _
            "was encountered while inserting the data.")
        Console.WriteLine("Neither record was written to database.")
    Finally
        myConnection.Close()
    End Try
End Sub 'RunTransaction
```

#### 23.2.3.8.3.2. C#

The following example shows how to use the `MySQLTransaction` class with C#:

```
public void RunTransaction(string myConnString)
{
    MySqlConnection myConnection = new MySqlConnection(myConnString);
    myConnection.Open();

    MySqlCommand myCommand = myConnection.CreateCommand();
    MySQLTransaction myTrans;

    // Start a local transaction
    myTrans = myConnection.BeginTransaction();
    // Must assign both transaction object and connection
    // to Command object for a pending local transaction
    myCommand.Connection = myConnection;
    myCommand.Transaction = myTrans;

    try
    {
        myCommand.CommandText = "Insert into Region (RegionID, RegionDescription)";
        myCommand.ExecuteNonQuery();
        myCommand.CommandText = "Insert into Region (RegionID, RegionDescription)";
        myCommand.ExecuteNonQuery();
        myTrans.Commit();
        Console.WriteLine("Both records are written to database.");
    }
    catch(Exception e)
    {
        try
        {
            myTrans.Rollback();
        }
        catch (MySQLException ex)
        {
            if (myTrans.Connection != null)
            {
                Console.WriteLine("An exception of type " + ex.GetType() +
                    " was encountered while attempting to roll back the");
            }
        }

        Console.WriteLine("An exception of type " + e.GetType() +
            " was encountered while inserting the data.");
        Console.WriteLine("Neither record was written to database.");
    }
    finally
    {
        myConnection.Close();
    }
}
```

## 23.2.4. Using MySQL Connector/NET

### 23.2.4.1. Introduction

In this section we will cover some of the more common use cases for Connector/NET, including BLOB handling, date handling, and using Connector/NET with common tools such as Crystal Reports.

### 23.2.4.2. Connecting to MySQL Using MySQL Connector/NET

#### 23.2.4.2.1. Introduction

All interaction between a .NET application and the MySQL server is routed through a `MySQLCon-`

nection object. Before your application can interact with the server, a `MySqlConnection` object must be instantiated, configured, and opened.

Even when using the `MySqlHelper` class, a `MySqlConnection` object is created by the helper class.

In this section, we will describe how to connect to MySQL using the `MySqlConnection` object.

### 23.2.4.2.2. Creating a Connection String

The `MySqlConnection` object is configured using a connection string. A connection string contains sever key/value pairs, separated by semicolons. Each key/value pair is joined with an equals sign.

The following is a sample connection string:

```
Server=127.0.0.1;Uid=root;Pwd=12345;Database=test;
```

In this example, the `MySqlConnection` object is configured to connect to a MySQL server at 127.0.0.1, with a username of `root` and a password of 12345. The default database for all statements will be the `test` database.

The following options are typically used (a full list of options is available in the API documentation):

- `Server`: The name or network address of the instance of MySQL to which to connect. The default is `localhost`. Aliases include `host`, `Data Source`, `DataSource`, `Address`, `Addr` and `Network Address`.
- `Uid`: The MySQL user account to use when connecting. Aliases include `User Id`, `Username` and `User name`.
- `Pwd`: The password for the MySQL account being used. Alias `Password` can also be used.
- `Database`: The default database that all statements are applied to. Default is `mysql`. Alias `Initial Catalog` can also be used.
- `Port`: The port MySQL is using to listen for connections. Default is 3306. Specify `-1` for this value to use a named-pipe connection.

### 23.2.4.2.3. Opening a Connection

Once you have created a connection string it can be used to open a connection to the MySQL server.

The following code is used to create a `MySqlConnection` object, assign the connection string, and open the connection.

[VB]

```
Dim conn As New MySql.Data.MySqlClient.MySqlConnection
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test;"

Try
    conn.ConnectionString = myConnectionString
    conn.Open()

Catch ex As MySql.Data.MySqlClient.MySqlException
```

```
    MessageBox.Show(ex.Message)
End Try
```

[C#]

```
MySQL.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySQL.Data.MySqlClient.MySqlConnection();
    conn.ConnectionString = myConnectionString;
    conn.Open();
}
catch (MySQL.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

You can also pass the connection string to the constructor of the `MySqlConnection` class:

[VB]

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test;"

Try
    Dim conn As New MySQL.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySQL.Data.MySqlClient.MySqlException
    MessageBox.Show(ex.Message)
End Try
```

[C#]

```
MySQL.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySQL.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
catch (MySQL.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

Once the connection is open it can be used by the other MySQL Connector/NET classes to communicate with the MySQL server.

#### 23.2.4.2.4. Handling Connection Errors

Because connecting to an external server is unpredictable, it is important to add error handling to your .NET application. When there is an error connecting, the `MySqlConnection` class will return a `MySqlException` object. This object has two properties that are of interest when handling errors:

- `Message`: A message that describes the current exception.
- `Number`: The MySQL error number.

When handling errors, you can your application's response based on the error number. The two most common error numbers when connecting are as follows:

- 0: Cannot connect to server.
- 1045: Invalid username and/or password.

The following code shows how to adapt the application's response based on the actual error:

[VB]

```
Dim myConnectionString as String
myConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
    Select Case ex.Number
        Case 0
            MessageBox.Show("Cannot connect to server. Contact administrator")
        Case 1045
            MessageBox.Show("Invalid username/password, please try again")
    End Select
End Try
```

[C#]

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    switch (ex.Number)
    {
        case 0:
            MessageBox.Show("Cannot connect to server. Contact administrator");
        case 1045:
            MessageBox.Show("Invalid username/password, please try again");
    }
}
```

```
}
```

**Important** Note that if you are using multilanguage databases you must specify the character set in the connection string. If you do not specify the character set, the connection defaults to the `latin1` charset. You can specify the character set as part of the connection string, for example:

```
MySQLConnection myConnection = new MySQLConnection("server=127.0.0.1;uid=root;"  
"pwd=12345;database=test;Charset=latin1;");
```

### 23.2.4.3. Using the MySQL Connector/NET with Prepared Statements

#### 23.2.4.3.1. Introduction

As of MySQL 4.1, it is possible to use prepared statements with MySQL Connector/NET. Use of prepared statements can provide significant performance improvements on queries that are executed more than once.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

#### 23.2.4.3.2. Preparing Statements in MySQL Connector/NET

To prepare a statement, create a command object and set the `.CommandText` property to your query.

After entering your statement, call the `.Prepare` method of the `MySQLCommand` object. After the statement is prepared, add parameters for each of the dynamic elements in the query.

After you enter your query and enter parameters, execute the statement using the `.ExecuteNonQuery()`, `.ExecuteScalar()`, or `.ExecuteReader` methods.

For subsequent executions, you need only modify the values of the parameters and call the `execute` method again, there is no need to set the `.CommandText` property or redefine the parameters.

[VB]

```
Dim conn As New MySQLConnection  
Dim cmd As New MySQLCommand  
  
conn.ConnectionString = strConnection  
  
Try  
    conn.Open()  
    cmd.Connection = conn  
  
    cmd.CommandText = "INSERT INTO myTable VALUES(NULL, ?number, ?text)"  
    cmd.Prepare()  
  
    cmd.Parameters.Add("?number", 1)  
    cmd.Parameters.Add("?text", "One")  
  
    For i = 1 To 1000  
        cmd.Parameters("?number").Value = i  
        cmd.Parameters("?text").Value = "A string value"
```

```

        cmd.ExecuteNonQuery()
    Next
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error")
End Try

```

[C#]

```

MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = strConnection;

try
{
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "INSERT INTO myTable VALUES(NULL, ?number, ?text)";
    cmd.Prepare();

    cmd.Parameters.Add("?number", 1);
    cmd.Parameters.Add("?text", "One");

    for (int i=1; i <= 1000; i++)
    {
        cmd.Parameters["?number"].Value = i;
        cmd.Parameters["?text"].Value = "A string value";

        cmd.ExecuteNonQuery();
    }
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

## 23.2.4.4. Accessing Stored Procedures with MySQL Connector/NET

### 23.2.4.4.1. Introduction

With the release of MySQL version 5 the MySQL server now supports stored procedures with the SQL 2003 stored procedure syntax.

A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored procedure instead.

Stored procedures can be particularly useful in situations such as the following:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures for all common operations. This provides a consistent and secure environment, and procedures can ensure that each operation is properly logged. In such a setup, applications and users would not get any access to the database tables directly, but can only execute specific stored procedures.

MySQL Connector/NET supports the calling of stored procedures through the `MySQLCommand` object. Data can be passed in and out of a MySQL stored procedure through use of the `MySQLCommand.Parameters` collection.

This section will not provide in-depth information on creating Stored Procedures. For such information, please refer to <http://dev.mysql.com/doc/mysql/en/stored-procedures.html>.

A sample application demonstrating how to use stored procedures with MySQL Connector/NET can be found in the `Samples` directory of your MySQL Connector/NET installation.

#### 23.2.4.4.2. Creating Stored Procedures from MySQL Connector/NET

Stored procedures in MySQL can be created using a variety of tools. First, stored procedures can be created using the `mysql` command-line client. Second, stored procedures can be created using the MySQL Query Browser GUI client. Finally, stored procedures can be created using the `.ExecuteNonQuery` method of the `MySQLCommand` object:

[VB]

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    conn.Open()
    cmd.Connection = conn

    cmd.CommandText = "CREATE PROCEDURE add_emp(" _
        & "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empno INT" _
        & "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " _
        & "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END"

    cmd.ExecuteNonQuery()
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error")
End Try
```

[C#]

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "CREATE PROCEDURE add_emp(" +
        "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empno INT" +
        "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " +
        "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END";

    cmd.ExecuteNonQuery();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
```

```

MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
    "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

It should be noted that, unlike the command-line and GUI clients, you are not required to specify a special delimiter when creating stored procedures in MySQL Connector/NET.

### 23.2.4.4.3. Calling a Stored Procedure from MySQL Connector/NET

To call a stored procedure using MySQL Connector/NET, create a `MySqlCommand` object and pass the stored procedure name as the `.CommandText` property. Set the `.CommandType` property to `CommandType.StoredProcedure`.

After the stored procedure is named, create one `MySqlCommand` parameter for every parameter in the stored procedure. IN parameters are defined with the parameter name and the object containing the value, OUT parameters are defined with the parameter name and the datatype that is expected to be returned. All parameters need the parameter direction defined.

After defining parameters, call the stored procedure by using the `MySqlCommand.ExecuteNonQuery()` method:

[VB]

```

Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    conn.Open()
    cmd.Connection = conn

    cmd.CommandText = "add_emp"
    cmd.CommandType = CommandType.StoredProcedure

    cmd.Parameters.Add("?lname", 'Jones')
    cmd.Parameters("?lname").Direction = ParameterDirection.Input

    cmd.Parameters.Add("?fname", 'Tom')
    cmd.Parameters("?fname").Direction = ParameterDirection.Input

    cmd.Parameters.Add("?bday", #12/13/1977 2:17:36 PM#)
    cmd.Parameters("?bday").Direction = ParameterDirection.Input

    cmd.Parameters.Add("?empno", MySqlDbType.Int32)
    cmd.Parameters("?empno").Direction = ParameterDirection.Output

    cmd.ExecuteNonQuery()

    MessageBox.Show(cmd.Parameters("?empno").Value)
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error")
End Try

```

[C#]

```

MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

```

```

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "add_emp";
    cmd.CommandType = CommandType.StoredProcedure;

    cmd.Parameters.Add("?lname", "Jones");
    cmd.Parameters["?lname"].Direction = ParameterDirection.Input;

    cmd.Parameters.Add("?fname", "Tom");
    cmd.Parameters["?fname"].Direction = ParameterDirection.Input;

    cmd.Parameters.Add("?bday", DateTime.Parse("12/13/1977 2:17:36 PM"));
    cmd.Parameters["?bday"].Direction = ParameterDirection.Input;

    cmd.Parameters.Add("?empno", MySqlDbType.Int32);
    cmd.Parameters["?empno"].Direction = ParameterDirection.Output;

    cmd.ExecuteNonQuery();

    MessageBox.Show(cmd.Parameters["?empno"].Value);
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

Once the stored procedure is called, the values of output parameters can be retrieved by using the `.Value` property of the `MySqlConnection.Parameters` collection.

## 23.2.4.5. Handling BLOB Data With Connector/NET

### 23.2.4.5.1. Introduction

One common use for MySQL is the storage of binary data in BLOB columns. MySQL supports four different BLOB datatypes: TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB.

Data stored in a BLOB column can be accessed using Connector/NET and manipulated using client-side code. There are no special requirements for using Connector/NET with BLOB data.

Simple code examples will be presented within this section, and a full sample application can be found in the `Samples` directory of the MySQL Connector/NET installation.

### 23.2.4.5.2. Preparing the MySQL Server

The first step in using MySQL with BLOB data is to configure the server. Let's start by creating a table to be accessed. In my file tables, I usually have four columns: an `AUTO_INCREMENT` column of appropriate size (`UNSIGNED SMALLINT`) to serve as a primary key to identify the file, a `VARCHAR` column that stores the filename, an `UNSIGNED MEDIUMINT` column that stores the size of the file, and a `MEDIUMBLOB` column that stores the file itself. For this example, I will use the following table definition:

```

CREATE TABLE file(
file_id SMALLINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
file_name VARCHAR(64) NOT NULL,
file_size MEDIUMINT UNSIGNED NOT NULL,
file MEDIUMBLOB NOT NULL);

```

After creating a table, you may need to modify the `max_allowed_packet` system variable. This variable determines how large of a packet (i.e. a single row) can be sent to the MySQL server. By default, the server will only accept a maximum size of 1 meg from our client application. If you do not intend to exceed 1 meg, this should be fine. If you do intend to exceed 1 meg in your file transfers, this number has to be increased.

The `max_allowed_packet` option can be modified using MySQL Administrator's Startup Variables screen. Adjust the Maximum allowed option in the Memory section of the Networking tab to an appropriate setting. After adjusting the value, click the Apply Changes button and restart the server using the Service Control screen of MySQL Administrator. You can also adjust this value directly in the `my.cnf` file (add a line that reads `max_allowed_packet=xxM`), or use the `SET max_allowed_packet=xxM`; syntax from within MySQL.

Try to be conservative when setting `max_allowed_packet`, as transfers of BLOB data can take some time to complete. Try to set a value that will be adequate for your intended use and increase the value if necessary.

### 23.2.4.5.3. Writing a File to the Database

To write a file to a database we need to convert the file to a byte array, then use the byte array as a parameter to an INSERT query.

The following code opens a file using a `FileStream` object, reads it into a byte array, and inserts it into the `file` table:

[VB]

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

Dim SQL As String

Dim fileSize As UInt32
Dim rawData() As Byte
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    fs = New FileStream("c:\image.png", FileMode.Open, FileAccess.Read)
    fileSize = fs.Length

    rawData = New Byte(fileSize) {}
    fs.Read(rawData, 0, fileSize)
    fs.Close()

    conn.Open()

    SQL = "INSERT INTO file VALUES(NULL, ?FileName, ?FileSize, ?File)"

    cmd.Connection = conn
    cmd.CommandText = SQL
    cmd.Parameters.Add("?FileName", strFileName)
    cmd.Parameters.Add("?FileSize", fileSize)
    cmd.Parameters.Add("?File", rawData)

    cmd.ExecuteNonQuery()

    MessageBox.Show("File Inserted into database successfully!", _
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

    conn.Close()
Catch ex As Exception
```

```

        MessageBox.Show("There was an error: " & ex.Message, "Error", _
            MessageBoxButtons.OK, MessageBoxIcon.Error)
    End Try

[C#]

MySQL.Data.MySqlClient.MySqlConnection conn;
MySQL.Data.MySqlClient.MySqlCommand cmd;

conn = new MySQL.Data.MySqlClient.MySqlConnection();
cmd = new MySQL.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    fs = new FileStream(@"c:\image.png", FileMode.Open, FileAccess.Read);
    FileSize = fs.Length;

    rawData = new byte[FileSize];
    fs.Read(rawData, 0, FileSize);
    fs.Close();

    conn.Open();

    SQL = "INSERT INTO file VALUES(NULL, ?FileName, ?FileSize, ?File)";

    cmd.Connection = conn;
    cmd.CommandText = SQL;
    cmd.Parameters.Add("?FileName", strFileName);
    cmd.Parameters.Add("?FileSize", FileSize);
    cmd.Parameters.Add("?File", rawData);

    cmd.ExecuteNonQuery();

    MessageBox.Show("File Inserted into database successfully!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    conn.Close();
}
catch (MySQL.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

The Read method of the FileStream object is used to load the file into a byte array which is sized according to the Length property of the FileStream object.

After assigning the byte array as a parameter of the MySqlCommand object, the ExecuteNonQuery method is called and the BLOB is inserted into the file table.

#### 23.2.4.5.4. Reading a BLOB from the Database to a File on Disk

Once a file is loaded into the file table, we can use the MySqlDataReader class to retrieve it.

The following code retrieves a row from the file table, then loads the data into a FileStream object to be written to disk:

[VB]

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myData As MySqlDataReader
Dim SQL As String
Dim rawData() As Byte
Dim FileSize As UInt32
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

SQL = "SELECT file_name, file_size, file FROM file"

Try
    conn.Open()

    cmd.Connection = conn
    cmd.CommandText = SQL

    myData = cmd.ExecuteReader

    If Not myData.HasRows Then Throw New Exception("There are no BLOBs to save")

    myData.Read()

    FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"))
    rawData = New Byte(FileSize) {}

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize)

    fs = New FileStream("C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write)
    fs.Write(rawData, 0, FileSize)
    fs.Close()

    MessageBox.Show("File successfully written to disk!", "Success!", MessageBoxButtons.OK)

    myData.Close()
    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", MessageBoxButtons.OK)
End Try
```

[C#]

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataReader myData;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

SQL = "SELECT file_name, file_size, file FROM file";

try
{
```

```

conn.Open();

cmd.Connection = conn;
cmd.CommandText = SQL;

myData = cmd.ExecuteReader();

if (! myData.HasRows)
    throw new Exception("There are no BLOBs to save");

myData.Read();

FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"));
rawData = new byte[FileSize];

myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize);

fs = new FileStream(@"C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write);
fs.Write(rawData, 0, FileSize);
fs.Close();

MessageBox.Show("File successfully written to disk!",
    "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

myData.Close();
conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

After connecting, the contents of the file table are loaded into a `MySqlDataReader` object. The `GetBytes` method of the `MySqlDataReader` is used to load the BLOB into a byte array, which is then written to disk using a `FileStream` object.

The `GetOrdinal` method of the `MySqlDataReader` can be used to determine the integer index of a named column. Use of the `GetOrdinal` method prevents errors if the column order of the `SELECT` query is changed.

## 23.2.4.6. Using MySQL Connector/NET with Crystal Reports

### 23.2.4.6.1. Introduction

Crystal Reports is a common tool used by Windows application developers to perform reporting and document generation. In this section we will show how to use Crystal Reports XI with MySQL and Connector/NET.

Complete sample applications are available in the `CrystalDemo` subdirectory of the `Samples` directory of your MySQL Connector/NET installation.

### 23.2.4.6.2. Creating a Data Source

When creating a report in Crystal Reports there are two options for accessing the MySQL data while designing your report.

The first option is to use Connector/ODBC as an ADO data source when designing your report. You will be able to browse your database and choose tables and fields using drag and drop to build your report. The disadvantage of this approach is that additional work must be performed within your application to produce a dataset that matches the one expected by your report.

The second option is to create a dataset in VB.NET and save it as XML. This XML file can then be

used to design a report. This works quite well when displaying the report in your application, but is less versatile at design time because you must choose all relevant columns when creating the dataset. If you forget a column you must re-create the dataset before the column can be added to the report.

The following code can be used to create a dataset from a query and write it to disk:

[VB]

```
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopul
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myData.WriteXml("C:\dataset.xml", XmlWriteMode.WriteSchema)
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

[C#]

```
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopul
        "country.name, country.population, country.continent " +
        "FROM country, city ORDER BY country.continent, country.name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myData.WriteXml(@"C:\dataset.xml", XmlWriteMode.WriteSchema);
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

The resulting XML file can be used as an ADO.NET XML datasource when designing your report.

If you choose to design your reports using Connector/ODBC, it can be downloaded from dev.mysql.com [<http://dev.mysql.com/downloads/connector/odbc/3.51.html>].

### 23.2.4.6.3. Creating the Report

For most purposes the Standard Report wizard should help with the initial creation of a report. To start the wizard, open Crystal Reports and choose the New > Standard Report option from the File menu.

The wizard will first prompt you for a data source. If you are using Connector/ODBC as your data source, use the OLEDB provider for ODBC option from the OLE DB (ADO) tree instead of the ODBC (RDO) tree when choosing a data source. If using a saved dataset, choose the ADO.NET (XML) option and browse to your saved dataset.

The remainder of the report creation process is done automatically by the wizard.

After the report is created, choose the Report Options... entry of the File menu. Un-check the Save Data With Report option. This prevents saved data from interfering with the loading of data within our application.

### 23.2.4.6.4. Displaying the Report

To display a report we first populate a dataset with the data needed for the report, then load the report and bind it to the dataset. Finally we pass the report to the crViewer control for display to the user.

The following references are needed in a project that displays a report:

- CrystalDecisions.CrystalReports.Engine
- CrystalDecisions.ReportSource
- CrystalDecisions.Shared
- CrystalDecisions.Windows.Forms

The following code assumes that you created your report using a dataset saved using the code shown in Section 23.2.4.6.2, "Creating a Data Source", and have a crViewer control on your form named myViewer.

[VB]

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myDataSet As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = _
    "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    conn.Open()
```

```

cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPop
    & "country.name, country.population, country.continent " _
    & "FROM country, city ORDER BY country.continent, country.name"
cmd.Connection = conn

myAdapter.SelectCommand = cmd
myAdapter.Fill(myData)

myReport.Load(".\world_report.rpt")
myReport.SetDataSource(myData)
myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK)
End Try

```

[C#]

```

using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPop
        "country.name, country.population, country.continent " +
        "FROM country, city ORDER BY country.continent, country.name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myReport.Load(@".\world_report.rpt");
    myReport.SetDataSource(myData);
    myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

A new dataset is generated using the same query used to generate the previously saved dataset. Once the dataset is filled, a ReportDocument is used to load the report file and bind it to the dataset. The ReportDocument is then passed as the ReportSource of the crViewer.

This same approach is taken when a report is created from a single table using Connector/ODBC. The dataset replaces the table used in the report and the report is displayed properly.

When a report is created from multiple tables using Connector/ODBC, a dataset with multiple tables must be created in our application. This allows each table in the report data source to be replaced with a report in the dataset.

We populate a dataset with multiple tables by providing multiple SELECT statements in our MySql-

Command object. These SELECT statements are based on the SQL query shown in Crystal Reports in the Database menu's Show SQL Query option. Assume the following query:

```
SELECT `country`.`Name`, `country`.`Continent`, `country`.`Population`, `city`.
FROM `world`.`country` `country` LEFT OUTER JOIN `world`.`city` `city` ON `coun
ORDER BY `country`.`Continent`, `country`.`Name`, `city`.`Name`
```

This query is converted to two SELECT queries and displayed with the following code:

[VB]

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER BY "
    & "SELECT name, population, code, continent FROM country ORDER BY conti
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(".\world_report.rpt")
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0))
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1))
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons
End Try
```

[C#]

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER " +
        "BY countrycode, name; SELECT name, population, code, continent FROM " +
```

```

        "country ORDER BY continent, name";
cmd.Connection = conn;

myAdapter.SelectCommand = cmd;
myAdapter.Fill(myData);

myReport.Load(@".\world_report.rpt");
myReport.Database.Tables(0).SetDataSource(myData.Tables(0));
myReport.Database.Tables(1).SetDataSource(myData.Tables(1));
myViewer.ReportSource = myReport;
}
catch ( MySql.Data.MySqlClient.MySqlException ex )
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}

```

It is important to order the SELECT queries in alphabetical order, as this is the order the report will expect its source tables to be in. One SetDataSource statement is needed for each table in the report.

This approach can cause performance problems because Crystal Reports must bind the tables together on the client-side, which will be slower than using a pre-saved dataset.

## 23.2.4.7. Handling Date and Time Information in MySQL Connector/NET

### 23.2.4.7.1. Introduction

MySQL and the .NET languages handle date and time information differently, with MySQL allowing dates that cannot be represented by a .NET data type, such as '0000-00-00 00:00:00'. These differences can cause problems if not properly handled.

In this section we will demonstrate how to properly handle date and time information when using MySQL Connector/NET.

### 23.2.4.7.2. Problems when Using Invalid Dates

The differences in date handling can cause problems for developers who use invalid dates. Invalid MySQL dates cannot be loaded into native .NET DateTime objects, including NULL dates.

Because of this issue, .NET DataSet objects cannot be populated by the Fill method of the MySqlDataAdapter class as invalid dates will cause a System.ArgumentOutOfRangeException exception to occur.

### 23.2.4.7.3. Restricting Invalid Dates

The best solution to the date problem is to restrict users from entering invalid dates. This can be done on either the client or the server side.

Restricting invalid dates on the client side is as simple as always using the .NET DateTime class to handle dates. The DateTime class will only allow valid dates, ensuring that the values in your database are also valid. The disadvantage of this is that it is not useful in a mixed environment where .NET and non .NET code are used to manipulate the database, as each application must perform its own date validation.

Users of MySQL 5.0.2 and higher can use the new traditional SQL mode to restrict invalid date values. For information on using the traditional SQL mode, see Section 5.2.5, "The Server SQL Mode".

### 23.2.4.7.4. Handling Invalid Dates

Although it is strongly recommended that you avoid the use of invalid dates within your .NET application, it is possible to use invalid dates by means of the `MySqlDateTime` datatype.

The `MySqlDateTime` datatype supports the same date values that are supported by the MySQL server. The default behavior of MySQL Connector/NET is to return a .NET `DateTime` object for valid date values, and return an error for invalid dates. This default can be modified to cause MySQL Connector/NET to return `MySqlDateTime` objects for invalid dates.

To instruct MySQL Connector/NET to return a `MySqlDateTime` object for invalid dates, add the following line to your connection string:

```
Allow Zero Datetime=True
```

Please note that the use of the `MySqlDateTime` class can still be problematic. The following are some known issues:

1. Data binding for invalid dates can still cause errors (zero dates like 0000-00-00 do not seem to have this problem).
2. The `ToString` method return a date formatted in the standard MySQL format (for example, 2005-02-23 08:50:25). This differs from the `ToString` behavior of the .NET `DateTime` class.
3. The `MySqlDateTime` class supports NULL dates, while the .NET `DateTime` class does not. This can cause errors when trying to convert a `MySqlDateTime` to a `DateTime` if you do not check for NULL first.

Because of the known issues, the best recommendation is still to use only valid dates in your application.

#### 23.2.4.7.5. Handling NULL Dates

The .NET `DateTime` datatype cannot handle NULL values. As such, when assigning values from a query to a `DateTime` variable, you must first check whether the value is in fact NULL.

When using a `MySqlDataReader`, use the `IsDBNull` method to check whether a value is NULL before making the assignment:

[VB]

```
If Not myReader.IsDBNull(myReader.GetOrdinal("mytime")) Then
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"))
Else
    myTime = DateTime.MinValue
End If
```

[C#]

```
if (! myReader.IsDBNull(myReader.GetOrdinal("mytime")))
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"));
else
    myTime = DateTime.MinValue;
```

NULL values will work in a dataset and can be bound to form controls without special handling.

### 23.2.5. MySQL Connector/NET Change History

### 23.2.5.1. Version 1.0.8

- The connection string parser did not allow single or double quotes in the password. (Bug#16659 [<http://bugs.mysql.com/16659>])
- The `CommandBuilder` ignored `Unsigned` flag at `Parameter` creation. (Bug#17375 [<http://bugs.mysql.com/17375>])
- `CHAR` type added to `MySqlDbType`. (Bug#17749 [<http://bugs.mysql.com/17749>])
- Unsigned data types were not properly supported. (Bug#16788 [<http://bugs.mysql.com/16788>])

### 23.2.5.2. Version 1.0.7

- The parameter collection object's `Add()` method added parameters to the list without first checking to see whether they already existed. Now it updates the value of the existing parameter object if it exists. (Bug#13927 [<http://bugs.mysql.com/13927>])
- A `#42000Query was empty` exception occurred when executing a query built with `MySqlCommandBuilder`, if the query string ended with a semicolon. (Bug#14631 [<http://bugs.mysql.com/14631>])
- Implemented the `MySqlCommandBuilder.DeriveParameters` method that is used to discover the parameters for a stored procedure. (Bug#13632 [<http://bugs.mysql.com/13632>])
- Added support for the `cp932` character set. (Bug#13806 [<http://bugs.mysql.com/13806>])
- Calling a stored procedure where a parameter contained special characters (such as `'@'`) would produce an exception. Note that `ANSI_QUOTES` had to be enabled to make this possible. (Bug#13753 [<http://bugs.mysql.com/13753>])
- A statement that contained multiple references to the same parameter could not be prepared. (Bug#13541 [<http://bugs.mysql.com/13541>])
- The `Ping()` method did not update the `State` property of the `Connection` object. (Bug#13658 [<http://bugs.mysql.com/13658>])

### 23.2.5.3. Version 1.0.6

- The `nant` build sequence had problems. (Bug#12978 [<http://bugs.mysql.com/12978>])
- Serializing a parameter failed if the first value passed in was `NULL`. (Bug#13276 [<http://bugs.mysql.com/13276>])
- Field names that contained the following characters caused errors: `()%<>/` (Bug#13036 [<http://bugs.mysql.com/13036>])
- The `MySQL Connector/NET 1.0.5` installer would not install alongside `MySQL Connector/NET 1.0.4`. (Bug#12835 [<http://bugs.mysql.com/12835>])
- `MySQL Connector/NET 1.0.5` could not connect on `Mono`. (Bug#13345 [<http://bugs.mysql.com/13345>])

### 23.2.5.4. Version 1.0.5

- With multiple hosts in the connection string, `MySQL Connector/NET` would not connect to the

last host in the list. (Bug#12628 [<http://bugs.mysql.com/12628>])

- MySQL Connector/NET interpreted the new decimal data type as a byte array. (Bug#11294 [<http://bugs.mysql.com/11294>])
- The `cp1250` character set was not supported. (Bug#11621 [<http://bugs.mysql.com/11621>])
- Connection could fail when `.NET` thread pool had no available worker threads. (Bug#10637 [<http://bugs.mysql.com/10637>])
- Decimal parameters caused syntax errors. (Bug#11550 [<http://bugs.mysql.com/11550>], Bug#10486 [<http://bugs.mysql.com/10486>], Bug#10152 [<http://bugs.mysql.com/10152>])
- A call to a stored procedure caused an exception if the stored procedure had no parameters. (Bug#11542 [<http://bugs.mysql.com/11542>])
- Certain malformed queries would trigger a `Connection must be valid and open` error message. (Bug#11490 [<http://bugs.mysql.com/11490>])
- The `MySqlCommandBuilder` class could not handle queries that referenced tables in a database other than the default database. (Bug#8382 [<http://bugs.mysql.com/8382>])
- MySQL Connector/NET could not work properly with certain regional settings. (WL#8228)
- Trying to use a stored procedure when `Connection.Database` was not populated generated an exception. (Bug#11450 [<http://bugs.mysql.com/11450>])
- Trying to read a `TIMESTAMP` column generated an exception. (Bug#7951 [<http://bugs.mysql.com/7951>])
- Parameters were not recognized when they were separated by linefeeds. (Bug#9722 [<http://bugs.mysql.com/9722>])
- Calling `MySqlConnection.Clone` when a connection string had not yet been set on the original connection would generate an error. (Bug#10281 [<http://bugs.mysql.com/10281>])
- Added support to call a stored function from MySQL Connector/NET. (Bug#10644 [<http://bugs.mysql.com/10644>])
- MySQL Connector/NET could not connect to MySQL 4.1.14. (Bug#12771 [<http://bugs.mysql.com/12771>])
- The `ConnectionString` property could not be set when a `MySqlConnection` object was added with the designer. (Bug#12551 [<http://bugs.mysql.com/12551>], Bug#8724 [<http://bugs.mysql.com/8724>])

### 23.2.5.5. Version 1.0.4 1-20-05

- Bug#7243 [<http://bugs.mysql.com/7243>] calling `prepare` causing exception [fixed]
- Fixed another small problem with prepared statements
- Bug#7258 [<http://bugs.mysql.com/7258>] `MySqlCommand.Connection` returns an `IDbConnection` [fixed]
- Bug#7345 [<http://bugs.mysql.com/7345>] `MySqlAdapter.Fill` method throws Error message : Non-negative number required [fixed]
- Bug#7478 [<http://bugs.mysql.com/7478>] Clone method bug in `MySqlCommand` [fixed]
- Bug#7612 [<http://bugs.mysql.com/7612>] `MySqlDataReader.GetString(index)` returns non-Null value when field is Null [fixed]

- Bug#7755 [<http://bugs.mysql.com/7755>] MySqlReader.GetInt32 throws exception if column is unsigned [fixed]
- Bug#7704 [<http://bugs.mysql.com/7704>] GetBytes is working no more [fixed]
- Bug#7724 [<http://bugs.mysql.com/7724>] Quote character \222 not quoted in EscapeString [fixed]
- Fixed problem that causes named pipes to not work with some blob functionality
- Fixed problem with shared memory connections
- Bug#7436 [<http://bugs.mysql.com/7436>] Problem with Multiple resultsets... [fixed]
- Added or filled out several more topics in the API reference documentation

### 23.2.5.6. Version 1.0.3-gamma 12-10-04

- Made MySQL the default named pipe name
- Now SHOW COLLATION is used upon connection to retrieve the full list of charset ids
- Fixed Invalid character set index: 200 (Bug#6547 [<http://bugs.mysql.com/6547>])
- Installer now includes options to install into GAC and create Start Menu items
- Bug#6863 [<http://bugs.mysql.com/6863>] - Int64 Support in MySqlCommand Parameters [fixed]
- Connections now do not have to give a database on the connection string
- Bug#6770 [<http://bugs.mysql.com/6770>] - MySqlDataReader.GetChar(int i) throws IndexOutOfRangeException Exception [fixed]
- Fixed problem where multiple resultsets having different numbers of columns would cause a problem
- Bug#6983 [<http://bugs.mysql.com/6983>] Exception stack trace lost when re-throwing exceptions [fixed]
- Fixed major problem with detecting null values when using prepared statements
- Bug#6902 [<http://bugs.mysql.com/6902>] Errors in parsing stored procedure parameters [fixed]
- Bug#6668 [<http://bugs.mysql.com/6668>] Integer "out" parameter from stored procedure returned as string [fixed]
- Bug#7032 [<http://bugs.mysql.com/7032>] MySqlDateTime in Datatables sorting by Text, not Date. [fixed]
- Bug#7133 [<http://bugs.mysql.com/7133>] Invalid query string when using inout parameters [fixed]
- Bug#6831 [<http://bugs.mysql.com/6831>] Test suite fails with MySQL 4.0 because of case sensitivity of table names [fixed]
- Bug#7132 [<http://bugs.mysql.com/7132>] Inserting DateTime causes System.InvalidCastException to be thrown [fixed]
- Bug#6879 [<http://bugs.mysql.com/6879>] InvalidCast when using DATE\_ADD-function [fixed]
- Bug#6634 [<http://bugs.mysql.com/6634>] An Open Connection has been Closed by the Host System [fixed]

- Added ServerThread property to MySqlConnection to expose server thread id
- Added Ping method to MySqlConnection
- Changed the name of the test suite to MySql.Data.Tests.dll

### **23.2.5.7. Version 1.0.2-gamma 04-11-15**

- Fixed problem with MySqlBinary where string values could not be used to update extended text columns
- Fixed Installation directory ignored using custom installation (Bug#6329 [<http://bugs.mysql.com/6329>])
- Fixed problem where setting command text leaves the command in a prepared state
- Fixed double type handling in MySqlParameter(string parameterName, object value) (Bug#6428 [<http://bugs.mysql.com/6428>])
- Fixed Zero date "0000-00-00" is returned wrong when filling Dataset (Bug#6429 [<http://bugs.mysql.com/6429>])
- Fixed problem where calling stored procedures might cause an "Illegal mix of collations" problem.
- Added charset connection string option
- Fixed #HY000 Illegal mix of collations (latin1\_swedish\_ci,IMPLICIT) and (utf8\_general\_ (Bug#6322 [<http://bugs.mysql.com/6322>])
- Added the TableEditor CS and VB sample
- Fixed Charset-map for UCS-2 (Bug#6541 [<http://bugs.mysql.com/6541>])
- Updated the installer to include the new samples
- Fixed Long inserts take very long time (Bu #5453)
- Fixed Objects not being disposed (Bug#6649 [<http://bugs.mysql.com/6649>])
- Provider is now using character set specified by server as default

### **23.2.5.8. Version 1.0.1-beta2 04-10-27**

- Fixed Bug#5602 [<http://bugs.mysql.com/5602>] Possible bug in MySqlParameter(string, object) constructor
- Fixed Bug#5458 [<http://bugs.mysql.com/5458>] Calling GetChars on a longtext column throws an exception
- Fixed Bug#5474 [<http://bugs.mysql.com/5474>] cannot run a stored procedure populating mysql-command.parameters
- Fixed Bug#5469 [<http://bugs.mysql.com/5469>] Setting DbType throws NullReferenceException
- Fixed problem where connector was not issuing a CMD\_QUIT before closing the socket
- Fixed Bug#5392 [<http://bugs.mysql.com/5392>] MySqlCommand sees "?" as parameters in string literals

- Fixed problem with ConnectionInternal where a key might be added more than once
- CP1252 is now used for Latin1 only when the server is 4.1.2 and later
- Fixed Bug#5388 [<http://bugs.mysql.com/5388>] DataReader reports all rows as NULL if one row is NULL
- Virtualized driver subsystem so future releases could easily support client or embedded server support
- Field buffers being reused to decrease memory allocations and increase speed
- Fixed problem where using old syntax while using the interfaces caused problems
- Using PacketWriter instead of Packet for writing to streams
- Refactored compression code into CompressedStream to clean up NativeDriver
- Added test case for resetting the command text on a prepared command
- Fixed problem where MySqlCommandParameterCollection.Add() would throw unclear exception when given a null value (Bug#5621 [<http://bugs.mysql.com/5621>])
- Fixed constructor initialize problems in MySqlCommand() (Bug#5613 [<http://bugs.mysql.com/5613>])
- Fixed Parsing the ';' char (Bug#5876 [<http://bugs.mysql.com/5876>])
- Fixed missing Reference in DbType setter (Bug#5897 [<http://bugs.mysql.com/5897>])
- Fixed System.OverflowException when using YEAR datatype (Bug#6036 [<http://bugs.mysql.com/6036>])
- Added Aggregate function test (wasn't really a bug)
- Fixed serializing of floating point parameters (double, numeric, single, decimal) (Bug#5900 [<http://bugs.mysql.com/5900>])
- IsNullable error (Bug#5796 [<http://bugs.mysql.com/5796>])
- Fixed problem where connection lifetime on the connect string was not being respected
- Fixed problem where Min Pool Size was not being respected
- Fixed MySqlDataReader and 'show tables from ...' behavior (Bug#5256 [<http://bugs.mysql.com/5256>])
- Implemented SequentialAccess
- Fixed MySqlDateTime sets IsZero property on all subseq.records after first zero found (Bug#6006 [<http://bugs.mysql.com/6006>])
- Fixed Can't display Chinese correctly (Bug#5288 [<http://bugs.mysql.com/5288>])
- Fixed Russian character support as well
- Fixed Method TokenizeSql() uses only a limited set of valid characters for parameters (Bug#6217 [<http://bugs.mysql.com/6217>])
- Fixed NET Connector source missing resx files (Bug#6216 [<http://bugs.mysql.com/6216>])
- Fixed DBNull Values causing problems with retrieving/updating queries. (Bug#5798 [<http://bugs.mysql.com/5798>])

- Fixed Yet Another "object reference not set to an instance of an object" (Bug#5496 [<http://bugs.mysql.com/5496>])
- Fixed problem in PacketReader where it could try to allocate the wrong buffer size in EnsureCapacity
- Fixed GetBoolean returns wrong values (Bug#6227 [<http://bugs.mysql.com/6227>])
- Fixed IndexOutOfBounds when reading BLOB with DataReader with GetString(index) (Bug#6230 [<http://bugs.mysql.com/6230>])

### **23.2.5.9. Version 1.0.0 04-09-01**

- Fixed BUG# 3889 Thai encoding not correctly supported
- Updated many of the test cases
- Fixed problem with using compression
- Bumped version number to 1.0.0 for beta 1 release
- Added COPYING.rtf file for use in installer
- Removed all of the XML comment warnings (I'll clean them up better later)
- Removed some last references to ByteFX

### **23.2.5.10. Version 0.9.0 04-08-30**

- Added test fixture for prepared statements
- All type classes now implement a SerializeBinary method for sending their data to a PacketWriter
- Added PacketWriter class that will enable future low-memory large object handling
- Fixed many small bugs in running prepared statements and stored procedures
- Changed command so that an exception will not be throw in executing a stored procedure with parameters in old syntax mode
- SingleRow behavior now working right even with limit
- GetBytes now only works on binary columns
- Logger now truncates long sql commands so blob columns don't blow out our log
- host and database now have a default value of "" unless otherwise set
- FIXED BUG# 5214 Connection Timeout seems to be ignored
- Added test case for bug# 5051: GetSchema not working correctly
- Fixed problem where GetSchema would return false for IsUnique when the column is key
- MySqlDataReader GetXXX methods now using the field level MySqlValue object and not performing conversions
- FIXED BUG# 5097: DataReader returning NULL for time column

- Added test case for LOAD DATA LOCAL INFILE
- Added replacetext custom nant task
- Added CommandBuilderTest fixture
- Added Last One Wins feature to CommandBuilder
- Fixed persist security info case problem
- Fixed GetBool so that 1, true, "true", and "yes" all count as trueWL# 2024 Make parameter mark configurable
- Added the "old syntax" connection string parameter to allow use of @ parameter marker
- Fixed Bug#4658 [<http://bugs.mysql.com/4658>] MySqlCommandBuilder
- Fixed Bug#4864 [<http://bugs.mysql.com/4864>] ByteFX.MySqlClient caches passwords if 'Persist Security Info' is false
- Updated license banner in all source files to include FLOSS exception
- Added new .Types namespace and implementations for most current MySql types
- Added MySqlField41 as a subclass of MySqlField
- Changed many classes to now use the new .Types types
- Changed type enum int to Int32, short to Int16, and bigint to Int64
- Added dummy types UInt16, UInt32, and UInt64 to allow an unsigned parameter to be made
- Connections are now reset when they are pulled from the connection pool
- Refactored auth code in driver so it can be used for both auth and reset
- Added UserReset test in PoolingTests.cs
- Connections are now reset using COM\_CHANGE\_USER when pulled from the pool
- Implemented SingleResultSet behavior
- Implemented support of unicode
- Added char set mappings for utf-8 and ucs-2
- fixed Bug#4520 [<http://bugs.mysql.com/4520>] time fields overflow using bytefx .net mysql driver
- Modified time test in data type test fixture to check for time spans where hours > 24
- Fixed Bug#4505 [<http://bugs.mysql.com/4505>] Wrong string with backslash escaping in Byte-Fx.Data.MySqlClient.MySqlParameter
- Added code to Parameter test case TestQuoting to test for backslashes
- Fixed Bug#4486 [<http://bugs.mysql.com/4486>] mysqlcommandbuilder fails with multi-word column names
- Fixed bug in TokenizeSql where underscore would terminate character capture in parameter name
- Added test case for spaces in column names
- Fixed bug# 4324 - MySqlDataReader.GetBytes don't works correctly

- Added GetBytes() test case to DataReader test fixture
- Now reading all server variables in InternalConnection.Configure into Hashtable
- Now using string[] for index map in CharSetMap
- Added CRInSQL test case for carriage returns in SQL
- setting maxPacketSize to default value in Driver.ctor
- Fixed Bug#4442 [<http://bugs.mysql.com/4442>] - Setting MySqlDbType on a parameter doesn't set generic type
- Removed obsolete data types Long and LongLong
- Fixed bug# 4071 - Overflow exception thrown when using "use pipe" on connection string
- Changed "use pipe" keyword to "pipe name" or just "pipe"
- Allow reading multiple resultsets from a single query
- Added flags attribute to ServerStatusFlags enum
- Changed name of ServerStatus enum to ServerStatusFlags
- Fixed Bug#4386 [<http://bugs.mysql.com/4386>] - Inserted data row doesn't update properly
- Fixed Bug#4074 [<http://bugs.mysql.com/4074>] - Error processing show create table
- Change Packet.ReadLenInteger to ReadPackedLong and added packet.ReadPackedInteger that always reads integers packed with 2,3,4
- Added syntax.cs test fixture to test various SQL syntax bugs
- Fixed bug# 4149 Improper handling of time values. Now time value of 00:00:00 is not treated as null.
- Moved all test suite files into TestSuite folder
- Fixed bug where null column would move the result packet pointer backward
- Added new nant build script
- Fixed Bug#3917 [<http://bugs.mysql.com/3917>] - clear tablename so it will be regen'ed properly during the next GenerateSchema.
- Fixed Bug#3915 [<http://bugs.mysql.com/3915>] - GetValues was always returning zero and was also always trying to copy all fields rather than respecting the size of the array passed in.
- Implemented shared memory access protocol
- Implemented prepared statements for MySQL 4.1
- Implemented stored procedures for MySQL 5.0
- Renamed MySqlInternalConnection to InternalConnection
- SQL is now parsed as chars, fixes problems with other languages
- Added logging and allow batch connection string options
- Fixed Bug#3888 [<http://bugs.mysql.com/3888>] - RowUpdating event not set when setting the DataAdapter property
- Fixed bug in char set mapping

- Implemented 4.1 authentication
- Improved open/auth code in driver
- Improved how connection bits are set during connection
- Database name is now passed to server during initial handshake
- Changed namespace for client to `MySql.Data.MySqlClient`
- Changed assembly name of client to `MySql.Data.dll`
- Changed license text in all source files to GPL
- Added the `MySqlClient.build` Nant file
- Removed the mono batch files
- Moved some of the unused files into `notused` folder so nant build file can use wildcards
- Implemented shared memory access
- Major revamp in code structure
- Prepared statements now working for `MySql 4.1.1` and later
- Finished implementing auth for `4.0`, `4.1.0`, and `4.1.1`
- Changed namespace from `MySQL.Data.MySQLClient` back to `MySql.Data.MySqlClient`
- Fixed bug in `CharSetMapping` where it was trying to use text names as ints
- Changed namespace to `MySQL.Data.MySQLClient`
- Integrated auth changes from UC2004
- Fixed bug where calling any of the `GetXXX` methods on a `datareader` before or after reading data would not throw the appropriate exception (thanks Luca Morelli <morelli.luca@iol.it>)
- Added `TimeSpan` code in `parameter.cs` to properly serialize a `timespan` object to `mysql` time format (thanks Gianluca Colombo <g.colombo@alfi.it>)
- Added `TimeStamp` to `parameter` serialization code. Prevented `DataAdapter` updates from working right (thanks Michael King)
- Fixed a misspelling in `MySqlHelper.cs` (thanks Patrick Kristiansen)

### **23.2.5.11. Version 0.76**

- Driver now using `charset` number given in handshake to create encoding
- Changed `command editor` to point to `MySqlClient.Design`
- Fixed bug in `Version.isAtLeast`
- Changed `DBConnectionString` to support changes done to `MySqlConnectionString`
- Removed `SqlCommandEditor` and `DataAdapterPreviewDialog`
- Using new long return values in many places
- Integrated new `CompressedStream` class

- Changed `ConnectionString` and added attributes to allow it to be used in `MySqlConnection.Design`
- Changed `packet.cs` to support newer lengths in `ReadLenInteger`
- changed other classes to use new properties and fields of `MySqlConnection`
- `ConnectionInternal` is now using PING to see whether the server is alive
- Moved toolbox bitmaps into resource/
- Changed `field.cs` to allow values to come directly from row buffer
- Changed to use the new `driver.Send` syntax
- Using a new packet queueing system
- started work handling the "broken" compression packet handling
- Fixed bug in `StreamCreator` where failure to connect to a host would continue to loop infinitely (thanks Kevin Casella)
- Improved connectstring handling
- Moved designers into Pro product
- Removed some old commented out code from `command.cs`
- Fixed a problem with compression
- Fixed connection object where an exception throw prior to the connection opening would not leave the connection in the connecting state (thanks Chris Cline )
- Added GUID support
- Fixed sequence out of order bug (thanks Mark Reay)

### **23.2.5.12. Version 0.75**

- Enum values now supported as parameter values (thanks Philipp Sumi)
- Year datatype now supported
- fixed compression
- Fixed bug where a parameter with a `TimeSpan` as the value would not serialize properly
- Fixed bug where default ctor would not set default connection string values
- Added some XML comments to some members
- Work to fix/improve compression handling
- Improved `ConnectionString` handling so that it better matches the standard set by `SqlConnection`.
- A `MySqlException` is now thrown if a username is not included in the connection string
- `localhost` is now used as the default if not specified on the connection string
- An exception is now thrown if an attempt is made to set the connection string while the connection is open
- Small changes to `ConnectionString` docs

- Removed MultiHostStream and MySqlStream. Replaced it with Common/StreamCreator
- Added support for Use Pipe connection string value
- Added Platform class for easier access to platform utility functions
- Fixed small pooling bug where new connection was not getting created after IsAlive fails
- Added Platform.cs and StreamCreator.cs
- Fixed Field.cs to properly handle 4.1 style timestamps
- Changed Common.Version to Common.DBVersion to avoid name conflict
- Fixed field.cs so that text columns return the right field type (thanks beni27@gmx.net)
- Added MySqlError class to provide some reference for error codes (thanks Geert Veenstra)

### **23.2.5.13. Version 0.74**

- Added Unix socket support (thanks Mohammad DAMT [md@mt.web.id])
- only calling Thread.Sleep when no data is available
- improved escaping of quote characters in parameter data
- removed misleading comments from parameter.cs
- fixed pooling bug
- same pooling bug fixed again!! ;-)
- Fixed ConnectionString editor dialog (thanks marco p (pomarc))
- UserId now supported in connection strings (thanks Jeff Neeley)
- Attempting to create a parameter that is not input throws an exception (thanks Ryan Gregg)
- Added much documentation
- checked in new MultiHostStream capability. Big thanks to Dan Guisinger for this. he originally submitted the code and idea of supporting multiple machines on the connect string.
- Added alot of documentation. Still alot to do.
- Fixed speed issue with 0.73
- changed to Thread.Sleep(0) in MySqlDataStream to help optimize the case where it doesn't need to wait (thanks Todd German)
- Prepopulating the idlepools to MinPoolSize
- Fixed MySqlPool deadlock condition as well as stupid bug where CreateNewPooledConnection was not ever adding new connections to the pool. Also fixed MySqlStream.ReadBytes and ReadByte to not use TicksPerSecond which does not appear to always be right. (thanks Matthew J. Peddlesden)
- Fix for precision and scale (thanks Matthew J. Peddlesden)
- Added Thread.Sleep(1) to stream reading methods to be more cpu friendly (thanks Sean McGinnis)

- Fixed problem where ExecuteReader would sometime return null (thanks Lloyd Dupont )
- Fixed major bug with null field handling (thanks Naucki)
- enclosed queries for max\_allowed\_packet and charset inside try catch (and set defaults)
- fixed problem where socket was not getting closed properly (thanks Steve!)
- Fixed problem where ExecuteNonQuery was not always returning the right value
- Fixed InternalConnection to not use @@session.max\_allowed\_packet but use @@max\_allowed\_packet. (Thanks Miguel)
- Added many new XML doc lines
- Fixed sql parsing to not send empty queries (thanks Rory)
- Fixed problem where the reader was not unpeeking the packet on close
- Fixed problem where user variables were not being handled (thanks Sami Vaaraniemi)
- Fixed loop checking in the MySQLPool (thanks Steve M. Brown)
- Fixed ParameterCollection.Add method to match SqlCommand (thanks Joshua Mouch)
- Fixed ConnectionString parsing to handle no and yes for boolean and not lowercase values (thanks Naucki)
- Added InternalConnection class, changes to pooling
- Implemented Persist Security Info
- Added security.cs and version.cs to project
- Fixed DateTime handling in Parameter.cs (thanks Burkhard Perkens-Golomb)
- Fixed parameter serialization where some types would throw a cast exception
- Fixed DataReader to convert all returned values to prevent casting errors (thanks Keith Murray)
- Added code to Command.ExecuteReader to return null if the initial SQL command throws an exception (thanks Burkhard Perkens-Golomb)
- Fixed ExecuteScalar bug introduced with restructure
- Restructure to allow for LOCAL DATA INFILE and better sequencing of packets
- Fixed several bugs related to restructure.
- Early work done to support more secure passwords in Mysql 4.1. Old passwords in 4.1 not supported yet
- Parameters appearing after system parameters are now handled correctly (Adam M. (adammi))
- strings can now be assigned directly to blob fields (Adam M.)
- Fixed float parameters (thanks Pent)
- Improved Parameter ctor and ParameterCollection.Add methods to better match SqlCommand (thx Joshua Mouch )
- Corrected Connection.CreateCommand to return a MySqlCommand type
- Fixed connection string designer dialog box problem (thanks Abraham Guyt)

- Fixed problem with sending commands not always reading the response packet (thanks Joshua Mouch )
- Fixed parameter serialization where some blobs types were not being handled (thanks Sean McGinnis )
- Removed spurious MessageBox.show from DataReader code (thanks Joshua Mouch )
- Fixed a nasty bug in the split sql code (thanks everyone! :-)

### **23.2.5.14. Version 0.71**

- Fixed bug in MySQLStream where too much data could attempt to be read (thanks Peter Belbin)
- Implemented HasRows (thanks Nash Pherson)
- Fixed bug where tables with more than 252 columns cause an exception ( thanks Joshua Kessler )
- Fixed bug where SQL statements ending in ; would cause a problem ( thanks Shane Krueger )
- Fixed bug in driver where error messages were getting truncated by 1 character (thanks Shane Krueger)
- Made MySqlConnection serializable (thanks Mathias Hasselmann)

### **23.2.5.15. Version 0.70**

- Updated some of the character code pages to be more accurate
- Fixed problem where readers could be opened on connections that had readers open
- Release of 0.70
- Moved test to separate assembly MySqlConnectionTests
- Fixed stupid problem in driver with sequence out of order (Thanks Peter Belbin)
- Added some pipe tests
- Increased default max pool size to 50
- Compiles with Mono 0-24
- Fixed connection and data reader dispose problems
- Added String datatype handling to parameter serialization
- Fixed sequence problem in driver that occurred after thrown exception (thanks Burkhard Perens-Golomb)
- Added support for CommandBehavior.SingleRow to DataReader
- Fixed command sql processing so quotes are better handled (thanks Theo Spears)
- Fixed parsing of double, single, and decimal values to account for non-English separators. You still have to use the right syntax if you using hard coded sql, but if you use parameters the code will convert floating point types to use '.' appropriately internal both into the server and out. [ Thanks anonymous ]

- Added `MySQLStream` class to simplify `timeOuts` and driver coding.
- Fixed `DataReader` so that it is closed properly when the associated connection is closed. [thanks smishra]
- Made client more `SqlClient` compliant so that `DataReaders` have to be closed before the connection can be used to run another command
- Improved `DBNull.Value` handling in the fields
- Added several unit tests
- Fixed `MySQLException` so that the base class is actually called :-o
- Improved driver coding
- Fixed bug where `NextResult` was returning false on the last resultset
- Added more tests for `MySQL`
- Improved casting problems by equating unsigned 32bit values to `Int64` and unsigned 16bit values to `Int32`, and so forth.
- Added new ctor for `MySQLParameter` for (name, type, size, srccol)
- Fixed bug in `MySQLDataReader` where it didn't check for null fieldlist before returning field count
- Started adding `MySQLClient` unit tests (added `MySQLClient/Tests` folder and some test cases)
- Fixed some things in `Connection String` handling
- Moved `INIT_DB` to `MySQLPool`. I may move it again, this is in preparation of the conference.
- Fixed bug inside `CommandBuilder` that prevented inserts from happening properly
- Reworked some of the internals so that all three `execute` methods of `Command` worked properly
- Fixed many small bugs found during benchmarking
- The first cut of `CoonectionPooling` is working. "min pool size" and "max pool size" are respected.
- Work to enable multiple resultsets to be returned
- Character sets are handled much more intelligently now. The driver queries `MySQL` at startup for the default character set. That character set is then used for conversions if that code page can be loaded. If not, then the default code page for the current OS is used.
- Added code to save the inferred type in the name,value ctor of `Parameter`
- Also, inferred type if value of null parameter is changed using `Value` property
- Converted all files to use proper Camel case. `MySQL` is now `MySql` in all files. `PgSQL` is now `PgSql`
- Added attribute to `PgSql` code to prevent designer from trying to show
- Added `MySQLDbType` property to `Parameter` object and added proper conversion code to convert from `DbType` to `MySQLDbType`)
- Removed unused `ObjectToString` method from `MySQLParameter.cs`
- Fixed `Add(..)` method in `ParameterCollection` so that it doesn't use `Add(name, value)` instead.

- Fixed IndexOf and Contains in ParameterCollection to be aware that parameter names are now stored without @
- Fixed Command.ConvertSQLToBytes so it only allows characters that can be in MySQL variable names
- Fixed DataReader and Field so that blob fields read their data from Field.cs and GetBytes works right
- Added simple query builder editor to CommandText property of MySqlCommand
- Fixed CommandBuilder and Parameter serialization to account for Parameters not storing @ in their names
- Removed MySQLFieldType enum from Field.cs. Now using MySQLDbType enum
- Added Designer attribute to several classes to prevent designer view when using VS.Net
- Fixed Initial catalog typo in ConnectionString designer
- Removed 3 parameter ctor for MySQLParameter that conflicted with (name, type, value)
- changed MySQLParameter so paramName is now stored without leading @ (this fixed null inserts when using designer)
- Changed TypeConverter for MySQLParameter to use the ctor with all properties

### **23.2.5.16. Version 0.68**

- Fixed sequence issue in driver
- Added DbParametersEditor to make parameter editing more like SqlClient
- Fixed Command class so that parameters can be edited using the designer
- Update connection string designer to support Use Compression flag
- Fixed string encoding so that European characters like ä will work correctly
- Creating base classes to aid in building new data providers
- Added support for UID key in connection string
- Field, parameter, command now using DBNull.Value instead of null
- CommandBuilder using DBNull.Value
- CommandBuilder now builds insert command correctly when an auto\_insert field is not present
- Field now uses typeof keyword to return System.Types (performance)

### **23.2.5.17. Version 0.65**

- MySqlCommandBuilder now implemented
- Transaction support now implemented (not all table types support this)
- GetSchemaTable fixed to not use xsd (for Mono)
- Driver is now Mono-compatible!!

- TIME data type now supported
- More work to improve Timestamp data type handling
- Changed signatures of all classes to match corresponding SqlClient classes

### 23.2.5.18. Version 0.60

- Protocol compression using SharpZipLib ([www.icsharpcode.net](http://www.icsharpcode.net))
- Named pipes on Windows now working properly
- Work done to improve Timestamp data type handling
- Implemented IEnumerable on DataReader so DataGrid would work

### 23.2.5.19. Version 0.50

- Speed increased dramatically by removing bugging network sync code
- Driver no longer buffers rows of data (more ADO.Net compliant)
- Conversion bugs related to TIMESTAMP and DATETIME fields fixed

## 23.3. MySQL Connector/J

MySQL provides connectivity for client applications developed in the Java programming language via a JDBC driver, which is called MySQL Connector/J.

MySQL Connector/J is a JDBC-3.0 “Type 4” driver, which means that is pure Java, implements version 3.0 of the JDBC specification, and communicates directly with the MySQL server using the MySQL protocol.

This document is arranged for a beginning JDBC developer. If you are already experienced with using JDBC, you might consider starting with the Section 23.3.2, “Installing Connector/J”.

Although JDBC is useful by itself, we would hope that if you are not familiar with JDBC that after reading the first few sections of this manual, that you would avoid using “naked” JDBC for all but the most trivial problems and consider using one of the popular persistence frameworks such as Hibernate [<http://www.hibernate.org/>], Spring's JDBC templates [<http://www.springframework.org/>] or Ibatis SQL Maps [<http://ibatis.apache.org/>] to do the majority of repetitive work and heavier lifting that is sometimes required with JDBC.

This section is not designed to be a complete JDBC tutorial. If you need more information about using JDBC you might be interested in the following online tutorials that are more in-depth than the information presented here:

- JDBC Basics [<http://java.sun.com/docs/books/tutorial/jdbc/basics/index.html>] — A tutorial from Sun covering beginner topics in JDBC
- JDBC Short Course [<http://java.sun.com/developer/onlineTraining/Database/JDBCShortCourse/index.html>] — A more in-depth tutorial from Sun and JGuru

### 23.3.1. Basic JDBC concepts

---

This section provides some general JDBC background.

### 23.3.1.1. Connecting to MySQL using the DriverManager Interface

When you are using JDBC outside of an application server, the `DriverManager` class manages the establishment of Connections.

The `DriverManager` needs to be told which JDBC drivers it should try to make Connections with. The easiest way to do this is to use `Class.forName()` on the class that implements the `java.sql.Driver` interface. With MySQL Connector/J, the name of this class is `com.mysql.jdbc.Driver`. With this method, you could use an external configuration file to supply the driver class name and driver parameters to use when connecting to a database.

The following section of Java code shows how you might register MySQL Connector/J from the `main()` method of your application:

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

// Notice, do not import com.mysql.jdbc.*
// or you will have problems!

public class LoadDriver {
    public static void main(String[] args) {
        try {
            // The newInstance() call is a work around for some
            // broken Java implementations

            Class.forName("com.mysql.jdbc.Driver").newInstance();
        } catch (Exception ex) {
            // handle the error
        }
    }
}
```

After the driver has been registered with the `DriverManager`, you can obtain a `Connection` instance that is connected to a particular database by calling `DriverManager.getConnection()`:

#### Example 23.1. Obtaining a Connection From the DriverManager

This example shows how you can obtain a `Connection` instance from the `DriverManager`. There are a few different signatures for the `getConnection()` method. You should see the API documentation that comes with your JDK for more specific information on how to use them.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

... try {
    Connection conn = DriverManager.getConnection("jdbc:mysql://localhost:3306/");

    // Do something with the Connection

    ....
} catch (SQLException ex) {
    // handle any errors
    System.out.println("SQLException: " + ex.getMessage());
    System.out.println("SQLState: " + ex.getSQLState());
    System.out.println("VendorError: " + ex.getErrorCode());
}
```

Once a `Connection` is established, it can be used to create `Statement` and `PreparedStatement` objects, as well as retrieve metadata about the database. This is explained in the following sections.

### 23.3.1.2. Using Statements to Execute SQL

`Statement` objects allow you to execute basic SQL queries and retrieve the results through the `ResultSet` class which is described later.

To create a `Statement` instance, you call the `createStatement()` method on the `Connection` object you have retrieved via one of the `DriverManager.getConnection()` or `DataSource.getConnection()` methods described earlier.

Once you have a `Statement` instance, you can execute a `SELECT` query by calling the `executeQuery(String)` method with the SQL you want to use.

To update data in the database, use the `executeUpdate(String SQL)` method. This method returns the number of rows affected by the update statement.

If you don't know ahead of time whether the SQL statement will be a `SELECT` or an `UPDATE/INSERT`, then you can use the `execute(String SQL)` method. This method will return `true` if the SQL query was a `SELECT`, or `false` if it was an `UPDATE`, `INSERT`, or `DELETE` statement. If the statement was a `SELECT` query, you can retrieve the results by calling the `getResultSet()` method. If the statement was an `UPDATE`, `INSERT`, or `DELETE` statement, you can retrieve the affected rows count by calling `getUpdateCount()` on the `Statement` instance.

#### Example 23.2. Using `java.sql.Statement` to Execute a `SELECT` Query

```
// assume that conn is an already created JDBC connection
Statement stmt = null;
ResultSet rs = null;

try {
    stmt = conn.createStatement();
    rs = stmt.executeQuery("SELECT foo FROM bar");

    // or alternatively, if you don't know ahead of time that
    // the query will be a SELECT...

    if (stmt.execute("SELECT foo FROM bar")) {
        rs = stmt.getResultSet();
    }

    // Now do something with the ResultSet ....
} finally {
    // it is a good idea to release
    // resources in a finally{} block
    // in reverse-order of their creation
    // if they are no-longer needed

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException sqlEx) { // ignore }

        rs = null;
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException sqlEx) { // ignore }
    }
}
```

```

        stmt = null;
    }
}

```

### 23.3.1.3. Using CallableStatements to Execute Stored Procedures

Starting with MySQL server version 5.0 when used with Connector/J 3.1.1 or newer, the `java.sql.CallableStatement` interface is fully implemented with the exception of the `getParameterMetaData()` method.

MySQL's stored procedure syntax is documented in the "Stored Procedures and Functions [<http://www.mysql.com/doc/en/stored-procedures.html>]" section of the MySQL Reference Manual.

Connector/J exposes stored procedure functionality through JDBC's `CallableStatement` interface.

The following example shows a stored procedure that returns the value of `inOutParam` incremented by 1, and the string passed in via `inputParam` as a `ResultSet`:

#### Example 23.3. Stored Procedure Example

```

CREATE PROCEDURE demoSp(IN inputParam VARCHAR(255), INOUT inOutParam INT)
BEGIN
    DECLARE z INT;
    SET z = inOutParam + 1;
    SET inOutParam = z;

    SELECT inputParam;

    SELECT CONCAT('zyxw', inputParam);
END

```

To use the `demoSp` procedure with Connector/J, follow these steps:

1. Prepare the callable statement by using `Connection.prepareCall()`.

Notice that you have to use JDBC escape syntax, and that the parentheses surrounding the parameter placeholders are not optional:

#### Example 23.4. Using `Connection.prepareCall()`

```

import java.sql.CallableStatement;

...

//
// Prepare a call to the stored procedure 'demoSp'
// with two parameters
//
// Notice the use of JDBC-escape syntax ({call ...})
//

CallableStatement cStmt = conn.prepareCall("{call demoSp(?, ?)}");

```

```
cStmt.setString(1, "abcdefg");
```

## Note

`Connection.prepareStatement()` is an expensive method, due to the metadata retrieval that the driver performs to support output parameters. For performance reasons, you should try to minimize unnecessary calls to `Connection.prepareStatement()` by reusing `CallableStatement` instances in your code.

2. Register the output parameters (if any exist)

To retrieve the values of output parameters (parameters specified as OUT or INOUT when you created the stored procedure), JDBC requires that they be specified before statement execution using the various `registerOutputParameter()` methods in the `CallableStatement` interface:

### Example 23.5. Registering Output Parameters

```
import java.sql.Types;
...
//
// Connector/J supports both named and indexed
// output parameters. You can register output
// parameters using either method, as well
// as retrieve output parameters using either
// method, regardless of what method was
// used to register them.
//
// The following examples show how to use
// the various methods of registering
// output parameters (you should of course
// use only one registration per parameter).
//
//
// Registers the second parameter as output, and
// uses the type 'INTEGER' for values returned from
// getObject()
//
cStmt.registerOutParameter(2, Types.INTEGER);
//
// Registers the named parameter 'inOutParam', and
// uses the type 'INTEGER' for values returned from
// getObject()
//
cStmt.registerOutParameter("inOutParam", Types.INTEGER);
...

```

3. Set the input parameters (if any exist)

Input and in/out parameters are set as for `PreparedStatement` objects. However, `CallableStatement` also supports setting parameters by name:

### Example 23.6. Setting `CallableStatement` Input Parameters

```
...  
  
    //  
    // Set a parameter by index  
    //  
  
    cStmt.setString(1, "abcdefg");  
  
    //  
    // Alternatively, set a parameter using  
    // the parameter name  
    //  
  
    cStmt.setString("inputParameter", "abcdefg");  
  
    //  
    // Set the 'in/out' parameter using an index  
    //  
  
    cStmt.setInt(2, 1);  
  
    //  
    // Alternatively, set the 'in/out' parameter  
    // by name  
    //  
  
    cStmt.setInt("inOutParam", 1);  
  
...
```

4. Execute the CallableStatement, and retrieve any result sets or output parameters.

Although CallableStatement supports calling any of the Statement execute methods (executeUpdate(), executeQuery() or execute()), the most flexible method to call is execute(), as you do not need to know ahead of time if the stored procedure returns result sets:

### **Example 23.7. Retrieving Results and Output Parameter Values**

```
...  
  
    boolean hadResults = cStmt.execute();  
  
    //  
    // Process all returned result sets  
    //  
  
    while (hadResults) {  
        ResultSet rs = cStmt.getResultSet();  
  
        // process result set  
        ...  
  
        hadResults = cStmt.getMoreResults();  
    }  
  
    //  
    // Retrieve output parameters  
    //  
    // Connector/J supports both index-based and  
    // name-based retrieval  
    //
```

```

int outputValue = cStmt.getInt(2); // index-based
outputValue = cStmt.getInt("inOutParam"); // name-based
...

```

### 23.3.1.4. Retrieving AUTO\_INCREMENT Column Values

Before version 3.0 of the JDBC API, there was no standard way of retrieving key values from databases that supported “auto increment” or identity columns. With older JDBC drivers for MySQL, you could always use a MySQL-specific method on the `Statement` interface, or issue the query `SELECT LAST_INSERT_ID()` after issuing an `INSERT` to a table that had an `AUTO_INCREMENT` key. Using the MySQL-specific method call isn't portable, and issuing a `SELECT` to get the `AUTO_INCREMENT` key's value requires another round-trip to the database, which isn't as efficient as possible. The following code snippets demonstrate the three different ways to retrieve `AUTO_INCREMENT` values. First, we demonstrate the use of the new JDBC-3.0 method `getGeneratedKeys()` which is now the preferred method to use if you need to retrieve `AUTO_INCREMENT` keys and have access to JDBC-3.0. The second example shows how you can retrieve the same value using a standard `SELECT LAST_INSERT_ID()` query. The final example shows how updatable result sets can retrieve the `AUTO_INCREMENT` value when using the `insertRow()` method.

#### Example 23.8. Retrieving AUTO\_INCREMENT Column Values using `Statement.getGeneratedKeys()`

```

Statement stmt = null;
ResultSet rs = null;

try {
    //
    // Create a Statement instance that we can use for
    // 'normal' result sets assuming you have a
    // Connection 'conn' to a MySQL database already
    // available

    stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                               java.sql.ResultSet.CONCUR_UPDATABLE);

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
        "CREATE TABLE autoIncTutorial ("
        + "priKey INT NOT NULL AUTO_INCREMENT, "
        + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Insert one row that will generate an AUTO INCREMENT
    // key in the 'priKey' field
    //

    stmt.executeUpdate(
        "INSERT INTO autoIncTutorial (dataField) "
        + "values ('Can I Get the Auto Increment Field?')",
        Statement.RETURN_GENERATED_KEYS);

    //

```

---

```

// Example of using Statement.getGeneratedKeys()
// to retrieve the value of an auto-increment
// value
//

int autoIncKeyFromApi = -1;

rs = stmt.getGeneratedKeys();

if (rs.next()) {
    autoIncKeyFromApi = rs.getInt(1);
} else {

    // throw an exception from here
}

rs.close();

rs = null;

System.out.println("Key returned from getGeneratedKeys():"
    + autoIncKeyFromApi);
} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
}

```

**Example 23.9. Retrieving AUTO\_INCREMENT Column Values using SELECT LAST\_INSERT\_ID()**

```

Statement stmt = null;
ResultSet rs = null;

try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets.

    stmt = conn.createStatement();

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
        "CREATE TABLE autoIncTutorial ("
        + "priKey INT NOT NULL AUTO_INCREMENT, "
        + "dataField VARCHAR(64), PRIMARY KEY (priKey))");
}

```

---

```

//
// Insert one row that will generate an AUTO INCREMENT
// key in the 'priKey' field
//

stmt.executeUpdate(
    "INSERT INTO autoIncTutorial (dataField) "
    + "values ('Can I Get the Auto Increment Field?')");

//
// Use the MySQL LAST_INSERT_ID()
// function to do the same thing as getGeneratedKeys()
//

int autoIncKeyFromFunc = -1;
rs = stmt.executeQuery("SELECT LAST_INSERT_ID()");

if (rs.next()) {
    autoIncKeyFromFunc = rs.getInt(1);
} else {
    // throw an exception from here
}

rs.close();

System.out.println("Key returned from " + "'SELECT LAST_INSERT_ID()': "
    + autoIncKeyFromFunc);
} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
}

```

### Example 23.10. Retrieving AUTO\_INCREMENT Column Values in Updatable ResultSets

```

Statement stmt = null;
ResultSet rs = null;

try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets as well as an 'updatable'
    // one, assuming you have a Connection 'conn' to
    // a MySQL database already available
    //

```

```
stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                             java.sql.ResultSet.CONCUR_UPDATABLE);

//
// Issue the DDL queries for the table for this example
//

stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
stmt.executeUpdate(
    "CREATE TABLE autoIncTutorial ("
    + "priKey INT NOT NULL AUTO_INCREMENT, "
    + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

//
// Example of retrieving an AUTO INCREMENT key
// from an updatable result set
//

rs = stmt.executeQuery("SELECT priKey, dataField "
    + "FROM autoIncTutorial");

rs.moveToInsertRow();

rs.updateString("dataField", "AUTO INCREMENT here?");
rs.insertRow();

//
// the driver adds rows at the end
//

rs.last();

//
// We should now be on the row we just inserted
//

int autoIncKeyFromRS = rs.getInt("priKey");

rs.close();

rs = null;

System.out.println("Key returned for inserted row: "
    + autoIncKeyFromRS);
} finally {
    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
```

When you run the preceding example code, you should get the following output: Key returned from

`getGeneratedKeys()`: 1 Key returned from `SELECT LAST_INSERT_ID()`: 1 Key returned for inserted row: 2 You should be aware, that at times, it can be tricky to use the `SELECT LAST_INSERT_ID()` query, as that function's value is scoped to a connection. So, if some other query happens on the same connection, the value will be overwritten. On the other hand, the `getGeneratedKeys()` method is scoped by the `Statement` instance, so it can be used even if other queries happen on the same connection, but not on the same `Statement` instance.

## 23.3.2. Installing Connector/J

Use the following instructions to install Connector/J

### 23.3.2.1. Required Software Versions

#### 23.3.2.1.1. Java Versions Supported

MySQL Connector/J supports Java-2 JVMs, including JDK-1.2.x, JDK-1.3.x, JDK-1.4.x and JDK-1.5.x, and requires JDK-1.4.x or newer to compile (but not run). MySQL Connector/J does not support JDK-1.1.x or JDK-1.0.x

Because of the implementation of `java.sql.Savepoint`, Connector/J 3.1.0 and newer will not run on JDKs older than 1.4 unless the class verifier is turned off (`-Xverify:none`), as the class verifier will try to load the class definition for `java.sql.Savepoint` even though it is not accessed by the driver unless you actually use `savepoint` functionality.

Caching functionality provided by Connector/J 3.1.0 or newer is also not available on JVMs older than 1.4.x, as it relies on `java.util.LinkedHashMap` which was first available in JDK-1.4.0.

#### 23.3.2.1.2. MySQL Server Version Guidelines

MySQL Connector/J supports all known MySQL server versions. Some features (foreign keys, updatable result sets) require more recent versions of MySQL to operate.

When connecting to MySQL server version 4.1 or newer, it is best to use MySQL Connector/J version 3.1, as it has full support for features in the newer versions of the server, including Unicode characters, views, stored procedures and server-side prepared statements.

Although Connector/J version 3.0 will connect to MySQL server, version 4.1 or newer, and implements Unicode characters and the new authorization mechanism, Connector/J 3.0 will not be updated to support new features in current and future server versions.

#### 23.3.2.1.3. Installing the Driver and Configuring the CLASSPATH

MySQL Connector/J is distributed as a .zip or .tar.gz archive containing the sources, the class files a class-file only “binary” .jar archive named “mysql-connector-java-[version]-bin.jar”, and starting with Connector/J 3.1.8 a “debug” build of the driver in a file named “mysql-connector-java-[version]-bin-g.jar”.

Starting with Connector/J 3.1.9, we don't ship the .class files “unbundled,” they are only available in the JAR archives that ship with the driver.

You should not use the “debug” build of the driver unless instructed to do so when reporting a problem or bug to MySQL AB, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

You will need to use the appropriate graphical or command-line utility to un-archive the distribution (for example, WinZip for the .zip archive, and `tar` for the .tar.gz archive). Because there are potentially long filenames in the distribution, we use the GNU tar archive format. You will need to use GNU tar (or an application that understands the GNU tar archive format) to unpack the .tar.gz variant of the distribution.

Once you have extracted the distribution archive, you can install the driver by placing `mysql-connector-java-[version]-bin.jar` in your classpath, either by adding the FULL path to it to your CLASSPATH environment variable, or by directly specifying it with the command line switch `-cp` when starting your JVM

If you are going to use the driver with the JDBC DriverManager, you would use `"com.mysql.jdbc.Driver"` as the class that implements `java.sql.Driver`.

### **Example 23.11. Setting the CLASSPATH Under UNIX**

The following command works for 'csh' under UNIX:

```
$ setenv CLASSPATH /path/to/mysql-connector-java-[version]-bin.jar:$CLASSPATH
```

The above command can be added to the appropriate startup file for the login shell to make MySQL Connector/J available to all Java applications.

If you want to use MySQL Connector/J with an application server such as Tomcat or JBoss, you will have to read your vendor's documentation for more information on how to configure third-party class libraries, as most application servers ignore the CLASSPATH environment variable. For configuration examples for some J2EE application servers, see Section 23.3.4, "Using Connector/J with J2EE and Other Java Frameworks". However, the authoritative source for JDBC connection pool configuration information for your particular application server is the documentation for that application server.

If you are developing servlets or JSPs, and your application server is J2EE-compliant, you can put the driver's .jar file in the WEB-INF/lib subdirectory of your webapp, as this is a standard location for third party class libraries in J2EE web applications.

You can also use the `MysqlDataSource` or `MysqlConnectionPoolDataSource` classes in the `com.mysql.jdbc.jdbc2.optional` package, if your J2EE application server supports or requires them. Starting with Connector/J 5.0.0, the `javax.sql.XADataSource` interface is implemented via the `com.mysql.jdbc.jdbc2.optional.MysqlXADataSource` class, which supports XA distributed transactions when used in combination with MySQL server version 5.0.

The various `MysqlDataSource` classes support the following parameters (through standard "set" mutators):

- user
- password
- serverName (see the previous section about fail-over hosts)
- databaseName
- port

## **23.3.2.2. Upgrading from an Older Version**

MySQL AB tries to keep the upgrade process as easy as possible, however as is the case with any software, sometimes changes need to be made in new versions to support new features, improve existing functionality, or comply with new standards.

This section has information about what users who are upgrading from one version of Connector/J to another (or to a new version of the MySQL server, with respect to JDBC functionality) should be aware of.

### 23.3.2.2.1. Upgrading from MySQL Connector/J 3.0 to 3.1

Connector/J 3.1 is designed to be backward-compatible with Connector/J 3.0 as much as possible. Major changes are isolated to new functionality exposed in MySQL-4.1 and newer, which includes Unicode character sets, server-side prepared statements, SQLState codes returned in error messages by the server and various performance enhancements that can be enabled or disabled via configuration properties.

- **Unicode Character Sets** — See the next section, as well as Chapter 10, *Character Set Support*, for information on this new feature of MySQL. If you have something misconfigured, it will usually show up as an error with a message similar to `Illegal mix of collations`.
- **Server-side Prepared Statements** — Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer).

Starting with version 3.1.7, the driver scans SQL you are preparing via all variants of `Connection.prepareStatement()` to determine if it is a supported type of statement to prepare on the server side, and if it is not supported by the server, it instead prepares it as a client-side emulated prepared statement. You can disable this feature by passing `'emulateUnsupportedPstmts=false'` in your JDBC URL.

If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the following connection property:

```
useServerPrepStmts=false
```

- **Datetimes with all-zero components ('0000-00-00 ...')** — These values can not be represented reliably in Java. Connector/J 3.0.x always converted them to NULL when being read from a `ResultSet`.

Connector/J 3.1 throws an exception by default when these values are encountered as this is the most correct behavior according to the JDBC and SQL standards. This behavior can be modified using the `'zeroDateTimeBehavior'` configuration property. The allowable values are: `'exception'` (the default), which throws an `SQLException` with an `SQLState` of `'S1009'`, `'convertToNull'`, which returns NULL instead of the date, and `'round'`, which rounds the date to the nearest closest value which is `'0001-01-01'`.

Starting with Connector/J 3.1.7, `ResultSet.getString()` can be decoupled from this behavior via `'noDatetimeStringSync=true'` (the default value is `'false'`) so that you can get retrieve the unaltered all-zero value as a `String`. It should be noted that this also precludes using any time zone conversions, therefore the driver will not allow you to enable `noDatetimeStringSync` and `useTimezone` at the same time.

- **New SQLState Codes** — Connector/J 3.1 uses SQL:1999 SQLState codes returned by the MySQL server (if supported), which are different from the “legacy” X/Open state codes that Connector/J 3.0 uses. If connected to a MySQL server older than MySQL-4.1.0 (the oldest version to return SQLStates as part of the error code), the driver will use a built-in mapping. You can revert to the old mapping by using the following configuration property:

```
useSqlStateCodes=false
```

- **Calling `ResultSet.getString()` on a BLOB column will now return the address of the `byte[]` array that represents it, instead of a `String` representation of the BLOB. BLOBs have no character set, so they can't be converted to `java.lang.Strings` without data loss or corruption.**

To store strings in MySQL with LOB behavior, use one of the TEXT types, which the driver will treat as a `java.sql.Clob`.

- Starting with Connector/J 3.1.8 a “debug” build of the driver in a file named `"mysql-connector-java-[version]-bin-g.jar"` is shipped alongside the normal “binary” jar file that is named `"mysql-connector-java-[version]-bin.jar"`.

Starting with Connector/J 3.1.9, we don't ship the .class files “unbundled,” they are only available in the JAR archives that ship with the driver.

You should not use the “debug” build of the driver unless instructed to do so when reporting a problem or bug to MySQL AB, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

### 23.3.2.2.2. JDBC-Specific Issues When Upgrading to MySQL Server 4.1 or Newer

- *Using the UTF-8 Character Encoding* - Prior to MySQL server version 4.1, the UTF-8 character encoding was not supported by the server, however the JDBC driver could use it, allowing storage of multiple character sets in latin1 tables on the server.

Starting with MySQL-4.1, this functionality is deprecated. If you have applications that rely on this functionality, and can not upgrade them to use the official Unicode character support in MySQL server version 4.1 or newer, you should add the following property to your connection URL:

```
useOldUTF8Behavior=true
```

- *Server-side Prepared Statements* - Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer). If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the following connection property:

```
useServerPrepStmts=false
```

### 23.3.2.3. Installing from the Development Source Tree

#### Caution

You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL Connector/J up and running on your system, you should use a standard release distribution.

To install MySQL Connector/J from the development source tree, make sure that you have the following prerequisites:

- Subversion, to check out the sources from our repository (available from <http://subversion.tigris.org/>).
- Apache Ant version 1.6 or newer (available from <http://ant.apache.org/>).
- JDK-1.4.2 or later. Although MySQL Connector/J can be installed on older JDKs, to compile it from source you must have at least JDK-1.4.2.

The Subversion source code repository for MySQL Connector/J is located at <http://svn.mysql.com/svnpublic/connector-j>. In general, you should not check out the entire repository because it contains every branch and tag for MySQL Connector/J and is quite large.

To check out and compile a specific branch of MySQL Connector/J, follow these steps:

1. At the time of this writing, there are three active branches of Connector/J: `branch_3_0`, `branch_3_1` and `branch_5_0`. Check out the latest code from the branch that you want with the following command (replacing `[major]` and `[minor]` with appropriate version numbers):

```
shell> svn co http://svn.mysql.com/svnpublic/connector-j/branches/branch_[ma
```

This creates a `connector-j` subdirectory in the current directory that contains the latest sources for the requested branch.

2. Change location to the `connector-j` directory to make it your current working directory:

```
shell> cd connector-j
```

3. Issue the following command to compile the driver and create a `.jar` file suitable for installation:

```
shell> ant dist
```

This creates a `build` directory in the current directory, where all build output will go. A directory is created in the `build` directory that includes the version number of the sources you are building from. This directory contains the sources, compiled `.class` files, and a `.jar` file suitable for deployment. For other possible targets, including ones that will create a fully packaged distribution, issue the following command:

```
shell> ant --projecthelp
```

4. A newly created `.jar` file containing the JDBC driver will be placed in the directory `build/mysql-connector-java-[version]`.

Install the newly created JDBC driver as you would a binary `.jar` file that you download from MySQL by following the instructions in Section 23.3.2.1.3, “Installing the Driver and Configuring the CLASSPATH”.

## 23.3.3. JDBC Reference

### 23.3.3.1. Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J

The name of the class that implements `java.sql.Driver` in MySQL Connector/J is `'com.mysql.jdbc.Driver'`. The `'org.gjt.mm.mysql.Driver'` class name is also usable to remain backward-compatible with MM.MySQL. You should use this class name when registering the driver, or when otherwise configuring software to use MySQL Connector/J.

The JDBC URL format for MySQL Connector/J is as follows, with items in square brackets (`[, ]`) being optional:

```
jdbc:mysql://[host][, failoverhost...][:port]/[database][?propertyName1][=proper
```

If the hostname is not specified, it defaults to `'127.0.0.1'`. If the port is not specified, it defaults to `'3306'`, the default port number for MySQL servers.

```
jdbc:mysql://[host:port],[host:port].../[database][?propertyName1][=propertyVal
```

If the database is not specified, the connection will be made with no default database. In this case,

you will need to either call the `setCatalog()` method on the `Connection` instance or fully-specify table names using the database name (i.e. 'SELECT dbname.tablename.colname FROM dbname.tablename...') in your SQL. Not specifying the database to use upon connection is generally only useful when building tools that work with multiple databases, such as GUI database managers.

MySQL Connector/J has fail-over support. This allows the driver to fail-over to any number of "slave" hosts and still perform read-only queries. Fail-over only happens when the connection is in an `autoCommit(true)` state, because fail-over can not happen reliably when a transaction is in progress. Most application servers and connection pools set `autoCommit` to 'true' at the end of every transaction/connection use.

The fail-over functionality has the following behavior:

If the URL property "autoReconnect" is false: Failover only happens at connection initialization, and fallback occurs when the driver determines that the first host has become available again.

If the URL property "autoReconnect" is true: Failover happens when the driver determines that the connection has failed (before *every* query), and falls back to the first host when it determines that the host has become available again (after queriesBeforeRetryMaster queries have been issued).

In either case, whenever you are connected to a "failed-over" server, the connection will be set to read-only state, so queries that would modify data will have exceptions thrown (the query will *never* be processed by the MySQL server).

Configuration properties define how Connector/J will make a connection to a MySQL server. Unless otherwise noted, properties can be set for a `DataSource` object or for a `Connection` object.

Configuration Properties can be set in one of the following ways:

- Using the `set*()` methods on MySQL implementations of `java.sql.DataSource` (which is the preferred method when using implementations of `java.sql.DataSource`):
  - `com.mysql.jdbc.jdbc2.optional.MysqlDataSource`
  - `com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource`
- As a key/value pair in the `java.util.Properties` instance passed to `DriverManager.getConnection()` or `Driver.connect()`
- As a JDBC URL parameter in the URL given to `java.sql.DriverManager.getConnection()`, `java.sql.Driver.connect()` or the MySQL implementations of `javax.sql.DataSource`'s `setURL()` method.

## Note

If the mechanism you use to configure a JDBC URL is XML-based, you will need to use the XML character literal `&amp;`; to separate configuration parameters, as the ampersand is a reserved character for XML.

The properties are listed in the following table:

**Table 23.1. Connection Properties**

Property Name	Definition	Required?	Default Value
<i>Connection/Authentication</i>			
user	The user to connect as	No	
password	The password to use when connecting	No	
socketFactory	The name of the class	No	<code>com.mysql.jdbc.Standa</code>

Property Name	Definition	Required?	Default Value
	that the driver should use for creating socket connections to the server. This class must implement the interface 'com.mysql.jdbc.SocketFactory' and have public no-args constructor.		rdSocketFactory
connectTimeout	Timeout for socket connect (in milliseconds), with 0 being no timeout. Only works on JDK-1.4 or newer. Defaults to '0'.	No	0
socketTimeout	Timeout on network socket operations (0, the default means no timeout).	No	0
useConfigs	Load the comma-delimited list of configuration properties before parsing the URL or applying user-specified properties. These configurations are explained in the 'Configurations' of the documentation.	No	
interactiveClient	Set the CLIENT_INTERACTIVE flag, which tells MySQL to timeout connections based on INTERACTIVE_TIMEOUT instead of WAIT_TIMEOUT	No	false
propertiesTransform	An implementation of com.mysql.jdbc.ConnectionPropertiesTransform that the driver will use to modify URL properties passed to the driver before attempting a connection	No	
useCompression	Use zlib compression when communicating with the server (true/false)? Defaults to 'false'.	No	false
<i>High Availability and Clustering</i>			
autoReconnect	Should the driver try to re-establish stale and/or dead connections? If enabled the driver will throw an exception for a queries issued on a stale or dead connec-	No	false

Property Name	Definition	Required?	Default Value
	tion, which belong to the current transaction, but will attempt reconnect before the next query issued on the connection in a new transaction. The use of this feature is not recommended, because it has side effects related to session state and data consistency when applications don't handle SQLExceptions properly, and is only designed to be used when you are unable to configure your application to handle SQLExceptions resulting from dead and stale connections properly. Alternatively, investigate setting the MySQL server variable "wait_timeout" to some high value rather than the default of 8 hours.		
autoReconnectForPools	Use a reconnection strategy appropriate for connection pools (defaults to 'false')	No	false
failOverReadOnly	When failing over in autoReconnect mode, should the connection be set to 'read-only'?	No	true
reconnectAtTxEnd	If autoReconnect is set to true, should the driver attempt reconnections at the end of every transaction?	No	false
roundRobinLoadBalance	When autoReconnect is enabled, and failover-ReadOnly is false, should we pick hosts to connect to on a round-robin basis?	No	false
queriesBeforeRetryMaster	Number of queries to issue before falling back to master when failed over (when using multi-host failover). Whichever condition is met first, 'queriesBeforeRetryMaster' or 'secondsBeforeRetryMaster' will cause an attempt to be made to reconnect to the master. Defaults to 50.	No	50

Property Name	Definition	Required?	Default Value
secondsBeforeRetryMaster	How long should the driver wait, when failed over, before attempting to reconnect to the master server? Whichever condition is met first, 'queriesBeforeRetryMaster' or 'secondsBeforeRetryMaster' will cause an attempt to be made to reconnect to the master. Time in seconds, defaults to 30	No	30
enableDeprecatedAutoreconnect	Auto-reconnect functionality is deprecated starting with version 3.2, and will be removed in version 3.3. Set this property to 'true' to disable the check for the feature being configured.	No	false
resourceId	A globally unique name that identifies the resource that this data-source or connection is connected to, used for XAResource.isSameRM() when the driver can't determine this value based on hostnames used in the URL	No	
<i>Security</i>			
allowMultiQueries	Allow the use of ';' to delimit multiple queries during one statement (true/false, defaults to 'false')	No	false
useSSL	Use SSL when communicating with the server (true/false), defaults to 'false'	No	false
requireSSL	Require SSL connection if useSSL=true? (defaults to 'false').	No	false
allowUrlInLocalInfile	Should the driver allow URLs in 'LOAD DATA LOCAL INFILE' statements?	No	false
paranoid	Take measures to prevent exposure sensitive information in error messages and clear data structures holding sensitive data when possible? (defaults to 'false')	No	false

Property Name	Definition	Required?	Default Value
<i>Performance Extensions</i>			
metadataCacheSize	The number of queries to cacheResultSetMetadata for if cacheResultSetMetaData is set to 'true' (default 50)	No	50
prepStmtCacheSize	If prepared statement caching is enabled, how many prepared statements should be cached?	No	25
prepStmtCacheSqlLimit	If prepared statement caching is enabled, what's the largest SQL the driver will cache the parsing for?	No	256
useCursorFetch	If connected to MySQL > 5.0.2, and setFetchSize() > 0 on a statement, should that statement use cursor-based fetching to retrieve rows?	No	false
blobSendChunkSize	Chunk to use when sending BLOB/CLOBs via ServerPreparedStatements	No	1048576
cacheCallableStmts	Should the driver cache the parsing stage of CallableStatements	No	false
cachePrepStmts	Should the driver cache the parsing stage of PreparedStatements of client-side prepared statements, the "check" for suitability of server-side prepared and server-side prepared statements themselves?	No	false
cacheResultSetMetadata	Should the driver cache ResultSetMetaData for Statements and PreparedStatements? (Req. JDK-1.4+, true/false, default 'false')	No	false
cacheServerConfiguration	Should the driver cache the results of 'SHOW VARIABLES' and 'SHOW COLLATION' on a per-URL basis?	No	false
defaultFetchSize	The driver will call setFetchSize(n) with this value on all newly-created Statements	No	0
dontTrackOpenResources	The JDBC specification requires the driver to	No	false

Property Name	Definition	Required?	Default Value
	automatically track and close resources, however if your application doesn't do a good job of explicitly calling close() on statements or result sets, this can cause memory leakage. Setting this property to true relaxes this constraint, and can be more memory efficient for some applications.		
dynamicCalendars	Should the driver retrieve the default calendar when required, or cache it per connection/session?	No	false
elideSetAutoCommits	If using MySQL-4.1 or newer, should the driver only issue 'set autocommit=n' queries when the server's state doesn't match the requested state by Connection.setAutoCommit(boolean)?	No	false
holdResultsOpenOverStatementClose	Should the driver close result sets on Statement.close() as required by the JDBC specification?	No	false
locatorFetchBufferSize	If 'emulateLocators' is configured to 'true', what size buffer should be used when fetching BLOB data for getBinaryInputStream?	No	1048576
rewriteBatchedStatements	Should the driver use multiqueries (irregardless of the setting of "allowMultiQueries") as well as rewriting of prepared statements for INSERT into multi-value inserts when executeBatch() is called? Notice that this has the potential for SQL injection if using plain java.sql.Statements and your code doesn't sanitize input correctly. Notice that for prepared statements, server-side prepared statements can not currently take advantage of this rewrite	No	false

Property Name	Definition	Required?	Default Value
	option, and that if you don't specify stream lengths when using PreparedStatement.set*Stream(), the driver won't be able to determine the optimum number of parameters per batch and you might receive an error from the driver that the resultant packet is too large. Statement.getGeneratedKeys() for these rewritten statements only works when the entire batch includes INSERT statements.		
useFastIntParsing	Use internal String->Integer conversion routines to avoid excessive object creation?	No	true
useLocalSessionState	Should the driver refer to the internal values of autocommit and transaction isolation that are set by Connection.setAutoCommit() and Connection.setTransactionIsolation(), rather than querying the database?	No	false
useReadAheadInput	Use newer, optimized non-blocking, buffered input stream when reading from the server?	No	true
<i>Debugging/Profiling</i>			
logger	The name of a class that implements 'com.mysql.jdbc.log.Log' that will be used to log messages to.(default is 'com.mysql.jdbc.log.StandardLogger', which logs to STDERR)	No	com.mysql.jdbc.log.StandardLogger
profileSQL	Trace queries and their execution/fetch times to the configured logger (true/false) defaults to 'false'	No	false
reportMetricsInterval-Millis	If 'gatherPerfMetrics' is enabled, how often should they be logged (in ms)?	No	30000
maxQuerySizeToLog	Controls the maximum	No	2048

Property Name	Definition	Required?	Default Value
	length/size of a query that will get logged when profiling or tracing		
packetDebugBufferSize	The maximum number of packets to retain when 'enablePacketDebug' is true	No	20
slowQueryThreshold-Millis	If 'logSlowQueries' is enabled, how long should a query (in ms) before it is logged as 'slow'?	No	2000
useUsageAdvisor	Should the driver issue 'usage' warnings advising proper and efficient usage of JDBC and MySQL Connector/J to the log (true/false, defaults to 'false')?	No	false
autoGenerateTestcase-Script	Should the driver dump the SQL it is executing, including server-side prepared statements to STDERR?	No	false
dumpMetadataOn-ColumnNotFound	Should the driver dump the field-level metadata of a result set into the exception message when ResultSet.findColumn() fails?	No	false
dumpQueriesOnException	Should the driver dump the contents of the query sent to the server in the message for SQLExceptions?	No	false
enablePacketDebug	When enabled, a ring-buffer of 'packetDebugBufferSize' packets will be kept, and dumped when exceptions are thrown in key areas in the driver's code	No	false
explainSlowQueries	If 'logSlowQueries' is enabled, should the driver automatically issue an 'EXPLAIN' on the server and send the results to the configured log at a WARN level?	No	false
logSlowQueries	Should queries that take longer than 'slowQueryThreshold-Millis' be logged?	No	false
traceProtocol	Should trace-level network protocol be	No	false

Property Name	Definition	Required?	Default Value
	logged?		
<i>Miscellaneous</i>			
useUnicode	Should the driver use Unicode character encodings when handling strings? Should only be used when the driver can't determine the character set mapping, or you are trying to 'force' the driver to use a character set that MySQL either doesn't natively support (such as UTF-8), true/false, defaults to 'true'	No	true
characterEncoding	If 'useUnicode' is set to true, what character encoding should the driver use when dealing with strings? (defaults is to 'autodetect')	No	
characterSetResults	Character set to tell the server to return results as.	No	
connectionCollation	If set, tells the server to use this collation via 'set collation_connection'	No	
sessionVariables	A comma-separated list of name/value pairs to be sent as SET SESSION ... to the server when the driver connects.	No	
allowNanAndInf	Should the driver allow NaN or +/- INF values in PreparedStatement.setDouble()?	No	false
autoClosePstmtStreams	Should the driver automatically call .close() on streams/readers passed as arguments via set*() methods?	No	false
autoDeserialize	Should the driver automatically detect and deserialize objects stored in BLOB fields?	No	false
capitalizeTypeNames	Capitalize type names in DatabaseMetaData? (usually only useful when using WebObjects, true/false, defaults to 'false')	No	false
clobCharacterEncoding	The character encoding to use for sending and retrieving TEXT, ME-	No	

Property Name	Definition	Required?	Default Value
	DIUMTEXT and LONGTEXT values instead of the configured connection character-Encoding		
clobberStreamingResults	This will cause a 'streaming' ResultSet to be automatically closed, and any outstanding data still streaming from the server to be discarded if another query is executed before all the data has been read from the server.	No	false
continueBatchOnError	Should the driver continue processing batch commands if one statement fails. The JDBC spec allows either way (defaults to 'true').	No	true
createDatabaseIfNotExist	Creates the database given in the URL if it doesn't yet exist. Assumes the configured user has permissions to create databases.	No	false
emptyStringsConvertToZero	Should the driver allow conversions from empty string fields to numeric values of '0'?	No	true
emulateLocators	N/A	No	false
emulateUnsupportedPstmts	Should the driver detect prepared statements that are not supported by the server, and replace them with client-side emulated versions?	No	true
ignoreNonTxTables	Ignore non-transactional table warning for rollback? (defaults to 'false').	No	false
jdbcCompliantTruncation	Should the driver throw java.sql.DataTruncation exceptions when data is truncated as is required by the JDBC specification when connected to a server that supports warnings(MySQL 4.1.0 and newer)?	No	true
maxRows	The maximum number of rows to return (0, the default means return all rows).	No	-1
noDatetimeStringSync	Don't ensure that Result-	No	false

Property Name	Definition	Required?	Default Value
	Set.getDatetimeType().to-String().equals(ResultSet.getString())		
noTimezoneConversionForTimeType	Don't convert TIME values using the server timezone if 'useTimezone'='true'	No	false
nullCatalogMeansCurrent	When DatabaseMetaDataMethods ask for a 'catalog' parameter, does the value null mean use the current catalog? (this is not JDBC-compliant, but follows legacy behavior from earlier versions of the driver)	No	true
nullNamePatternMatchesAll	Should DatabaseMetaData methods that accept *pattern parameters treat null the same as '%' (this is not JDBC-compliant, however older versions of the driver accepted this departure from the specification)	No	true
overrideSupportsIntegrityEnhancementFacility	Should the driver return "true" for DatabaseMetaData.supportsIntegrityEnhancementFacility() even if the database doesn't support it to workaround applications that require this method to return "true" to signal support of foreign keys, even though the SQL specification states that this facility contains much more than just foreign key support (one such application being OpenOffice)?	No	false
pedantic	Follow the JDBC spec to the letter.	No	false
processEscapeCodesForPrepStmts	Should the driver process escape codes in queries that are prepared?	No	true
relaxAutoCommit	If the version of MySQL the driver connects to does not support transactions, still allow calls to commit(), rollback() and setAutoCommit() (true/false,	No	false

Property Name	Definition	Required?	Default Value
	defaults to 'false')?		
retainStatementAfterResultSetClose	Should the driver retain the Statement reference in a ResultSet after ResultSet.close() has been called. This is not JDBC-compliant after JDBC-4.0.	No	false
rollbackOnPooledClose	Should the driver issue a rollback() when the logical connection in a pool is closed?	No	true
runningCTS13	Enables workarounds for bugs in Sun's JDBC compliance testsuite version 1.3	No	false
serverTimezone	Override detection/mapping of timezone. Used when timezone from server doesn't map to Java timezone	No	
strictFloatingPoint	Used only in older versions of compliance test	No	false
strictUpdates	Should the driver do strict checking (all primary keys selected) of updatable result sets (true, false, defaults to 'true')?	No	true
tinyIntIsBit	Should the driver treat the datatype TINYINT(1) as the BIT type (because the server silently converts BIT -> TINYINT(1) when creating tables)?	No	true
transformedBitIsBoolean	If the driver converts TINYINT(1) to a different type, should it use BOOLEAN instead of BIT for future compatibility with MySQL-5.0, as MySQL-5.0 has a BIT type?	No	false
ultraDevHack	Create PreparedStatement for prepareCall() when required, because UltraDev is broken and issues a prepareCall() for _all_ statements? (true/false, defaults to 'false')	No	false
useGmtMillisForDates	Convert between session timezone and GMT before creating Date and Timestamp instances (value of "false" is legacy beha-	No	false

Property Name	Definition	Required?	Default Value
	rior, "true" leads to more JDBC-compliant behavior.		
useHostsInPrivileges	Add '@hostname' to users in DatabaseMetaData.getColumn/TablePrivileges() (true/false), defaults to 'true'.	No	true
useInformationSchema	When connected to MySQL-5.0.7 or newer, should the driver use the INFORMATION_SCHEMA to derive information used by DatabaseMetaData?	No	false
useJDBCCompliant-TimezoneShift	Should the driver use JDBC-compliant rules when converting TIME/TIMESTAMP/DATE-TIME values' timezone information for those JDBC arguments which take a java.util.Calendar argument? (Notice that this option is exclusive of the "use-Timezone=true" configuration option.)	No	false
useOldUTF8Behavior	Use the UTF-8 behavior the driver did when communicating with 4.0 and older servers	No	false
useOnlyServerErrorMessages	Don't prepend 'standard' SQLState error messages to error messages returned by the server.	No	true
useServerPrepStmts	Use server-side prepared statements if the server supports them? (defaults to 'true').	No	true
useSqlStateCodes	Use SQL Standard state codes instead of 'legacy' X/Open/SQL state codes (true/false), default is 'true'	No	true
useStreamLengthsInPrepStmts	Honor stream length parameter in PreparedStatement/ResultSet.setXXXStream() method calls (true/false, defaults to 'true')?	No	true
useTimezone	Convert time/date types between client and server timezones (true/false, defaults to	No	false

Property Name	Definition	Required?	Default Value
	'false')?'		
useUnbufferedInput	Don't use BufferedInputStream for reading data from the server	No	true
yearIsDateType	Should the JDBC driver treat the MySQL type "YEAR" as a java.sql.Date, or as a SHORT?	No	true
zeroDateTimeBehavior	What should happen when the driver encounters DATETIME values that are composed entirely of zeroes (used by MySQL to represent invalid dates)? Valid values are 'exception', 'round' and 'convertToNull'.	No	exception

Connector/J also supports access to MySQL via named pipes on Windows NT/2000/XP using the 'NamedPipeSocketFactory' as a plugin-socket factory via the 'socketFactory' property. If you don't use a 'namedPipePath' property, the default of '\\.\pipe\MySQL' will be used. If you use the NamedPipeSocketFactory, the hostname and port number values in the JDBC url will be ignored.

Adding the following property to your URL will enable the NamedPipeSocketFactory:

```
socketFactory=com.mysql.jdbc.NamedPipeSocketFactory
```

Named pipes only work when connecting to a MySQL server on the same physical machine as the one the JDBC driver is being used on. In simple performance tests, it appears that named pipe access is between 30%-50% faster than the standard TCP/IP access.

You can create your own socket factories by following the example code in `com.mysql.jdbc.NamedPipeSocketFactory`, or `com.mysql.jdbc.StandardSocketFactory`.

### 23.3.3.2. JDBC API Implementation Notes

MySQL Connector/J passes all of the tests in the publicly-available version of Sun's JDBC compliance test suite. However, in many places the JDBC specification is vague about how certain functionality should be implemented, or the specification allows leeway in implementation.

This section gives details on a interface-by-interface level about how certain implementation decisions may affect how you use MySQL Connector/J.

- Blob

The Blob implementation does not allow in-place modification (they are 'copies', as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, you should use the corresponding `PreparedStatement.setBlob()` or `ResultSet.updateBlob()` (in the case of updatable result sets) methods to save changes back to the database.

Starting with Connector/J version 3.1.0, you can emulate Blobs with locators by adding the property 'emulateLocators=true' to your JDBC URL. You must then use a column alias with the value of the column set to the actual name of the Blob column in the SELECT that you write to retrieve the Blob. The SELECT must also reference only one table, the table must have a primary key, and the SELECT must cover all columns that make up the primary key. The driver will then delay loading the actual Blob data until you retrieve the Blob and call retrieval meth-

ods (`getInputStream()`, `getBytes()`, and so forth) on it.

- **CallableStatement**

Starting with Connector/J 3.1.1, stored procedures are supported when connecting to MySQL version 5.0 or newer via the `CallableStatement` interface. Currently, the `getParameterMetaData()` method of `CallableStatement` is not supported.

- **Clob**

The Clob implementation does not allow in-place modification (they are 'copies', as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, you should use the `PreparedStatement.setClob()` method to save changes back to the database. The JDBC API does not have a `ResultSet.updateClob()` method.

- **Connection**

Unlike older versions of MM.MySQL the `isClosed()` method does not “ping” the server to determine if it is alive. In accordance with the JDBC specification, it only returns true if `closed()` has been called on the connection. If you need to determine if the connection is still valid, you should issue a simple query, such as “SELECT 1”. The driver will throw an exception if the connection is no longer valid.

- **DatabaseMetaData**

Foreign Key information (`getImported/ExportedKeys()` and `getCrossReference()`) is only available from 'InnoDB'-type tables. However, the driver uses 'SHOW CREATE TABLE' to retrieve this information, so when other storage engines support foreign keys, the driver will transparently support them as well.

- **Driver**

- **PreparedStatement**

PreparedStatements are implemented by the driver, as MySQL does not have a prepared statement feature. Because of this, the driver does not implement `getParameterMetaData()` or `getMetaData()` as it would require the driver to have a complete SQL parser in the client.

Starting with version 3.1.0 MySQL Connector/J, server-side prepared statements and 'binary-encoded' result sets are used when the server supports them.

Take care when using a server-side prepared statement with “large” parameters that are set via `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()`, or `setClob()`. If you want to re-execute the statement with any “large” parameter changed to a non-“large” parameter, it is necessary to call `clearParameters()` and set all parameters again. The reason for this is as follows:

- The driver streams the 'large' data 'out-of-band' to the prepared statement on the server side when the parameter is set (before execution of the prepared statement).
- Once that has been done, the stream used to read the data on the client side is closed (as per the JDBC spec), and can't be read from again.
- If a parameter changes from “large” to non-“large,” the driver must reset the server-side state of the prepared statement to allow the parameter that is being changed to take the place of the prior “large” value. This removes all of the 'large' data that has already been sent to the server, thus requiring the data to be re-sent, via the `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()` or `setClob()` methods.

Consequently, if you want to change the “type” of a parameter to a non-“large” one, you must call `clearParameters()` and set all parameters of the prepared statement again before it can be re-executed.

- **ResultSet**

---

By default, ResultSets are completely retrieved and stored in memory. In most cases this is the most efficient way to operate, and due to the design of the MySQL network protocol is easier to implement. If you are working with ResultSets that have a large number of rows or large values, and can not allocate heap space in your JVM for the memory required, you can tell the driver to 'stream' the results back one row at a time.

To enable this functionality, you need to create a Statement instance in the following manner:

```
stmt = conn.createStatement( java.sql.ResultSet.TYPE_FORWARD_ONLY,
                             java.sql.ResultSet.CONCUR_READ_ONLY );
stmt.setFetchSize( Integer.MIN_VALUE );
```

The combination of a forward-only, read-only result set, with a fetch size of `Integer.MIN_VALUE` serves as a signal to the driver to "stream" result sets row-by-row. After this any result sets created with the statement will be retrieved row-by-row.

There are some caveats with this approach. You will have to read all of the rows in the result set (or close it) before you can issue any other queries on the connection, or an exception will be thrown.

The earliest the locks these statements hold can be released (whether they be MyISAM table-level locks or row-level locks in some other storage engine such as InnoDB) is when the statement completes.

If the statement is within scope of a transaction, then locks are released when the transaction completes (which implies that the statement needs to complete first). As with most other databases, statements are not complete until all the results pending on the statement are read or the active result set for the statement is closed.

Therefore, if using "streaming" results, you should process them as quickly as possible if you want to maintain concurrent access to the tables referenced by the statement producing the result set.

- `ResultSetMetaData`

The `isAutoIncrement()` method only works when using MySQL servers 4.0 and newer.

- `Statement`

When using versions of the JDBC driver earlier than 3.2.1, and connected to server versions earlier than 5.0.3, the `setFetchSize()` method has no effect, other than to toggle result set streaming as described above.

MySQL does not support SQL cursors, and the JDBC driver doesn't emulate them, so `setCursorName()` has no effect.

### 23.3.3.3. Java, JDBC and MySQL Types

MySQL Connector/J is flexible in the way it handles conversions between MySQL data types and Java data types.

In general, any MySQL data type can be converted to a `java.lang.String`, and any numerical type can be converted to any of the Java numerical types, although round-off, overflow, or loss of precision may occur.

Starting with Connector/J 3.1.0, the JDBC driver will issue warnings or throw `DataTruncation` exceptions as is required by the JDBC specification unless the connection was configured not to do so by using the property `"jdbcCompliantTruncation"` and setting it to `"false"`.

The conversions that are always guaranteed to work are listed in the following table:

**Table 23.2. Conversion Table**

These MySQL Data Types	Can always be converted to these Java types
CHAR, VARCHAR, BLOB, TEXT, ENUM, and SET	java.lang.String, java.io.InputStream, java.io.Reader, java.sql.Blob, java.sql.Clob
FLOAT, REAL, DOUBLE PRECISION, NUMERIC, DECIMAL, TINYINT, SMALLINT, MEDIUMINT, INTEGER, BIGINT	java.lang.String, java.lang.Short, java.lang.Integer, java.lang.Long, java.lang.Double, java.math.BigDecimal  <b>Note</b>  round-off, overflow or loss of precision may occur if you choose a Java numeric data type that has less precision or capacity than the MySQL data type you are converting to/from.
DATE, TIME, DATETIME, TIMESTAMP	java.lang.String, java.sql.Date, java.sql.Timestamp

The `ResultSet.getObject()` method uses the following type conversions between MySQL and Java types, following the JDBC specification where appropriate:

**Table 23.3. MySQL Types to Java Types for `ResultSet.getObject()`**

MySQL Type Name	Returned as Java Class
BIT(1) (new in MySQL-5.0)	java.lang.Boolean
BIT(> 1) (new in MySQL-5.0)	byte[]
TINYINT	java.lang.Boolean if the configuration property "tinyIntIsBit" is set to "true" (the default) and the storage size is "1", or java.lang.Integer if not.
BOOL, BOOLEAN	See TINYINT, above as these are aliases for TINYINT(1), currently.
SMALLINT[(M)] [UNSIGNED]	java.lang.Integer (regardless if UNSIGNED or not)
MEDIUMINT[(M)] [UNSIGNED]	java.lang.Integer, if UNSIGNED java.lang.Long
INT, INTEGER[(M)] [UNSIGNED]	java.lang.Integer, if UNSIGNED java.lang.Long
BIGINT[(M)] [UNSIGNED]	java.lang.Long, if UNSIGNED java.math.BigInteger
FLOAT[(M,D)]	java.lang.Float
DOUBLE[(M,B)]	java.lang.Double
DECIMAL[(M[,D])]	java.math.BigDecimal
DATE	java.sql.Date
DATETIME	java.sql.Timestamp

MySQL Type Name	Returned as Java Class
TIMESTAMP[(M)]	<code>java.sql.Timestamp</code>
TIME	<code>java.sql.Time</code>
YEAR[(2 4)]	<code>java.sql.Date</code> (with the date set two January 1st, at midnight)
CHAR(M)	<code>java.lang.String</code> (unless the character set for the column is BINARY, then <code>byte[]</code> is returned).
VARCHAR(M) [BINARY]	<code>java.lang.String</code> (unless the character set for the column is BINARY, then <code>byte[]</code> is returned).
BINARY(M)	<code>byte[]</code>
VARBINARY(M)	<code>byte[]</code>
TINYBLOB	<code>byte[]</code>
TINYTEXT	<code>java.lang.String</code>
BLOB	<code>byte[]</code>
TEXT	<code>java.lang.String</code>
MEDIUMBLOB	<code>byte[]</code>
MEDIUMTEXT	<code>java.lang.String</code>
LOBLOB	<code>byte[]</code>
LONGTEXT	<code>java.lang.String</code>
ENUM('value1','value2',...)	<code>java.lang.String</code>
SET('value1','value2',...)	<code>java.lang.String</code>

### 23.3.3.4. Using Character Sets and Unicode

All strings sent from the JDBC driver to the server are converted automatically from native Java Unicode form to the client character encoding, including all queries sent via `Statement.execute()`, `Statement.executeUpdate()`, `Statement.executeQuery()` as well as all `PreparedStatement` and `CallableStatement` parameters with the exclusion of parameters set using `setBytes()`, `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()` and `setBlob()`.

Prior to MySQL Server 4.1, Connector/J supported a single character encoding per connection, which could either be automatically detected from the server configuration, or could be configured by the user through the `"useUnicode"` and `"characterEncoding"` properties.

Starting with MySQL Server 4.1, Connector/J supports a single character encoding between client and server, and any number of character encodings for data returned by the server to the client in `ResultSet`s.

The character encoding between client and server is automatically detected upon connection. The encoding used by the driver is specified on the server via the `character_set` system variable for server versions older than 4.1.0 and `character_set_server` for server versions 4.1.0 and newer. For more information, see Section 10.3.1, "Server Character Set and Collation".

To override the automatically-detected encoding on the client side, use the `characterEncoding` property in the URL used to connect to the server.

When specifying character encodings on the client side, Java-style names should be used. The following table lists Java-style names for MySQL character sets:

**Table 23.4. MySQL to Java Encoding Name Translations**

MySQL Character Set Name	Java-Style Character Encoding Name
usa7	US-ASCII
big5	Big5
gbk	GBK
sjis	SJIS (or Cp932 or MS932 for MySQL Server < 4.1.11)
cp932	Cp932 or MS932 (MySQL Server > 4.1.11)
gb2312	EUC_CN
ujis	EUC_JP
euc_kr	EUC_KR
latin1	ISO8859_1
latin1_de	ISO8859_1
german1	ISO8859_1
danish	ISO8859_1
latin2	ISO8859_2
czech	ISO8859_2
hungarian	ISO8859_2
croat	ISO8859_2
greek	ISO8859_7
hebrew	ISO8859_8
latin5	ISO8859_9
latvian	ISO8859_13
latvian1	ISO8859_13
estonia	ISO8859_13
dos	Cp437
platin2	Cp852
cp866	Cp866
koi8_ru	KOI8_R
tis620	TIS620
win1250	Cp1250
win1250ch	Cp1250
win1251	Cp1251
cp1251	Cp1251
win1251ukr	Cp1251
cp1257	Cp1257
macroman	MacRoman
macce	MacCentralEurope
utf8	UTF-8
ucs2	UnicodeBig

## Warning

Do not issue the query 'set names' with Connector/J, as the driver will not detect that the character set has changed, and will continue to use the character set detected during the initial connection setup.

To allow multiple character sets to be sent from the client, the "UTF-8" encoding should be used,

either by configuring "utf8" as the default server character set, or by configuring the JDBC driver to use "UTF-8" through the *characterEncoding* property.

### 23.3.3.5. Connecting Securely Using SSL

SSL in MySQL Connector/J encrypts all data (other than the initial handshake) between the JDBC driver and the server. The performance penalty for enabling SSL is an increase in query processing time between 35% and 50%, depending on the size of the query, and the amount of data it returns.

For SSL Support to work, you must have the following:

- A JDK that includes JSSE (Java Secure Sockets Extension), like JDK-1.4.1 or newer. SSL does not currently work with a JDK that you can add JSSE to, like JDK-1.2.x or JDK-1.3.x due to the following JSSE bug: <http://developer.java.sun.com/developer/bugParade/bugs/4273544.html>
- A MySQL server that supports SSL and has been compiled and configured to do so, which is MySQL-4.0.4 or later, see: <http://www.mysql.com/doc/en/secure-connections.html>
- A client certificate (covered later in this section)

You will first need to import the MySQL server CA Certificate into a Java truststore. A sample MySQL server CA Certificate is located in the 'SSL' subdirectory of the MySQL source distribution. This is what SSL will use to determine if you are communicating with a secure MySQL server.

To use Java's 'keytool' to create a truststore in the current directory, and import the server's CA certificate ('cacert.pem'), you can do the following (assuming that 'keytool' is in your path. It's located in the 'bin' subdirectory of your JDK or JRE):

```
shell> keytool -import -alias mysqlServerCACert -file cacert.pem -keystore truststore
```

Keytool will respond with the following information:

```
Enter keystore password: *****
Owner: EMAILADDRESS=walrus@example.com, CN=Walrus, O=MySQL AB, L=Orenburg, ST=State, C=RU
Issuer: EMAILADDRESS=walrus@example.com, CN=Walrus, O=MySQL AB, L=Orenburg, ST=State, C=RU
Serial number: 0
Valid from: Fri Aug 02 16:55:53 CDT 2002 until: Sat Aug 02 16:55:53 CDT 2003
Certificate fingerprints:
    MD5: 61:91:A0:F2:03:07:61:7A:81:38:66:DA:19:C4:8D:AB
    SHA1: 25:77:41:05:D5:AD:99:8C:14:8C:CA:68:9C:2F:B8:89:C3:34:4D:6C
Trust this certificate? [no]: yes
Certificate was added to keystore
```

You will then need to generate a client certificate, so that the MySQL server knows that it is talking to a secure client:

```
shell> keytool -genkey -keyalg rsa -alias mysqlClientCertificate -keystore keystore
```

Keytool will prompt you for the following information, and create a keystore named 'keystore' in the current directory.

You should respond with information that is appropriate for your situation:

```
Enter keystore password: *****
What is your first and last name?
[Unknown]: Matthews
What is the name of your organizational unit?
```

```

[Unknown]: Software Development
What is the name of your organization?
[Unknown]: MySQL AB
What is the name of your City or Locality?
[Unknown]: Flossmoor
What is the name of your State or Province?
[Unknown]: IL
What is the two-letter country code for this unit?
[Unknown]: US
Is <CN=Matthews, OU=Software Development, O=MySQL AB,
L=Flossmoor, ST=IL, C=US> correct?
[no]: y

Enter key password for <mysqlClientCertificate>
(RETURN if same as keystore password):

```

Finally, to get JSSE to use the keystore and truststore that you have generated, you need to set the following system properties when you start your JVM, replacing 'path\_to\_keystore\_file' with the full path to the keystore file you created, 'path\_to\_truststore\_file' with the path to the truststore file you created, and using the appropriate password values for each property.

```

-Djavax.net.ssl.keyStore=path_to_keystore_file
-Djavax.net.ssl.keyStorePassword=*****
-Djavax.net.ssl.trustStore=path_to_truststore_file
-Djavax.net.ssl.trustStorePassword=*****

```

You will also need to set 'useSSL' to 'true' in your connection parameters for MySQL Connector/J, either by adding 'useSSL=true' to your URL, or by setting the property 'useSSL' to 'true' in the java.util.Properties instance you pass to DriverManager.getConnection().

You can test that SSL is working by turning on JSSE debugging (as detailed below), and look for the following key events:

```

...

...

```

JSSE provides debugging (to STDOUT) when you set the following system property: -

Djavax.net.debug=all This will tell you what keystores and truststores are being used, as well as what is going on during the SSL handshake and certificate exchange. It will be helpful when trying to determine what is not working when trying to get an SSL connection to happen.

### 23.3.3.6. Using Master/Slave Replication with ReplicationConnection

Starting with Connector/J 3.1.7, we've made available a variant of the driver that will automatically send queries to a read/write master, or a failover or round-robin loadbalanced set of slaves based on the state of `Connection.getReadOnly()`.

An application signals that it wants a transaction to be read-only by calling `Connection.setReadOnly(true)`, this "replication-aware" connection will use one of the slave connections, which are load-balanced per-vm using a round-robin scheme (a given connection is "sticky" to a slave unless that slave is removed from service). If you have a write transaction, or if you have a read that is "time-sensitive" (remember, replication in MySQL is asynchronous), set the connection to be not read-only, by calling `Connection.setReadOnly(false)` and the driver will ensure that further calls are sent to the "master" MySQL server. The driver takes care of propagating the current state of autocommit, isolation level, and catalog between all of the connections that it uses to accomplish this load balancing functionality.

To enable this functionality, use the `com.mysql.jdbc.ReplicationDriver` class when configuring your application server's connection pool or when creating an instance of a JDBC driver for your standalone application. Because it accepts the same URL format as the standard MySQL JDBC driver, `ReplicationDriver` does not currently work with `java.sql.DriverManager`-based connection creation unless it is the only MySQL JDBC driver registered with the `DriverManager`.

Here is a short, simple example of how `ReplicationDriver` might be used in a standalone application.

```
import java.sql.Connection;
import java.sql.ResultSet;
import java.util.Properties;

import com.mysql.jdbc.ReplicationDriver;

public class ReplicationDriverDemo {

    public static void main(String[] args) throws Exception {
        ReplicationDriver driver = new ReplicationDriver();

        Properties props = new Properties();

        // We want this for failover on the slaves
        props.put("autoReconnect", "true");

        // We want to load balance between the slaves
        props.put("roundRobinLoadBalance", "true");

        props.put("user", "foo");
        props.put("password", "bar");

        //
        // Looks like a normal MySQL JDBC url, with a comma-separated list
        // of hosts, the first being the 'master', the rest being any number
        // of slaves that the driver will load balance against
        //

        Connection conn =
            driver.connect("jdbc:mysql://master,slave1,slave2,slave3/test",
                props);

        //
        // Perform read/write work on the master
        // by setting the read-only flag to "false"
    }
}
```

```
//  
  
conn.setReadOnly(false);  
conn.setAutoCommit(false);  
conn.createStatement().executeUpdate("UPDATE some_table ....");  
conn.commit();  
  
//  
// Now, do a query from a slave, the driver automatically picks one  
// from the list  
//  
  
conn.setReadOnly(true);  
  
ResultSet rs = conn.createStatement().executeQuery("SELECT a,b,c FROM s  
.....  
} }  
}
```

## 23.3.4. Using Connector/J with J2EE and Other Java Frameworks

This section describes how to use Connector/J in several contexts.

### 23.3.4.1. General J2EE Concepts

This section provides general background on J2EE concepts that pertain to use of Connector/J.

#### 23.3.4.1.1. Understanding Connection Pooling

Connection pooling is a technique of creating and managing a pool of connections that are ready for use by any thread that needs them.

This technique of “pooling” connections is based on the fact that most applications only need a thread to have access to a JDBC connection when they are actively processing a transaction, which usually take only milliseconds to complete. When not processing a transaction, the connection would otherwise sit idle. Instead, connection pooling allows the idle connection to be used by some other thread to do useful work.

In practice, when a thread needs to do work against a MySQL or other database with JDBC, it requests a connection from the pool. When the thread is finished using the connection, it returns it to the pool, so that it may be used by any other threads that want to use it.

When the connection is “loaned out” from the pool, it is used exclusively by the thread that requested it. From a programming point of view, it is the same as if your thread called `DriverManager.getConnection()` every time it needed a JDBC connection, however with connection pooling, your thread may end up using either a new, or already-existing connection.

Connection pooling can greatly increase the performance of your Java application, while reducing overall resource usage. The main benefits to connection pooling are:

- Reduced connection creation time

Although this is not usually an issue with the quick connection setup that MySQL offers compared to other databases, creating new JDBC connections still incurs networking and JDBC driver overhead that will be avoided if connections are “recycled.”

- Simplified programming model

When using connection pooling, each individual thread can act as though it has created its own

JDBC connection, allowing you to use straight-forward JDBC programming techniques.

- Controlled resource usage

If you don't use connection pooling, and instead create a new connection every time a thread needs one, your application's resource usage can be quite wasteful and lead to unpredictable behavior under load.

Remember that each connection to MySQL has overhead (memory, CPU, context switches, and so forth) on both the client and server side. Every connection limits how many resources there are available to your application as well as the MySQL server. Many of these resources will be used whether or not the connection is actually doing any useful work!

Connection pools can be tuned to maximize performance, while keeping resource utilization below the point where your application will start to fail rather than just run slower.

Luckily, Sun has standardized the concept of connection pooling in JDBC through the JDBC-2.0 "Optional" interfaces, and all major application servers have implementations of these APIs that work fine with MySQL Connector/J.

Generally, you configure a connection pool in your application server configuration files, and access it via the Java Naming and Directory Interface (JNDI). The following code shows how you might use a connection pool from an application deployed in a J2EE application server:

### **Example 23.12. Using a Connection Pool with a J2EE Application Server**

```
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;

import javax.naming.InitialContext;
import javax.sql.DataSource;

public class MyServletJspOrEjb {

    public void doSomething() throws Exception {
        /*
         * Create a JNDI Initial context to be able to
         * lookup the DataSource
         *
         * In production-level code, this should be cached as
         * an instance or static variable, as it can
         * be quite expensive to create a JNDI context.
         *
         * Note: This code only works when you are using servlets
         * or EJBs in a J2EE application server. If you are
         * using connection pooling in standalone Java code, you
         * will have to create/configure datasources using whatever
         * mechanisms your particular connection pooling library
         * provides.
         */

        InitialContext ctx = new InitialContext();

        /*
         * Lookup the DataSource, which will be backed by a pool
         * that the application server provides. DataSource instances
         * are also a good candidate for caching as an instance
         * variable, as JNDI lookups can be expensive as well.
         */

        DataSource ds = (DataSource)ctx.lookup("java:comp/env/jdbc/MySQLDB");
```

```

/*
 * The following code is what would actually be in your
 * Servlet, JSP or EJB 'service' method...where you need
 * to work with a JDBC connection.
 */

Connection conn = null;
Statement stmt = null;

try {
    conn = ds.getConnection();

    /*
     * Now, use normal JDBC programming to work with
     * MySQL, making sure to close each resource when you're
     * finished with it, which allows the connection pool
     * resources to be recovered as quickly as possible
     */

    stmt = conn.createStatement();
    stmt.execute("SOME SQL QUERY");

    stmt.close();
    stmt = null;

    conn.close();
    conn = null;
} finally {
    /*
     * close any jdbc instances here that weren't
     * explicitly closed during normal code path, so
     * that we don't 'leak' resources...
     */

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException sqlex) {
            // ignore -- as we can't do anything about it here
        }

        stmt = null;
    }

    if (conn != null) {
        try {
            conn.close();
        } catch (SQLException sqlex) {
            // ignore -- as we can't do anything about it here
        }

        conn = null;
    }
}
}
}
}
}

```

As shown in the example above, after obtaining the JNDI InitialContext, and looking up the DataSource, the rest of the code should look familiar to anyone who has done JDBC programming in the past.

The most important thing to remember when using connection pooling is to make sure that no matter what happens in your code (exceptions, flow-of-control, and so forth), connections, and anything created by them (such as statements or result sets) are closed, so that they may be re-used, otherwise they will be “stranded,” which in the best case means that the MySQL server resources they represent (such as buffers, locks, or sockets) may be tied up for some time, or worst case, may be tied up

forever.

#### What's the Best Size for my Connection Pool?

As with all other configuration rules-of-thumb, the answer is "It depends." Although the optimal size depends on anticipated load and average database transaction time, the optimum connection pool size is smaller than you might expect. If you take Sun's Java Petstore blueprint application for example, a connection pool of 15-20 connections can serve a relatively moderate load (600 concurrent users) using MySQL and Tomcat with response times that are acceptable.

To correctly size a connection pool for your application, you should create load test scripts with tools such as Apache JMeter or The Grinder, and load test your application.

An easy way to determine a starting point is to configure your connection pool's maximum number of connections to be "unbounded," run a load test, and measure the largest amount of concurrently used connections. You can then work backward from there to determine what values of minimum and maximum pooled connections give the best performance for your particular application.

### 23.3.4.2. Using Connector/J with Tomcat

The following instructions are based on the instructions for Tomcat-5.x, available at <http://jakarta.apache.org/tomcat/tomcat-5.0-doc/jndi-datasource-examples-howto.html> which is current at the time this document was written.

First, install the .jar file that comes with Connector/J in `$CATALINA_HOME/common/lib` so that it is available to all applications installed in the container.

Next, Configure the JNDI DataSource by adding a declaration resource to `$CATALINA_HOME/conf/server.xml` in the context that defines your web application:

```
<Context ....>
  ...
  <Resource name="jdbc/MySQLDB"
            auth="Container"
            type="javax.sql.DataSource"/>

  <!-- The name you used above, must match _exactly_ here!

         The connection pool will be bound into JNDI with the name
         "java:/comp/env/jdbc/MySQLDB"
  -->

  <ResourceParams name="jdbc/MySQLDB">
    <parameter>
      <name>factory</name>
      <value>org.apache.commons.dbcp.BasicDataSourceFactory</value>
    </parameter>

    <!-- Don't set this any higher than max_connections on your
         MySQL server, usually this should be a 10 or a few 10's
         of connections, not hundreds or thousands -->

    <parameter>
      <name>maxActive</name>
      <value>10</value>
    </parameter>

    <!-- You don't want to many idle connections hanging around
         if you can avoid it, only enough to soak up a spike in
         the load -->

    <parameter>
      <name>maxIdle</name>
      <value>5</value>
```

```
</parameter>

<!-- Don't use autoReconnect=true, it's going away eventually
and it's a crutch for older connection pools that couldn't
test connections. You need to decide whether your application is
supposed to deal with SQLExceptions (hint, it should), and
how much of a performance penalty you're willing to pay
to ensure 'freshness' of the connection -->

<parameter>
  <name>validationQuery</name>
  <value>SELECT 1</value>
</parameter>

<!-- The most conservative approach is to test connections
before they're given to your application. For most applications
this is okay, the query used above is very small and takes
no real server resources to process, other than the time used
to traverse the network.

If you have a high-load application you'll need to rely on
something else. -->

<parameter>
  <name>testOnBorrow</name>
  <value>true</value>
</parameter>

<!-- Otherwise, or in addition to testOnBorrow, you can test
while connections are sitting idle -->

<parameter>
  <name>testWhileIdle</name>
  <value>true</value>
</parameter>

<!-- You have to set this value, otherwise even though
you've asked connections to be tested while idle,
the idle evicter thread will never run -->

<parameter>
  <name>timeBetweenEvictionRunsMillis</name>
  <value>10000</value>
</parameter>

<!-- Don't allow connections to hang out idle too long,
never longer than what wait_timeout is set to on the
server...A few minutes or even fraction of a minute
is sometimes okay here, it depends on your application
and how much spikey load it will see -->

<parameter>
  <name>minEvictableIdleTimeMillis</name>
  <value>60000</value>
</parameter>

<!-- Username and password used when connecting to MySQL -->

<parameter>
  <name>username</name>
  <value>someuser</value>
</parameter>

<parameter>
  <name>password</name>
  <value>somepass</value>
</parameter>

<!-- Class name for the Connector/J driver -->
```

```

<parameter>
  <name>driverClassName</name>
  <value>com.mysql.jdbc.Driver</value>
</parameter>

<!-- The JDBC connection url for connecting to MySQL, notice
that if you want to pass any other MySQL-specific parameters
you should pass them here in the URL, setting them using the
parameter tags above will have no effect, you will also
need to use &amp; to separate parameter values as the
ampersand is a reserved character in XML -->

<parameter>
  <name>url</name>
  <value>jdbc:mysql://localhost:3306/test</value>
</parameter>

</ResourceParams>
</Context>

```

In general, you should follow the installation instructions that come with your version of Tomcat, as the way you configure datasources in Tomcat changes from time-to-time, and unfortunately if you use the wrong syntax in your XML file, you will most likely end up with an exception similar to the following:

```
Error: java.sql.SQLException: Cannot load JDBC driver class 'null ' SQL
state: null
```

### 23.3.4.3. Using Connector/J with JBoss

These instructions cover JBoss-4.x. To make the JDBC driver classes available to the application server, copy the .jar file that comes with Connector/J to the lib directory for your server configuration (which is usually called "default"). Then, in the same configuration directory, in the subdirectory named "deploy," create a datasource configuration file that ends with "-ds.xml", which tells JBoss to deploy this file as a JDBC Datasource. The file should have the following contents:

```

<datasources>
  <local-tx-datasource>
    <!-- This connection pool will be bound into JNDI with the name
         "java:/MySQLDB" -->

    <jndi-name>MySQLDB</jndi-name>
    <connection-url>jdbc:mysql://localhost:3306/dbname</connection-url>
    <driver-class>com.mysql.jdbc.Driver</driver-class>
    <user-name>user</user-name>
    <password>pass</password>

    <min-pool-size>5</min-pool-size>

    <!-- Don't set this any higher than max_connections on your
         MySQL server, usually this should be a 10 or a few 10's
         of connections, not hundreds or thousands -->

    <max-pool-size>20</max-pool-size>

    <!-- Don't allow connections to hang out idle too long,
         never longer than what wait_timeout is set to on the
         server...A few minutes is usually okay here,
         it depends on your application
         and how much spikey load it will see -->

    <idle-timeout-minutes>5</idle-timeout-minutes>

    <!-- If you're using Connector/J 3.1.8 or newer, you can use

```

```
our implementation of these to increase the robustness
of the connection pool. -->

<exception-sorter-class-name>com.mysql.jdbc.integration.jboss.ExtendedM
<valid-connection-checker-class-name>com.mysql.jdbc.integration.jboss.M

</local-tx-datasource>
</datasources>
```

## 23.3.5. Diagnosing Connector/J Problems

This section describes how to solve problems that you may encounter when using Connector/J.

### 23.3.5.1. Common Problems and Solutions

There are a few issues that seem to be commonly encountered often by users of MySQL Connector/J. This section deals with their symptoms, and their resolutions.

#### 24.3.5.1.1:

Question:

When I try to connect to the database with MySQL Connector/J, I get the following exception:

```
SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0
```

What's going on? I can connect just fine with the MySQL command-line client.

Answer:

MySQL Connector/J must use TCP/IP sockets to connect to MySQL, as Java does not support Unix Domain Sockets. Therefore, when MySQL Connector/J connects to MySQL, the security manager in MySQL server will use its grant tables to determine whether the connection should be allowed.

You must add grants to allow this to happen. The following is an example of how to do this (but not the most secure).

From the `mysql` command-line client, logged in as a user that can grant privileges, issue the following command:

```
GRANT ALL PRIVILEGES ON [dbname].* to
    '[user]@[hostname]' identified by
    '[password]'
```

replacing `[dbname]` with the name of your database, `[user]` with the user name, `[hostname]` with the host that MySQL Connector/J will be connecting from, and `[password]` with the password you want to use. Be aware that RedHat Linux is broken with respect to the hostname portion for the case when you are connecting from localhost. You need to use "localhost.localdomain" for the `[hostname]` value in this case. Follow this by issuing the "FLUSH PRIVILEGES" command.

### Note

Testing your connectivity with the `mysql` command-line client will not work unless you add the `--host` flag, and use something other than `localhost` for the host. The `mysql` command-line client will use Unix domain sockets if you use the special hostname `localhost`. If you are testing connectivity to `localhost`, use `127.0.0.1` as the host-name instead.

## Warning

If you don't understand what the 'GRANT' command does, or how it works, you should read and understand the 'General Security Issues and the MySQL Access Privilege System' [[http://www.mysql.com/doc/en/Privilege\\_system.html](http://www.mysql.com/doc/en/Privilege_system.html)] section of the MySQL manual before attempting to change privileges.

Changing privileges and permissions improperly in MySQL can potentially cause your server installation to not have optimal security properties.

### 24.3.5.1.2:

Question:

My application throws an SQLException 'No Suitable Driver'. Why is this happening?

Answer:

One of two things are happening. Either the driver is not in your CLASSPATH or your URL format is incorrect (see the Section 23.3.2, "Installing Connector/J" section.).

### 24.3.5.1.3:

Question:

I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```
SQLException: Cannot connect to MySQL server on host:3306.  
Is there a MySQL server running on the machine/port you  
are trying to connect to?
```

```
(java.security.AccessControlException)  
SQLState: 08S01  
VendorError: 0
```

Answer:

Either you're running an Applet, your MySQL server has been installed with the "--skip-networking" option set, or your MySQL server has a firewall sitting in front of it.

Applets can only make network connections back to the machine that runs the web server that served the .class files for the applet. This means that MySQL must run on the same machine (or you must have some sort of port re-direction) for this to work. This also means that you will not be able to test applets from your local file system, you must always deploy them to a web server.

MySQL Connector/J can only communicate with MySQL using TCP/IP, as Java does not support Unix domain sockets. TCP/IP communication with MySQL might be affected if MySQL was started with the "--skip-networking" flag, or if it is firewalled.

If MySQL has been started with the "--skip-networking" option set (the Debian Linux package of MySQL server does this for example), you need to comment it out in the file /etc/mysql/my.cnf or /etc/my.cnf. Of course your my.cnf file might also exist in the data directory of your MySQL server, or anywhere else (depending on how MySQL was compiled for your system). Binaries created by MySQL AB always look in /etc/my.cnf and [datadir]/my.cnf. If your MySQL server has been firewalled, you will need to have the firewall configured to allow TCP/IP connections from the host where your Java code is running to the MySQL server on the port that MySQL is listening to (by default, 3306).

### 24.3.5.1.4:

Question:

I have a servlet/application that works fine for a day, and then stops working overnight

Answer:

MySQL closes connections after 8 hours of inactivity. You either need to use a connection pool that handles stale connections or use the "autoReconnect" parameter (see Section 23.3.3.1, "Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J").

Also, you should be catching SQLExceptions in your application and dealing with them, rather than propagating them all the way until your application exits, this is just good programming practice. MySQL Connector/J will set the SQLState (see `java.sql.SQLException.getSQLState()` in your APIDocs) to "08S01" when it encounters network-connectivity issues during the processing of a query. Your application code should then attempt to re-connect to MySQL at this point.

The following (simplistic) example shows what code that can handle these exceptions might look like:

### Example 23.13. Example of transaction with retry logic

```
public void doBusinessOp() throws SQLException {
    Connection conn = null;
    Statement stmt = null;
    ResultSet rs = null;

    //
    // How many times do you want to retry the transaction
    // (or at least _getting_ a connection)?
    //
    int retryCount = 5;

    boolean transactionCompleted = false;

    do {
        try {
            conn = getConnection(); // assume getting this from a
                                   // javax.sql.DataSource, or the
                                   // java.sql.DriverManager

            conn.setAutoCommit(false);

            //
            // Okay, at this point, the 'retry-ability' of the
            // transaction really depends on your application logic,
            // whether or not you're using autocommit (in this case
            // not), and whether you're using transactional storage
            // engines
            //
            // For this example, we'll assume that it's _not_ safe
            // to retry the entire transaction, so we set retry count
            // to 0 at this point
            //
            // If you were using exclusively transaction-safe tables,
            // or your application could recover from a connection going
            // bad in the middle of an operation, then you would not
            // touch 'retryCount' here, and just let the loop repeat
            // until retryCount == 0.
            //
            retryCount = 0;

            stmt = conn.createStatement();

            String query = "SELECT foo FROM bar ORDER BY baz";

            rs = stmt.executeQuery(query);

            while (rs.next()) {
```

```
    }

    rs.close();
    rs = null;

    stmt.close();
    stmt = null;

    conn.commit();
    conn.close();
    conn = null;

    transactionCompleted = true;
} catch (SQLException sqlEx) {

    //
    // The two SQL states that are 'retry-able' are 08S01
    // for a communications error, and 40001 for deadlock.
    //
    // Only retry if the error was due to a stale connection,
    // communications problem or deadlock
    //
    String sqlState = sqlEx.getSQLState();

    if ("08S01".equals(sqlState) || "40001".equals(sqlState)) {
        retryCount--;
    } else {
        retryCount = 0;
    }
} finally {
    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException sqlEx) {
            // You'd probably want to log this . . .
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException sqlEx) {
            // You'd probably want to log this as well . . .
        }
    }

    if (conn != null) {
        try {
            //
            // If we got here, and conn is not null, the
            // transaction should be rolled back, as not
            // all work has been done

            try {
                conn.rollback();
            } finally {
                conn.close();
            }
        } catch (SQLException sqlEx) {
            //
            // If we got an exception here, something
            // pretty serious is going on, so we better
            // pass it up the stack, rather than just
            // logging it. . .

            throw sqlEx;
        }
    }
}
```

```
    }  
  } while (!transactionCompleted && (retryCount > 0));  
}
```

#### 24.3.5.1.5:

Question:

I'm trying to use JDBC-2.0 updatable result sets, and I get an exception saying my result set is not updatable.

Answer:

Because MySQL does not have row identifiers, MySQL Connector/J can only update result sets that have come from queries on tables that have at least one primary key, the query must select every primary key and the query can only span one table (that is, no joins). This is outlined in the JDBC specification.

### 23.3.5.2. How to Report Connector/J Bugs or Problems

The normal place to report bugs is <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public, and can be browsed and searched by anyone. If you log in to the system, you will also be able to enter new reports.

If you have found a sensitive security bug in MySQL, you can send email to [security@mysql.com](mailto:security@mysql.com) [mailto:security@mysql.com].

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release.

This section will help you write your report correctly so that you don't waste your time doing things that may not help us much or at all.

If you have a repeatable bug report, please report it to the bugs database at <http://bugs.mysql.com/>.

Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

To report other problems, you can use one of the MySQL mailing lists.

Remember that it is possible for us to respond to a message containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details don't matter.

A good principle is this: If you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of Connector/J or MySQL used, and (b) not fully describing the platform on which Connector/J is installed (including the JVM version, and the platform type and version number that MySQL itself is installed on).

This is highly relevant information, and in 99 cases out of 100, the bug report is useless without it. Very often we get questions like, "Why doesn't this work for me?" Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has already been fixed in newer MySQL versions.

Sometimes the error is platform-dependent; in such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If at all possible, you should create a repeatable, standalone testcase that doesn't involve any third-

party classes.

To streamline this process, we ship a base class for testcases with Connector/J, named `com.mysql.jdbc.util.BaseBugReport`. To create a testcase for Connector/J using this class, create your own class that inherits from `com.mysql.jdbc.util.BaseBugReport` and override the methods `setUp()`, `tearDown()` and `runTest()`.

In the `setUp()` method, create code that creates your tables, and populates them with any data needed to demonstrate the bug.

In the `runTest()` method, create code that demonstrates the bug using the tables and data you created in the `setUp` method.

In the `tearDown()` method, drop any tables you created in the `setUp()` method.

In any of the above three methods, you should use one of the variants of the `getConnection()` method to create a JDBC connection to MySQL:

- `getConnection()` - Provides a connection to the JDBC URL specified in `getUrl()`. If a connection already exists, that connection is returned, otherwise a new connection is created.
- `getNewConnection()` - Use this if you need to get a new connection for your bug report (i.e. there's more than one connection involved).
- `getConnection(String url)` - Returns a connection using the given URL.
- `getConnection(String url, Properties props)` - Returns a connection using the given URL and properties.

If you need to use a JDBC URL that is different from `'jdbc:mysql:///test'`, override the method `getUrl()` as well.

Use the `assertTrue(boolean expression)` and `assertTrue(String failureMessage, boolean expression)` methods to create conditions that must be met in your testcase demonstrating the behavior you are expecting (vs. the behavior you are observing, which is why you are most likely filing a bug report).

Finally, create a `main()` method that creates a new instance of your testcase, and calls the `run` method:

```
public static void main(String[] args) throws Exception {
    new MyBugReport().run();
}
```

Once you have finished your testcase, and have verified that it demonstrates the bug you are reporting, upload it with your bug report to <http://bugs.mysql.com/>.

## 23.3.6. MySQL Connector/J Change History

### 23.3.6.1. Changes in MySQL Connector/J 5.0.0-beta (22 December 2005)

- `XADataSource` implemented (ported from 3.2 branch which won't be released as a product). Use `com.mysql.jdbc.jdbc2.optional.MysqlXADataSource` as your datasource class name in your application server to utilize XA transactions in MySQL-5.0.10 and newer.
- `PreparedStatement.setString()` didn't work correctly when `sql_mode` on server contained `NO_BACKSLASH_ESCAPES` and no characters that needed escaping were present in the string.

- Attempt detection of the MySQL type `BINARY` (it's an alias, so this isn't always reliable), and use the `java.sql.Types.BINARY` type mapping for it.
- Moved `-bin-g.jar` file into separate debug subdirectory to avoid confusion.
- Don't allow `.setAutoCommit(true)`, or `.commit()` or `.rollback()` on an XA-managed connection as per the JDBC specification.
- If the connection `useTimezone` is set to `true`, then also respect time zone conversions in escape-processed string literals (e.g. `"{ts ...}"` and `"{t ...}"`).
- Return original column name for `RSMD.getColumnNames()` if the column was aliased, alias name for `.getColumnLabel()` (if aliased), and original table name for `.getTableName()`. Note this only works for MySQL-4.1 and newer, as older servers don't make this information available to clients.
- Setting `useJDBCCompliantTimezoneShift=true` (it's not the default) causes the driver to use GMT for *all* `TIMESTAMP/DATETIME` time zones, and the current VM time zone for any other type that refers to time zones. This feature can not be used when `useTimezone=true` to convert between server and client time zones.
- Add one level of indirection of internal representation of `CallableStatement` parameter metadata to avoid class not found issues on JDK-1.3 for `ParameterMetadata` interface (which doesn't exist prior to JDBC-3.0).
- Added unit tests for `XADatasource`, as well as friendlier exceptions for XA failures compared to the "stock" `XAException` (which has no messages).
- Idle timeouts cause `XAConnections` to whine about rolling themselves back. (Bug#14729 [<http://bugs.mysql.com/14729>])
- Added support for Connector/MXJ integration via url subprotocol `jdbc:mysql:mxj://...`
- Moved all `SQLException` constructor usage to a factory in `SQLException` (ground-work for JDBC-4.0 `SQLState`-based exception classes).
- Removed Java5-specific calls to `BigDecimal` constructor (when result set value is `''`, `(int)0` was being used as an argument indirectly via method return value. This signature doesn't exist prior to Java5.)
- Added service-provider entry to `META-INF/services/java.sql.Driver` for JDBC-4.0 support.
- Return `"[VAR]BINARY"` for `RSMD.getColumnTypeName()` when that is actually the type, and it can be distinguished (MySQL-4.1 and newer).
- When fix for Bug#14562 [<http://bugs.mysql.com/14562>] was merged from 3.1.12, added functionality for `CallableStatement`'s parameter metadata to return correct information for `.getParameterClassName()`.
- Fuller synchronization of `Connection` to avoid deadlocks when using multithreaded frameworks that multithread a single connection (usually not recommended, but the JDBC spec allows it anyways), part of fix to Bug#14972 [<http://bugs.mysql.com/14972>]).
- Implementation of `Statement.cancel()` and `Statement.setQueryTimeout()`. Both require MySQL-5.0.0 or newer server, require a separate connection to issue the `KILL QUERY` statement, and in the case of `setQueryTimeout()` creates an additional thread to handle the timeout functionality.

Note: Failures to cancel the statement for `setQueryTimeout()` may manifest themselves as `RuntimeExceptions` rather than failing silently, as there is currently no way to unblock the thread that is executing the query being cancelled due to timeout expiration and have it throw the

exception instead.

### 23.3.6.2. Changes in MySQL Connector/J 3.1.13 (xx xxx 2005)

- `INOUT` parameter does not store `IN` value. (Bug#15464 [<http://bugs.mysql.com/15464>])
- Exception thrown for new decimal type when using updatable result sets. (Bug#14609 [<http://bugs.mysql.com/14609>])
- No "dos" character set in MySQL > 4.1.0. (Bug#15544 [<http://bugs.mysql.com/15544>])
- `PreparedStatement.setObject()` serializes `BigInteger` as object, rather than sending as numeric value (and is thus not complementary to `getObject()` on an `UNSIGNED LONG` type). (Bug#15383 [<http://bugs.mysql.com/15383>])
- `ResultSet.getShort()` for `UNSIGNED TINYINT` returned wrong values. (Bug#11874 [<http://bugs.mysql.com/11874>])
- `lib-nodist` directory missing from package breaks out-of-box build. (Bug#15676 [<http://bugs.mysql.com/15676>])
- `DBMD.getColumns()` returns wrong type for `BIT`. (Bug#15854 [<http://bugs.mysql.com/15854>])

### 23.3.6.3. Changes in MySQL Connector/J 3.1.12 (30 November 2005)

- Fixed client-side prepared statement bug with embedded `?` characters inside quoted identifiers (it was recognized as a placeholder, when it was not).
- Don't allow `executeBatch()` for `CallableStatements` with registered `OUT/INOUT` parameters (JDBC compliance).
- Fall back to platform-encoding for `URLDecoder.decode()` when parsing driver URL properties if the platform doesn't have a two-argument version of this method.
- Java type conversion may be incorrect for `MEDIUMINT`. (Bug#14562 [<http://bugs.mysql.com/14562>])
- Added configuration property `useGmtMillisForDatetimes` which when set to `true` causes `ResultSet.getDate()`, `ResultSet.getTimestamp()` to return correct millis-since GMT when `ResultSet.getTime()` is called on the return value (currently default is `false` for legacy behavior).
- Fixed `DatabaseMetaData.stores*Identifiers()`:
  - If `lower_case_table_names=0` (on server):
    - `storesLowerCaseIdentifiers()` returns `false`
    - `storesLowerCaseQuotedIdentifiers()` returns `false`
    - `storesMixedCaseIdentifiers()` returns `true`
    - `storesMixedCaseQuotedIdentifiers()` returns `true`
    - `storesUpperCaseIdentifiers()` returns `false`
    - `storesUpperCaseQuotedIdentifiers()` returns `true`

- If `lower_case_table_names=1` (on server):
  - `storesLowerCaseIdentifiers()` returns true
  - `storesLowerCaseQuotedIdentifiers()` returns true
  - `storesMixedCaseIdentifiers()` returns false
  - `storesMixedCaseQuotedIdentifiers()` returns false
  - `storesUpperCaseIdentifiers()` returns false
  - `storesUpperCaseQuotedIdentifiers()` returns true
- `DatabaseMetaData.getColumns()` doesn't return `TABLE_NAME` correctly. (Bug#14815 [<http://bugs.mysql.com/14815>])
- Escape processor replaces quote character in quoted string with string delimiter. (Bug#14909 [<http://bugs.mysql.com/14909>])
- `OpenOffice` expects `DBMD.supportsIntegrityEnhancementFacility()` to return true if foreign keys are supported by the datasource, even though this method also covers support for check constraints, which MySQL *doesn't* have. Setting the configuration property `overrideSupportsIntegrityEnhancementFacility` to true causes the driver to return true for this method. (Bug#12975 [<http://bugs.mysql.com/12975>])
- Added `com.mysql.jdbc.testsuite.url.default` system property to set default JDBC url for testsuite (to speed up bug resolution when I'm working in Eclipse).
- Unable to initialize character set mapping tables (due to J2EE classloader differences). (Bug#14938 [<http://bugs.mysql.com/14938>])
- Deadlock while closing server-side prepared statements from multiple threads sharing one connection. (Bug#14972 [<http://bugs.mysql.com/14972>])
- `logSlowQueries` should give better info. (Bug#12230 [<http://bugs.mysql.com/12230>])
- Extraneous sleep on `autoReconnect`. (Bug#13775 [<http://bugs.mysql.com/13775>])
- Driver incorrectly closes streams passed as arguments to `PreparedStatement`. Reverts to legacy behavior by setting the JDBC configuration property `autoClosePstmtStreams` to true (also included in the 3-0-Compat configuration "bundle"). (Bug#15024 [<http://bugs.mysql.com/15024>])
- `maxQuerySizeToLog` is not respected. Added logging of bound values for `execute()` phase of server-side prepared statements when `profileSQL=true` as well. (Bug#13048 [<http://bugs.mysql.com/13048>])
- Usage advisor complains about unreferenced columns, even though they've been referenced. (Bug#15065 [<http://bugs.mysql.com/15065>])
- Don't increase timeout for failover/reconnect. (Bug#6577 [<http://bugs.mysql.com/6577>])
- Process escape tokens in `Connection.prepareStatement(...)`. (Bug#15141 [<http://bugs.mysql.com/15141>]) You can disable this behavior by setting the JDBC URL configuration property `processEscapeCodesForPrepStmts` to false.
- Reconnect during middle of `executeBatch()` should not occur if `autoReconnect` is enabled. (Bug#13255 [<http://bugs.mysql.com/13255>])

#### 23.3.6.4. Changes in MySQL Connector/J 3.1.11-stable (07 Octo-

**ber 2005)**

- Spurious ! on console when character encoding is utf8. (Bug#11629 [<http://bugs.mysql.com/11629>])
- Fixed statements generated for testcases missing ; for “plain” statements.
- Incorrect generation of testcase scripts for server-side prepared statements. (Bug#11663 [<http://bugs.mysql.com/11663>])
- Fixed regression caused by fix for Bug#11552 [<http://bugs.mysql.com/11552>] that caused driver to return incorrect values for unsigned integers when those integers were within the range of the positive signed type.
- Moved source code to Subversion repository.
- Escape tokenizer doesn't respect stacked single quotes for escapes. (Bug#11797 [<http://bugs.mysql.com/11797>])
- GEOMETRY type not recognized when using server-side prepared statements.
- ReplicationConnection won't switch to slave, throws “Catalog can't be null” exception. (Bug#11879 [<http://bugs.mysql.com/11879>])
- Properties shared between master and slave with replication connection. (Bug#12218 [<http://bugs.mysql.com/12218>])
- Statement.getWarnings() fails with NPE if statement has been closed. (Bug#10630 [<http://bugs.mysql.com/10630>])
- Only get char[] from SQL in PreparedStatement.ParseInfo() when needed.
- Geometry types not handled with server-side prepared statements. (Bug#12104 [<http://bugs.mysql.com/12104>])
- StringUtils.getBytes() doesn't work when using multi-byte character encodings and a length in *characters* is specified. (Bug#11614 [<http://bugs.mysql.com/11614>])
- Pstmt.setObject(..., Types.BOOLEAN) throws exception. (Bug#11798 [<http://bugs.mysql.com/11798>])
- maxPerformance.properties mis-spells “elideSetAutoCommits”. (Bug#11976 [<http://bugs.mysql.com/11976>])
- DBMD.storesLower/Mixed/UpperIdentifiers() reports incorrect values for servers deployed on Windows. (Bug#11575 [<http://bugs.mysql.com/11575>])
- ResultSet.moveToCurrentRow() fails to work when preceded by a call to ResultSet.moveToInsertRow(). (Bug#11190 [<http://bugs.mysql.com/11190>])
- VARBINARY data corrupted when using server-side prepared statements and .setBytes(). (Bug#11115 [<http://bugs.mysql.com/11115>])
- explainSlowQueries hangs with server-side prepared statements. (Bug#12229 [<http://bugs.mysql.com/12229>])
- Escape processor didn't honor strings demarcated with double quotes. (Bug#11498 [<http://bugs.mysql.com/11498>])
- Lifted restriction of changing streaming parameters with server-side prepared statements. As long as all streaming parameters were set before execution, .clearParameters() does not have to be called. (due to limitation of client/server protocol, prepared statements can not re-

set *individual* stream data on the server side).

- Reworked `Field` class, `*Buffer`, and `MysqlIO` to be aware of field lengths > `Integer.MAX_VALUE`.
- Updated `DBMD.supportsCorrelatedQueries()` to return `true` for versions > 4.1, `supportsGroupByUnrelated()` to return `true` and `getResultSetHoldability()` to return `HOLD_CURSORS_OVER_COMMIT`.
- Handling of catalog argument in `DatabaseMetaData.getIndexInfo()`, which also means changes to the following methods in `DatabaseMetaData`: (Bug#12541 [<http://bugs.mysql.com/12541>])
  - `getBestRowIdentifier()`
  - `getColumns()`
  - `getCrossReference()`
  - `getExportedKeys()`
  - `getImportedKeys()`
  - `getIndexInfo()`
  - `getPrimaryKeys()`
  - `getProcedures()` (and thus indirectly `getProcedureColumns()`)
  - `getTables()`

The catalog argument in all of these methods now behaves in the following way:

- Specifying `NULL` means that catalog will not be used to filter the results (thus all databases will be searched), unless you've set `nullCatalogMeansCurrent=true` in your JDBC URL properties.
- Specifying `" "` means “current” catalog, even though this isn't quite JDBC spec compliant, it's there for legacy users.
- Specifying a catalog works as stated in the API docs.
- Made `Connection.clientPrepare()` available from “wrapped” connections in the `jdbc2.optional` package (connections built by `ConnectionPoolDataSource` instances).
- Added `Connection.isMasterConnection()` for clients to be able to determine if a multi-host master/slave connection is connected to the first host in the list.
- Tokenizer for `=` in URL properties was causing `sessionVariables=...` to be parameterized incorrectly. (Bug#12753 [<http://bugs.mysql.com/12753>])
- Foreign key information that is quoted is parsed incorrectly when `DatabaseMetaData` methods use that information. (Bug#11781 [<http://bugs.mysql.com/11781>])
- The `sendBlobChunkSize` property is now clamped to `max_allowed_packet` with consideration of stream buffer size and packet headers to avoid `PacketTooBigExceptions` when `max_allowed_packet` is similar in size to the default `sendBlobChunkSize` which is 1M.
- `CallableStatement.clearParameters()` now clears resources associated with `IN-OUT/OUTPUT` parameters as well as `INPUT` parameters.
- `Connection.prepareCall()` is database name case-sensitive (on Windows systems).

Bug#12417 [<http://bugs.mysql.com/12417>])

- `cp1251` incorrectly mapped to `win1251` for servers newer than 4.0.x. (Bug#12752 [<http://bugs.mysql.com/12752>])
- `java.sql.Types.OTHER` returned for `BINARY` and `VARBINARY` columns when using `DatabaseMetaData.getColumns()`. (Bug#12970 [<http://bugs.mysql.com/12970>])
- `ServerPreparedStatement.getBinding()` now checks if the statement is closed before attempting to reference the list of parameter bindings, to avoid throwing a `NullPointerException`.
- `ResultSetMetaData` from `Statement.getGeneratedKeys()` caused a `NullPointerException` to be thrown whenever a method that required a connection reference was called. (Bug#13277 [<http://bugs.mysql.com/13277>])
- Backport of `Field` class, `ResultSetMetaData.getColumnClassName()`, and `ResultSet.getObject(int)` changes from 5.0 branch to fix behavior surrounding `VARCHAR BINARY/VARBINARY` and related types.
- Fixed `NullPointerException` when converting catalog parameter in many `DatabaseMetaDataMethods` to `byte[]`s (for the result set) when the parameter is `null`. (`null` isn't technically allowed by the JDBC specification, but we've historically allowed it).
- Backport of `VAR[BINARY|CHAR] [BINARY]` types detection from 5.0 branch.
- Read response in `MySQLIO.sendFileToServer()`, even if the local file can't be opened, otherwise next query issued will fail, because it's reading the response to the empty `LOAD DATA INFILE` packet sent to the server.
- Workaround for Bug#13374 [<http://bugs.mysql.com/13374>]: `ResultSet.getStatement()` on closed result set returns `NULL` (as per JDBC 4.0 spec, but not backward-compatible). Set the connection property `retainStatementAfterResultSetClose` to `true` to be able to retrieve a `ResultSet`'s statement after the `ResultSet` has been closed via `.getStatement()` (the default is `false`, to be JDBC-compliant and to reduce the chance that code using JDBC leaks `Statement` instances).
- URL configuration parameters don't allow `'&'` or `'='` in their values. The JDBC driver now parses configuration parameters as if they are encoded using the `application/x-www-form-urlencoded` format as specified by `java.net.URLDecoder` (<http://java.sun.com/j2se/1.5.0/docs/api/java/net/URLDecoder.html>). (Bug#13453 [<http://bugs.mysql.com/13453>])  
If the `'%'` character is present in a configuration property, it must now be represented as `%25`, which is the encoded form of `'%'` when using `application/x-www-form-urlencoded` encoding.
- The configuration property `sessionVariables` now allows you to specify variables that start with the `'@'` sign.
- When `gatherPerfMetrics` is enabled for servers older than 4.1.0, a `NullPointerException` is thrown from the constructor of `ResultSet` if the query doesn't use any tables. (Bug#13043 [<http://bugs.mysql.com/13043>])

### 23.3.6.5. Changes in MySQL Connector/J 3.1.10-stable (23 June 2005)

- Fixed connecting without a database specified raised an exception in `MySQLIO.changeDatabaseTo()`.
- Initial implementation of `ParameterMetadata` for `PreparedStatement.getParameterMetadata()`. Only works fully for `CallableStatements`, as

current server-side prepared statements return every parameter as a VARCHAR type.

### 23.3.6.6. Changes in MySQL Connector/J 3.1.9-stable (22 June 2005)

- Overhaul of character set configuration, everything now lives in a properties file.
- Driver now correctly uses CP932 if available on the server for Windows-31J, CP932 and MS932 java encoding names, otherwise it resorts to SJIS, which is only a close approximation. Currently only MySQL-5.0.3 and newer (and MySQL-4.1.12 or .13, depending on when the character set gets backported) can reliably support any variant of CP932.
- `com.mysql.jdbc.PreparedStatement.ParseInfo` does unnecessary call to `toCharArray()`. (Bug#9064 [<http://bugs.mysql.com/9064>])
- Memory leak in `ServerPreparedStatement` if `serverPrepare()` fails. (Bug#10144 [<http://bugs.mysql.com/10144>])
- Actually write manifest file to correct place so it ends up in the binary jar file.
- Added `createDatabaseIfNotExist` property (default is `false`), which will cause the driver to ask the server to create the database specified in the URL if it doesn't exist. You must have the appropriate privileges for database creation for this to work.
- Unsigned SMALLINT treated as signed for `ResultSet.getInt()`, fixed all cases for UNSIGNED integer values and server-side prepared statements, as well as `ResultSet.getObject()` for UNSIGNED TINYINT. (Bug#10156 [<http://bugs.mysql.com/10156>])
- Double quotes not recognized when parsing client-side prepared statements. (Bug#10155 [<http://bugs.mysql.com/10155>])
- Made `enableStreamingResults()` visible on `com.mysql.jdbc.jdbc2.optional.StatementWrapper`.
- Made `ServerPreparedStatement.asSql()` work correctly so auto-explain functionality would work with server-side prepared statements.
- Made JDBC2-compliant wrappers public in order to allow access to vendor extensions.
- Cleaned up logging of profiler events, moved code to dump a profiler event as a string to `com.mysql.jdbc.log.LogUtils` so that third parties can use it.
- `DatabaseMetaData.supportsMultipleOpenResults()` now returns `true`. The driver has supported this for some time, DBMD just missed that fact.
- Driver doesn't support `{?=CALL(...)}` for calling stored functions. This involved adding support for function retrieval to `DatabaseMetaData.getProcedures()` and `getProcedureColumns()` as well. (Bug#10310 [<http://bugs.mysql.com/10310>])
- `SQLException` thrown when retrieving YEAR(2) with `ResultSet.getString()`. The driver will now always treat YEAR types as `java.sql.Date`s and return the correct values for `getString()`. Alternatively, the `yearIsDateType` connection property can be set to `false` and the values will be treated as SHORTs. (Bug#10485 [<http://bugs.mysql.com/10485>])
- The datatype returned for TINYINT(1) columns when `tinyInt1isBit=true` (the default) can be switched between `Types.BOOLEAN` and `Types.BIT` using the new configuration property `transformedBitIsBoolean`, which defaults to `false`. If set to `false` (the default), `DatabaseMetaData.getColumns()` and `ResultSetMetaData.getColumnType()` will return `Types.BOOLEAN` for TINYINT(1) columns. If `true`, `Types.BOOLEAN` will be returned instead. Regardless of this configuration property, if `tinyInt1isBit` is enabled, columns with the type TINYINT(1) will be returned as

`java.lang.Boolean` instances from `ResultSet.getObject(...)`, and `ResultSetMetaData.getColumnClassName()` will return `java.lang.Boolean`.

- `SQLException` is thrown when using property `characterSetResults` with `cp932` or `ucjms`. (Bug#10496 [<http://bugs.mysql.com/10496>])
- Reorganized directory layout. Sources now are in `src` folder. Don't pollute parent directory when building, now output goes to `./build`, distribution goes to `./dist`.
- Added support/bug hunting feature that generates `.sql` test scripts to `STDERR` when `autoGenerateTestcaseScript` is set to `true`.
- 0-length streams not sent to server when using server-side prepared statements. (Bug#10850 [<http://bugs.mysql.com/10850>])
- Setting `cachePrepStmts=true` now causes the `Connection` to also cache the check the driver performs to determine if a prepared statement can be server-side or not, as well as caches server-side prepared statements for the lifetime of a connection. As before, the `prepStmtCacheSize` parameter controls the size of these caches.
- Try to handle `OutOfMemoryErrors` more gracefully. Although not much can be done, they will in most cases close the connection they happened on so that further operations don't run into a connection in some unknown state. When an OOM has happened, any further operations on the connection will fail with a "Connection closed" exception that will also list the OOM exception as the reason for the implicit connection close event.
- Don't send `COM_RESET_STMT` for each execution of a server-side prepared statement if it isn't required.
- Driver detects if you're running MySQL-5.0.7 or later, and does not scan for `LIMIT ?[,?]` in statements being prepared, as the server supports those types of queries now.
- `VARBINARY` data corrupted when using server-side prepared statements and `ResultSet.getBytes()`. (Bug#11115 [<http://bugs.mysql.com/11115>])
- `Connection.setCatalog()` is now aware of the `useLocalSessionState` configuration property, which when set to `true` will prevent the driver from sending `USE ...` to the server if the requested catalog is the same as the current catalog.
- Added the following configuration bundles, use one or many via the `useConfigs` configuration property:
  - `maxPerformance` — maximum performance without being reckless
  - `solarisMaxPerformance` — maximum performance for Solaris, avoids syscalls where it can
  - `3-0-Compat` — Compatibility with Connector/J 3.0.x functionality
- Added `maintainTimeStats` configuration property (defaults to `true`), which tells the driver whether or not to keep track of the last query time and the last successful packet sent to the server's time. If set to `false`, removes two syscalls per query.
- `autoReconnect ping` causes exception on connection startup. (Bug#11259 [<http://bugs.mysql.com/11259>])
- Connector/J dumping query into `SQLException` twice. (Bug#11360 [<http://bugs.mysql.com/11360>])
- Fixed `PreparedStatement.setClob()` not accepting `null` as a parameter.
- Production package doesn't include JBoss integration classes. (Bug#11411 [<http://bugs.mysql.com/11411>])

- Removed nonsensical “costly type conversion” warnings when using usage advisor.

### 23.3.6.7. Changes in MySQL Connector/J 3.1.8-stable (14 April 2005)

- Fixed `DatabaseMetaData.getTables()` returning views when they were not asked for as one of the requested table types.
- Added support for new precision-math `DECIMAL` type in MySQL 5.0.3 and up.
- Fixed `ResultSet.getTime()` on a `NULL` value for server-side prepared statements throws `NPE`.
- Made `Connection.ping()` a public method.
- `DATE_FORMAT()` queries returned as `BLOBs` from `getObject()`. (Bug#8868 [<http://bugs.mysql.com/8868>])
- `ServerPreparedStatement` now correctly “stream” `BLOB/CLOB` data to the server. You can configure the threshold chunk size using the JDBC URL property `blobSendChunkSize` (the default is 1MB).
- `BlobFromLocator` now uses correct identifier quoting when generating prepared statements.
- Server-side session variables can be preset at connection time by passing them as a comma-delimited list for the connection property `sessionVariables`.
- Fixed regression in `ping()` for users using `autoReconnect=true`.
- `PreparedStatement.addBatch()` doesn't work with server-side prepared statements and streaming `BINARY` data. (Bug#9040 [<http://bugs.mysql.com/9040>])
- `DBMD.supportsMixedCase*Identifiers()` returns wrong value on servers running on case-sensitive filesystems. (Bug#8800 [<http://bugs.mysql.com/8800>])
- Cannot use `UTF-8` for `characterSetResults` configuration property. (Bug#9206 [<http://bugs.mysql.com/9206>])
- A continuation of Bug#8868 [<http://bugs.mysql.com/8868>], where functions used in queries that should return non-string types when resolved by temporary tables suddenly become opaque binary strings (work-around for server limitation). Also fixed fields with type of `CHAR(n) CHARACTER SET BINARY` to return correct/matching classes for `RSMD.getColumnClassName()` and `ResultSet.getObject()`. (Bug#9236 [<http://bugs.mysql.com/9236>])
- `DBMD.supportsResultSetConcurrency()` not returning `true` for forward-only/read-only result sets (we obviously support this). (Bug#8792 [<http://bugs.mysql.com/8792>])
- `DATA_TYPE` column from `DBMD.getBestRowIdentifier()` causes `ArrayIndexOutOfBoundsException` when accessed (and in fact, didn't return any value). (Bug#8803 [<http://bugs.mysql.com/8803>])
- Check for empty strings ( ' ') when converting `CHAR/VARCHAR` column data to numbers, throw exception if `emptyStringsConvertToZero` configuration property is set to `false` (for backward-compatibility with 3.0, it is now set to `true` by default, but will most likely default to `false` in 3.2).
- `PreparedStatement.getMetaData()` inserts blank row in database under certain conditions when not using server-side prepared statements. (Bug#9320 [<http://bugs.mysql.com/9320>])
- `Connection.canHandleAsPreparedStatement()` now makes “best effort” to distin-

guish LIMIT clauses with placeholders in them from ones without in order to have fewer false positives when generating work-arounds for statements the server cannot currently handle as server-side prepared statements.

- Fixed `build.xml` to not compile `log4j` logging if `log4j` not available.
- Added support for the `c3p0` connection pool's (<http://c3p0.sf.net/>) validation/connection checker interface which uses the lightweight `COM_PING` call to the server if available. To use it, configure your `c3p0` connection pool's `connectionTesterClassName` property to use `com.mysql.jdbc.integration.c3p0.MySqlConnectionTester`.
- Better detection of LIMIT inside/outside of quoted strings so that the driver can more correctly determine whether a prepared statement can be prepared on the server or not.
- Stored procedures with same name in different databases confuse the driver when it tries to determine parameter counts/types. (Bug#9319 [<http://bugs.mysql.com/9319>])
- Added finalizers to `ResultSet` and `Statement` implementations to be JDBC spec-compliant, which requires that if not explicitly closed, these resources should be closed upon garbage collection.
- Stored procedures with DECIMAL parameters with storage specifications that contained `'`, in them would fail. (Bug#9682 [<http://bugs.mysql.com/9682>])
- `PreparedStatement.setObject(int, Object, int type, int scale)` now uses scale value for `BigDecimal` instances.
- `Statement.getMoreResults()` could throw NPE when existing result set was `.close()`d. (Bug#9704 [<http://bugs.mysql.com/9704>])
- The performance metrics feature now gathers information about number of tables referenced in a SELECT.
- The logging system is now automatically configured. If the value has been set by the user, via the URL property `logger` or the system property `com.mysql.jdbc.logger`, then use that, otherwise, autodetect it using the following steps:
  1. `Log4j`, if it's available,
  2. Then JDK1.4 logging,
  3. Then fallback to our `STDERR` logging.
- `DBMD.getTables()` shouldn't return tables if views are asked for, even if the database version doesn't support views. (Bug#9778 [<http://bugs.mysql.com/9778>])
- Fixed driver not returning `true` for `-1` when `ResultSet.getBoolean()` was called on result sets returned from server-side prepared statements.
- Added a `Manifest.MF` file with implementation information to the `.jar` file.
- More tests in `Field.isOpaqueBinary()` to distinguish opaque binary (i.e. fields with type `CHAR(n)` and `CHARACTER SET BINARY`) from output of various scalar and aggregate functions that return strings.
- Should accept `null` for catalog (meaning use current) in `DBMD` methods, even though it's not JDBC-compliant for legacy's sake. Disable by setting connection property `nullCatalogMeansCurrent` to `false` (which will be the default value in C/J 3.2.x). (Bug#9917 [<http://bugs.mysql.com/9917>])
- Should accept `null` for name patterns in `DBMD` (meaning `'%'`), even though it isn't JDBC compliant, for legacy's sake. Disable by setting connection property `nullNamePatternMatchesAll` to `false` (which will be the default value in C/J 3.2.x). (Bug#9769 [<http://bugs.mysql.com/9769>])

### 23.3.6.8. Changes in MySQL Connector/J 3.1.7-stable (18 February 2005)

- Timestamp key column data needed `_binary` stripped for `UpdatableResultSet.refreshRow()`. (Bug#7686 [<http://bugs.mysql.com/7686>])
- Timestamps converted incorrectly to strings with server-side prepared statements and updatable result sets. (Bug#7715 [<http://bugs.mysql.com/7715>])
- Detect new `sql_mode` variable in string form (it used to be integer) and adjust quoting method for strings appropriately.
- Added `holdResultsOpenOverStatementClose` property (default is `false`), that keeps result sets open over `statement.close()` or new execution on same statement (suggested by Kevin Burton).
- Infinite recursion when “falling back” to master in failover configuration. (Bug#7952 [<http://bugs.mysql.com/7952>])
- Disable multi-statements (if enabled) for MySQL-4.1 versions prior to version 4.1.10 if the query cache is enabled, as the server returns wrong results in this configuration.
- Fixed duplicated code in `configureClientCharset()` that prevented `useOldUTF8Behavior=true` from working properly.
- Removed `dontUnpackBinaryResults` functionality, the driver now always stores results from server-side prepared statements as is from the server and unpacks them on demand.
- Emulated locators corrupt binary data when using server-side prepared statements. (Bug#8096 [<http://bugs.mysql.com/8096>])
- Fixed synchronization issue with `ServerPreparedStatement.serverPrepare()` that could cause deadlocks/crashes if connection was shared between threads.
- By default, the driver now scans SQL you are preparing via all variants of `Connection.prepareStatement()` to determine if it is a supported type of statement to prepare on the server side, and if it is not supported by the server, it instead prepares it as a client-side emulated prepared statement. You can disable this by passing `emulateUnsupportedPstmts=false` in your JDBC URL. (Bug#4718 [<http://bugs.mysql.com/4718>])
- Remove `_binary` introducer from parameters used as in/out parameters in `CallableStatement`.
- Always return `byte[]`s for output parameters registered as `*BINARY`.
- Send correct value for “boolean” true to server for `PreparedStatement.setObject(n, "true", Types.BIT)`.
- Fixed bug with `Connection` not caching statements from `prepareStatement()` when the statement wasn't a server-side prepared statement.
- Choose correct “direction” to apply time adjustments when both client and server are in GMT time zone when using `ResultSet.get(..., cal)` and `PreparedStatement.set(..., cal)`.
- Added `dontTrackOpenResources` option (default is `false`, to be JDBC compliant), which helps with memory use for non-well-behaved apps (that is, applications that don't close `Statement` objects when they should).
- `ResultSet.getString()` doesn't maintain format stored on server, bug fix only enabled when `noDatetimeStringSync` property is set to `true` (the default is `false`). (Bug#8428 [<http://bugs.mysql.com/8428>])

- Fixed NPE in `ResultSet.realClose()` when using usage advisor and result set was already closed.
- `PreparedStatement` not creating streaming result sets. (Bug#8478 [<http://bugs.mysql.com/8478>])
- Don't pass `NULL` to `String.valueOf()` in `ResultSet.getNativeConvertToString()`, as it stringifies it (that is, returns null), which is not correct for the method in question.
- `ResultSet.getBigDecimal()` throws exception when rounding would need to occur to set scale. The driver now chooses a rounding mode of “half up” if non-rounding `BigDecimal.setScale()` fails. (Bug#8484 [<http://bugs.mysql.com/8484>])
- Added `useLocalSessionState` configuration property, when set to `true` the JDBC driver trusts that the application is well-behaved and only sets autocommit and transaction isolation levels using the methods provided on `java.sql.Connection`, and therefore can manipulate these values in many cases without incurring round-trips to the database server.
- Added `enableStreamingResults()` to `Statement` for connection pool implementations that check `Statement.setFetchSize()` for specification-compliant values. Call `Statement.setFetchSize(>=0)` to disable the streaming results for that statement.
- Added support for `BIT` type in MySQL-5.0.3. The driver will treat `BIT(1-8)` as the JDBC standard `BIT` type (which maps to `java.lang.Boolean`), as the server does not currently send enough information to determine the size of a bitfield when `< 9` bits are declared. `BIT(>9)` will be treated as `VARBINARY`, and will return `byte[]` when `getObject()` is called.

### 23.3.6.9. Changes in MySQL Connector/J 3.1.6-stable (23 December 2004)

- Fixed hang on `SocketInputStream.read()` with `Statement.setMaxRows()` and multiple result sets when driver has to truncate result set directly, rather than tacking a `LIMIT n` on the end of it.
- `DBMD.getProcedures()` doesn't respect `catalog` parameter. (Bug#7026 [<http://bugs.mysql.com/7026>])

### 23.3.6.10. Changes in MySQL Connector/J 3.1.5-gamma (02 December 2004)

- Fix comparisons made between string constants and dynamic strings that are converted with either `toUpperCase()` or `toLowerCase()` to use `Locale.ENGLISH`, as some locales “override” case rules for English. Also use `StringUtils.indexOfIgnoreCase()` instead of `.toUpperCase().indexOf()`, avoids creating a very short-lived transient `String` instance.
- Server-side prepared statements did not honor `zeroDateTimeBehavior` property, and would cause class-cast exceptions when using `ResultSet.getObject()`, as the all-zero string was always returned. (Bug#5235 [<http://bugs.mysql.com/5235>])
- Fixed batched updates with server prepared statements weren't looking if the types had changed for a given batched set of parameters compared to the previous set, causing the server to return the error “Wrong arguments to `mysql_stmt_execute()`”.
- Handle case when string representation of timestamp contains trailing `'.'` with no numbers following it.

- Inefficient detection of pre-existing string instances in `ResultSet.getNativeString()`. (Bug#5706 [<http://bugs.mysql.com/5706>])
- Don't throw exceptions for `Connection.releaseSavepoint()`.
- Use a per-session `Calendar` instance by default when decoding dates from `ServerPreparedStatements` (set to old, less performant behavior by setting property `dynamicCalendars=true`).
- Added experimental configuration property `dontUnpackBinaryResults`, which delays unpacking binary result set values until they're asked for, and only creates object instances for non-numerical values (it is set to `false` by default). For some usecase/jvm combinations, this is friendlier on the garbage collector.
- `UNSIGNED BIGINT` unpacked incorrectly from server-side prepared statement result sets. (Bug#5729 [<http://bugs.mysql.com/5729>])
- `ServerSidePreparedStatement` allocating short-lived objects unnecessarily. (Bug#6225 [<http://bugs.mysql.com/6225>])
- Removed unwanted new `Throwable()` in `ResultSet` constructor due to bad merge (caused a new object instance that was never used for every result set created). Found while profiling for Bug#6359 [<http://bugs.mysql.com/6359>].
- Fixed too-early creation of `StringBuffer` in `EscapeProcessor.escapeSQL()`, also return `String` when escaping not needed (to avoid unnecessary object allocations). Found while profiling for Bug#6359 [<http://bugs.mysql.com/6359>].
- Use null-safe-equals for key comparisons in updatable result sets.
- `SUM()` on `DECIMAL` with server-side prepared statement ignores scale if zero-padding is needed (this ends up being due to conversion to `DOUBLE` by server, which when converted to a string to parse into `BigDecimal`, loses all "padding" zeros). (Bug#6537 [<http://bugs.mysql.com/6537>])
- Use `DatabaseMetaData.getIdentifierQuoteString()` when building DBMD queries.
- Use `1MB` packet for sending file for `LOAD DATA LOCAL INFILE` if that is `< max_allowed_packet` on server.
- `ResultSetMetaData.getColumnDisplaySize()` returns incorrect values for multi-byte charsets. (Bug#6399 [<http://bugs.mysql.com/6399>])
- Make auto-deserialization of `java.lang.Objects` stored in `BLOB` columns configurable via `autoDeserialize` property (defaults to `false`).
- Re-work `Field.isOpaqueBinary()` to detect `CHAR(n) CHARACTER SET BINARY` to support fixed-length binary fields for `ResultSet.getObject()`.
- Use our own implementation of buffered input streams to get around blocking behavior of `java.io.BufferedReader`. Disable this with `useReadAheadInput=false`.
- Failing to connect to the server when one of the addresses for the given host name is `IPV6` (which the server does not yet bind on). The driver now loops through *all* IP addresses for a given host, and stops on the first one that `accepts()` a `socket.connect()`. (Bug#6348 [<http://bugs.mysql.com/6348>])

### 23.3.6.11. Changes in MySQL Connector/J 3.1.4-beta (04 September 2004)

- 
- Connector/J 3.1.3 beta does not handle integers correctly (caused by changes to support unsigned reads in `Buffer.readInt()` -> `Buffer.readShort()`). (Bug#4510 [<http://bugs.mysql.com/4510>])
  - Added support in `DatabaseMetaData.getTables()` and `getTableTypes()` for views, which are now available in MySQL server 5.0.x.
  - `ServerPreparedStatement.execute*()` sometimes threw `ArrayIndexOutOfBoundsException` when unpacking field metadata. (Bug#4642 [<http://bugs.mysql.com/4642>])
  - Optimized integer number parsing, enable “old” slower integer parsing using JDK classes via `useFastIntParsing=false` property.
  - Added `useOnlyServerErrorMessages` property, which causes message text in exceptions generated by the server to only contain the text sent by the server (as opposed to the SQL-State’s “standard” description, followed by the server’s error message). This property is set to true by default.
  - `ResultSet.isNull()` does not work for primitives if a previous null was returned. (Bug#4689 [<http://bugs.mysql.com/4689>])
  - Track packet sequence numbers if `enablePacketDebug=true`, and throw an exception if packets received out-of-order.
  - `ResultSet.getObject()` returns wrong type for strings when using prepared statements. (Bug#4482 [<http://bugs.mysql.com/4482>])
  - Calling `MysqlPooledConnection.close()` twice (even though an application error), caused NPE. Fixed.
  - `ServerPreparedStatements` dealing with return of `DECIMAL` type don't work. (Bug#5012 [<http://bugs.mysql.com/5012>])
  - `ResultSet.getObject()` doesn't return type `Boolean` for pseudo-bit types from prepared statements on 4.1.x (shortcut for avoiding extra type conversion when using binary-encoded result sets obscured test in `getObject()` for “pseudo” bit type). (Bug#5032 [<http://bugs.mysql.com/5032>])
  - You can now use URLs in `LOAD DATA LOCAL INFILE` statements, and the driver will use Java’s built-in handlers for retrieving the data and sending it to the server. This feature is not enabled by default, you must set the `allowUrlInLocalInfile` connection property to true.
  - The driver is more strict about truncation of numerics on `ResultSet.get*()`, and will throw an `SQLException` when truncation is detected. You can disable this by setting `jdbcCompliantTruncation` to false (it is enabled by default, as this functionality is required for JDBC compliance).
  - Added three ways to deal with all-zero datetimes when reading them from a `ResultSet`: `exception` (the default), which throws an `SQLException` with an `SQLState` of `S1009`; `convertToNull`, which returns `NULL` instead of the date; and `round`, which rounds the date to the nearest closest value which is `'0001-01-01'`.
  - Fixed `ServerPreparedStatement` to read prepared statement metadata off the wire, even though it’s currently a placeholder instead of using `MysqlIO.clearInputStream()` which didn’t work at various times because data wasn’t available to read from the server yet. This fixes sporadic errors users were having with `ServerPreparedStatements` throwing `ArrayIndexOutOfBoundsException`s.
  - Use `com.mysql.jdbc.Message`’s classloader when loading resource bundle, should fix sporadic issues when the caller’s classloader can’t locate the resource bundle.
-

### 23.3.6.12. Changes in MySQL Connector/J 3.1.3-beta (07 July 2004)

- Mangle output parameter names for `CallableStatements` so they will not clash with user variable names.
- Added support for `INOUT` parameters in `CallableStatements`.
- Null bitmask sent for server-side prepared statements was incorrect. (Bug#4119 [<http://bugs.mysql.com/4119>])
- Use SQL Standard SQL states by default, unless `useSqlStateCodes` property is set to `false`.
- Added packet debugging code (see the `enablePacketDebug` property documentation).
- Added constants for MySQL error numbers (publicly accessible, see `com.mysql.jdbc.MySqlErrorNumbers`), and the ability to generate the mappings of vendor error codes to `SQLStates` that the driver uses (for documentation purposes).
- Externalized more messages (on-going effort).
- Error in retrieval of `mediumint` column with prepared statements and binary protocol. (Bug#4311 [<http://bugs.mysql.com/4311>])
- Support new time zone variables in MySQL-4.1.3 when `useTimezone=true`.
- Support for unsigned numerics as return types from prepared statements. This also causes a change in `ResultSet.getObject()` for the `bigint unsigned` type, which used to return `BigDecimal` instances, it now returns instances of `java.lang.BigInteger`.

### 23.3.6.13. Changes in MySQL Connector/J 3.1.2-alpha (09 June 2004)

- Fixed stored procedure parameter parsing info when size was specified for a parameter (for example, `char()`, `varchar()`).
- Enabled callable statement caching via `cacheCallableStmts` property.
- Fixed case when no output parameters specified for a stored procedure caused a bogus query to be issued to retrieve out parameters, leading to a syntax error from the server.
- Fixed case when no parameters could cause a `NullPointerException` in `CallableStatement.setOutputParameters()`.
- Removed wrapping of exceptions in `MySQLIO.changeUser()`.
- Fixed sending of split packets for large queries, enabled `nio` ability to send large packets as well.
- Added `.toString()` functionality to `ServerPreparedStatement`, which should help if you're trying to debug a query that is a prepared statement (it shows SQL as the server would process).
- Added `gatherPerformanceMetrics` property, along with properties to control when/where this info gets logged (see docs for more info).
- `ServerPreparedStatements` weren't actually de-allocating server-side resources when `.close()` was called.

- Added `logSlowQueries` property, along with `slowQueriesThresholdMillis` property to control when a query should be considered “slow.”
- Correctly map output parameters to position given in `prepareCall()` versus. order implied during `registerOutParameter()`. (Bug#3146 [<http://bugs.mysql.com/3146>])
- Correctly detect initial character set for servers  $\geq 4.1.0$ .
- Cleaned up detection of server properties.
- Support placeholder for parameter metadata for server  $\geq 4.1.2$ .
- `getProcedures()` does not return any procedures in result set. (Bug#3539 [<http://bugs.mysql.com/3539>])
- `getProcedureColumns()` doesn't work with wildcards for procedure name. (Bug#3540 [<http://bugs.mysql.com/3540>])
- `DBMD.getSQLStateType()` returns incorrect value. (Bug#3520 [<http://bugs.mysql.com/3520>])
- Added `connectionCollation` property to cause driver to issue `set collation_connection=...` query on connection init if default collation for given charset is not appropriate.
- Fixed `DatabaseMetaData.getProcedures()` when run on MySQL-5.0.0 (output of `SHOW PROCEDURE STATUS` changed between 5.0.0 and 5.0.1).
- `getWarnings()` returns `SQLWarning` instead of `DataTruncation`. (Bug#3804 [<http://bugs.mysql.com/3804>])
- Don't enable server-side prepared statements for server version 5.0.0 or 5.0.1, as they aren't compatible with the '4.1.2+' style that the driver uses (the driver expects information to come back that isn't there, so it hangs).

### 23.3.6.14. Changes in MySQL Connector/J 3.1.1-alpha (14 February 2004)

- Fixed bug with `UpdatableResultSets` not using client-side prepared statements.
- Fixed character encoding issues when converting bytes to ASCII when MySQL doesn't provide the character set, and the JVM is set to a multi-byte encoding (usually affecting retrieval of numeric values).
- Unpack “unknown” data types from server prepared statements as `Strings`.
- Implemented long data (Blobs, Clobs, `InputStreams`, `Readers`) for server prepared statements.
- Implemented `Statement.getWarnings()` for MySQL-4.1 and newer (using `SHOW WARNINGS`).
- Default result set type changed to `TYPE_FORWARD_ONLY` (JDBC compliance).
- Centralized setting of result set type and concurrency.
- Refactored how connection properties are set and exposed as `DriverPropertyInfo` as well as `Connection` and `DataSource` properties.
- Support for NIO. Use `useNIO=true` on platforms that support NIO.
- Support for transaction savepoints (MySQL  $\geq 4.0.14$  or 4.1.1).

- Support for `mysql_change_user()`. See the `changeUser()` method in `com.mysql.jdbc.Connection`.
- Reduced number of methods called in average query to be more efficient.
- Prepared Statements will be re-prepared on auto-reconnect. Any errors encountered are postponed until first attempt to re-execute the re-prepared statement.
- Ensure that warnings are cleared before executing queries on prepared statements, as-per JDBC spec (now that we support warnings).
- Support “old” `profileSql` capitalization in `ConnectionProperties`. This property is deprecated, you should use `profileSQL` if possible.
- Optimized `Buffer.readLenByteArray()` to return shared empty byte array when length is 0.
- Allow contents of `PreparedStatement.setBlob()` to be retained between calls to `.execute*()`.
- Deal with 0-length tokens in `EscapeProcessor` (caused by callable statement escape syntax).
- Check for closed connection on delete/update/insert row operations in `UpdatableResultSet`.
- Fix support for table aliases when checking for all primary keys in `UpdatableResultSet`.
- Removed `useFastDates` connection property.
- Correctly initialize datasource properties from JNDI Refs, including explicitly specified URLs.
- `DatabaseMetaData` now reports `supportsStoredProcedures()` for MySQL versions  $\geq 5.0.0$
- Fixed stack overflow in `Connection.prepareCall()` (bad merge).
- Fixed `IllegalAccessError` to `Calendar.getTimeInMillis()` in `DateTimeValue` (for JDK < 1.4).
- `DatabaseMetaData.getColumns()` is not returning correct column ordinal info for non-`'%'` column name patterns. (Bug#1673 [<http://bugs.mysql.com/1673>])
- Merged fix of datatype mapping from MySQL type `FLOAT` to `java.sql.Types.REAL` from 3.0 branch.
- Detect collation of column for `RSMD.isCaseSensitive()`.
- Fixed sending of queries larger than 16M.
- Added named and indexed input/output parameter support to `CallableStatement`. MySQL-5.0.x or newer.
- Fixed `NullPointerException` in `ServerPreparedStatement.setTimestamp()`, as well as year and month discrepancies in `ServerPreparedStatement.setTimestamp(), setDate()`.
- Added ability to have multiple database/JVM targets for compliance and regression/unit tests in `build.xml`.
- Fixed NPE and year/month bad conversions when accessing some datetime functionality in `ServerPreparedStatements` and their resultant result sets.
- Display where/why a connection was implicitly closed (to aid debugging).

- `CommunicationsException` implemented, that tries to determine why communications was lost with a server, and displays possible reasons when `.getMessage()` is called.
- NULL values for numeric types in binary encoded result sets causing `NullPointerException`s. (Bug#2359 [<http://bugs.mysql.com/2359>])
- Implemented `Connection.prepareCall()`, and `DatabaseMetaData.getProcedures()` and `getProcedureColumns()`.
- Reset long binary parameters in `ServerPreparedStatement` when `clearParameters()` is called, by sending `COM_RESET_STMT` to the server.
- Merged prepared statement caching, and `.getMetaData()` support from 3.0 branch.
- Fixed off-by-1900 error in some cases for years in `TimeUtil.fastDate/TimeCreate()` when unpacking results from server-side prepared statements.
- Fixed charset conversion issue in `getTables()`. (Bug#2502 [<http://bugs.mysql.com/2502>])
- Implemented multiple result sets returned from a statement or stored procedure.
- Server-side prepared statements were not returning datatype `YEAR` correctly. (Bug#2606 [<http://bugs.mysql.com/2606>])
- Enabled streaming of result sets from server-side prepared statements.
- Class-cast exception when using scrolling result sets and server-side prepared statements. (Bug#2623 [<http://bugs.mysql.com/2623>])
- Merged unbuffered input code from 3.0.
- Fixed `ConnectionProperties` that weren't properly exposed via accessors, cleaned up `ConnectionProperties` code.
- NULL fields were not being encoded correctly in all cases in server-side prepared statements. (Bug#2671 [<http://bugs.mysql.com/2671>])
- Fixed rare buffer underflow when writing numbers into buffers for sending prepared statement execution requests.
- Use DocBook version of docs for shipped versions of drivers.

### **23.3.6.15. Changes in MySQL Connector/J 3.1.0-alpha (18 February 2003)**

- Added `requireSSL` property.
- Added `useServerPrepStmts` property (default `false`). The driver will use server-side prepared statements when the server version supports them (4.1 and newer) when this property is set to `true`. It is currently set to `false` by default until all bind/fetch functionality has been implemented. Currently only DML prepared statements are implemented for 4.1 server-side prepared statements.
- Track open Statements, close all when `Connection.close()` is called (JDBC compliance).

### **23.3.6.16. Changes in MySQL Connector/J 3.0.17-ga (23 June 2005)**

- Timestamp/Time conversion goes in the wrong “direction” when `useTimeZone=true` and server time zone differs from client time zone. (Bug#5874 [<http://bugs.mysql.com/5874>])
- `DatabaseMetaData.getIndexInfo()` ignored `unique` parameter. (Bug#7081 [<http://bugs.mysql.com/7081>])
- Support new protocol type `MYSQL_TYPE_VARCHAR`.
- Added `useOldUTF8Behavior` configuration property, which causes JDBC driver to act like it did with MySQL-4.0.x and earlier when the character encoding is `utf-8` when connected to MySQL-4.1 or newer.
- Statements created from a pooled connection were returning physical connection instead of logical connection when `getConnection()` was called. (Bug#7316 [<http://bugs.mysql.com/7316>])
- PreparedStatements don't encode Big5 (and other multi-byte) character sets correctly in static SQL strings. (Bug#7033 [<http://bugs.mysql.com/7033>])
- Connections starting up failed-over (due to down master) never retry master. (Bug#6966 [<http://bugs.mysql.com/6966>])
- `PreparedStatement.fixDecimalExponent()` adding extra `+`, making number unparseable by MySQL server. (Bug#7061 [<http://bugs.mysql.com/7061>])
- Timestamp key column data needed `_binary` stripped for `UpdatableResultSet.refreshRow()`. (Bug#7686 [<http://bugs.mysql.com/7686>])
- Backported SQLState codes mapping from Connector/J 3.1, enable with `useSqlStateCodes=true` as a connection property, it defaults to `false` in this release, so that we don't break legacy applications (it defaults to `true` starting with Connector/J 3.1).
- `PreparedStatement.fixDecimalExponent()` adding extra `+`, making number unparseable by MySQL server. (Bug#7601 [<http://bugs.mysql.com/7601>])
- Escape sequence `{fn convert(..., type)}` now supports ODBC-style types that are prepended by `SQL_`.
- Fixed duplicated code in `configureClientCharset()` that prevented `useOldUTF8Behavior=true` from working properly.
- Handle streaming result sets with more than 2 billion rows properly by fixing wraparound of row number counter.
- `MS932`, `SHIFT_JIS`, and `Windows_31J` not recognized as aliases for `sjis`. (Bug#7607 [<http://bugs.mysql.com/7607>])
- Adding `CP943` to aliases for `sjis`. (Bug#6549 [<http://bugs.mysql.com/6549>], fixed while fixing Bug#7607 [<http://bugs.mysql.com/7607>])
- Which requires hex escaping of binary data when using multi-byte charsets with prepared statements. (Bug#8064 [<http://bugs.mysql.com/8064>])
- `NON_UNIQUE` column from `DBMD.getIndexInfo()` returned inverted value. (Bug#8812 [<http://bugs.mysql.com/8812>])
- Workaround for server Bug#9098 [<http://bugs.mysql.com/9098>]: Default values of `CURRENT_*` for `DATE`, `TIME`, `DATETIME`, and `TIMESTAMP` columns can't be distinguished from `string` values, so `UpdatableResultSet.moveToInsertRow()` generates bad SQL for inserting default values.
- `EUCKR` charset is sent as `SET NAMES euc_kr` which MySQL-4.1 and newer doesn't understand. (Bug#8629 [<http://bugs.mysql.com/8629>])

- `DatabaseMetaData.supportsSelectForUpdate()` returns correct value based on server version.
- Use hex escapes for `PreparedStatement.setBytes()` for double-byte charsets including “aliases” Windows-31J, CP934, MS932.
- Added support for the `EUC_JP_Solaris` character encoding, which maps to a MySQL encoding of `eucjpm`s (backported from 3.1 branch). This only works on servers that support `eucjpm`s, namely 5.0.3 or later.

### 23.3.6.17. Changes in MySQL Connector/J 3.0.16-ga (15 November 2004)

- Re-issue character set configuration commands when re-using pooled connections and/or `Connection.changeUser()` when connected to MySQL-4.1 or newer.
- Fixed `ResultSetMetaData.isReadOnly()` to detect non-writable columns when connected to MySQL-4.1 or newer, based on existence of “original” table and column names.
- `ResultSet.updateByte()` when on insert row throws `ArrayOutOfBoundsException`. (Bug#5664 [<http://bugs.mysql.com/5664>])
- Fixed `DatabaseMetaData.getTypes()` returning incorrect (this is, non-negative) scale for the `NUMERIC` type.
- Off-by-one bug in `Buffer.readString(string)`. (Bug#5664 [<http://bugs.mysql.com/5664>])
- Made `TINYINT(1) -> BIT/Boolean` conversion configurable via `tinyIntIsBit` property (default true to be JDBC compliant out of the box).
- Only set `character_set_results` during connection establishment if server version  $\geq$  4.1.1.
- Fixed regression where `useUnbufferedInput` was defaulting to false.
- `ResultSet.getTimestamp()` on a column with `TIME` in it fails. (Bug#5664 [<http://bugs.mysql.com/5664>])

### 23.3.6.18. Changes in MySQL Connector/J 3.0.15-production (04 September 2004)

- `StringUtils.escapeEasternUnicodeByteStream` was still broken for GBK. (Bug#4010 [<http://bugs.mysql.com/4010>])
- Failover for `autoReconnect` not using port numbers for any hosts, and not retrying all hosts. (**Warning:** This required a change to the `SocketFactory.connect()` method signature, which is now `public Socket connect(String host, int portNumber, Properties props)`; therefore, any third-party socket factories will have to be changed to support this signature. (Bug#4334 [<http://bugs.mysql.com/4334>])
- Logical connections created by `MysqlConnectionPoolDataSource` will now issue a `rollback()` when they are closed and sent back to the pool. If your application server/connection pool already does this for you, you can set the `rollbackOnPooledClose` property to false to avoid the overhead of an extra `rollback()`.
- Removed redundant calls to `checkRowPos()` in `ResultSet`.

- `DOUBLE` mapped twice in `DBMD.getTypeInfo()`. (Bug#4742 [<http://bugs.mysql.com/4742>])
- Added FLOSS license exemption.
- Calling `.close()` twice on a `PooledConnection` causes NPE. (Bug#4808 [<http://bugs.mysql.com/4808>])
- `DBMD.getColumns()` returns incorrect JDBC type for unsigned columns. This affects type mappings for all numeric types in the `RSMD.getColumnType()` and `RSMD.getColumnTypeNames()` methods as well, to ensure that “like” types from `DBMD.getColumns()` match up with what `RSMD.getColumnType()` and `getColumnTypeNames()` return. (Bug#4138 [<http://bugs.mysql.com/4138>], Bug#4860 [<http://bugs.mysql.com/4860>])
- “Production” is now “GA” (General Availability) in naming scheme of distributions.
- `RSMD.getPrecision()` returning 0 for non-numeric types (should return max length in chars for non-binary types, max length in bytes for binary types). This fix also fixes mapping of `RSMD.getColumnType()` and `RSMD.getColumnTypeName()` for the BLOB types based on the length sent from the server (the server doesn't distinguish between TINYBLOB, BLOB, MEDIUMBLOB or LONGBLOB at the network protocol level). (Bug#4880 [<http://bugs.mysql.com/4880>])
- `ResultSet` should release `Field[]` instance in `.close()`. (Bug#5022 [<http://bugs.mysql.com/5022>])
- `ResultSet.getMetaData()` should not return incorrectly initialized metadata if the result set has been closed, but should instead throw an `SQLException`. Also fixed for `getRow()` and `getWarnings()` and traversal methods by calling `checkClosed()` before operating on instance-level fields that are nullified during `.close()`. (Bug#5069 [<http://bugs.mysql.com/5069>])
- Parse new time zone variables from 4.1.x servers.
- Use `_binary` introducer for `PreparedStatement.setBytes()` and `set*Stream()` when connected to MySQL-4.1.x or newer to avoid misinterpretation during character conversion.

### 23.3.6.19. Changes in MySQL Connector/J 3.0.14-production (28 May 2004)

- Fixed URL parsing error.

### 23.3.6.20. Changes in MySQL Connector/J 3.0.13-production (27 May 2004)

- Using a `MySQLDataSource` without server name fails. (Bug#3848 [<http://bugs.mysql.com/3848>])
- No Database Selected when using `MysqlConnectionPoolDataSource`. (Bug#3920 [<http://bugs.mysql.com/3920>])
- `PreparedStatement.getGeneratedKeys()` method returns only 1 result for batched insertions. (Bug#3873 [<http://bugs.mysql.com/3873>])

### 23.3.6.21. Changes in MySQL Connector/J 3.0.12-production (18 May 2004)

- Add unsigned attribute to `DatabaseMetaData.getColumns()` output in the `TYPE_NAME` column.
- Added `failOverReadOnly` property, to allow end-user to configure state of connection (read-only/writable) when failed over.
- Backported “change user” and “reset server state” functionality from 3.1 branch, to allow clients of `MysqlConnectionPoolDataSource` to reset server state on `getConnection()` on a pooled connection.
- Don't escape SJIS/GBK/BIG5 when using MySQL-4.1 or newer.
- Allow `url` parameter for `MysqlDataSource` and `MysqlConnectionPoolDataSource` so that passing of other properties is possible from inside appservers.
- Map duplicate key and foreign key errors to `SQLState` of 23000.
- Backport documentation tooling from 3.1 branch.
- Return creating statement for `ResultSets` created by `getGeneratedKeys()`. (Bug#2957 [<http://bugs.mysql.com/2957>])
- Allow `java.util.Date` to be sent in as parameter to `PreparedStatement.setObject()`, converting it to a `Timestamp` to maintain full precision. (Bug#103 [<http://bugs.mysql.com/103>]).
- Don't truncate BLOB or CLOB values when using `setBytes()` and/or `setBinary/CharacterStream()`. (Bug#2670 [<http://bugs.mysql.com/2670>]).
- Dynamically configure character set mappings for field-level character sets on MySQL-4.1.0 and newer using `SHOW COLLATION` when connecting.
- Map binary character set to `US-ASCII` to support `DATETIME` charset recognition for servers  $\geq 4.1.2$ .
- Use `SET character_set_results` during initialization to allow any charset to be returned to the driver for result sets.
- Use `charsetnr` returned during connect to encode queries before issuing `SET NAMES` on MySQL  $\geq 4.1.0$ .
- Add helper methods to `ResultSetMetaData` (`getColumnCharacterEncoding()` and `getColumnCharacterSet()`) to allow end-users to see what charset the driver thinks it should be using for the column.
- Only set `character_set_results` for MySQL  $\geq 4.1.0$ .
- `StringUtils.escapeSJISByteStream()` not covering all eastern double-byte charsets correctly. (Bug#3511 [<http://bugs.mysql.com/3511>])
- Renamed `StringUtils.escapeSJISByteStream()` to more appropriate `escapeEasternUnicodeByteStream()`.
- Not specifying database in URL caused `MalformedURLException` exception. (Bug#3554 [<http://bugs.mysql.com/3554>])
- Auto-convert MySQL encoding names to Java encoding names if used for `characterEncoding` property.

- Added encoding names that are recognized on some JVMs to fix case where they were reverse-mapped to MySQL encoding names incorrectly.
- Use `junit.textui.TestRunner` for all unit tests (to allow them to be run from the command line outside of Ant or Eclipse).
- `UpdatableResultSet` not picking up default values for `moveToInsertRow()`. (Bug#3557 [<http://bugs.mysql.com/3557>])
- Inconsistent reporting of data type. The server still doesn't return all types for `*BLOBs *TEXT` correctly, so the driver won't return those correctly. (Bug#3570 [<http://bugs.mysql.com/3570>])
- `DBMD.getSQLStateType()` returns incorrect value. (Bug#3520 [<http://bugs.mysql.com/3520>])
- Fixed regression in `PreparedStatement.setString()` and eastern character encodings.
- Made `StringRegressionTest` 4.1-unicode aware.

### 23.3.6.22. Changes in MySQL Connector/J 3.0.11-stable (19 February 2004)

- Trigger a `SET NAMES utf8` when encoding is forced to `utf8` or `utf-8` via the `characterEncoding` property. Previously, only the Java-style encoding name of `utf-8` would trigger this.
- `AutoReconnect` time was growing faster than exponentially. (Bug#2447 [<http://bugs.mysql.com/2447>])
- Fixed failover always going to last host in list. (Bug#2578 [<http://bugs.mysql.com/2578>])
- Added `useUnbufferedInput` parameter, and now use it by default (due to JVM issue <http://developer.java.sun.com/developer/bugParade/bugs/4401235.html>)
- Detect on/off or 1, 2, 3 form of `lower_case_table_names` value on server.
- Return `java.lang.Integer` for `TINYINT` and `SMALLINT` types from `ResultSetMetaData.getColumnClassName()`. (Bug#2852 [<http://bugs.mysql.com/2852>])
- Return `java.lang.Double` for `FLOAT` type from `ResultSetMetaData.getColumnClassName()`. (Bug#2855 [<http://bugs.mysql.com/2855>])
- Return `[B` instead of `java.lang.Object` for `BINARY`, `VARBINARY` and `LONGVARBINARY` types from `ResultSetMetaData.getColumnClassName()` (JDBC compliance).
- Issue connection events on all instances created from a `ConnectionPoolDataSource`.

### 23.3.6.23. Changes in MySQL Connector/J 3.0.10-stable (13 January 2004)

- Don't count quoted IDs when inside a 'string' in `PreparedStatement` parsing. (Bug#1511 [<http://bugs.mysql.com/1511>])
- "Friendlier" exception message for `PacketTooLargeException`. (Bug#1534 [<http://bugs.mysql.com/1534>])
- Backported fix for aliased tables and `UpdatableResultSets` in `checkUpdatability()` method from 3.1 branch.

- 
- Fix for `ArrayIndexOutOfBoundsException` exception when using `Statement.setMaxRows()`. (Bug#1695 [<http://bugs.mysql.com/1695>])
  - Barge blobs and split packets not being read correctly. (Bug#1576 [<http://bugs.mysql.com/1576>])
  - Fixed regression of `Statement.getGeneratedKeys()` and `REPLACE` statements.
  - Subsequent call to `ResultSet.updateFoo()` causes NPE if result set is not updatable. (Bug#1630 [<http://bugs.mysql.com/1630>])
  - Fix for 4.1.1-style authentication with no password.
  - Foreign Keys column sequence is not consistent in `DatabaseMetaData.getImported/Exported/CrossReference()`. (Bug#1731 [<http://bugs.mysql.com/1731>])
  - `DatabaseMetaData.getSystemFunction()` returning bad function `VResultsSion`. (Bug#1775 [<http://bugs.mysql.com/1775>])
  - Cross-database updatable result sets are not checked for updatability correctly. (Bug#1592 [<http://bugs.mysql.com/1592>])
  - `DatabaseMetaData.getColumns()` should return `Types.LONGVARCHAR` for MySQL `LONGTEXT` type.
  - `ResultSet.getObject()` on `TINYINT` and `SMALLINT` columns should return Java type `Integer`. (Bug#1913 [<http://bugs.mysql.com/1913>])
  - Added `alwaysClearStream` connection property, which causes the driver to always empty any remaining data on the input stream before each query.
  - Added more descriptive error message `Server Configuration Denies Access to DataSource`, as well as retrieval of message from server.
  - Autoreconnect code didn't set catalog upon reconnect if it had been changed.
  - Implement `ResultSet.updateClob()`.
  - `ResultSetMetaData.isCaseSensitive()` returned wrong value for `CHAR/VARCHAR` columns.
  - Connection property `maxRows` not honored. (Bug#1933 [<http://bugs.mysql.com/1933>])
  - Statements being created too many times in `DBMD.extractForeignKeyFromCreateTable()`. (Bug#1925 [<http://bugs.mysql.com/1925>])
  - Support escape sequence `{fn convert ... }`. (Bug#1914 [<http://bugs.mysql.com/1914>])
  - `ArrayIndexOutOfBoundsException` when parameter number == number of parameters + 1. (Bug#1958 [<http://bugs.mysql.com/1958>])
  - `ResultSet.findColumn()` should use first matching column name when there are duplicate column names in `SELECT` query (JDBC-compliance). (Bug#2006 [<http://bugs.mysql.com/2006>])
  - Removed static synchronization bottleneck from `PreparedStatement.setTimestamp()`.
  - Removed static synchronization bottleneck from instance factory method of `SingleByteCharsetConverter`.
  - Enable caching of the parsing stage of prepared statements via the `cachePrepStmts`, `prep-`
-

`stmtCacheSize`, and `prepStmtCacheSqlLimit` properties (disabled by default).

- Speed up parsing of `PreparedStatement`s, try to use one-pass whenever possible.
- Fixed security exception when used in Applets (applets can't read the system property `file.encoding` which is needed for `LOAD DATA LOCAL INFILE`).
- Use constants for `SQLStates`.
- Map charset `ko18_ru` to `ko18r` when connected to MySQL-4.1.0 or newer.
- Ensure that `Buffer.writeString()` saves room for the `\0`.
- Fixed exception `Unknown character set 'danish'` on connect with JDK-1.4.0
- Fixed mappings in `SQLException` to report deadlocks with `SQLStates` of 41000.
- `maxRows` property would affect internal statements, so check it for all statement creation internal to the driver, and set to 0 when it is not.

### 23.3.6.24. Changes in MySQL Connector/J 3.0.9-stable (07 October 2003)

- Faster date handling code in `ResultSet` and `PreparedStatement` (no longer uses `Date` methods that synchronize on static calendars).
- Fixed test for end of buffer in `Buffer.readString()`.
- Fixed `ResultSet.previous()` behavior to move current position to before result set when on first row of result set. (Bug#496 [<http://bugs.mysql.com/496>])
- Fixed `Statement` and `PreparedStatement` issuing bogus queries when `setMaxRows()` had been used and a `LIMIT` clause was present in the query.
- `refreshRow` didn't work when primary key values contained values that needed to be escaped (they ended up being doubly escaped). (Bug#661 [<http://bugs.mysql.com/661>])
- Support InnoDB constraint names when extracting foreign key information in `DatabaseMetaData` (implementing ideas from Parwinder Sekhon). (Bug#517 [<http://bugs.mysql.com/517>], Bug#664 [<http://bugs.mysql.com/664>])
- Backported 4.1 protocol changes from 3.1 branch (server-side SQL states, new field information, larger client capability flags, connect-with-database, and so forth).
- Fix `UpdatableResultSet` to return values for `getXXX()` when on insert row. (Bug#675 [<http://bugs.mysql.com/675>])
- The `insertRow` in an `UpdatableResultSet` is now loaded with the default column values when `moveToInsertRow()` is called. (Bug#688 [<http://bugs.mysql.com/688>])
- `DatabaseMetaData.getColumns()` wasn't returning `NULL` for default values that are specified as `NULL`.
- Change default statement type/concurrency to `TYPE_FORWARD_ONLY` and `CONCUR_READ_ONLY` (spec compliance).
- Don't try and reset isolation level on reconnect if MySQL doesn't support them.
- Don't wrap `SQLExceptions` in `RowDataDynamic`.
- Don't change timestamp TZ twice if `useTimezone==true`. (Bug#774)

[<http://bugs.mysql.com/774>])

- Fixed regression in large split-packet handling. (Bug#848 [<http://bugs.mysql.com/848>])
- Better diagnostic error messages in exceptions for “streaming” result sets.
- Issue exception on `ResultSet.getXXX()` on empty result set (wasn't caught in some cases).
- Don't hide messages from exceptions thrown in I/O layers.
- Don't fire connection closed events when closing pooled connections, or on `PooledConnection.getConnection()` with already open connections. (Bug#884 [<http://bugs.mysql.com/884>])
- Clip +/- INF (to smallest and largest representative values for the type in MySQL) and NaN (to 0) for `setDouble/setFloat()`, and issue a warning on the statement when the server does not support +/- INF or NaN.
- Double-escaping of `'\'` when charset is SJIS or GBK and `'\'` appears in non-escaped input. (Bug#879 [<http://bugs.mysql.com/879>])
- When emptying input stream of unused rows for “streaming” result sets, have the current thread `yield()` every 100 rows in order to not monopolize CPU time.
- `DatabaseMetaData.getColumns()` getting confused about the keyword “set” in character columns. (Bug#1099 [<http://bugs.mysql.com/1099>])
- Fixed deadlock issue with `Statement.setMaxRows()`.
- Fixed `CLOB.truncate()`. (Bug#1130 [<http://bugs.mysql.com/1130>])
- Optimized `CLOB.setCharacterStream()`. (Bug#1131 [<http://bugs.mysql.com/1131>])
- Made `databaseName`, `portNumber`, and `serverName` optional parameters for `MySQLDataSourceFactory`. (Bug#1246 [<http://bugs.mysql.com/1246>])
- `ResultSet.get/setString` mashing char 127. (Bug#1247 [<http://bugs.mysql.com/1247>])
- Backported authentication changes for 4.1.1 and newer from 3.1 branch.
- Added `com.mysql.jdbc.util.BaseBugReport` to help creation of testcases for bug reports.
- Added property to “clobber” streaming results, by setting the `clobberStreamingResults` property to `true` (the default is `false`). This will cause a “streaming” `ResultSet` to be automatically closed, and any outstanding data still streaming from the server to be discarded if another query is executed before all the data has been read from the server.

### 23.3.6.25. Changes in MySQL Connector/J 3.0.8-stable (23 May 2003)

- Allow bogus URLs in `Driver.getPropertyInfo()`.
- Return list of generated keys when using multi-value INSERTS with `Statement.getGeneratedKeys()`.
- Use JVM charset with filenames and `LOAD DATA [LOCAL] INFILE`.
- Fix infinite loop with `Connection.cleanup()`.
- Changed Ant target `compile-core` to `compile-driver`, and made test suite compilation a

separate target.

- Fixed result set not getting set for `Statement.executeUpdate()`, which affected `getGeneratedKeys()` and `getUpdateCount()` in some cases.
- Unicode character `0xFFFF` in a string would cause the driver to throw an `ArrayOutOfBoundsException`. (Bug#378 [<http://bugs.mysql.com/378>]).
- Return correct number of generated keys when using `REPLACE` statements.
- Fix problem detecting server character set in some cases.
- Fix row data decoding error when using *very* large packets.
- Optimized row data decoding.
- Issue exception when operating on an already closed prepared statement.
- Fixed SJIS encoding bug, thanks to Naoto Sato.
- Optimized usage of `EscapeProcessor`.
- Allow multiple calls to `Statement.close()`.

### **23.3.6.26. Changes in MySQL Connector/J 3.0.7-stable (08 April 2003)**

- Fixed `MysqlPooledConnection.close()` calling wrong event type.
- Fixed `StringIndexOutOfBoundsException` in `PreparedStatement.setClob()`.
- 4.1 Column Metadata fixes
- Remove synchronization from `Driver.connect()` and `Driver.acceptsUrl()`.
- `IOExceptions` during a transaction now cause the `Connection` to be closed.
- Fixed missing conversion for 'YEAR' type in `ResultSetMetaData.getColumnTypeName()`.
- Don't pick up indexes that start with 'pri' as primary keys for `DBMD.getPrimaryKeys()`.
- Throw `SQLExceptions` when trying to do operations on a forcefully closed `Connection` (i.e. when a communication link failure occurs).
- You can now toggle profiling on/off using `Connection.setProfileSql(boolean)`.
- Fixed charset issues with database metadata (charset was not getting set correctly).
- Updatable `ResultSets` can now be created for aliased tables/columns when connected to MySQL-4.1 or newer.
- Fixed 'LOAD DATA LOCAL INFILE' bug when `file > max_allowed_packet`.
- Fixed escaping of `0x5c ('\')` character for GBK and Big5 charsets.
- Fixed `ResultSet.getTimestamp()` when underlying field is of type `DATE`.
- Ensure that packet size from `alignPacketSize()` does not exceed `MAX_ALLOWED_PACKET` (JVM bug)
- Don't reset `Connection.isReadOnly()` when `autoReconnecting`.

### 23.3.6.27. Changes in MySQL Connector/J 3.0.6-stable (18 February 2003)

- Fixed `ResultSetMetaData` to return "" when catalog not known. Fixes `NullPointerException`s with Sun's `CachedRowSet`.
- Fixed `DBMD.getTypeInfo()` and `DBMD.getColumns()` returning different value for precision in `TEXT/BLOB` types.
- Allow ignoring of warning for 'non transactional tables' during rollback (compliance/usability) by setting 'ignoreNonTxTables' property to `true`.
- Fixed `SQLException`s getting swallowed on initial connect.
- Fixed `Statement.setMaxRows()` to stop sending 'LIMIT' type queries when not needed (performance)
- Clean up `Statement` query/method mismatch tests (i.e. `INSERT` not allowed with `.executeQuery()`).
- More checks added in `ResultSet` traversal method to catch when in closed state.
- Fixed `ResultSetMetaData.isWritable()` to return correct value.
- Add 'window' of different `NULL` sorting behavior to `DBMD.nullsAreSortedAtStart` (4.0.2 to 4.0.10, `true`, otherwise, `no`).
- Implemented `Blob.setBytes()`. You still need to pass the resultant `Blob` back into an updatable `ResultSet` or `PreparedStatement` to persist the changes, as MySQL does not support 'locators'.
- Backported 4.1 charset field info changes from Connector/J 3.1

### 23.3.6.28. Changes in MySQL Connector/J 3.0.5-gamma (22 January 2003)

- Fixed `Buffer.fastSkipLenString()` causing `ArrayIndexOutOfBoundsException` exceptions with some queries when unpacking fields.
- Implemented an empty `TypeMap` for `Connection.getTypeMap()` so that some third-party apps work with MySQL (IBM WebSphere 5.0 Connection pool).
- Added missing `LONGTEXT` type to `DBMD.getColumns()`.
- Retrieve `TX_ISOLATION` from database for `Connection.getTransactionIsolation()` when the MySQL version supports it, instead of an instance variable.
- Quote table names in `DatabaseMetaData.getColumns()`, `getPrimaryKeys()`, `getIndexInfo()`, `getBestRowIdentifier()`
- Greatly reduce memory required for `setBinaryStream()` in `PreparedStatement`s.
- Fixed `ResultSet.isBeforeFirst()` for empty result sets.
- Added update options for foreign key metadata.

### 23.3.6.29. Changes in MySQL Connector/J 3.0.4-gamma (06 January 2003)

- Added quoted identifiers to database names for `Connection.setCatalog()`.
- Added support for quoted identifiers in `PreparedStatement` parser.
- Streamlined character conversion and `byte[]` handling in `PreparedStatements` for `setByte()`.
- Reduce memory footprint of `PreparedStatements` by sharing outbound packet with `MySQLIO`.
- Added 'strictUpdates' property to allow control of amount of checking for 'correctness' of updatable result sets. Set this to `false` if you want faster updatable result sets and you know that you create them from `SELECTs` on tables with primary keys and that you have selected all primary keys in your query.
- Added support for 4.0.8-style large packets.
- Fixed `PreparedStatement.executeBatch()` parameter overwriting.

### **23.3.6.30. Changes in MySQL Connector/J 3.0.3-dev (17 December 2002)**

- Changed `charsToByte` in `SingleByteCharConverter` to be non-static
- Changed `SingleByteCharConverter` to use lazy initialization of each converter.
- Fixed charset handling in `Fields.java`
- Implemented `Connection.nativeSQL()`
- More robust escape tokenizer -- recognize '--' comments, and allow nested escape sequences (see `testsuite.EscapeProcessingTest`)
- `DBMD.getImported/ExportedKeys()` now handles multiple foreign keys per table.
- Fixed `ResultSetMetaData.getPrecision()` returning incorrect values for some floating point types.
- Fixed `ResultSetMetaData.getColumnTypeName()` returning `BLOB` for `TEXT` and `TEXT` for `BLOB` types.
- Fixed `Buffer.isLastDataPacket()` for 4.1 and newer servers.
- Added `CLIENT_LONG_FLAG` to be able to get more column flags (`isAutoIncrement()` being the most important)
- Because of above, implemented `ResultSetMetaData.isAutoIncrement()` to use `Field.isAutoIncrement()`.
- Honor 'lower\_case\_table\_names' when enabled in the server when doing table name comparisons in `DatabaseMetaData` methods.
- Some `MySQL-4.1` protocol support (extended field info from selects)
- Use non-aliased table/column names and database names to fully qualify tables and columns in `UpdatableResultSet` (requires `MySQL-4.1` or newer)
- Allow user to alter behavior of `Statement/ PreparedStatement.executeBatch()` via 'continueBatchOnError' property (defaults to `true`).
- Check for connection closed in more `Connection` methods (`createStatement`, `prepareStatement`, `setTransactionIsolation`, `setAutoCommit`).
- More robust implementation of updatable result sets. Checks that `_all_` primary keys of the table

have been selected.

- 'LOAD DATA LOCAL INFILE ...' now works, if your server is configured to allow it. Can be turned off with the 'allowLoadLocalInfile' property (see the README).
- Substitute '?' for unknown character conversions in single-byte character sets instead of '\0'.
- NamedPipeSocketFactory now works (only intended for Windows), see README for instructions.

### **23.3.6.31. Changes in MySQL Connector/J 3.0.2-dev (08 November 2002)**

- Fixed issue with updatable result sets and PreparedStatements not working
- Fixed ResultSet.setFetchDirection(FETCH\_UNKNOWN)
- Fixed issue when calling Statement.setFetchSize() when using arbitrary values
- Fixed incorrect conversion in ResultSet.getLong()
- Implemented ResultSet.updateBlob().
- Removed duplicate code from UpdatableResultSet (it can be inherited from ResultSet, the extra code for each method to handle updatability I thought might someday be necessary has not been needed).
- Fixed "UnsupportedEncodingException" thrown when "forcing" a character encoding via properties.
- Fixed various non-ASCII character encoding issues.
- Added driver property 'useHostsInPrivileges'. Defaults to true. Affects whether or not '@hostname' will be used in DBMD.getColumn/TablePrivileges.
- All DBMD result set columns describing schemas now return NULL to be more compliant with the behavior of other JDBC drivers for other database systems (MySQL does not support schemas).
- Added SSL support. See README for information on how to use it.
- Properly restore connection properties when autoReconnecting or failing-over, including autoCommit state, and isolation level.
- Use 'SHOW CREATE TABLE' when possible for determining foreign key information for DatabaseMetaData...also allows cascade options for DELETE information to be returned
- Escape 0x5c character in strings for the SJIS charset.
- Fixed start position off-by-1 error in Clob.getSubString()
- Implemented Clob.truncate()
- Implemented Clob.setString()
- Implemented Clob.setAsciiStream()
- Implemented Clob.setCharacterStream()
- Added com.mysql.jdbc.MiniAdmin class, which allows you to send 'shutdown' command to MySQL server...Intended to be used when 'embedding' Java and MySQL server together in an

end-user application.

- Added 'connectTimeout' parameter that allows users of JDK-1.4 and newer to specify a maximum time to wait to establish a connection.
- Failover and autoReconnect only work when the connection is in a autoCommit(false) state, in order to stay transaction safe
- Added 'queriesBeforeRetryMaster' property that specifies how many queries to issue when failed over before attempting to reconnect to the master (defaults to 50)
- Fixed DBMD.supportsResultSetConcurrency() so that it returns true for ResultSet.TYPE\_SCROLL\_INSENSITIVE and ResultSet.CONCUR\_READ\_ONLY or ResultSet.CONCUR\_UPDATABLE
- Fixed ResultSet.isLast() for empty result sets (should return false).
- PreparedStatement now honors stream lengths in setBinary/Ascii/Character Stream() unless you set the connection property 'useStreamLengthsInPrepStmts' to false.
- Removed some not-needed temporary object creation by using Strings smarter in EscapeProcessor, Connection and DatabaseMetaData classes.

### **23.3.6.32. Changes in MySQL Connector/J 3.0.1-dev (21 September 2002)**

- Fixed ResultSet.getRow() off-by-one bug.
- Fixed RowDataStatic.getAt() off-by-one bug.
- Added limited Clob functionality (ResultSet.getClob(), PreparedStatement.setClob(), PreparedStatement.setObject(Clob)).
- Added socketTimeout parameter to URL.
- Connection.isClosed() no longer "pings" the server.
- Connection.close() issues rollback() when getAutoCommit() == false
- Added "paranoid" parameter...sanitizes error messages removing "sensitive" information from them (such as hostnames, ports, or usernames), as well as clearing "sensitive" data structures when possible.
- Fixed ResultSetMetaData.isSigned() for TINYINT and BIGINT.
- Charsets now automatically detected. Optimized code for single-byte character set conversion.
- Implemented ResultSet.getCharacterStream()
- Added "LOCAL TEMPORARY" to table types in DatabaseMetaData.getTableTypes()
- Massive code clean-up to follow Java coding conventions (the time had come)

### **23.3.6.33. Changes in MySQL Connector/J 3.0.0-dev (31 July 2002)**

- !!! LICENSE CHANGE !!! The driver is now GPL. If you need non-GPL licenses, please contact me <mark@mysql.com>

- JDBC-3.0 functionality including Statement/PreparedStatement.getGeneratedKeys() and ResultSet.getURL()
- Performance enhancements - driver is now 50-100% faster in most situations, and creates fewer temporary objects
- Repackaging...new driver name is "com.mysql.jdbc.Driver", old name still works, though (the driver is now provided by MySQL-AB)
- Better checking for closed connections in Statement and PreparedStatement.
- Support for streaming (row-by-row) result sets (see README) Thanks to Doron.
- Support for large packets (new addition to MySQL-4.0 protocol), see README for more information.
- JDBC Compliance -- Passes all tests besides stored procedure tests
- Fix and sort primary key names in DBMetaData (SF bugs 582086 and 582086)
- Float types now reported as java.sql.Types.FLOAT (SF bug 579573)
- ResultSet.getTimestamp() now works for DATE types (SF bug 559134)
- ResultSet.getDate/Time/Timestamp now recognizes all forms of invalid values that have been set to all zeroes by MySQL (SF bug 586058)
- Testsuite now uses Junit (which you can get from [www.junit.org](http://www.junit.org))
- The driver now only works with JDK-1.2 or newer.
- Added multi-host failover support (see README)
- General source-code cleanup.
- Overall speed improvements via controlling transient object creation in MySQLIO class when reading packets
- Performance improvements in string handling and field metadata creation (lazily instantiated) contributed by Alex Twisleton-Wykeham-Fiennes

#### **23.3.6.34. Changes in MySQL Connector/J 2.0.14 (16 May 2002)**

- More code cleanup
- PreparedStatement now releases resources on .close() (SF bug 553268)
- Quoted identifiers not used if server version does not support them. Also, if server started with -ansi or --sql-mode=ANSI\_QUOTES then "" will be used as an identifier quote, otherwise '' will be used.
- ResultSet.getDouble() now uses code built into JDK to be more precise (but slower)
- LogicalHandle.isClosed() calls through to physical connection
- Added SQL profiling (to STDERR). Set "profileSql=true" in your JDBC url. See README for more information.
- Fixed typo for relaxAutoCommit parameter.

#### **23.3.6.35. Changes in MySQL Connector/J 2.0.13 (24 April 2002)**

- More code cleanup.
- Fixed unicode chars being read incorrectly (SF bug 541088)
- Faster blob escaping for PreparedStatement
- Added set/getPortNumber() to DataSource(s) (SF bug 548167)
- Added setURL() to MySQLXADataSource (SF bug 546019)
- PreparedStatement.toString() fixed (SF bug 534026)
- ResultSetMetaData.getColumnClassName() now implemented
- Rudimentary version of Statement.getGeneratedKeys() from JDBC-3.0 now implemented (you need to be using JDK-1.4 for this to work, I believe)
- DBMetaData.getIndexInfo() - bad PAGES fixed (SF BUG 542201)

### **23.3.6.36. Changes in MySQL Connector/J 2.0.12 (07 April 2002)**

- General code cleanup.
- Added getIdleFor() method to Connection and MySQLLogicalHandle.
- Relaxed synchronization in all classes, should fix 520615 and 520393.
- Added getTable/ColumnPrivileges() to DBMD (fixes 484502).
- Added new types to getTypeInfo(), fixed existing types thanks to Al Davis and Kid Kalanon.
- Added support for BIT types (51870) to PreparedStatement.
- Fixed getRow() bug (527165) in ResultSet
- Fixes for ResultSet updatability in PreparedStatement.
- Fixed time zone off by 1-hour bug in PreparedStatement (538286, 528785).
- ResultSet: Fixed updatability (values being set to null if not updated).
- DataSources - fixed setUrl bug (511614, 525565), wrong datasource class name (532816, 528767)
- Added identifier quoting to all DatabaseMetaData methods that need them (should fix 518108)
- Added support for YEAR type (533556)
- ResultSet.insertRow() should now detect auto\_increment fields in most cases and use that value in the new row. This detection will not work in multi-valued keys, however, due to the fact that the MySQL protocol does not return this information.
- ResultSet.refreshRow() implemented.
- Fixed testsuite.Traversal afterLast() bug, thanks to Igor Lastric.

### **23.3.6.37. Changes in MySQL Connector/J 2.0.11 (27 January 2002)**

- Fixed missing DELETE\_RULE value in DBMD.getImported/ExportedKeys() and getCross-Reference().
- Full synchronization of Statement.java.
- More changes to fix "Unexpected end of input stream" errors when reading BLOBs. This should be the last fix.

### **23.3.6.38. Changes in MySQL Connector/J 2.0.10 (24 January 2002)**

- Fixed spurious "Unexpected end of input stream" errors in MysqlIO (bug 507456).
- Fixed null-pointer-exceptions when using MySqlConnectionPoolDataSource with Websphere 4 (bug 505839).

### **23.3.6.39. Changes in MySQL Connector/J 2.0.9 (13 January 2002)**

- Ant build was corrupting included jar files, fixed (bug 487669).
- Fixed extra memory allocation in MysqlIO.readPacket() (bug 488663).
- Implementation of DatabaseMetaData.getExported/ImportedKeys() and getCrossReference().
- Full synchronization on methods modifying instance and class-shared references, driver should be entirely thread-safe now (please let me know if you have problems)
- DataSource implementations moved to org.gjt.mm.mysql.jdbc2.optional package, and (initial) implementations of PooledConnectionDataSource and XADataSource are in place (thanks to Todd Wolff for the implementation and testing of PooledConnectionDataSource with IBM WebSphere 4).
- Added detection of network connection being closed when reading packets (thanks to Todd Lizambri).
- Fixed quoting error with escape processor (bug 486265).
- Report batch update support through DatabaseMetaData (bug 495101).
- Fixed off-by-one-hour error in PreparedStatement.setTimestamp() (bug 491577).
- Removed concatenation support from driver (the '||' operator), as older versions of VisualAge seem to be the only thing that use it, and it conflicts with the logical '||' operator. You will need to start mysqld with the "--ansi" flag to use the '||' operator as concatenation (bug 491680)
- Fixed casting bug in PreparedStatement (bug 488663).

### **23.3.6.40. Changes in MySQL Connector/J 2.0.8 (25 November 2001)**

- Batch updates now supported (thanks to some inspiration from Daniel Rall).
- XADataSource/ConnectionPoolDataSource code (experimental)
- PreparedStatement.setAnyNumericType() now handles positive exponents correctly (adds "+" so MySQL can understand it).

- `DatabaseMetaData.getPrimaryKeys()` and `getBestRowIdentifier()` are now more robust in identifying primary keys (matches regardless of case or abbreviation/full spelling of Primary Key in `Key_type` column).

### **23.3.6.41. Changes in MySQL Connector/J 2.0.7 (24 October 2001)**

- `PreparedStatement.setCharacterStream()` now implemented
- Fixed dangling socket problem when in high availability (`autoReconnect=true`) mode, and finalizer for `Connection` will close any dangling sockets on GC.
- Fixed `ResultSetMetaData.getPrecision()` returning one less than actual on newer versions of MySQL.
- `ResultSet.getBlob()` now returns null if column value was null.
- Character sets read from database if `useUnicode=true` and `characterEncoding` is not set. (thanks to Dmitry Vereshchagin)
- Initial transaction isolation level read from database (if available) (thanks to Dmitry Vereshchagin)
- Fixed `DatabaseMetaData.supportsTransactions()`, and `supportsTransactionIsolationLevel()` and `getTypeInfo()` `SQL_DATETIME_SUB` and `SQL_DATA_TYPE` fields not being readable.
- Fixed `PreparedStatement` generating SQL that would end up with syntax errors for some queries.
- Fixed `ResultSet.isAfterLast()` always returning false.
- Fixed time zone issue in `PreparedStatement.setTimestamp()` (thanks to Erik Olofsson)
- Capitalize type names when "`capitalizeTypeNames=true`" is passed in URL or properties (for `WebObjects`, thanks to Anjo Krank)
- Updatable result sets now correctly handle NULL values in fields.
- `PreparedStatement.setDouble()` now uses full-precision doubles (reverting a fix made earlier to truncate them).
- `PreparedStatement.setBoolean()` will use 1/0 for values if your MySQL version is 3.21.23 or higher.

### **23.3.6.42. Changes in MySQL Connector/J 2.0.6 (16 June 2001)**

- Fixed `PreparedStatement` parameter checking
- Fixed case-sensitive column names in `ResultSet.java`

### **23.3.6.43. Changes in MySQL Connector/J 2.0.5 (13 June 2001)**

- Fixed `ResultSet.getBlob()` `ArrayIndex` out-of-bounds
- Fixed `ResultSetMetaData.getColumnTypeName` for TEXT/BLOB
- Fixed `ArrayIndexOutOfBounds` when sending large BLOB queries (Max size packet was not being set)

- Added ISOLATION level support to `Connection.setIsolationLevel()`
- Fixed NPE on `PreparedStatement.executeUpdate()` when all columns have not been set.
- Fixed data parsing of `TIMESTAMPS` with 2-digit years
- Added `Byte` to `PreparedStatement.setObject()`
- `ResultSet.getBoolean()` now recognizes `'-1'` as `true`
- `ResultSet` has `+/-Inf/inf` support
- `ResultSet.insertRow()` works now, even if not all columns are set (they will be set to "NULL")
- `DataBaseMetaData.getCrossReference()` no longer `ArrayIndexOOB`
- `getObject()` on `ResultSet` correctly does `TINYINT->Byte` and `SMALLINT->Short`

#### **23.3.6.44. Changes in MySQL Connector/J 2.0.3 (03 December 2000)**

- Implemented `getBigDecimal()` without scale component for `JDBC2`.
- Fixed composite key problem with updatable result sets.
- Added detection of `-/+INF` for doubles.
- Faster ASCII string operations.
- Fixed incorrect detection of `MAX_ALLOWED_PACKET`, so sending large blobs should work now.
- Fixed off-by-one error in `java.sql.Blob` implementation code.
- Added "ultraDevHack" URL parameter, set to "true" to allow (broken) Macromedia UltraDev to use the driver.

#### **23.3.6.45. Changes in MySQL Connector/J 2.0.1 (06 April 2000)**

- Fixed `RSMD.isWritable()` returning wrong value. Thanks to Moritz Maass.
- Cleaned up exception handling when driver connects
- Columns that are of type `TEXT` now return as `Strings` when you use `getObject()`
- `DatabaseMetaData.getPrimaryKeys()` now works correctly wrt to `key_seq`. Thanks to Brian Slesinsky.
- No escape processing is done on `PreparedStatements` anymore per `JDBC` spec.
- Fixed many `JDBC-2.0` traversal, positioning bugs, especially wrt to empty result sets. Thanks to Ron Smits, Nick Brook, Cessar Garcia and Carlos Martinez.
- Fixed some issues with updatability support in `ResultSet` when using multiple primary keys.

#### **23.3.6.46. Changes in MySQL Connector/J 2.0.0pre5 (21 February 2000)**

- Fixed Bad Handshake problem.

### **23.3.6.47. Changes in MySQL Connector/J 2.0.0pre4 (10 January 2000)**

- Fixes to ResultSet for insertRow() - Thanks to Cesar Garcia
- Fix to Driver to recognize JDBC-2.0 by loading a JDBC-2.0 class, instead of relying on JDK version numbers. Thanks to John Baker.
- Fixed ResultSet to return correct row numbers
- Statement.getUpdateCount() now returns rows matched, instead of rows actually updated, which is more SQL-92 like.

10-29-99

- Statement/PreparedStatement.getMoreResults() bug fixed. Thanks to Noel J. Bergman.
- Added Short as a type to PreparedStatement.setObject(). Thanks to Jeff Crowder
- Driver now automagically configures maximum/preferred packet sizes by querying server.
- Autoreconnect code uses fast ping command if server supports it.
- Fixed various bugs wrt. to packet sizing when reading from the server and when alloc'ing to write to the server.

### **23.3.6.48. Changes in MySQL Connector/J 2.0.0pre (17 August 1999)**

- Now compiles under JDK-1.2. The driver supports both JDK-1.1 and JDK-1.2 at the same time through a core set of classes. The driver will load the appropriate interface classes at runtime by figuring out which JVM version you are using.
- Fixes for result sets with all nulls in the first row. (Pointed out by Tim Endres)
- Fixes to column numbers in SQLExceptions in ResultSet (Thanks to Blas Rodriguez Somoza)
- The database no longer needs to be specified to connect. (Thanks to Christian Motschke)

### **23.3.6.49. Changes in MySQL Connector/J 1.2b (04 July 1999)**

- Better Documentation (in progress), in doc/mm.doc/book1.html
- DBMD now allows null for a column name pattern (not in spec), which it changes to '%'
- DBMD now has correct types/lengths for getXXX().
- ResultSet.getDate(), getTime(), and getTimestamp() fixes. (contributed by Alan Wilken)
- EscapeProcessor now handles \{ \} and { or } inside quotes correctly. (thanks to Alik for some ideas on how to fix it)

- Fixes to properties handling in Connection. (contributed by Juho Tikkala)
- `ResultSet.getObject()` now returns null for NULL columns in the table, rather than bombing out. (thanks to Ben Grosman)
- `ResultSet.getObject()` now returns Strings for types from MySQL that it doesn't know about. (Suggested by Chris Perdue)
- Removed `DataInput/Output` streams, not needed, 1/2 number of method calls per IO operation.
- Use default character encoding if one is not specified. This is a work-around for broken JVMs, because according to spec, EVERY JVM must support "ISO8859\_1", but they don't.
- Fixed Connection to use the platform character encoding instead of "ISO8859\_1" if one isn't explicitly set. This fixes problems people were having loading the character- converter classes that didn't always exist (JVM bug). (thanks to Fritz Elfert for pointing out this problem)
- Changed `MySQLIO` to re-use packets where possible to reduce memory usage.
- Fixed escape-processor bugs pertaining to { } inside quotes.

### **23.3.6.50. Changes in MySQL Connector/J 1.2a (14 April 1999)**

- Fixed character-set support for non-Javasoftware JVMs (thanks to many people for pointing it out)
- Fixed `ResultSet.getBoolean()` to recognize 'y' & 'n' as well as '1' & '0' as boolean flags. (thanks to Tim Pizey)
- Fixed `ResultSet.getTimestamp()` to give better performance. (thanks to Richard Swift)
- Fixed `getBytes()` for numeric types. (thanks to Ray Bellis)
- Fixed `DatabaseMetaData.getTypeInfo()` for DATE type. (thanks to Paul Johnston)
- Fixed `EscapeProcessor` for "fn" calls. (thanks to Piyush Shah at locomotive.org)
- Fixed `EscapeProcessor` to not do extraneous work if there are no escape codes. (thanks to Ryan Gustafson)
- Fixed Driver to parse URLs of the form "jdbc:mysql://host:port" (thanks to Richard Lobb)

### **23.3.6.51. Changes in MySQL Connector/J 1.1i (24 March 1999)**

- Fixed Timestamps for PreparedStatements
- Fixed null pointer exceptions in RSMD and RS
- Re-compiled with jikes for valid class files (thanks ms!)

### **23.3.6.52. Changes in MySQL Connector/J 1.1h (08 March 1999)**

- Fixed escape processor to deal with unmatched { and } (thanks to Craig Coles)
- Fixed escape processor to create more portable (between DATETIME and TIMESTAMP types) representations so that it will work with BETWEEN clauses. (thanks to Craig Longman)
- `MySQLIO.quit()` now closes the socket connection. Before, after many failed connections some

OS's would run out of file descriptors. (thanks to Michael Brinkman)

- Fixed NullPointerException in Driver.getPropertyInfo. (thanks to Dave Potts)
- Fixes to MySQLDefs to allow all \*text fields to be retrieved as Strings. (thanks to Chris at Leverage)
- Fixed setDouble in PreparedStatement for large numbers to avoid sending scientific notation to the database. (thanks to J.S. Ferguson)
- Fixed getScale() and getPrecision() in RSMD. (contrib'd by James Klicman)
- Fixed getObject() when field was DECIMAL or NUMERIC (thanks to Bert Hobbs)
- DBMD.getTables() bombed when passed a null table-name pattern. Fixed. (thanks to Richard Lobb)
- Added check for "client not authorized" errors during connect. (thanks to Hannes Wallnoefer)

### **23.3.6.53. Changes in MySQL Connector/J 1.1g (19 February 1999)**

- Result set rows are now byte arrays. Blobs and Unicode work bidirectionally now. The useUnicode and encoding options are implemented now.
- Fixes to PreparedStatement to send binary set by setXXXStream to be sent untouched to the MySQL server.
- Fixes to getDriverPropertyInfo().

### **23.3.6.54. Changes in MySQL Connector/J 1.1f (31 December 1998)**

- Changed all ResultSet fields to Strings, this should allow Unicode to work, but your JVM must be able to convert between the character sets. This should also make reading data from the server be a bit quicker, because there is now no conversion from StringBuffer to String.
- Changed PreparedStatement.streamToString() to be more efficient (code from Uwe Schaefer).
- URL parsing is more robust (throws SQL exceptions on errors rather than NullPointerExceptions)
- PreparedStatement now can convert Strings to Time/Date values via setObject() (code from Robert Currey).
- IO no longer hangs in Buffer.readInt(), that bug was introduced in 1.1d when changing to all byte-arrays for result sets. (Pointed out by Samo Login)

### **23.3.6.55. Changes in MySQL Connector/J 1.1b (03 November 1998)**

- Fixes to DatabaseMetaData to allow both IBM VA and J-Builder to work. Let me know how it goes. (thanks to Jac Kersing)
- Fix to ResultSet.getBoolean() for NULL strings (thanks to Barry Lagerweij)

- Beginning of code cleanup, and formatting. Getting ready to branch this off to a parallel JDBC-2.0 source tree.
- Added "final" modifier to critical sections in MySQLIO and Buffer to allow compiler to inline methods for speed.

9-29-98

- If object references passed to setXXX() in PreparedStatement are null, setNull() is automatically called for you. (Thanks for the suggestion goes to Erik Ostrom)
- setObject() in PreparedStatement will now attempt to write a serialized representation of the object to the database for objects of Types.OTHER and objects of unknown type.
- Util now has a static method readObject() which given a ResultSet and a column index will re-instantiate an object serialized in the above manner.

### **23.3.6.56. Changes in MySQL Connector/J 1.1 (02 September 1998)**

- Got rid of "ugly hack" in MySQLIO.nextRow(). Rather than catch an exception, Buffer.isLastDataPacket() was fixed.
- Connection.getCatalog() and Connection.setCatalog() should work now.
- Statement.setMaxRows() works, as well as setting by property maxRows. Statement.setMaxRows() overrides maxRows set via properties or url parameters.
- Automatic re-connection is available. Because it has to "ping" the database before each query, it is turned off by default. To use it, pass in "autoReconnect=true" in the connection URL. You may also change the number of reconnect tries, and the initial timeout value via "maxReconnects=n" (default 3) and "initialTimeout=n" (seconds, default 2) parameters. The timeout is an exponential backoff type of timeout, e.g. if you have initial timeout of 2 seconds, and maxReconnects of 3, then the driver will timeout 2 seconds, 4 seconds, then 16 seconds between each re-connection attempt.

### **23.3.6.57. Changes in MySQL Connector/J 1.0 (24 August 1998)**

- Fixed handling of blob data in Buffer.java
- Fixed bug with authentication packet being sized too small.
- The JDBC Driver is now under the LPGL

8-14-98

- Fixed Buffer.readLenString() to correctly read data for BLOBS.
- Fixed PreparedStatement.toString() to correctly read data for BLOBS.
- Fixed PreparedStatement.setDate() to not add a day. (above fixes thanks to Vincent Partington)
- Added URL parameter parsing (?user=... and so forth).

### **23.3.6.58. Changes in MySQL Connector/J 0.9d (04 August 1998)**

- Big news! New package name. Tim Endres from ICE Engineering is starting a new source tree for GNU GPL'd Java software. He's graciously given me the org.gjt.mm package directory to use, so now the driver is in the org.gjt.mm.mysql package scheme. I'm "legal" now. Look for more information on Tim's project soon.
- Now using dynamically sized packets to reduce memory usage when sending commands to the DB.
- Small fixes to getTypeInfo() for parameters, and so forth.
- DatabaseMetaData is now fully implemented. Let me know if these drivers work with the various IDEs out there. I've heard that they're working with JBuilder right now.
- Added JavaDoc documentation to the package.
- Package now available in .zip or .tar.gz.

### **23.3.6.59. Changes in MySQL Connector/J 0.9 (28 July 1998)**

- Implemented getTypeInfo(). Connection.rollback() now throws an SQLException per the JDBC spec.
- Added PreparedStatement that supports all JDBC API methods for PreparedStatement including InputStreams. Please check this out and let me know if anything is broken.
- Fixed a bug in ResultSet that would break some queries that only returned 1 row.
- Fixed bugs in DatabaseMetaData.getTables(), DatabaseMetaData.getColumns() and DatabaseMetaData.getCatalogs().
- Added functionality to Statement that allows executeUpdate() to store values for IDs that are automatically generated for AUTO\_INCREMENT fields. Basically, after an executeUpdate(), look at the SQLWarnings for warnings like "LAST\_INSERTED\_ID = 'some number', COMMAND = 'your SQL query'". If you are using AUTO\_INCREMENT fields in your tables and are executing a lot of executeUpdate(s) on one Statement, be sure to clearWarnings() every so often to save memory.

### **23.3.6.60. Changes in MySQL Connector/J 0.8 (06 July 1998)**

- Split MySQLIO and Buffer to separate classes. Some ClassLoaders gave an IllegalAccessException error for some fields in those two classes. Now mm.mysql works in applets and all classloaders. Thanks to Joe Ennis <jce@mail.boone.com> for pointing out the problem and working on a fix with me.

### **23.3.6.61. Changes in MySQL Connector/J 0.7 (01 July 1998)**

- Fixed DatabaseMetadata problems in getColumns() and bug in switch statement in the Field constructor. Thanks to Costin Manolache <costin@tdiinc.com> for pointing these out.

### **23.3.6.62. Changes in MySQL Connector/J 0.6 (21 May 1998)**

- Incorporated efficiency changes from Richard Swift <Richard.Swift@kanatek.ca> in `MySQLIO.java` and `ResultSet.java`:
- We're now 15% faster than gwe's driver.
- Started working on `DatabaseMetaData`.
- The following methods are implemented:
  - `getTables()`
  - `getTableTypes()`
  - `getColumns`
  - `getCatalogs()`

## 23.4. MySQL Connector/MXJ

### 23.4.1. Introduction

MySQL Connector/MXJ is a Java Utility package for deploying and managing a MySQL database. Connector/MXJ may be bundled in to an existing Java application or may be deployed as a JMX MBean. Deploying and using MySQL can be as easy as adding an additional parameter to the JDBC connection url, which will result in the database being started when the first connection is made. This makes it easy for Java developers to deploy applications which require a database by reducing installation barriers for their end-users.

MySQL Connector/MXJ makes the MySQL database appear to be a java-based component. It does this by determining what platform the system is running on, selecting the appropriate binary, and launching the executable. It will also optionally deploy an initial database, with any specified parameters.

As a JMX MBean, MySQL Connector/MXJ requires a JMX v1.2 compliant MBean container, such as JBoss version 4. The MBean will use the standard JMX management APIs to present (and allow the setting of) parameters which are appropriate for that platform.

Included are instructions for use with a JDBC driver and deploying as a JMX MBean to JBoss.

You can download sources and binaries from: <http://dev.mysql.com/downloads/connector/mxj/>

This a beta release and feedback is welcome and encouraged.

Please send questions or comments to [java@lists.mysql.com](mailto:java@lists.mysql.com) [<mailto:java@lists.mysql.com>].

### 23.4.2. Supported Platforms

- Linux, i386
- Windows NT, x86
- Windows 2000, x86
- Windows XP, x86
- Solaris 9, SPARC 32

### 23.4.3. JUnit Test Requirements

The best way to ensure that your platform is supported is to run the JUnit tests.

The first thing to do is make sure that the components will work on the platform. The `MySQLDriverSource` class is really a wrapper for a native version of MySQL, so not all platforms are supported. At the time of this writing, Linux on the i386 architecture has been tested and seems to work quite well, as does OS X v10.3. There has been limited testing on Windows and Solaris.

Requirements:

1. JDK-1.4 or newer (or the JRE if you aren't going to be compiling the source or JSPs).
2. MySQL Connector/J version 3.1 or newer (from <http://dev.mysql.com/downloads/connector/j/>) installed and available via your CLASSPATH.
3. The `javax.management` classes for JMX version 1.2.1, these are present in the following application servers:
  - JBoss - 4.0rc1 or newer
  - Apache Tomcat - 5.0 or newer
  - Sun's JMX reference implementation version 1.2.1 (from <http://java.sun.com/products/JavaManagement/>)
4. Junit 3.8.1 (from <http://www.junit.org/>)

If building from source, All of the requirements from above, plus:

1. Ant version 1.5 or newer (download from <http://ant.apache.org/>)

## 23.4.4. Running the JUnit Tests

1. The tests attempt to launch MySQL on the port 3336. If you have a MySQL running, it may conflict, but this isn't very likely because the default port for MySQL is 3306. However, You may set the "c-mxj\_test\_port" Java property to a port of your choosing. Alternatively, you may wish to start by shutting down any instances of MySQL you have running on the target machine.

The tests suppress output to the console by default. For verbose output, you may set the "c-mxj\_test\_silent" Java property to "false".

2. To run the JUnit test suite, the CLASSPATH must include the following:
  - JUnit
  - JMX
  - Connector/J
  - MySQL Connector/MXJ
3. If `connector-mxj.jar` is not present in your download, unzip MySQL Connector/MXJ source archive.

```
cd mysql djmx
ant dist
```

Then add `$TEMP/cmxj/stage/connector-mxj/connector-mxj.jar` to the `CLASSPATH`.

- if you have `junit`, execute the unit tests. From the command line, type:

```
java junit.textui.TestRunner com.mysql.management.AllTestsSuite
```

The output should look something like this:

```
.....
.....
.....
Time: 259.438

OK (101 tests)
```

Note that the tests are a bit slow near the end, so please be patient.

## 23.4.5. Running as part of the JDBC Driver

A feature of the MySQL Connector/J JDBC driver is the ability to specify a "SocketFactory" as a parameter in the JDBC connection string. MySQL Connector/MXJ includes a custom SocketFactory. The SocketFactory will, upon the first connection, deploy and launch the MySQL database. The SocketFactory also exposes a "shutdown" method.

To try it specify the "socketFactory" parameter on the JDBC connection string with a value equal to "com.mysql.management.driverlaunched.ServerLauncherSocketFactory"

In the following example, we have a program which creates a connection, executes a query, and prints the result to the `System.out`. The MySQL database will be deployed and started as part of the connection process, and shutdown as part of the finally block.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.Statement;

import com.mysql.management.driverlaunched.ServerLauncherSocketFactory;

public class ConnectorMXJTestExample {
    public static void main(String[] args) throws Exception {
        String hostColonPort = "localhost:3336";

        String driver = com.mysql.jdbc.Driver.class.getName();
        String url = "jdbc:mysql://" + hostColonPort + "/" + "?"
            + "socketFactory="
            + ServerLauncherSocketFactory.class.getName();
        String userName = "root";
        String password = "";

        Class.forName(driver);
        Connection conn = null;
        try {
            conn = DriverManager.getConnection(url, userName, password);
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("SELECT VERSION()");
            rs.next();
            String version = rs.getString(1);
            rs.close();
            stmt.close();
        }
    }
}
```

```

        System.out.println("-----");
        System.out.println(version);
        System.out.println("-----");
    } finally {
        try {
            conn.close();
        } catch (Exception e) {
            e.printStackTrace();
        }
        ServerLauncherSocketFactory.shutdown(hostColonPort);
    }
}
}
}

```

To run the above program, be sure to have `connector-mxj.jar` and `Connector/J` in the `CLASSPATH`. Then type:

```
java ConnectorMXJTestExample
```

Of course there are many options we may wish to set for a MySQL database. These options may be specified as part of the JDBC connection string simply by prefixing each server option with "server.". In the following example we set three driver parameters and two server parameters:

```

String url = "jdbc:mysql://" + hostColonPort + "/"
    + "?"
    + "socketFactory="
    + ServerLauncherSocketFactory.class.getName();
    + "&"
    + "cacheServerConfiguration=true"
    + "&"
    + "useLocalSessionState=true"
    + "&"
    + "server.basedir=/opt/myapp/db"
    + "&"
    + "server.datadir=/mnt/bigdisk/myapp/data";

```

## 23.4.6. Running within a Java Object

If you have a java application and wish to "embed" a MySQL database, make use of the `com.mysql.management.MysqldResource` class directly. This class may be instantiated with the default (no argument) constructor, or by passing in a `java.io.File` object representing the directory you wish the server to be "unzipped" into. It may also be instantiated with printstreams for "stdout" and "stderr" for logging.

Once instantiated, a `java.util.Map`, the object will be able to provide a `java.util.Map` of server options appropriate for the platform and version of MySQL which you will be using.

The `MysqldResource` enables you to "start" MySQL with a `java.util.Map` of server options which you provide, as well as "shutdown" the database. The following example shows a simplistic way to embed MySQL in an application using plain java objects:

```

import com.mysql.management.MysqldResource;

...

public void startMySQL() {
    File baseDir = new File(ourAppDir, "mysql");
    MysqldResource = new MysqldResource(baseDir);
    Map options = new HashMap();

```

```

        options.put("port", "3336");
        String threadName = "OurApp MySQL";
        mysqldResource.start(threadName, options);
    }

    public void stopMySQL() {
        if (mysqldResource != null) {
            mysqldResource.shutdown();
        }
        mysqldResource = null;
    }

    public java.sql.Connection getConnection() throws Exception {
        String db = "test";
        String url = "jdbc:mysql://localhost:3336/" + db;
        String userName = "root";
        String password = "";
        Class.forName(com.mysql.jdbc.Driver.class.getName());
        return DriverManager.getConnection(url, userName, password);
    }
}

```

## 23.4.7. The MysqldResource API

Constructors:

- `public MysqldResource(File baseDir, PrintStream out, PrintStream err);`

Allows the setting of the "basedir" to deploy the MySQL files to, as well as out put streams for standard out and standard err.

- `public MysqldResource(File baseDir);`

Allows the setting of the "basedir" to deploy the MySQL files to. Output for standard out and standard err are directed to System.out and System.err.

- `public MysqldResource();`

The basedir is defaulted to a subdirectory of the java.io.tmpdir. Output for standard out and standard err are directed to System.out and System.err;

MysqldResource API includes the following methods:

- `void start(String threadName, Map mysqldArgs);`

Deploys and starts MySQL. The "threadName" string is used to name the thread which actually performs the execution of the MySQL command line. The map is the set of arguments and their values to be passed to the command line.

- `void shutdown();`

Shuts down the MySQL instance managed by the MysqldResource object.

- `Map getServerOptions();`

Returns a map of all the options and their current (or default, if not running) options available for the MySQL database.

- `boolean isRunning();`

Returns true if the MySQL database is running.

- `boolean isReadyForConnections();`  
Returns true once the database reports that is ready for connections.
- `void setKillDelay(int millis);`  
The default “Kill Delay” is 30 seconds. This represents the amount of time to wait between the initial request to shutdown and issuing a “force kill” if the database has not shutdown by itself.
- `void addCompletionListenser(Runnable listener);`  
Allows for applications to be notified when the server process completes. Each "listener" will be fired off in its own thread.
- `String getVersion();`  
returns the version of MySQL.
- `void setVersion(int MajorVersion, int minorVersion, int patchLevel);`  
The standard distribution comes with only one version of MySQL packaged. However, it is possible to package multiple versions, and specify which version to use.

## 23.4.8. Running within a JMX Agent (custom)

If you are not using the SUN Reference implementation of the JMX libraries, you should skip this section. Or, if you are deploying to JBoss, you also may wish to skip to the next section.

We want to see the `MysqldDynamicMBean` in action inside of a JMX agent. In the `com.mysql.management.jmx.sunri` package is a custom JMX agent with two MBeans:

1. the `MysqldDynamicMBean`, and
2. a `com.sun.jdmk.comm.HtmlAdaptorServer`, which provides a web interface for manipulating the beans inside of a JMX agent.

When this very simple agent is started, it will allow a MySQL database to be started and stopped with a web browser.

1. Complete the testing of the platform as above.
  - current JDK, JUnit, Connector/J, MySQL Connector/MXJ
  - this section *requires* the SUN reference implementation of JMX
  - PATH, JAVA\_HOME, ANT\_HOME, CLASSPATH
2. If not building from source, skip to next step  
rebuild with the "sunri.present"  

```
ant -Dsunri.present=true dist
re-run tests:
java junit.textui.TestRunner com.mysql.management.AllTestsSuite
```
3. launch the test agent from the command line:  

```
java com.mysql.management.jmx.sunri.MysqldTestAgentSunHtmlAdaptor &
```

4. from a browser:  
`http://localhost:9092/`
5. under MysqlAgent,  
`select "name=mysqlid"`
6. Observe the MBean View
7. scroll to the bottom of the screen press the startMysqlid button
8. click Back to MBean View
9. scroll to the bottom of the screen press stopMysqlid button
10. kill the java process running the Test Agent (jmx server)

## 23.4.9. Deployment in a standard JMX Agent environment (JBoss)

Once there is confidence that the MBean will function on the platform, deploying the MBean inside of a standard JMX Agent is the next step. Included are instructions for deploying to JBoss.

1. Ensure a current version of java development kit (v1.4.x), see above.
  - Ensure JAVA\_HOME is set (JBoss requires JAVA\_HOME)
  - Ensure JAVA\_HOME/bin is in the PATH (You will NOT need to set your CLASSPATH, nor will you need any of the jars used in the previous tests).
2. Ensure a current version of JBoss (v4.0RC1 or better)  

```
http://www.jboss.org/index.html
select "Downloads"
select "jboss-4.0.zip"
pick a mirror
unzip ~/dload/jboss-4.0.zip
create a JBOSS_HOME environment variable set to the unzipped directory
unix only:
cd $JBOSS_HOME/bin
chmod +x *.sh
```
3. Deploy (copy) the connector-mxj.jar to \$JBOSS\_HOME/server/default/lib.
4. Deploy (copy) mysql-connector-java-3.1.4-beta-bin.jar to \$JBOSS\_HOME/server/default/lib.
5. Create a mxjtest.war directory in \$JBOSS\_HOME/server/default/deploy.
6. Deploy (copy) index.jsp to \$JBOSS\_HOME/server/default/deploy/mxjtest.war.
7. Create a mysqlid-service.xml file in \$JBOSS\_HOME/server/default/deploy.

```
<?xml version="1.0" encoding="UTF-8"?>
<server>
```

```

<mbean code="com.mysql.management.jmx.jboss.JBossMySqlDynamicMBean"
      name="mysql:type=service,name=mysql">
<attribute name="datadir">/tmp/xxx_data_xxx</attribute>
<attribute name="autostart">true</attribute>
</mbean>
</server>

```

8. Start jboss:

- on unix: \$JBOSS\_HOME/bin/run.sh
- on windows: %JBOSS\_HOME%\bin\run.bat

Be ready: JBoss sends a lot of output to the screen.

9. When JBoss seems to have stopped sending output to the screen, open a web browser to: `http://localhost:8080/jmx-console`
10. Scroll down to the bottom of the page in the `mysql` section, select the bulleted `mysqld` link.
11. Observe the JMX MBean View page. MySQL should already be running.
12. (If "autostart=true" was set, you may skip this step.) Scroll to the bottom of the screen. You may press the `Invoke` button to stop (or start) MySQL observe `Operation completed successfully` without a return value. Click `Back` to MBean View
13. To confirm MySQL is running, open a web browser to `http://localhost:8080/mxjtest/` and you should see that

```
SELECT 1
```

returned with a result of

```
1
```

14. Guided `by` the `$JBOSS_HOME/server/default/deploy/mxjtest.war/index.jsp` you will be able to use MySQL in your Web Application. There is a test database and a root user (no password) ready to experiment with. Try creating a table, inserting some rows, and doing some selects.
15. Shut down MySQL. MySQL will be stopped automatically when JBoss is stopped, or: from the browser, scroll down to the bottom of the MBean View press the stop service `Invoke` button to halt the service. Observe `Operation completed successfully` without a return value. Using `ps` or task manager see that MySQL is no longer running

As of 1.0.6-beta version is the ability to have the MBean start the MySQL database upon start up. Also, we've taken advantage of the JBoss life-cycle extension methods so that the database will gracefully shut down when JBoss is shutdown.

## 23.4.10. Installation

If you've worked through the above sections, you've already performed these steps. But we list them here for quick reference.

Driver Launched:

1. Download and unzip Connector/MXJ, add connector-mxj.jar to the CLASSPATH
2. To the JDBC connection string add the following parameter: "socketFactory=" + Server-LauncherSocketFactory.class.getName()

JBoss:

1. Download Connector/MXJ copy the connector-mxj.jar file to the \$JBOSS\_HOME/server/default/lib directory.
2. Download Connector/J copy the connector-mxj.jar file to the \$JBOSS\_HOME/server/default/lib directory.
3. Create an MBean service xml file in the \$JBOSS\_HOME/server/default/deploy directory with any attributes set, for instance the datadir and autostart.
4. Set the JDBC parameters of your web application to use:

```
String driver = "com.mysql.jdbc.Driver";
String url = "jdbc:mysql:///test?propertiesTransform="+
"com.mysql.management.jmx.ConnectorMXJPropertiesTransform";
String user = "root";
String password = "";
Class.forName(driver);
Connection conn = DriverManager.getConnection(url, user, password);
```

You may wish to create a separate users and database table spaces for each application, rather than using "root and test".

We highly suggest having a routine backup procedure for backing up the database files in the datadir.

## 23.5. Connector/PHP

The PHP distribution and documentation are available from the PHP Web site. MySQL provides the `mysql` and `mysql_i` extensions for the Windows operating system for MySQL versions as of 5.0.18 on <http://dev.mysql.com/downloads/connector/php/>. You can find information why you should preferably use the extensions provided by MySQL on that page. For platforms other than Windows, you should use the `mysql` or `mysql_i` extensions shipped with the PHP sources. See Section 22.3, "MySQL PHP API".

---

# Chapter 24. Extending MySQL

## 24.1. MySQL Internals

This chapter describes a lot of things that you need to know when working on the MySQL code. If you plan to contribute to MySQL development, want to have access to the bleeding-edge versions of the code, or just want to keep track of development, follow the instructions in Section 2.9.3, “Installing from the Development Source Tree”. If you are interested in MySQL internals, you should also subscribe to our `internals` mailing list. This list has relatively low traffic. For details on how to subscribe, please see Section 1.7.1, “MySQL Mailing Lists”. All developers at MySQL AB are on the `internals` list and we help other people who are working on the MySQL code. Feel free to use this list both to ask questions about the code and to send patches that you would like to contribute to the MySQL project!

### 24.1.1. MySQL Threads

The MySQL server creates the following threads:

- One thread manages TCP/IP file connection requests and creates a new dedicated thread to handle the authentication and SQL statement processing for each connection. (On Unix, this thread also manages Unix socket file connection requests.) On Windows, a similar thread manages shared-memory connection requests, and on Windows NT-based systems, a thread manages named-pipe connection requests. Every client connection has its own thread, although the manager threads try to avoid creating threads by consulting the thread cache first to see whether a cached thread can be used for a new connection.
- On Windows NT, there is a named pipe handler thread that does the same work as the TCP/IP connection thread on named pipe connect requests.
- On a master replication server, slave server connections are like client connections: There is one thread per connected slave.
- On a slave replication server, an I/O thread is started to connect to the master server and read updates from it. An SQL thread is started to apply updates read from the master. These two threads run independently and can be started and stopped independently.
- The signal thread handles all signals. This thread also normally handles alarms and calls `process_alarm()` to force timeouts on connections that have been idle too long.
- If `mysqld` is compiled with `-DUSE_ALARM_THREAD`, a dedicated thread that handles alarms is created. This is only used on some systems where there are problems with `sigwait()` or if you want to use the `thr_alarm()` code in your application without a dedicated signal handling thread.
- If the server is started with the `--flush_time=val` option, a dedicated thread is created to flush all tables every `val` seconds.
- Each table for which `INSERT DELAYED` statements are issued gets its own thread.

`mysqladmin processlist` only shows the connection, `INSERT DELAYED`, and replication threads.

### 24.1.2. MySQL Test Suite

The test system that is included in Unix source and binary distributions makes it possible for users and developers to perform regression tests on the MySQL code. These tests can be run on Unix. They cannot currently be run in a native Windows environment.

The current set of test cases doesn't test everything in MySQL, but it should catch most obvious bugs in the SQL processing code, operating system or library issues, and is quite thorough in testing replication. Our goal is to have the tests cover 100% of the code. We welcome contributions to our test suite. You may especially want to contribute tests that examine the functionality critical to your system because this ensures that all future MySQL releases work well with your applications.

### 24.1.2.1. Running the MySQL Test Suite

The test system consists of a test language interpreter (`mysqltest`), a shell script to run all tests (`mysql-test-run`), the actual test cases written in a special test language, and their expected results. To run the test suite on your system after a build, type `make test` or `mysql-test/mysql-test-run` from the source root directory. If you have installed a binary distribution, change location to the installation root directory (for example, `/usr/local/mysql`), and run `mysql-test/mysql-test-run`. All tests should succeed. If any do not, you should try to find out why and report the problem if it indicates a bug in MySQL. See Section 24.1.2.3, “How to Report Bugs in the MySQL Test Suite”.

If you have a copy of `mysqld` running on the machine where you want to run the test suite, you do not have to stop it, as long as it is not using ports 9306 or 9307. If either of those ports is taken, you should edit `mysql-test-run` and change the values of the master or slave port to one that is available.

You can run one individual test case with `mysql-test/mysql-test-run test_name`.

If one test fails, you should run `mysql-test-run` with the `--force` option to check whether any other tests fail.

### 24.1.2.2. Extending the MySQL Test Suite

You can use the `mysqltest` language to write your own test cases. Unfortunately, we have not yet written full documentation for it. You can, however, look at our current test cases and use them as an example. The following points should help you get started:

- The tests are located in `mysql-test/t/*.test`
- A test case consists of statements terminated by `;` and is similar to the input of `mysql` command-line client. A statement by default is an SQL statement to be sent to MySQL server, unless it is recognized as an internal `mysqltest` command (for example, `sleep`).
- All statements that produce results—for example, `SELECT`, `SHOW`, or `EXPLAIN`—must be preceded with `@/path/to/result/file`. The file must contain the expected results. An easy way to generate the result file is to run `mysqltest -r < t/test_name.test` from the `mysql-test` directory, and then edit the generated result files, if needed, to adjust them to the expected output. In that case, be very careful about not adding or deleting any invisible characters. Make sure to only change the text or delete lines. If you have to insert a line, make sure that the fields are separated by a hard tab, and that there is a hard tab at the end. You may want to use `od -c` to make sure that your text editor has not messed up anything during editing. We hope that you never have to edit the output of `mysqltest -r` because this should be necessary only when you find a bug.
- To be consistent with our setup, you should put your result files in the `mysql-test/r` directory and name them `test_name.result`. If the test produces more than one result, you should use `test_name.a.result`, `test_name.b.result`, and so forth.
- If a statement is expected to return an error, you should specify it with `--error error_number` on the line before the statement. You can specify more than one error number, separated by commas.
- If you are writing a replication test case, the first line of the test file should be `source include/master-slave.inc;`. To switch between master and slave, use `connection master;` and `connection slave;`. If you need to do something on an alternative connec-

tion, you can do `connection master1;` for the master, and `connection slave1;` for the slave.

- If you need to do something in a loop, you can use something like this:

```
let $1=1000;
while ($1)
{
  # do your queries here
  dec $1;
}
```

- To sleep between statements, use the `sleep` command. It supports fractions of a second. For example, `sleep 1.3;` sleeps 1.3 seconds.
- To run the slave with additional options for your test case, put them in the command-line format in `mysql-test/t/test_name-slave.opt`. For the master, put them in `mysql-test/t/test_name-master.opt`.
- If you have a question about the test suite, or have a test case to contribute, send an email message to the MySQL `internals` mailing list. See Section 1.7.1, “MySQL Mailing Lists”. This list does not accept attachments, so you should FTP all the relevant files to: `ftp://ftp.mysql.com/pub/mysql/upload/`

### 24.1.2.3. How to Report Bugs in the MySQL Test Suite

If test cases from the test suite fail, you should do the following:

- Do not file a bug report before you have found out as much as possible about what when wrong. See the instructions at Section 1.8, “How to Report Bugs or Problems”.
- Make sure to include the output of `mysql-test-run`, as well as contents of all `.reject` files in the `mysql-test/r` directory.
- Check whether an individual test in the test suite also fails when run on its own:

```
cd mysql-test
mysql-test-run --local test_name
```

If this fails, you should configure MySQL with `--with-debug` and run `mysql-test-run` with the `--debug` option. If this also fails, send the trace file `mysql-test/var/tmp/master.trace` to `ftp://ftp.mysql.com/pub/mysql/upload/` so that we can examine it. Please remember to also include a full description of your system, the version of the `mysqld` binary and how you compiled it.

- Run `mysql-test-run` with the `--force` option to see whether any other tests fail.
- If you have compiled MySQL yourself, check our manual to see whether there are any platform-specific issues for your system (see Section 2.13, “Operating System-Specific Notes”). There might be configuration workarounds to deal with the problems that you observe. Also, consider using one of the binaries we have compiled for you at `http://dev.mysql.com/downloads/`. All our standard binaries should pass the test suite!
- If you get an error such as `Result length mismatch` or `Result content mismatch` it means that the output of the test was not an exact match for the expected output. This could be a bug in MySQL or it could be that your version of `mysqld` produces slightly different results under some circumstances.

The results file is located in the `r` directory and has a name with a `.result` extension. A failed test result is put in a file with the same basename as the result file and a `.reject` extension. If

your test case is failing, you should use `diff` to compare the `.result` and `.reject` files. If you cannot see how they are different, examine both with `od -c` and also check their lengths.

- If a test fails completely, you should check the logs file in the `mysql-test/var/log` directory for hints of what went wrong.
- If you have compiled MySQL with debugging, you can try to debug test failures by running `mysql-test-run` with either or both of the `--gdb` and `--debug` options. See Section E.1.2, “Creating Trace Files”.

If you have not compiled MySQL for debugging you should probably do so by specifying the `--with-debug` option when you invoke `configure`. See Section 2.9.2, “Typical configure Options”.

## 24.2. Adding New Functions to MySQL

There are two ways to add new functions to MySQL:

- You can add functions through the user-defined function (UDF) interface. User-defined functions are compiled as object files and then added to and removed from the server dynamically using the `CREATE FUNCTION` and `DROP FUNCTION` statements. See Section 24.2.2, “CREATE FUNCTION Syntax”.
- You can add functions as native (built-in) MySQL functions. Native functions are compiled into the `mysqld` server and become available on a permanent basis.

Each method has advantages and disadvantages:

- If you write user-defined functions, you must install object files in addition to the server itself. If you compile your function into the server, you don't need to do that.
- Native functions require you to modify a source distribution. UDFs do not. You can add UDFs to a binary MySQL distribution. No access to MySQL source is necessary.
- If you upgrade your MySQL distribution, you can continue to use your previously installed UDFs, unless you upgrade to a newer version for which the UDF interface changes. For native functions, you must repeat your modifications each time you upgrade.

Whichever method you use to add new functions, they can be invoked in SQL statements just like native functions such as `ABS()` or `SOUNDEX()`.

Another way to add functions is by creating stored functions. These are written using SQL statements rather than by compiling object code. The syntax for writing stored functions is described in Chapter 17, *Stored Procedures and Functions*.

The following sections describe features of the UDF interface, provide instructions for writing UDFs, discuss security precautions that MySQL takes to prevent UDF misuse, and describe how to add native MySQL functions.

For example source code that illustrates how to write UDFs, take a look at the `sql/udf_example.cc` file that is provided in MySQL source distributions.

### 24.2.1. Features of the User-Defined Function Interface

The MySQL interface for user-defined functions provides the following features and capabilities:

- Functions can return string, integer, or real values.
- You can define simple functions that operate on a single row at a time, or aggregate functions that operate on groups of rows.
- Information is provided to functions that enables them to check the number and types of the arguments passed to them.
- You can tell MySQL to coerce arguments to a given type before passing them to a function.
- You can indicate that a function returns NULL or that an error occurred.

## 24.2.2. CREATE FUNCTION Syntax

```
CREATE [AGGREGATE] FUNCTION function_name RETURNS {STRING|INTEGER|REAL|DECIMAL}
SONAME shared_library_name
```

A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`.

*function\_name* is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. As of MySQL 5.0.3, `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

*shared\_library\_name* is the basename of the shared object file that contains the code that implements the function. The file must be located in a directory that is searched by your system's dynamic linker.

To create a function, you must have the `INSERT` and `privilege` for the `mysql` database. This is necessary because `CREATE FUNCTION` adds a row to the `mysql.func` system table that records the function's name, type, and shared library name. If you do not have this table, you should run the `mysql_upgrade` command to create it. See Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see Section 24.2.4, “Adding a New User-Defined Function”. For the UDF mechanism to work, functions must be written in C or C++, your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

An `AGGREGATE` function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`. For `AGGREGATE` to work, your `mysql.func` table must contain a `type` column. If your `mysql.func` table does not have this column, you should run the `mysql_upgrade` program to create it (see Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”).

## 24.2.3. DROP FUNCTION Syntax

```
DROP FUNCTION function_name
```

This statement drops the user-defined function (UDF) named *function\_name*.

To drop a function, you must have the `DELETE` privilege for the `mysql` database. This is because `DROP FUNCTION` removes a row from the `mysql.func` system table that records the function's name, type, and shared library name.

## 24.2.4. Adding a New User-Defined Function

For the UDF mechanism to work, functions must be written in C or C++ and your operating system must support dynamic loading. The MySQL source distribution includes a file `sql/udf_example.cc` that defines 5 new functions. Consult this file to see how UDF calling conventions work.

A UDF contains code that becomes part of the running server, so when you write a UDF, you are bound by any and all constraints that otherwise apply to writing server code. For example, you may have problems if you attempt to use functions from the `libstdc++` library. Note that these constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to UDFs that were originally written for older servers. For information about these constraints, see Section 2.9.2, “Typical configure Options”, and Section 2.9.4, “Dealing with Problems Compiling MySQL”.

To be able to use UDFs, you need to link `mysqld` dynamically. Don't configure MySQL using `--with-mysqld-ldflags=-all-static`. If you want to use a UDF that needs to access symbols from `mysqld` (for example, the `metaphone` function in `sql/udf_example.cc` that uses `default_charset_info`), you must link the program with `-rdynamic` (see `man dlopen`). If you plan to use UDFs, the rule of thumb is to configure MySQL with `--with-mysqld-ldflags=-rdynamic` unless you have a very good reason not to.

If you must use a precompiled distribution of MySQL, use MySQL-Max, which contains a dynamically linked server that supports dynamic loading.

For each function that you want to use in SQL statements, you should define corresponding C (or C++) functions. In the following discussion, the name “xxx” is used for an example function name. To distinguish between SQL and C/C++ usage, `XXX()` (uppercase) indicates an SQL function call, and `xxx()` (lowercase) indicates a C/C++ function call.

The C/C++ functions that you write to implement the interface for `XXX()` are:

- `xxx()` (required)

The main function. This is where the function result is computed. The correspondence between the SQL function data type and the return type of your C/C++ function is shown here:

SQL Type	C/C++ Type
STRING	char *
INTEGER	long long
REAL	double

It is also possible to declare a `DECIMAL` function, but currently the value is returned as a string, so you should write the UDF as though it were a `STRING` function.

- `xxx_init()` (optional)

The initialization function for `xxx()`. It can be used for the following purposes:

- To check the number of arguments to `XXX()`.
- To check that the arguments are of a required type or, alternatively, to tell MySQL to coerce arguments to the types you want when the main function is called.
- To allocate any memory required by the main function.
- To specify the maximum length of the result.
- To specify (for `REAL` functions) the maximum number of decimal places in the result.

- To specify whether the result can be `NULL`.
- `xxx_deinit()` (optional)

The deinitialization function for `xxx()`. It should deallocate any memory allocated by the initialization function.

When an SQL statement invokes `xxx()`, MySQL calls the initialization function `xxx_init()` to let it perform any required setup, such as argument checking or memory allocation. If `xxx_init()` returns an error, MySQL aborts the SQL statement with an error message and does not call the main or deinitialization functions. Otherwise, MySQL calls the main function `xxx()` once for each row. After all rows have been processed, MySQL calls the deinitialization function `xxx_deinit()` so that it can perform any required cleanup.

For aggregate functions that work like `SUM()`, you must also provide the following functions:

- `xxx_clear()` (required in 5.0)

Reset the current aggregate value but do not insert the argument as the initial aggregate value for a new group.

- `xxx_add()` (required)

Add the argument to the current aggregate value.

MySQL handles aggregate UDFs as follows:

1. Call `xxx_init()` to let the aggregate function allocate any memory it needs for storing results.
2. Sort the table according to the `GROUP BY` expression.
3. Call `xxx_clear()` for the first row in each new group.
4. Call `xxx_add()` for each new row that belongs in the same group.
5. Call `xxx()` to get the result for the aggregate when the group changes or after the last row has been processed.
6. Repeat 3-5 until all rows has been processed
7. Call `xxx_deinit()` to let the UDF free any memory it has allocated.

All functions must be thread-safe. This includes not just the main function, but the initialization and deinitialization functions as well, and also the additional functions required by aggregate functions. A consequence of this requirement is that you are not allowed to allocate any global or static variables that change! If you need memory, you should allocate it in `xxx_init()` and free it in `xxx_deinit()`.

### 24.2.4.1. UDF Calling Sequences for Simple Functions

This section describes the different functions that you need to define when you create a simple UDF. Section 24.2.4, “Adding a New User-Defined Function”, describes the order in which MySQL calls these functions.

The main `xxx()` function should be declared as shown in this section. Note that the return type and parameters differ, depending on whether you declare the SQL function `XXX()` to return `STRING`, `INTEGER`, or `REAL` in the `CREATE FUNCTION` statement:

For STRING functions:

```
char *xxx(UDF_INIT *initid, UDF_ARGS *args,
          char *result, unsigned long *length,
          char *is_null, char *error);
```

For INTEGER functions:

```
long long xxx(UDF_INIT *initid, UDF_ARGS *args,
              char *is_null, char *error);
```

For REAL functions:

```
double xxx(UDF_INIT *initid, UDF_ARGS *args,
           char *is_null, char *error);
```

The initialization and deinitialization functions are declared like this:

```
my_bool xxx_init(UDF_INIT *initid, UDF_ARGS *args, char *message);
void xxx_deinit(UDF_INIT *initid);
```

The `initid` parameter is passed to all three functions. It points to a `UDF_INIT` structure that is used to communicate information between functions. The `UDF_INIT` structure members follow. The initialization function should fill in any members that it wishes to change. (To use the default for a member, leave it unchanged.)

- `my_bool maybe_null`

`xxx_init()` should set `maybe_null` to 1 if `xxx()` can return NULL. The default value is 1 if any of the arguments are declared `maybe_null`.

- `unsigned int decimals`

The number of decimal digits to the right of the decimal point. The default value is the maximum number of decimal digits in the arguments passed to the main function. (For example, if the function is passed 1.34, 1.345, and 1.3, the default would be 3, because 1.345 has 3 decimal digits.)

- `unsigned int max_length`

The maximum length of the result. The default `max_length` value differs depending on the result type of the function. For string functions, the default is the length of the longest argument. For integer functions, the default is 21 digits. For real functions, the default is 13 plus the number of decimal digits indicated by `initid->decimals`. (For numeric functions, the length includes any sign or decimal point characters.)

If you want to return a blob value, you can set `max_length` to 65KB or 16MB. This memory is not allocated, but the value is used to decide which data type to use if there is a need to temporarily store the data.

- `char *ptr`

A pointer that the function can use for its own purposes. For example, functions can use `initid->ptr` to communicate allocated memory among themselves. `xxx_init()` should allocate the memory and assign it to this pointer:

```
initid->ptr = allocated_memory;
```

In `xxx()` and `xxx_deinit()`, refer to `initid->ptr` to use or deallocate the memory.

- `my_bool const_item`

`xxx_init()` should set `const_item` to 1 if `xxx()` always returns the same value and to 0 otherwise.

## 24.2.4.2. UDF Calling Sequences for Aggregate Functions

This section describes the different functions that you need to define when you create an aggregate UDF. Section 24.2.4, “Adding a New User-Defined Function”, describes the order in which MySQL calls these functions.

- `xxx_reset()`

This function is called when MySQL finds the first row in a new group. It should reset any internal summary variables and then use the given `UDF_ARGS` argument as the first value in your internal summary value for the group. Declare `xxx_reset()` as follows:

```
char *xxx_reset(UDF_INIT *initid, UDF_ARGS *args,
               char *is_null, char *error);
```

`xxx_reset()` is not needed or used in MySQL 5.0, in which the UDF interface uses `xxx_clear()` instead. However, you can define both `xxx_reset()` and `xxx_clear()` if you want to have your UDF work with older versions of the server. (If you do include both functions, the `xxx_reset()` function in many cases can be implemented internally by calling `xxx_clear()` to reset all variables, and then calling `xxx_add()` to add the `UDF_ARGS` argument as the first value in the group.)

- `xxx_clear()`

This function is called when MySQL needs to reset the summary results. It is called at the beginning for each new group but can also be called to reset the values for a query where there were no matching rows. Declare `xxx_clear()` as follows:

```
char *xxx_clear(UDF_INIT *initid, char *is_null, char *error);
```

`is_null` is set to point to `CHAR(0)` before calling `xxx_clear()`.

If something went wrong, you can store a value in the variable to which the `error` argument points. `error` points to a single-byte variable, not to a string buffer.

`xxx_clear()` is required by MySQL 5.0.

- `xxx_add()`

This function is called for all rows that belong to the same group, except for the first row. You should use it to add the value in the `UDF_ARGS` argument to your internal summary variable.

```
char *xxx_add(UDF_INIT *initid, UDF_ARGS *args,
              char *is_null, char *error);
```

The `xxx()` function for an aggregate UDF should be declared the same way as for a non-aggregate UDF. See Section 24.2.4.1, “UDF Calling Sequences for Simple Functions”.

For an aggregate UDF, MySQL calls the `xxx()` function after all rows in the group have been processed. You should normally never access its `UDF_ARGS` argument here but instead return a value

based on your internal summary variables.

Return value handling in `xxx()` should be done the same way as for a non-aggregate UDF. See Section 24.2.4.4, “UDF Return Values and Error Handling”.

The `xxx_reset()` and `xxx_add()` functions handle their `UDF_ARGS` argument the same way as functions for non-aggregate UDFs. See Section 24.2.4.3, “UDF Argument Processing”.

The pointer arguments to `is_null` and `error` are the same for all calls to `xxx_reset()`, `xxx_clear()`, `xxx_add()` and `xxx()`. You can use this to remember that you got an error or whether the `xxx()` function should return `NULL`. You should not store a string into `*error`! `error` points to a single-byte variable, not to a string buffer.

`*is_null` is reset for each group (before calling `xxx_clear()`). `*error` is never reset.

If `*is_null` or `*error` are set when `xxx()` returns, MySQL returns `NULL` as the result for the group function.

### 24.2.4.3. UDF Argument Processing

The `args` parameter points to a `UDF_ARGS` structure that has the members listed here:

- `unsigned int arg_count`

The number of arguments. Check this value in the initialization function if you require your function to be called with a particular number of arguments. For example:

```
if (args->arg_count != 2)
{
    strcpy(message, "XXX() requires two arguments");
    return 1;
}
```

- `enum Item_result *arg_type`

A pointer to an array containing the types for each argument. The possible type values are `STRING_RESULT`, `INT_RESULT`, and `REAL_RESULT`.

To make sure that arguments are of a given type and return an error if they are not, check the `arg_type` array in the initialization function. For example:

```
if (args->arg_type[0] != STRING_RESULT ||
    args->arg_type[1] != INT_RESULT)
{
    strcpy(message, "XXX() requires a string and an integer");
    return 1;
}
```

As an alternative to requiring your function's arguments to be of particular types, you can use the initialization function to set the `arg_type` elements to the types you want. This causes MySQL to coerce arguments to those types for each call to `xxx()`. For example, to specify that the first two arguments should be coerced to string and integer, respectively, do this in `xxx_init()`:

```
args->arg_type[0] = STRING_RESULT;
args->arg_type[1] = INT_RESULT;
```

- `char **args`

`args->args` communicates information to the initialization function about the general nature of the arguments passed to your function. For a constant argument `i`, `args->args[i]` points to the argument value. (See below for instructions on how to access the value properly.) For a non-constant argument, `args->args[i]` is 0. A constant argument is an expression that uses

only constants, such as 3 or  $4*7-2$  or  $SIN(3.14)$ . A non-constant argument is an expression that refers to values that may change from row to row, such as column names or functions that are called with non-constant arguments.

For each invocation of the main function, `args->args` contains the actual arguments that are passed for the row currently being processed.

Functions can refer to an argument `i` as follows:

- An argument of type `STRING_RESULT` is given as a string pointer plus a length, to allow handling of binary data or data of arbitrary length. The string contents are available as `args->args[i]` and the string length is `args->lengths[i]`. You should not assume that strings are null-terminated.

- For an argument of type `INT_RESULT`, you must cast `args->args[i]` to a long long value:

```
long long int_val;
int_val = *((long long*) args->args[i]);
```

- For an argument of type `REAL_RESULT`, you must cast `args->args[i]` to a double value:

```
double real_val;
real_val = *((double*) args->args[i]);
```

- `unsigned long *lengths`

For the initialization function, the `lengths` array indicates the maximum string length for each argument. You should not change these. For each invocation of the main function, `lengths` contains the actual lengths of any string arguments that are passed for the row currently being processed. For arguments of types `INT_RESULT` or `REAL_RESULT`, `lengths` still contains the maximum length of the argument (as for the initialization function).

#### 24.2.4.4. UDF Return Values and Error Handling

The initialization function should return 0 if no error occurred and 1 otherwise. If an error occurs, `xxx_init()` should store a null-terminated error message in the `message` parameter. The message is returned to the client. The message buffer is `MYSQL_ERRMSG_SIZE` characters long, but you should try to keep the message to less than 80 characters so that it fits the width of a standard terminal screen.

The return value of the main function `xxx()` is the function value, for `long long` and `double` functions. A string function should return a pointer to the result and set `*result` and `*length` to the contents and length of the return value. For example:

```
memcpy(result, "result string", 13);
*length = 13;
```

The `result` buffer that is passed to the `xxx()` function is 255 bytes long. If your result fits in this, you don't have to worry about memory allocation for results.

If your string function needs to return a string longer than 255 bytes, you must allocate the space for it with `malloc()` in your `xxx_init()` function or your `xxx()` function and free it in your `xxx_deinit()` function. You can store the allocated memory in the `ptr` slot in the `UDF_INIT` structure for reuse by future `xxx()` calls. See Section 24.2.4.1, "UDF Calling Sequences for Simple Functions".

To indicate a return value of `NULL` in the main function, set `*is_null` to 1:

```
*is_null = 1;
```

To indicate an error return in the main function, set `*error` to 1:

```
*error = 1;
```

If `xxx()` sets `*error` to 1 for any row, the function value is `NULL` for the current row and for any subsequent rows processed by the statement in which `XXX()` was invoked. (`xxx()` is not even called for subsequent rows.)

## 24.2.4.5. Compiling and Installing User-Defined Functions

Files implementing UDFs must be compiled and installed on the host where the server runs. This process is described below for the example UDF file `sql/udf_example.cc` that is included in the MySQL source distribution.

The immediately following instructions are for Unix. Instructions for Windows are given later in this section.

The `udf_example.cc` file contains the following functions:

- `metaphon()` returns a metaphon string of the string argument. This is something like a soundex string, but it's more tuned for English.
- `myfunc_double()` returns the sum of the ASCII values of the characters in its arguments, divided by the sum of the length of its arguments.
- `myfunc_int()` returns the sum of the length of its arguments.
- `sequence([const int])` returns a sequence starting from the given number or 1 if no number has been given.
- `lookup()` returns the IP number for a hostname.
- `reverse_lookup()` returns the hostname for an IP number. The function may be called either with a single string argument of the form `'xxx.xxx.xxx.xxx'` or with four numbers.

A dynamically loadable file should be compiled as a sharable object file, using a command something like this:

```
shell> gcc -shared -o udf_example.so udf_example.cc
```

If you are using `gcc`, you should be able to create `udf_example.so` with a simpler command:

```
shell> make udf_example.so
```

You can easily determine the correct compiler options for your system by running this command in the `sql` directory of your MySQL source tree:

```
shell> make udf_example.o
```

You should run a compile command similar to the one that `make` displays, except that you should remove the `-c` option near the end of the line and add `-o udf_example.so` to the end of the line. (On some systems, you may need to leave the `-c` on the command.)

After you compile a shared object containing UDFs, you must install it and tell MySQL about it. Compiling a shared object from `udf_example.cc` produces a file named something like `udf_example.so` (the exact name may vary from platform to platform). Copy this file to some

directory such as `/usr/lib` that searched by your system's dynamic (runtime) linker, or add the directory in which you placed the shared object to the linker configuration file (for example, `/etc/ld.so.conf`).

The dynamic linker name is system-specific (for example, `ld-elf.so.1` on FreeBSD, `ld.so` on Linux, or `dyld` on Mac OS X). Consult your system documentation for information about the linker name and how to configure it.

On many systems, you can also set the `LD_LIBRARY` or `LD_LIBRARY_PATH` environment variable to point at the directory where you have the files for your UDF. The `dlopen` manual page tells you which variable you should use on your system. You should set this in `mysql.server` or `mysqld_safe` startup scripts and restart `mysqld`.

On some systems, the `ldconfig` program that configures the dynamic linker does not recognize a shared object unless its name begins with `lib`. In this case you should rename a file such as `udf_example.so` to `libudf_example.so`.

On Windows, you can compile user-defined functions by using the following procedure:

1. You need to obtain the BitKeeper source repository for MySQL 5.0. See Section 2.9.3, "Installing from the Development Source Tree".
2. In the source repository, look in the `VC++Files/examples/udf_example` directory. There are files named `udf_example.def`, `udf_example.dsp`, and `udf_example.dsw` there.
3. In the source repository, look in the `sql` directory. Copy the `udf_example.cc` from this directory to the `VC++Files/examples/udf_example` directory and rename the file to `udf_example.cpp`.
4. Open the `udf_example.dsw` file with Visual Studio VC++ and use it to compile the UDFs as a normal project.

After the shared object file has been installed, notify `mysqld` about the new functions with these statements:

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_double RETURNS REAL SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_int RETURNS INTEGER SONAME 'udf_example.so';
mysql> CREATE FUNCTION lookup RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION reverse_lookup
-> RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE AGGREGATE FUNCTION avgcost
-> RETURNS REAL SONAME 'udf_example.so';
```

Functions can be deleted using `DROP FUNCTION`:

```
mysql> DROP FUNCTION metaphon;
mysql> DROP FUNCTION myfunc_double;
mysql> DROP FUNCTION myfunc_int;
mysql> DROP FUNCTION lookup;
mysql> DROP FUNCTION reverse_lookup;
mysql> DROP FUNCTION avgcost;
```

The `CREATE FUNCTION` and `DROP FUNCTION` statements update the `func` system table in the `mysql` database. The function's name, type and shared library name are saved in the table. You must have the `INSERT` and `DELETE` privileges for the `mysql` database to create and drop functions.

You should not use `CREATE FUNCTION` to add a function that has previously been created. If you need to reinstall a function, you should remove it with `DROP FUNCTION` and then reinstall it with `CREATE FUNCTION`. You would need to do this, for example, if you recompile a new version of

your function, so that `mysqld` gets the new version. Otherwise, the server continues to use the old version.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

### 24.2.4.6. User-Defined Function Security Precautions

MySQL takes the following measures to prevent misuse of user-defined functions.

You must have the `INSERT` privilege to be able to use `CREATE FUNCTION` and the `DELETE` privilege to be able to use `DROP FUNCTION`. This is necessary because these statements add and delete rows from the `mysql.func` table.

UDFs should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. As of MySQL 5.0.3, `mysqld` supports an `--allow-suspicious-udfs` option that controls whether UDFs that have only an `xxx` symbol can be loaded. By default, the option is off, to prevent attempts at loading functions from shared object files other than those containing legitimate UDFs. If you have older UDFs that contain only the `xxx` symbol and that cannot be recompiled to include an auxiliary symbol, it may be necessary to specify the `--allow-suspicious-udfs` option. Otherwise, you should avoid enabling this capability.

UDF object files cannot be placed in arbitrary directories. They must be located in some system directory that the dynamic linker is configured to search. To enforce this restriction and prevent attempts at specifying pathnames outside of directories searched by the dynamic linker, MySQL checks the shared object file name specified in `CREATE FUNCTION` statements for pathname delimiter characters. As of MySQL 5.0.3, MySQL also checks for pathname delimiters in filenames stored in the `mysql.func` table when it loads functions. This prevents attempts at specifying illegitimate pathnames through direct manipulation of the `mysql.func` table. For information about UDFs and the runtime linker, see Section 24.2.4.5, “Compiling and Installing User-Defined Functions”.

### 24.2.5. Adding a New Native Function

The procedure for adding a new native function is described here. Note that you cannot add native functions to a binary distribution because the procedure involves modifying MySQL source code. You must compile MySQL yourself from a source distribution. Also note that if you migrate to another version of MySQL (for example, when a new version is released), you need to repeat the procedure with the new version.

To add a new native MySQL function, follow these steps:

1. Add one line to `lex.h` that defines the function name in the `sql_functions[]` array.
2. If the function prototype is simple (just takes zero, one, two or three arguments), you should in `lex.h` specify `SYM(FUNC_ARGN)` (where *N* is the number of arguments) as the second argument in the `sql_functions[]` array and add a function that creates a function object in `item_create.cc`. Take a look at "ABS" and `create_funcs_abs()` for an example of this.

If the function prototype is complicated (for example, if it takes a variable number of arguments), you should add two lines to `sql_yacc.yy`. One indicates the preprocessor symbol that `yacc` should define (this should be added at the beginning of the file). Then define the function parameters and add an “item” with these parameters to the `simple_expr` parsing rule. For an example, check all occurrences of `ATAN` in `sql_yacc.yy` to see how this is done.

3. In `item_func.h`, declare a class inheriting from `Item_num_func` or `Item_str_func`,

depending on whether your function returns a number or a string.

4. In `item_func.cc`, add one of the following declarations, depending on whether you are defining a numeric or string function:

```
double   Item_func_newname::val()
longlong Item_func_newname::val_int()
String  *Item_func_newname::Str(String *str)
```

If you inherit your object from any of the standard items (like `Item_num_func`), you probably only have to define one of these functions and let the parent object take care of the other functions. For example, the `Item_str_func` class defines a `val()` function that executes `atof()` on the value returned by `::str()`.

5. You should probably also define the following object function:

```
void Item_func_newname::fix_length_and_dec()
```

This function should at least calculate `max_length` based on the given arguments. `max_length` is the maximum number of characters the function may return. This function should also set `maybe_null = 0` if the main function can't return a NULL value. The function can check whether any of the function arguments can return NULL by checking the arguments' `maybe_null` variable. You can take a look at `Item_func_mod::fix_length_and_dec` for a typical example of how to do this.

All functions must be thread-safe. In other words, don't use any global or static variables in the functions without protecting them with mutexes)

If you want to return NULL, from `::val()`, `::val_int()` or `::str()` you should set `null_value` to 1 and return 0.

For `::str()` object functions, there are some additional considerations to be aware of:

- The `String *str` argument provides a string buffer that may be used to hold the result. (For more information about the `String` type, take a look at the `sql_string.h` file.)
- The `::str()` function should return the string that holds the result or `(char*) 0` if the result is NULL.
- All current string functions try to avoid allocating any memory unless absolutely necessary!

## 24.3. Adding New Procedures to MySQL

In MySQL, you can define a procedure in C++ that can access and modify the data in a query before it is sent to the client. The modification can be done on a row-by-row or GROUP BY level.

We have created an example procedure to show you what can be done.

Additionally, we recommend that you take a look at `mysqlua`. With this you can use the LUA language to load a procedure at runtime into `mysqld`.

### 24.3.1. Procedure Analyse

```
analyse([max_elements],[max_memory])
```

This procedure is defined in the `sql/sql_analyse.cc`. This examines the result from your query and returns an analysis of the results:

- *max\_elements* (default 256) is the maximum number of distinct values `analyse` does notice per column. This is used by `analyse` to check whether the optimal data type should be of type `ENUM`.
- *max\_memory* (default 8192) is the maximum amount of memory that `analyse` should allocate per column while trying to find all distinct values.

```
SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements],[max_memory])
```

## 24.3.2. Writing a Procedure

For the moment, the only documentation for this is the source.

You can find all information about procedures by examining the following files:

- `sql/sql_analyse.cc`
- `sql/procedure.h`
- `sql/procedure.cc`
- `sql/sql_select.cc`

---

# Appendix A. Problems and Common Errors

This appendix lists some common problems and error messages that you may encounter. It describes how to determine the causes of the problems and what to do to solve them.

## A.1. How to Determine What Is Causing a Problem

When you run into a problem, the first thing you should do is to find out which program or piece of equipment is causing it:

- If you have one of the following symptoms, then it is probably a hardware problem (such as memory, motherboard, CPU, or hard disk) or kernel problem:
  - The keyboard doesn't work. This can normally be checked by pressing the Caps Lock key. If the Caps Lock light doesn't change, you have to replace your keyboard. (Before doing this, you should try to restart your computer and check all cables to the keyboard.)
  - The mouse pointer doesn't move.
  - The machine doesn't answer to a remote machine's pings.
  - Other programs that are not related to MySQL don't behave correctly.
  - Your system restarted unexpectedly. (A faulty user-level program should never be able to take down your system.)

In this case, you should start by checking all your cables and run some diagnostic tool to check your hardware! You should also check whether there are any patches, updates, or service packs for your operating system that could likely solve your problem. Check also that all your libraries (such as `glibc`) are up to date.

It's always good to use a machine with ECC memory to discover memory problems early.

- If your keyboard is locked up, you may be able to recover by logging in to your machine from another machine and executing `kbd_mode -a`.
- Please examine your system log file (`/var/log/messages` or similar) for reasons for your problem. If you think the problem is in MySQL, you should also examine MySQL's log files. See Section 5.12, "MySQL Server Logs".
- If you don't think you have hardware problems, you should try to find out which program is causing problems. Try using `top`, `ps`, Task Manager, or some similar program, to check which program is taking all CPU or is locking the machine.
- Use `top`, `df`, or a similar program to check whether you are out of memory, disk space, file descriptors, or some other critical resource.
- If the problem is some runaway process, you can always try to kill it. If it doesn't want to die, there is probably a bug in the operating system.

If after you have examined all other possibilities and you have concluded that the MySQL server or a MySQL client is causing the problem, it's time to create a bug report for our mailing list or our support team. In the bug report, try to give a very detailed description of how the system is behaving and what you think is happening. You should also state why you think that MySQL is causing the

problem. Take into consideration all the situations in this chapter. State any problems exactly how they appear when you examine your system. Use the “copy and paste” method for any output and error messages from programs and log files.

Try to describe in detail which program is not working and all symptoms you see. We have in the past received many bug reports that state only “the system doesn't work.” This doesn't provide us with any information about what could be the problem.

If a program fails, it's always useful to know the following information:

- Has the program in question made a segmentation fault (did it dump core)?
- Is the program taking up all available CPU time? Check with `top`. Let the program run for a while, it may simply be evaluating something computationally intensive.
- If the `mysqld` server is causing problems, can you get any response from it with `mysqladmin -u root ping` or `mysqladmin -u root processlist`?
- What does a client program say when you try to connect to the MySQL server? (Try with `mysql`, for example.) Does the client jam? Do you get any output from the program?

When sending a bug report, you should follow the outline described in Section 1.8, “How to Report Bugs or Problems”.

## A.2. Common Errors When Using MySQL Programs

This section lists some errors that users frequently encounter when running MySQL programs. Although the problems show up when you try to run client programs, the solutions to many of the problems involves changing the configuration of the MySQL server.

### A.2.1. Access denied

An `Access denied` error can have many causes. Often the problem is related to the MySQL accounts that the server allows client programs to use when connecting. See Section 5.8.8, “Causes of Access denied Errors”, and Section 5.8.2, “How the Privilege System Works”.

### A.2.2. Can't connect to [local] MySQL server

A MySQL client on Unix can connect to the `mysqld` server in two different ways: By using a Unix socket file to connect through a file in the filesystem (default `/tmp/mysql.sock`), or by using TCP/IP, which connects through a port number. A Unix socket file connection is faster than TCP/IP, but can be used only when connecting to a server on the same computer. A Unix socket file is used if you don't specify a hostname or if you specify the special hostname `localhost`.

If the MySQL server is running on Windows 9x or Me, you can connect only via TCP/IP. If the server is running on Windows NT, 2000, XP, or 2003 and is started with the `--enable-named-pipe` option, you can also connect with named pipes if you run the client on the host where the server is running. The name of the named pipe is `MySQL` by default. If you don't give a hostname when connecting to `mysqld`, a MySQL client first tries to connect to the named pipe. If that doesn't work, it connects to the TCP/IP port. You can force the use of named pipes on Windows by using `.` as the hostname.

The error (2002) `Can't connect to ...` normally means that there is no MySQL server running on the system or that you are using an incorrect Unix socket filename or TCP/IP port number when trying to connect to the server.

Start by checking whether there is a process named `mysqld` running on your server host. (Use `ps`

xa | grep mysqld on Unix or the Task Manager on Windows.) If there is no such process, you should start the server. See Section 2.10.2.3, “Starting and Troubleshooting the MySQL Server”.

If a `mysqld` process is running, you can check it by trying the following commands. The port number or Unix socket filename might be different in your setup. `host_ip` represents the IP number of the machine where the server is running.

```
shell> mysqladmin version
shell> mysqladmin variables
shell> mysqladmin -h `hostname` version variables
shell> mysqladmin -h `hostname` --port=3306 version
shell> mysqladmin -h host_ip version
shell> mysqladmin --protocol=socket --socket=/tmp/mysql.sock version
```

Note the use of backticks rather than forward quotes with the `hostname` command; these cause the output of `hostname` (that is, the current hostname) to be substituted into the `mysqladmin` command. If you have no `hostname` command or are running on Windows, you can manually type the hostname of your machine (without backticks) following the `-h` option. You can also try `-h 127.0.0.1` to connect with TCP/IP to the local host.

Here are some reasons the Can't connect to local MySQL server error might occur:

- `mysqld` is not running. Check your operating system's process list to ensure the `mysqld` process is present.
- You're running a MySQL server on Windows with many TCP/IP connections to it. If you're experiencing that quite often your clients get that error, you can find a workaround here: Section A.2.2.1, “Connection to MySQL Server Failing on Windows”.
- You are running on a system that uses MIT-pthreads. If you are running on a system that doesn't have native threads, `mysqld` uses the MIT-pthreads package. See Section 2.1.1, “Operating Systems Supported by MySQL”. However, not all MIT-pthreads versions support Unix socket files. On a system without socket file support, you must always specify the hostname explicitly when connecting to the server. Try using this command to check the connection to the server:

```
shell> mysqladmin -h `hostname` version
```

- Someone has removed the Unix socket file that `mysqld` uses (`/tmp/mysql.sock` by default). For example, you might have a `cron` job that removes old files from the `/tmp` directory. You can always run `mysqladmin version` to check whether the Unix socket file that `mysqladmin` is trying to use really exists. The fix in this case is to change the `cron` job to not remove `mysql.sock` or to place the socket file somewhere else. See Section A.4.5, “How to Protect or Change the MySQL Unix Socket File”.
- You have started the `mysqld` server with the `--socket=/path/to/socket` option, but forgotten to tell client programs the new name of the socket file. If you change the socket path-name for the server, you must also notify the MySQL clients. You can do this by providing the same `--socket` option when you run client programs. You also need to ensure that clients have permission to access the `mysql.sock` file. To find out where the socket file is, you can do:

```
shell> netstat -ln | grep mysql
```

See Section A.4.5, “How to Protect or Change the MySQL Unix Socket File”.

- You are using Linux and one server thread has died (dumped core). In this case, you must kill the other `mysqld` threads (for example, with `kill` or with the `mysql_zap` script) before you can restart the MySQL server. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.
- The server or client program might not have the proper access privileges for the directory that holds the Unix socket file or the socket file itself. In this case, you must either change the access

privileges for the directory or socket file so that the server and clients can access them, or restart `mysqld` with a `--socket` option that specifies a socket filename in a directory where the server can create it and where client programs can access it.

If you get the error message `Can't connect to MySQL server on some_host`, you can try the following things to find out what the problem is:

- Check whether the server is running on that host by executing `telnet some_host 3306` and pressing the Enter key a couple of times. (3306 is the default MySQL port number. Change the value if your server is listening to a different port.) If there is a MySQL server running and listening to the port, you should get a response that includes the server's version number. If you get an error such as `telnet: Unable to connect to remote host: Connection refused`, then there is no server running on the given port.
- If the server is running on the local host, try using `mysqladmin -h localhost variables` to connect using the Unix socket file. Verify the TCP/IP port number that the server is configured to listen to (it is the value of the `port` variable.)
- Make sure that your `mysqld` server was not started with the `--skip-networking` option. If it was, you cannot connect to it using TCP/IP.
- Check to make sure that there is no firewall blocking access to MySQL. Applications such as ZoneAlarm and the Windows XP personal firewall may need to be configured to allow external access to a MySQL server.

### A.2.2.1. Connection to MySQL Server Failing on Windows

When you're running a MySQL server on Windows with many TCP/IP connections to it, and you're experiencing that quite often your clients get a `Can't connect to MySQL server` error, the reason might be that Windows doesn't allow for enough ephemeral (short-lived) ports to serve those connections.

By default, Windows allows 5000 ephemeral (short-lived) TCP ports to the user. After any port is closed it will remain in a `TIME_WAIT` status for 120 seconds. This status allows the connection to be reused at a much lower cost than reinitializing a brand new connection. However, the port will not be available again until this time expires.

With a small stack of available TCP ports (5000) and a high number of TCP ports being open and closed over a short period of time along with the `TIME_WAIT` status you have a good chance for running out of ports. There are two ways to address this problem:

- Reduce the number of TCP ports consumed quickly by investigating connection pooling or persistent connections where possible
- Tune some settings in the Windows registry (see below)

**IMPORTANT: The following procedure involves modifying the Windows registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore the registry if a problem occurs. For information about how to back up, restore, and edit the registry, view the following article in the Microsoft Knowledge Base: <http://support.microsoft.com/kb/256986/EN-US/>.**

1. Start Registry Editor (`Regedt32.exe`).
2. Locate the following key in the registry:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters
```

3. On the Edit menu, click Add Value, and then add the following registry value:

```
Value Name: MaxUserPort
Data Type: REG_DWORD
Value: 65534
```

This sets the number of ephemeral ports available to any user. The valid range is between 5000 and 65534 (decimal). The default value is 0x1388 (5000 decimal).

4. On the Edit menu, click Add Value, and then add the following registry value:

```
Value Name: TcpTimedWaitDelay
Data Type: REG_DWORD
Value: 30
```

This sets the number of seconds to hold a TCP port connection in TIME\_WAIT state before closing. The valid range is between 0 (zero) and 300 (decimal). The default value is 0x78 (120 decimal).

5. Quit Registry Editor.
6. Reboot the machine.

Note: Undoing the above should be as simple as deleting the registry entries you've created.

## A.2.3. Client does not support authentication protocol

MySQL 5.0 uses an authentication protocol based on a password hashing algorithm that is incompatible with that used by older (pre-4.1) clients. If you upgrade the server from 4.1, attempts to connect to it with an older client may fail with the following message:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

To solve this problem, you should use one of the following approaches:

- Upgrade all client programs to use a 4.1.1 or newer client library.
- When connecting to the server with a pre-4.1 client program, use an account that still has a pre-4.1-style password.
- Reset the password to pre-4.1 style for each user that needs to use a pre-4.1 client program. This can be done using the SET PASSWORD statement and the OLD\_PASSWORD( ) function:

```
mysql> SET PASSWORD FOR
      -> 'some_user'@'some_host' = OLD_PASSWORD('newpwd');
```

Alternatively, use UPDATE and FLUSH PRIVILEGES:

```
mysql> UPDATE mysql.user SET Password = OLD_PASSWORD('newpwd')
      -> WHERE Host = 'some_host' AND User = 'some_user';
mysql> FLUSH PRIVILEGES;
```

Substitute the password you want to use for “*newpwd*” in the preceding examples. MySQL cannot tell you what the original password was, so you'll need to pick a new one.

- Tell the server to use the older password hashing algorithm:
  1. Start `mysqld` with the `--old-passwords` option.
  2. Assign an old-format password to each account that has had its password updated to the longer 4.1 format. You can identify these accounts with the following query:

```
mysql> SELECT Host, User, Password FROM mysql.user
-> WHERE LENGTH>Password) > 16;
```

For each account record displayed by the query, use the `Host` and `User` values and assign a password using the `OLD_PASSWORD()` function and either `SET PASSWORD` or `UPDATE`, as described earlier.

**Note:** In older versions of PHP, the `mysql` extension does not support the authentication protocol in MySQL 4.1.1 and higher. This is true regardless of the PHP version being used. If you wish to use the `mysql` extension with MySQL 4.1 or newer, you may need to follow one of the options discussed above for configuring MySQL to work with old clients. The `mysqli` extension (stands for “MySQL, Improved”; added in PHP 5) is compatible with the improved password hashing employed in MySQL 4.1 and higher, and no special configuration of MySQL need be done to use this MySQL client library. For more information about the `mysqli` extension, see <http://php.net/mysqli>.

It may also be possible to compile the older `mysql` extension against the new MySQL client library. This is beyond the scope of this Manual; consult the PHP documentation for more information. You also be able to obtain assistance with these issues in our MySQL with PHP forum [<http://forums.mysql.com/list.php?52>].

For additional background on password hashing and authentication, see Section 5.8.9, “Password Hashing as of MySQL 4.1”.

## A.2.4. Password Fails When Entered Interactively

MySQL client programs prompt for a password when invoked with a `--password` or `-p` option that has no following password value:

```
shell> mysql -u user_name -p
Enter password:
```

On some systems, you may find that your password works when specified in an option file or on the command line, but not when you enter it interactively at the `Enter password:` prompt. This occurs when the library provided by the system to read passwords limits password values to a small number of characters (typically eight). That is a problem with the system library, not with MySQL. To work around it, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

## A.2.5. Host '*host\_name*' is blocked

If you get the following error, it means that `mysqld` has received many connect requests from the host '*host\_name*' that have been interrupted in the middle:

```
Host 'host_name' is blocked because of many connection errors.
Unblock with 'mysqladmin flush-hosts'
```

The number of interrupted connect requests allowed is determined by the value of the

`max_connect_errors` system variable. After `max_connect_errors` failed requests, `mysqld` assumes that something is wrong (for example, that someone is trying to break in), and blocks the host from further connections until you execute a `mysqladmin flush-hosts` command or issue a `FLUSH HOSTS` statement. See Section 5.2.2, “Server System Variables”.

By default, `mysqld` blocks a host after 10 connection errors. You can adjust the value by starting the server like this:

```
shell> mysqld_safe --max_connect_errors=10000 &
```

If you get this error message for a given host, you should first verify that there isn't anything wrong with TCP/IP connections from that host. If you are having network problems, it does you no good to increase the value of the `max_connect_errors` variable.

## A.2.6. Too many connections

If you get a `Too many connections` error when you try to connect to the `mysqld` server, this means that all available connections are in use by other clients.

The number of connections allowed is controlled by the `max_connections` system variable. Its default value is 100. If you need to support more connections, you should restart `mysqld` with a larger value for this variable.

`mysqld` actually allows `max_connections+1` clients to connect. The extra connection is reserved for use by accounts that have the `SUPER` privilege. By granting the `SUPER` privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See Section 13.5.4.19, “`SHOW PROCESSLIST` Syntax”.

The maximum number of connections MySQL can support depends on the quality of the thread library on a given platform. Linux or Solaris should be able to support 500-1000 simultaneous connections, depending on how much RAM you have and what your clients are doing. Static Linux binaries provided by MySQL AB can support up to 4000 connections.

## A.2.7. Out of memory

If you issue a query using the `mysql` client program and receive an error like the following one, it means that `mysql` does not have enough memory to store the entire query result:

```
mysql: Out of memory at line 42, 'malloc.c'  
mysql: needed 8136 byte (8k), memory in use: 12481367 bytes (12189k)  
ERROR 2008: MySQL client ran out of memory
```

To remedy the problem, first check whether your query is correct. Is it reasonable that it should return so many rows? If not, correct the query and try again. Otherwise, you can invoke `mysql` with the `--quick` option. This causes it to use the `mysql_use_result()` C API function to retrieve the result set, which places less of a load on the client (but more on the server).

## A.2.8. MySQL server has gone away

This section also covers the related `Lost connection to server during query` error.

The most common reason for the `MySQL server has gone away` error is that the server timed out and closed the connection. In this case, you normally get one of the following error codes (which one you get is operating system-dependent):

Error Code	Description
<code>CR_SERVER_GONE_ERROR</code>	The client couldn't send a question to the server.
<code>CR_SERVER_LOST</code>	The client didn't get an error when writing to the server, but it didn't get a full answer (or any answer) to the question.

By default, the server closes the connection after eight hours if nothing has happened. You can change the time limit by setting the `wait_timeout` variable when you start `mysqld`. See Section 5.2.2, “Server System Variables”.

If you have a script, you just have to issue the query again for the client to do an automatic reconnection. This assumes that you have automatic reconnection in the client enabled (which is the default for the `mysql` command-line client).

Some other common reasons for the `MySQL server has gone away` error are:

- You (or the db administrator) has killed the running thread with a `KILL` statement or a `mysql-admin kill` command.
- You tried to run a query after closing the connection to the server. This indicates a logic error in the application that should be corrected.
- You got a timeout from the TCP/IP connection on the client side. This may happen if you have been using the commands: `mysql_options(..., MYSQL_OPT_READ_TIMEOUT, ...)` or `mysql_options(..., MYSQL_OPT_WRITE_TIMEOUT, ...)`. In this case increasing the timeout may help solve the problem.
- You have encountered a timeout on the server side and the automatic reconnection in the client is disabled (the `reconnect` flag in the `MYSQL` structure is equal to 0).
- You are using a windows client and the server had dropped the connection (probably because `wait_timeout` expired) before the command was issued.

The problem on windows is that in some cases MySQL doesn't get an error from the OS when writing to the TCP/IP connection to the server, but instead gets the error when trying to read the answer from connection.

Prior to MySQL 5.0.19, even if the `reconnect` flag in the `MYSQL` structure is equal to 1, MySQL does not automatically reconnect and re-issue the query as it doesn't know if the server did get the original query or not.

The solution to this is to either do a `mysql_ping` on the connection if there has been a long time since the last query (this is what `MyODBC` does) or set `wait_timeout` on the `mysqld` server so high that it in practice never times out.

- You can also get these errors if you send a query to the server that is incorrect or too large. If `mysqld` receives a packet that is too large or out of order, it assumes that something has gone wrong with the client and closes the connection. If you need big queries (for example, if you are working with big BLOB columns), you can increase the query limit by setting the server's `max_allowed_packet` variable, which has a default value of 1MB. You may also need to increase the maximum packet size on the client end. More information on setting the packet size is given in Section A.2.9, “Packet too large”.
- You also get a lost connection if you are sending a packet 16MB or larger if your client is older than 4.0.8 and your server is 4.0.8 and above, or the other way around.
- You may also see the `MySQL server has gone away` error if MySQL is started with the `--skip-networking` option.
- You have encountered a bug where the server died while executing the query.

You can check whether the MySQL server died and restarted by executing `mysqladmin version` and examining the server's uptime. If the client connection was broken because `mysqld` crashed and restarted, you should concentrate on finding the reason for the crash. Start by checking whether issuing the query again kills the server again. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

You can get more information about the lost connections by starting `mysqld` with the -

`-log-warnings=2` option. This logs some of the disconnected errors in the `hostname.err` file. See Section 5.12.1, “The Error Log”.

If you want to create a bug report regarding this problem, be sure that you include the following information:

- Indicate whether the MySQL server died. You can find information about this in the server error log. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.
- If a specific query kills `mysqld` and the tables involved were checked with `CHECK TABLE` before you ran the query, can you provide a reproducible test case? See Section E.1.6, “Making a Test Case If You Experience Table Corruption”.
- What is the value of the `wait_timeout` system variable in the MySQL server? (`mysqladmin variables` gives you the value of this variable.)
- Have you tried to run `mysqld` with the `--log` option to determine whether the problem query appears in the log?

See also Section A.2.10, “Communication Errors and Aborted Connections”, and Section 1.8, “How to Report Bugs or Problems”.

## A.2.9. Packet too large

A communication packet is a single SQL statement sent to the MySQL server or a single row that is sent to the client.

The largest possible packet that can be transmitted to or from a MySQL 5.0 server or client is 1GB.

When a MySQL client or the `mysqld` server receives a packet bigger than `max_allowed_packet` bytes, it issues a `Packet too large` error and closes the connection. With some clients, you may also get a `Lost connection to MySQL server during query` error if the communication packet is too large.

Both the client and the server have their own `max_allowed_packet` variable, so if you want to handle big packets, you must increase this variable both in the client and in the server.

If you are using the `mysql` client program, its default `max_allowed_packet` variable is 16MB. To set a larger value, start `mysql` like this:

```
shell> mysql --max_allowed_packet=32M
```

That sets the packet size to 32MB.

The server's default `max_allowed_packet` value is 1MB. You can increase this if the server needs to handle big queries (for example, if you are working with big BLOB columns). For example, to set the variable to 16MB, start the server like this:

```
shell> mysqld --max_allowed_packet=16M
```

You can also use an option file to set `max_allowed_packet`. For example, to set the size for the server to 16MB, add the following lines in an option file:

```
[mysqld]  
max_allowed_packet=16M
```

It is safe to increase the value of this variable because the extra memory is allocated only when needed. For example, `mysqld` allocates more memory only when you issue a long query or when `mysqld` must return a large result row. The small default value of the variable is a precaution to catch incorrect packets between the client and server and also to ensure that you do not run out of

memory by using large packets accidentally.

You can also get strange problems with large packets if you are using large BLOB values but have not given `mysqld` access to enough memory to handle the query. If you suspect this is the case, try adding `ulimit -d 256000` to the beginning of the `mysqld_safe` script and restarting `mysqld`.

## A.2.10. Communication Errors and Aborted Connections

The server error log can be a useful source of information about connection problems. See Section 5.12.1, “The Error Log”. If you start the server with the `--log-warnings` option, you might find messages like this in your error log:

```
010301 14:38:23 Aborted connection 854 to db: 'users' user: 'josh'
```

If `Aborted connections` messages appear in the error log, the cause can be any of the following:

- The client program did not call `mysql_close()` before exiting.
- The client had been sleeping more than `wait_timeout` or `interactive_timeout` seconds without issuing any requests to the server. See Section 5.2.2, “Server System Variables”.
- The client program ended abruptly in the middle of a data transfer.

When any of these things happen, the server increments the `Aborted_clients` status variable.

The server increments the `Aborted_connects` status variable when the following things happen:

- A client doesn't have privileges to connect to a database.
- A client uses an incorrect password.
- A connection packet doesn't contain the right information.
- It takes more than `connect_timeout` seconds to get a connect packet. See Section 5.2.2, “Server System Variables”.

If these kinds of things happen, it might indicate that someone is trying to break into your server!

Other reasons for problems with aborted clients or aborted connections:

- Use of Ethernet protocol with Linux, both half and full duplex. Many Linux Ethernet drivers have this bug. You should test for this bug by transferring a huge file via FTP between the client and server machines. If a transfer goes in burst-pause-burst-pause mode, you are experiencing a Linux duplex syndrome. The only solution is switching the duplex mode for both your network card and hub/switch to either full duplex or to half duplex and testing the results to determine the best setting.
- Some problem with the thread library that causes interrupts on reads.
- Badly configured TCP/IP.
- Faulty Ethernets, hubs, switches, cables, and so forth. This can be diagnosed properly only by replacing hardware.

- The `max_allowed_packet` variable value is too small or queries require more memory than you have allocated for `mysqld`. See Section A.2.9, “Packet too large”.

See also Section A.2.8, “MySQL server has gone away”.

## A.2.11. The table is full

There are several ways a full-table error can occur:

- You are using a MySQL server older than 3.23 and an in-memory temporary table becomes larger than `tmp_table_size` bytes. To avoid this problem, you can use the `--tmp_table_size=val` option to make `mysqld` increase the temporary table size or use the SQL option `SQL_BIG_TABLES` before you issue the problematic query. See Section 13.5.3, “SET Syntax”.

You can also start `mysqld` with the `--big-tables` option. This is exactly the same as using `SQL_BIG_TABLES` for all queries.

As of MySQL 3.23, this problem should not occur. If an in-memory temporary table becomes larger than `tmp_table_size`, the server automatically converts it to a disk-based MyISAM table.

- You are using InnoDB tables and run out of room in the InnoDB tablespace. In this case, the solution is to extend the InnoDB tablespace. See Section 14.2.7, “Adding and Removing InnoDB Data and Log Files”.
- You are using ISAM or MyISAM tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.
- You are using a MyISAM table and the space required for the table exceeds what is allowed by the internal pointer size. If you don't specify the `MAX_ROWS` table option when you create a table, MySQL uses the `myisam_data_pointer_size` system variable. From MySQL 5.0.6 on, the default value is 6 bytes, which is enough to allow 256TB of data. Before MySQL 5.0.6, the default value is 4 bytes, which is enough to allow only 4GB of data. See Section 5.2.2, “Server System Variables”.

You can check the maximum data/index sizes by using this statement:

```
SHOW TABLE STATUS FROM database LIKE 'tbl_name';
```

You also can use `myisamchk -dv /path/to/table-index-file`.

If the pointer size is too small, you can fix the problem by using `ALTER TABLE`:

```
ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;
```

You have to specify `AVG_ROW_LENGTH` only for tables with BLOB or TEXT columns; in this case, MySQL can't optimize the space required based only on the number of rows.

## A.2.12. Can't create/write to file

If you get an error of the following type for some queries, it means that MySQL cannot create a temporary file for the result set in the temporary directory:

```
Can't create/write to file '\\sqla3fe_0.ism'.
```

The preceding error is a typical message for Windows; the Unix message is similar.

One fix is to start `mysqld` with the `--tmpdir` option or to add the option to the `[mysqld]` section of your option file. For example, to specify a directory of `C:\temp`, use these lines:

```
[mysqld]
tmpdir=C:/temp
```

The `C:\temp` directory must exist and have sufficient space for the MySQL server to write to. See Section 4.3.2, “Using Option Files”.

Another cause of this error can be permissions issues. Make sure that the MySQL server can write to the `tmpdir` directory.

Check also the error code that you get with  `perror`. One reason the server cannot write to a table is that the filesystem is full:

```
shell> perror 28
Error code 28: No space left on device
```

## A.2.13. Commands out of sync

If you get `Commands out of sync; you can't run this command now` in your client code, you are calling client functions in the wrong order.

This can happen, for example, if you are using `mysql_use_result()` and try to execute a new query before you have called `mysql_free_result()`. It can also happen if you try to execute two queries that return data without calling `mysql_use_result()` or `mysql_store_result()` in between.

## A.2.14. Ignoring user

If you get the following error, it means that when `mysqld` was started or when it reloaded the grant tables, it found an account in the `user` table that had an invalid password.

```
Found wrong password for user 'some_user'@'some_host'; ignoring
user
```

As a result, the account is simply ignored by the permission system.

The following list indicates possible causes of and fixes for this problem:

- You may be running a new version of `mysqld` with an old `user` table. You can check this by executing `mysqlshow mysql user` to see whether the `Password` column is shorter than 16 characters. If so, you can correct this condition by running the `scripts/add_long_password` script.
- The account has an old password (eight characters long) and you didn't start `mysqld` with the `--old-protocol` option. Update the account in the `user` table to have a new password or restart `mysqld` with the `--old-protocol` option.
- You have specified a password in the `user` table without using the `PASSWORD()` function. Use `mysql` to update the account in the `user` table with a new password, making sure to use the `PASSWORD()` function:

```
mysql> UPDATE user SET Password=PASSWORD('newpwd')
-> WHERE User='some_user' AND Host='some_host';
```

## A.2.15. Table '*tbl\_name*' doesn't exist

If you get either of the following errors, it usually means that no table exists in the default database with the given name:

```
Table 'tbl_name' doesn't exist
Can't find file: 'tbl_name' (errno: 2)
```

In some cases, it may be that the table does exist but that you are referring to it incorrectly:

- Because MySQL uses directories and files to store databases and tables, database and table names are case sensitive if they are located on a filesystem that has case-sensitive filenames.
- Even for filesystems that are not case sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

You can check which tables are in the default database with `SHOW TABLES`. See Section 13.5.4, “SHOW Syntax”.

## A.2.16. Can't initialize character set

You might see an error like this if you have character set problems:

```
MySQL Connection Failed: Can't initialize character set charset_name
```

This error can have any of the following causes:

- The character set is a multi-byte character set and you have no support for the character set in the client. In this case, you need to recompile the client by running `configure` with the `--with-charset=charset_name` or `--with-extra-charsets=charset_name` option. See Section 2.9.2, “Typical configure Options”.

All standard MySQL binaries are compiled with `--with-extra-character-sets=complex`, which enables support for all multi-byte character sets. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

- The character set is a simple character set that is not compiled into `mysqld`, and the character set definition files are not in the place where the client expects to find them.

In this case, you need to use one of the following methods to solve the problem:

- Recompile the client with support for the character set. See Section 2.9.2, “Typical configure Options”.
- Specify to the client the directory where the character set definition files are located. For many clients, you can do this with the `--character-sets-dir` option.
- Copy the character definition files to the path where the client expects them to be.

## A.2.17. File Not Found

If you get `ERROR '...' not found (errno: 23), Can't open file: ... (errno: 24)`, or any other error with `errno 23` or `errno 24` from MySQL, it means that you haven't allocated enough file descriptors for the MySQL server. You can use the `perror` utility to get a description of what the error number means:

```
shell> perror 23
Error code 23: File table overflow
shell> perror 24
```

```
Error code 24: Too many open files
shell> perror 11
Error code 11: Resource temporarily unavailable
```

The problem here is that `mysqld` is trying to keep open too many files simultaneously. You can either tell `mysqld` not to open so many files at once or increase the number of file descriptors available to `mysqld`.

To tell `mysqld` to keep open fewer files at a time, you can make the table cache smaller by reducing the value of the `table_cache` system variable (the default value is 64). Reducing the value of `max_connections` also reduces the number of open files (the default value is 100).

To change the number of file descriptors available to `mysqld`, you can use the `--open-files-limit` option to `mysqld_safe` or (as of MySQL 3.23.30) set the `open_files_limit` system variable. See Section 5.2.2, “Server System Variables”. The easiest way to set these values is to add an option to your option file. See Section 4.3.2, “Using Option Files”. If you have an old version of `mysqld` that doesn't support setting the open files limit, you can edit the `mysqld_safe` script. There is a commented-out line `ulimit -n 256` in the script. You can remove the `#` character to uncomment this line, and change the number 256 to set the number of file descriptors to be made available to `mysqld`.

`--open-files-limit` and `ulimit` can increase the number of file descriptors, but only up to the limit imposed by the operating system. There is also a “hard” limit that can be overridden only if you start `mysqld_safe` or `mysqld` as `root` (just remember that you also need to start the server with the `--user` option in this case so that it does not continue to run as `root` after it starts up). If you need to increase the operating system limit on the number of file descriptors available to each process, consult the documentation for your system.

**Note:** If you run the `tcsh` shell, `ulimit` does not work! `tcsh` also reports incorrect values when you ask for the current limits. In this case, you should start `mysqld_safe` using `sh`.

## A.3. Installation-Related Issues

### A.3.1. Problems Linking to the MySQL Client Library

When you are linking an application program to use the MySQL client library, you might get undefined reference errors for symbols that start with `mysql_`, such as those shown here:

```
/tmp/ccFKsdPa.o: In function `main':
/tmp/ccFKsdPa.o(.text+0xb): undefined reference to `mysql_init'
/tmp/ccFKsdPa.o(.text+0x31): undefined reference to `mysql_real_connect'
/tmp/ccFKsdPa.o(.text+0x57): undefined reference to `mysql_real_connect'
/tmp/ccFKsdPa.o(.text+0x69): undefined reference to `mysql_error'
/tmp/ccFKsdPa.o(.text+0x9a): undefined reference to `mysql_close'
```

You should be able to solve this problem by adding `-ldir_path -lmysqlclient` at the end of your link command, where `dir_path` represents the pathname of the directory where the client library is located. To determine the correct directory, try this command:

```
shell> mysql_config --libs
```

The output from `mysql_config` might indicate other libraries that should be specified on the link command as well.

If you get undefined reference errors for the `uncompress` or `compress` function, add `-lz` to the end of your link command and try again.

If you get undefined reference errors for a function that should exist on your system, such as `connect`, check the manual page for the function in question to determine which libraries you should add to the link command.

You might get undefined reference errors such as the following for functions that don't exist on your system:

```
mf_format.o(.text+0x201): undefined reference to `__lxstat'
```

This usually means that your MySQL client library was compiled on a system that is not 100% compatible with yours. In this case, you should download the latest MySQL source distribution and compile MySQL yourself. See Section 2.9, “MySQL Installation Using a Source Distribution”.

You might get undefined reference errors at runtime when you try to execute a MySQL program. If these errors specify symbols that start with `mysql_` or indicate that the `mysqlclient` library can't be found, it means that your system can't find the shared `libmysqlclient.so` library. The fix for this is to tell your system to search for shared libraries where the library is located. Use whichever of the following methods is appropriate for your system:

- Add the path to the directory where `libmysqlclient.so` is located to the `LD_LIBRARY_PATH` environment variable.
- Add the path to the directory where `libmysqlclient.so` is located to the `LD_LIBRARY` environment variable.
- Copy `libmysqlclient.so` to some directory that is searched by your system, such as `/lib`, and update the shared library information by executing `ldconfig`.

Another way to solve this problem is by linking your program statically with the `-static` option, or by removing the dynamic MySQL libraries before linking your code. Before trying the second method, you should be sure that no other programs are using the dynamic libraries.

## A.3.2. Problems with File Permissions

If you have problems with file permissions, the `UMASK` environment variable might be set incorrectly when `mysqld` starts. For example, MySQL might issue the following error message when you create a table:

```
ERROR: Can't find file: 'path/with/filename.frm' (Errcode: 13)
```

The default `UMASK` value is 0660. You can change this behavior by starting `mysqld_safe` as follows:

```
shell> UMASK=384 # = 600 in octal
shell> export UMASK
shell> mysqld_safe &
```

By default, MySQL creates database and RAID directories with an access permission value of 0700. You can modify this behavior by setting the `UMASK_DIR` variable. If you set its value, new directories are created with the combined `UMASK` and `UMASK_DIR` values. For example, if you want to give group access to all new directories, you can do this:

```
shell> UMASK_DIR=504 # = 770 in octal
shell> export UMASK_DIR
shell> mysqld_safe &
```

In MySQL 3.23.25 and above, MySQL assumes that the value for `UMASK` and `UMASK_DIR` is in octal if it starts with a zero.

See Appendix F, *Environment Variables*.

## A.4. Administration-Related Issues

### A.4.1. How to Reset the Root Password

If you have never set a `root` password for MySQL, the server does not require a password at all for connecting as `root`. However, it is recommended to set a password for each account. See Section 5.7.1, “General Security Guidelines”.

If you set a `root` password previously, but have forgotten what it was, you can set a new password. The following procedure is for Windows systems. The procedure for Unix systems is given later in this section.

The procedure under Windows:

1. Log on to your system as Administrator.
2. Stop the MySQL server if it is running. For a server that is running as a Windows service, go to the Services manager:

```
Start Menu -> Control Panel -> Administrative Tools -> Services
```

Then find the MySQL service in the list, and stop it.

If your server is not running as a service, you may need to use the Task Manager to force it to stop.

3. Create a text file and place the following command within it on a single line:

```
SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPassword');
```

Save the file with any name. For this example the file will be `C:\mysql-init.txt`.

4. Open a console window to get to the DOS command prompt:

```
Start Menu -> Run -> cmd
```

5. We are assuming that you installed MySQL to `C:\mysql`. If you installed MySQL to another location, adjust the following commands accordingly.

At the DOS command prompt, execute this command:

```
C:\> C:\mysql\bin\mysqld-nt --init-file=C:\mysql-init.txt
```

The contents of the file named by the `--init-file` option are executed at server startup, changing the `root` password. After the server has started successfully, you should delete `C:\mysql-init.txt`.

If you install MySQL using the MySQL Installation Wizard, you may need to specify a `--defaults-file` option:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqld-nt.exe"  
      --defaults-file="C:\Program Files\MySQL\MySQL Server 5.0\my.ini"  
      --init-file=C:\mysql-init.txt
```

The appropriate `--defaults-file` setting can be found using the Services Manager:

```
Start Menu -> Control Panel -> Administrative Tools -> Services
```

Find the MySQL service in the list, right-click on it, and choose the `Properties` option. The `Path to executable` field contains the `--defaults-file` setting.

6. Stop the MySQL server, then restart it in normal mode again. If you run the server as a service, start it from the Windows Services window. If you start the server manually, use whatever command you normally use.
7. You should be able to connect using the new password.

In a Unix environment, the procedure for resetting the root password is as follows:

1. Log on to your system as either the Unix root user or as the same user that the `mysqld` server runs as.
2. Locate the `.pid` file that contains the server's process ID. The exact location and name of this file depend on your distribution, hostname, and configuration. Common locations are `/var/lib/mysql/`, `/var/run/mysqld/`, and `/usr/local/mysql/data/`. Generally, the filename has the extension of `.pid` and begins with either `mysqld` or your system's hostname.

You can stop the MySQL server by sending a normal kill (not `kill -9`) to the `mysqld` process, using the pathname of the `.pid` file in the following command:

```
shell> kill `cat /mysql-data-directory/host_name.pid`
```

Note the use of backticks rather than forward quotes with the `cat` command; these cause the output of `cat` to be substituted into the `kill` command.

3. Create a text file and place the following command within it on a single line:

```
SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPassword');
```

Save the file with any name. For this example the file will be `~/mysql-init`.

4. Restart the MySQL server with the special `--init-file=~/mysql-init` option:

```
shell> mysqld_safe --init-file=~/mysql-init &
```

The contents of the `init-file` are executed at server startup, changing the root password. After the server has started successfully you should delete `~/mysql-init`.

5. You should be able to connect using the new password.

Alternatively, on any platform, you can set the new password using the `mysql` client (but this approach is less secure):

1. Stop `mysqld` and restart it with the `--skip-grant-tables --user=root` options (Windows users omit the `--user=root` portion).

2. Connect to the `mysqld` server with this command:

```
shell> mysql -u root
```

3. Issue the following statements in the `mysql` client:

```
mysql> UPDATE mysql.user SET Password=PASSWORD('newpwd')
```

```
mysql> FLUSH PRIVILEGES; WHERE User='root';
```

Replace “*newpwd*” with the actual `root` password that you want to use.

4. You should be able to connect using the new password.

## A.4.2. What to Do If MySQL Keeps Crashing

Each MySQL version is tested on many platforms before it is released. This doesn't mean that there are no bugs in MySQL, but if there are bugs, they should be very few and can be hard to find. If you have a problem, it always helps if you try to find out exactly what crashes your system, because you have a much better chance of getting the problem fixed quickly.

First, you should try to find out whether the problem is that the `mysqld` server dies or whether your problem has to do with your client. You can check how long your `mysqld` server has been up by executing `mysqladmin version`. If `mysqld` has died and restarted, you may find the reason by looking in the server's error log. See Section 5.12.1, “The Error Log”.

On some systems, you can find in the error log a stack trace of where `mysqld` died that you can resolve with the `resolve_stack_dump` program. See Section E.1.4, “Using a Stack Trace”. Note that the variable values written in the error log may not always be 100% correct.

Many server crashes are caused by corrupted data files or index files. MySQL updates the files on disk with the `write()` system call after every SQL statement and before the client is notified about the result. (This is not true if you are running with `--delay-key-write`, in which case data files are written but not index files.) This means that data file contents are safe even if `mysqld` crashes, because the operating system ensures that the unflushed data is written to disk. You can force MySQL to flush everything to disk after every SQL statement by starting `mysqld` with the `-flush` option.

The preceding means that normally you should not get corrupted tables unless one of the following happens:

- The MySQL server or the server host was killed in the middle of an update.
- You have found a bug in `mysqld` that caused it to die in the middle of an update.
- Some external program is manipulating data files or index files at the same time as `mysqld` without locking the table properly.
- You are running many `mysqld` servers using the same data directory on a system that doesn't support good filesystem locks (normally handled by the `lockd` lock manager), or you are running multiple servers with external locking disabled.
- You have a crashed data file or index file that contains very corrupt data that confused `mysqld`.
- You have found a bug in the data storage code. This isn't likely, but it's at least possible. In this case, you can try to change the storage engine to another engine by using `ALTER TABLE` on a repaired copy of the table.

Because it is very difficult to know why something is crashing, first try to check whether things that work for others crash for you. Please try the following things:

- Stop the `mysqld` server with `mysqladmin shutdown`, run `myisamchk --silent -force */*.MYI` from the data directory to check all MyISAM tables, and restart `mysqld`. This ensures that you are running from a clean state. See Chapter 5, *Database Administration*.

- Start `mysqld` with the `--log` option and try to determine from the information written to the log whether some specific query kills the server. About 95% of all bugs are related to a particular query. Normally, this is one of the last queries in the log file just before the server restarts. See Section 5.12.2, “The General Query Log”. If you can repeatedly kill MySQL with a specific query, even when you have checked all tables just before issuing it, then you have been able to locate the bug and should submit a bug report for it. See Section 1.8, “How to Report Bugs or Problems”.
- Try to make a test case that we can use to repeat the problem. See Section E.1.6, “Making a Test Case If You Experience Table Corruption”.
- Try running the tests in the `mysql-test` directory and the MySQL benchmarks. See Section 24.1.2, “MySQL Test Suite”. They should test MySQL rather well. You can also add code to the benchmarks that simulates your application. The benchmarks can be found in the `sql-bench` directory in a source distribution or, for a binary distribution, in the `sql-bench` directory under your MySQL installation directory.
- Try the `fork_big.pl` script. (It is located in the `tests` directory of source distributions.)
- If you configure MySQL for debugging, it is much easier to gather information about possible errors if something goes wrong. Configuring MySQL for debugging causes a safe memory allocator to be included that can find some errors. It also provides a lot of output about what is happening. Reconfigure MySQL with the `--with-debug` or `--with-debug=full` option to configure and then recompile. See Section E.1, “Debugging a MySQL Server”.
- Make sure that you have applied the latest patches for your operating system.
- Use the `--skip-external-locking` option to `mysqld`. On some systems, the `lockd` lock manager does not work properly; the `--skip-external-locking` option tells `mysqld` not to use external locking. (This means that you cannot run two `mysqld` servers on the same data directory and that you must be careful if you use `myisamchk`. Nevertheless, it may be instructive to try the option as a test.)
- Have you tried `mysqladmin -u root processlist` when `mysqld` appears to be running but not responding? Sometimes `mysqld` is not comatose even though you might think so. The problem may be that all connections are in use, or there may be some internal lock problem. `mysqladmin -u root processlist` usually is able to make a connection even in these cases, and can provide useful information about the current number of connections and their status.
- Run the command `mysqladmin -i 5 status` or `mysqladmin -i 5 -r status` in a separate window to produce statistics while you run your other queries.
- Try the following:
  1. Start `mysqld` from `gdb` (or another debugger). See Section E.1.3, “Debugging `mysqld` under `gdb`”.
  2. Run your test scripts.
  3. Print the backtrace and the local variables at the three lowest levels. In `gdb`, you can do this with the following commands when `mysqld` has crashed inside `gdb`:

```
backtrace
info local
up
info local
up
info local
```

With `gdb`, you can also examine which threads exist with `info threads` and switch to a specific thread with `thread N`, where `N` is the thread ID.

- Try to simulate your application with a Perl script to force MySQL to crash or misbehave.
- Send a normal bug report. See Section 1.8, “How to Report Bugs or Problems”. Be even more detailed than usual. Because MySQL works for many people, it may be that the crash results from something that exists only on your computer (for example, an error that is related to your particular system libraries).
- If you have a problem with tables containing dynamic-length rows and you are using only VARCHAR columns (not BLOB or TEXT columns), you can try to change all VARCHAR to CHAR with `ALTER TABLE`. This forces MySQL to use fixed-size rows. Fixed-size rows take a little extra space, but are much more tolerant to corruption.

The current dynamic row code has been in use at MySQL AB for several years with very few problems, but dynamic-length rows are by nature more prone to errors, so it may be a good idea to try this strategy to see whether it helps.

- Do not rule out your server hardware when diagnosing problems. Defective hardware can be the cause of data corruption. Particular attention should be paid to both RAMS and hard-drives when troubleshooting hardware.

### A.4.3. How MySQL Handles a Full Disk

This section describes how MySQL responds to disk-full errors (such as “no space left on device”), and to quota-exceeded errors (such as “write failed” or “user block limit reached”).

This section is relevant for writes to MyISAM tables. It also applies for writes to binary log files and binary log index file, except that references to “row” and “record” should be understood to mean “event.”

When a disk-full condition occurs, MySQL does the following:

- It checks once every minute to see whether there is enough space to write the current row. If there is enough space, it continues as if nothing had happened.
- Every 10 minutes it writes an entry to the log file, warning about the disk-full condition.

To alleviate the problem, you can take the following actions:

- To continue, you only have to free enough disk space to insert all records.
- To abort the thread, you must use `mysqladmin kill`. The thread is aborted the next time it checks the disk (in one minute).
- Other threads might be waiting for the table that caused the disk-full condition. If you have several “locked” threads, killing the one thread that is waiting on the disk-full condition allows the other threads to continue.

Exceptions to the preceding behavior are when you use `REPAIR TABLE` or `OPTIMIZE TABLE` or when the indexes are created in a batch after `LOAD DATA INFILE` or after an `ALTER TABLE` statement. All of these statements may create large temporary files that, if left to themselves, would cause big problems for the rest of the system. If the disk becomes full while MySQL is doing any of these operations, it removes the big temporary files and mark the table as crashed. The exception is that for `ALTER TABLE`, the old table is left unchanged.

### A.4.4. Where MySQL Stores Temporary Files

MySQL uses the value of the `TMPDIR` environment variable as the pathname of the directory in

which to store temporary files. If you don't have `TMPDIR` set, MySQL uses the system default, which is normally `/tmp`, `/var/tmp`, or `/usr/tmp`. If the filesystem containing your temporary file directory is too small, you can use the `--tmpdir` option to `mysqld` to specify a directory in a filesystem where you have enough space.

In MySQL 5.0, the `--tmpdir` option can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (':') on Unix and semicolon characters (;) on Windows, NetWare, and OS/2. **Note:** To spread the load effectively, these paths should be located on different *physical* disks, not different partitions of the same disk.

If the MySQL server is acting as a replication slave, you should not set `--tmpdir` to point to a directory on a memory-based filesystem or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

MySQL creates all temporary files as hidden files. This ensures that the temporary files are removed if `mysqld` is terminated. The disadvantage of using hidden files is that you do not see a big temporary file that fills up the filesystem in which the temporary file directory is located.

When sorting (`ORDER BY` or `GROUP BY`), MySQL normally uses one or two temporary files. The maximum disk space required is determined by the following expression:

```
(length of what is sorted + sizeof(row pointer))
* number of matched rows
* 2
```

The row pointer size is usually four bytes, but may grow in the future for really big tables.

For some `SELECT` queries, MySQL also creates temporary SQL tables. These are not hidden and have names of the form `SQL_*`.

`ALTER TABLE` creates a temporary table in the same directory as the original table.

## A.4.5. How to Protect or Change the MySQL Unix Socket File

The default location for the Unix socket file that the server uses for communication with local clients is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On some versions of Unix, anyone can delete files in the `/tmp` directory or other similar directories used for temporary files. If the socket file is located in such a directory on your system, this might cause problems.

On most versions of Unix, you can protect your `/tmp` directory so that files can be deleted only by their owners or the superuser (`root`). To do this, set the `sticky` bit on the `/tmp` directory by logging in as `root` and using the following command:

```
shell> chmod +t /tmp
```

You can check whether the `sticky` bit is set by executing `ls -ld /tmp`. If the last permission character is `t`, the bit is set.

Another approach is to change the place where the server creates the Unix socket file. If you do this, you should also let client programs know the new location of the file. You can specify the file location in several ways:

- Specify the path in a global or local option file. For example, put the following lines in `/etc/my.cnf`:

```
[mysqld]
socket=/path/to/socket
```

```
[client]
socket=/path/to/socket
```

See Section 4.3.2, “Using Option Files”.

- Specify a `--socket` option on the command line to `mysqld_safe` and when you run client programs.
- Set the `MYSQL_UNIX_PORT` environment variable to the path of the Unix socket file.
- Recompile MySQL from source to use a different default Unix socket file location. Define the path to the file with the `--with-unix-socket-path` option when you run `configure`. See Section 2.9.2, “Typical configure Options”.

You can test whether the new socket location works by attempting to connect to the server with this command:

```
shell> mysqladmin --socket=/path/to/socket version
```

## A.4.6. Time Zone Problems

If you have a problem with `SELECT NOW()` returning values in UTC and not your local time, you have to tell the server your current time zone. The same applies if `UNIX_TIMESTAMP()` returns the wrong value. This should be done for the environment in which the server runs; for example, in `mysqld_safe` or `mysql.server`. See Appendix F, *Environment Variables*.

You can set the time zone for the server with the `--timezone=timezone_name` option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`.

The allowable values for `--timezone` or `TZ` are system-dependent. Consult your operating system documentation to see what values are acceptable.

## A.5. Query-Related Issues

### A.5.1. Case Sensitivity in Searches

By default, MySQL searches are not case sensitive (although there are some character sets that are never case insensitive, such as `czech`). This means that if you search with `col_name LIKE 'a%'`, you get all column values that start with A or a. If you want to make this search case sensitive, make sure that one of the operands has a case sensitive or binary collation. For example, if you are comparing a column and a string that both have the `latin1` character set, you can use the `COLLATE` operator to cause either operand to have the `latin1_general_cs` or `latin1_bin` collation. For example:

```
col_name COLLATE latin1_general_cs LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_general_cs
col_name COLLATE latin1_bin LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_bin
```

If you want a column always to be treated in case-sensitive fashion, declare it with a case sensitive or binary collation. See Section 13.1.5, “CREATE TABLE Syntax”.

Simple comparison operations (`>=`, `>`, `=`, `<`, `<=`, sorting, and grouping) are based on each

character's "sort value." Characters with the same sort value (such as 'E', 'e', and 'Ã©') are treated as the same character.

## A.5.2. Problems Using DATE Columns

The format of a DATE value is 'YYYY-MM-DD'. According to standard SQL, no other format is allowed. You should use this format in UPDATE expressions and in the WHERE clause of SELECT statements. For example:

```
mysql> SELECT * FROM tbl_name WHERE date >= '2003-05-05';
```

As a convenience, MySQL automatically converts a date to a number if the date is used in a numeric context (and vice versa). It is also smart enough to allow a "relaxed" string form when updating and in a WHERE clause that compares a date to a TIMESTAMP, DATE, or DATETIME column. ("Relaxed form" means that any punctuation character may be used as the separator between parts. For example, '2004-08-15' and '2004#08#15' are equivalent.) MySQL can also convert a string containing no separators (such as '20040815'), provided it makes sense as a date.

When you compare a DATE, TIME, DATETIME, or TIMESTAMP to a constant string with the <, <=, =, >=, >, or BETWEEN operators, MySQL normally converts the string to an internal long integer for faster comparison (and also for a bit more "relaxed" string checking). However, this conversion is subject to the following exceptions:

- When you compare two columns
- When you compare a DATE, TIME, DATETIME, or TIMESTAMP column to an expression
- When you use any other comparison method than those just listed, such as IN or STRCMP().

For these exceptional cases, the comparison is done by converting the objects to strings and performing a string comparison.

To keep things safe, assume that strings are compared as strings and use the appropriate string functions if you want to compare a temporal value to a string.

The special date '0000-00-00' can be stored and retrieved as '0000-00-00'. When using a '0000-00-00' date through MyODBC, it is automatically converted to NULL in MyODBC 2.50.12 and above, because ODBC can't handle this kind of date.

Because MySQL performs the conversions described above, the following statements work:

```
mysql> INSERT INTO tbl_name (idate) VALUES (19970505);
mysql> INSERT INTO tbl_name (idate) VALUES ('19970505');
mysql> INSERT INTO tbl_name (idate) VALUES ('97-05-05');
mysql> INSERT INTO tbl_name (idate) VALUES ('1997.05.05');
mysql> INSERT INTO tbl_name (idate) VALUES ('1997 05 05');
mysql> INSERT INTO tbl_name (idate) VALUES ('0000-00-00');

mysql> SELECT idate FROM tbl_name WHERE idate >= '1997-05-05';
mysql> SELECT idate FROM tbl_name WHERE idate >= 19970505;
mysql> SELECT MOD(idate,100) FROM tbl_name WHERE idate >= 19970505;
mysql> SELECT idate FROM tbl_name WHERE idate >= '19970505';
```

However, the following does not work:

```
mysql> SELECT idate FROM tbl_name WHERE STRCMP(idate,'20030505')=0;
```

STRCMP() is a string function, so it converts idate to a string in 'YYYY-MM-DD' format and performs a string comparison. It does not convert '20030505' to the date '2003-05-05' and perform a date comparison.

If you are using the `ALLOW_INVALID_DATES` SQL mode, MySQL allows you to store dates that are given only limited checking: MySQL requires only that the day is in the range from 1 to 31 and the month is in the range from 1 to 12.

This makes MySQL very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation).

If you are not using the `NO_ZERO_IN_DATE` SQL mode, the day or month part can be zero. This is convenient if you want to store a birthdate in a `DATE` column and you know only part of the date.

If you are not using the `NO_ZERO_DATE` SQL mode, MySQL also allows you to store `'0000-00-00'` as a “dummy date.” This is in some cases more convenient than using `NULL` values.

If the date cannot be converted to any reasonable value, a 0 is stored in the `DATE` column, which is retrieved as `'0000-00-00'`. This is both a speed and a convenience issue. We believe that the database server's responsibility is to retrieve the same date you stored (even if the data was not logically correct in all cases). We think it is up to the application and not the server to check the dates.

If you want MySQL to check all dates and accept only legal dates (unless overridden by `IGNORE`), you should set `sql_mode` to `"NO_ZERO_IN_DATE,NO_ZERO_DATE"`.

Date handling in MySQL 5.0.1 and earlier works like MySQL 5.0.2 with the `ALLOW_INVALID_DATES` SQL mode enabled.

### A.5.3. Problems with NULL Values

The concept of the `NULL` value is a common source of confusion for newcomers to SQL, who often think that `NULL` is the same thing as an empty string `' '`. This is not the case. For example, the following statements are completely different:

```
mysql> INSERT INTO my_table (phone) VALUES (NULL);
mysql> INSERT INTO my_table (phone) VALUES ('');
```

Both statements insert a value into the `phone` column, but the first inserts a `NULL` value and the second inserts an empty string. The meaning of the first can be regarded as “phone number is not known” and the meaning of the second can be regarded as “the person is known to have no phone, and thus no phone number.”

To help with `NULL` handling, you can use the `IS NULL` and `IS NOT NULL` operators and the `IFNULL()` function.

In SQL, the `NULL` value is never true in comparison to any other value, even `NULL`. An expression that contains `NULL` always produces a `NULL` value unless otherwise indicated in the documentation for the operators and functions involved in the expression. All columns in the following example return `NULL`:

```
mysql> SELECT NULL, 1+NULL, CONCAT('Invisible',NULL);
```

If you want to search for column values that are `NULL`, you cannot use an `expr = NULL` test. The following statement returns no rows, because `expr = NULL` is never true for any expression:

```
mysql> SELECT * FROM my_table WHERE phone = NULL;
```

To look for `NULL` values, you must use the `IS NULL` test. The following statements show how to find the `NULL` phone number and the empty phone number:

```
mysql> SELECT * FROM my_table WHERE phone IS NULL;
mysql> SELECT * FROM my_table WHERE phone = '';
```

See Section 3.3.4.6, “Working with NULL Values”, for additional information and examples.

You can add an index on a column that can have NULL values if you are using the MyISAM, InnoDB, or BDB, or MEMORY storage engine. Otherwise, you must declare an indexed column NOT NULL, and you cannot insert NULL into the column.

When reading data with `LOAD DATA INFILE`, empty or missing columns are updated with ' '. If you want a NULL value in a column, you should use `\N` in the data file. The literal word “NULL” may also be used under some circumstances. See Section 13.2.5, “LOAD DATA INFILE Syntax”.

When using `DISTINCT`, `GROUP BY`, or `ORDER BY`, all NULL values are regarded as equal.

When using `ORDER BY`, NULL values are presented first, or last if you specify `DESC` to sort in descending order.

Aggregate (summary) functions such as `COUNT()`, `MIN()`, and `SUM()` ignore NULL values. The exception to this is `COUNT(*)`, which counts rows and not individual column values. For example, the following statement produces two counts. The first is a count of the number of rows in the table, and the second is a count of the number of non-NULL values in the `age` column:

```
mysql> SELECT COUNT(*), COUNT(age) FROM person;
```

For some data types, MySQL handles NULL values specially. If you insert NULL into a `TIMESTAMP` column, the current date and time is inserted. If you insert NULL into an integer column that has the `AUTO_INCREMENT` attribute, the next number in the sequence is inserted.

## A.5.4. Problems with Column Aliases

You can use an alias to refer to a column in `GROUP BY`, `ORDER BY`, or `HAVING` clauses. Aliases can also be used to give columns better names:

```
SELECT SQRT(a*b) AS root FROM tbl_name GROUP BY root HAVING root > 0;  
SELECT id, COUNT(*) AS cnt FROM tbl_name GROUP BY id HAVING cnt > 0;  
SELECT id AS 'Customer identity' FROM tbl_name;
```

Standard SQL doesn't allow you to refer to a column alias in a `WHERE` clause. This restriction is imposed because when the `WHERE` code is executed, the column value may not yet be determined. For example, the following query is illegal:

```
SELECT id, COUNT(*) AS cnt FROM tbl_name WHERE cnt > 0 GROUP BY id;
```

The `WHERE` statement is executed to determine which rows should be included in the `GROUP BY` part, whereas `HAVING` is used to decide which rows from the result set should be used.

## A.5.5. Rollback Failure for Non-Transactional Tables

If you receive the following message when trying to perform a `ROLLBACK`, it means that one or more of the tables you used in the transaction do not support transactions:

```
Warning: Some non-transactional changed tables couldn't be rolled back
```

These non-transactional tables are not affected by the `ROLLBACK` statement.

If you were not deliberately mixing transactional and non-transactional tables within the transaction, the most likely cause for this message is that a table you thought was transactional actually is not. This can happen if you try to create a table using a transactional storage engine that is not supported by your `mysqld` server (or that was disabled with a startup option). If `mysqld` doesn't support a storage engine, it instead creates the table as a MyISAM table, which is non-transactional.

You can check the storage engine for a table by using either of these statements:

```
SHOW TABLE STATUS LIKE 'tbl_name';  
SHOW CREATE TABLE tbl_name;
```

See Section 13.5.4.21, “SHOW TABLE STATUS Syntax”, and Section 13.5.4.6, “SHOW CREATE TABLE Syntax”.

You can check which storage engines your `mysqld` server supports by using this statement:

```
SHOW ENGINES;
```

You can also use the following statement, and check the value of the variable that is associated with the storage engine in which you are interested:

```
SHOW VARIABLES LIKE 'have_%';
```

For example, to determine whether the InnoDB storage engine is available, check the value of the `have_innodb` variable.

See Section 13.5.4.10, “SHOW ENGINES Syntax”, and Section 13.5.4.24, “SHOW VARIABLES Syntax”.

## A.5.6. Deleting Rows from Related Tables

If the total length of the `DELETE` statement for `related_table` is more than 1MB (the default value of the `max_allowed_packet` system variable), you should split it into smaller parts and execute multiple `DELETE` statements. You probably get the fastest `DELETE` by specifying only 100 to 1,000 `related_column` values per statement if the `related_column` is indexed. If the `related_column` isn't indexed, the speed is independent of the number of arguments in the `IN` clause.

## A.5.7. Solving Problems with No Matching Rows

If you have a complicated query that uses many tables but that doesn't return any rows, you should use the following procedure to find out what is wrong:

1. Test the query with `EXPLAIN` to check whether you can find something that is obviously wrong. See Section 7.2.1, “Optimizing Queries with `EXPLAIN`”.
2. Select only those columns that are used in the `WHERE` clause.
3. Remove one table at a time from the query until it returns some rows. If the tables are large, it's a good idea to use `LIMIT 10` with the query.
4. Issue a `SELECT` for the column that should have matched a row against the table that was last removed from the query.
5. If you are comparing `FLOAT` or `DOUBLE` columns with numbers that have decimals, you can't use equality (`=`) comparisons. This problem is common in most computer languages because not all floating-point values can be stored with exact precision. In some cases, changing the `FLOAT` to a `DOUBLE` fixes this. See Section A.5.8, “Problems with Floating-Point Comparisons”.

Similar problems may be encountered when comparing `DECIMAL` values prior to MySQL 5.0.3.

6. If you still can't figure out what's wrong, create a minimal test that can be run with `mysql test < query.sql` that shows your problems. You can create a test file by dumping the

tables with `mysqldump --quick db_name tbl_name_1 ... tbl_name_n > query.sql`. Open the file in an editor, remove some insert lines (if there are more than needed to demonstrate the problem), and add your `SELECT` statement at the end of the file.

Verify that the test file demonstrates the problem by executing these commands:

```
shell> mysqladmin create test2
shell> mysql test2 < query.sql
```

Attach the test file to a bug report, which you can file using the instructions in Section 1.8, “How to Report Bugs or Problems”.

## A.5.8. Problems with Floating-Point Comparisons

Floating-point numbers sometimes cause confusion because they are approximate. That is, they are not stored as exact values inside computer architecture. What you can see on the screen usually is not the exact value of the number. The `FLOAT` and `DOUBLE` data types are such, and `DECIMAL` operations before MySQL 5.0.3 are approximate as well.

Prior to MySQL 5.0.3, `DECIMAL` columns store values with exact precision because they are represented as strings, but calculations on `DECIMAL` values are done using floating-point operations. As of 5.0.3, MySQL performs `DECIMAL` operations with a precision of 64 decimal digits, which should solve most common inaccuracy problems when it comes to `DECIMAL` columns. (If your server is from MySQL 5.0.3 or higher, but you have `DECIMAL` columns in tables that were created before 5.0.3, the old behavior still applies to those columns. To convert the tables to the newer `DECIMAL` format, dump them with `mysqldump` and reload them.)

The following example (for versions of MySQL older than 5.0.3) demonstrates the problem. It shows that even for older `DECIMAL` columns, calculations that are done using floating-point operations are subject to floating-point error. (Were you to replace the `DECIMAL` columns with `FLOAT`, similar problems would occur for all versions of MySQL.)

```
mysql> CREATE TABLE t1 (i INT, d1 DECIMAL(9,2), d2 DECIMAL(9,2));
mysql> INSERT INTO t1 VALUES (1, 101.40, 21.40), (1, -80.00, 0.00),
-> (2, 0.00, 0.00), (2, -13.20, 0.00), (2, 59.60, 46.40),
-> (2, 30.40, 30.40), (3, 37.00, 7.40), (3, -29.60, 0.00),
-> (4, 60.00, 15.40), (4, -10.60, 0.00), (4, -34.00, 0.00),
-> (5, 33.00, 0.00), (5, -25.80, 0.00), (5, 0.00, 7.20),
-> (6, 0.00, 0.00), (6, -51.40, 0.00);
```

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b
-> FROM t1 GROUP BY i HAVING a <> b;
```

i	a	b
1	21.40	21.40
2	76.80	76.80
3	7.40	7.40
4	15.40	15.40
5	7.20	7.20
6	-51.40	0.00

The result is correct. Although the first five records look like they should not satisfy the comparison (the values of `a` and `b` do not appear to be different), they may do so because the difference between the numbers shows up around the tenth decimal or so, depending on factors such as computer architecture or the compiler version or optimization level. For example, different CPUs may evaluate floating-point numbers differently.

As of MySQL 5.0.3, you will get only the last row in the above result.

The problem cannot be solved by using `ROUND()` or similar functions, because the result is still a

floating-point number:

```
mysql> SELECT i, ROUND(SUM(d1), 2) AS a, ROUND(SUM(d2), 2) AS b
-> FROM t1 GROUP BY i HAVING a <> b;
```

i	a	b
1	21.40	21.40
2	76.80	76.80
3	7.40	7.40
4	15.40	15.40
5	7.20	7.20
6	-51.40	0.00

This is what the numbers in column a look like when displayed with more decimal places:

```
mysql> SELECT i, ROUND(SUM(d1), 2)*1.0000000000000000 AS a,
-> ROUND(SUM(d2), 2) AS b FROM t1 GROUP BY i HAVING a <> b;
```

i	a	b
1	21.3999999999999986	21.40
2	76.7999999999999972	76.80
3	7.4000000000000004	7.40
4	15.4000000000000004	15.40
5	7.2000000000000002	7.20
6	-51.3999999999999986	0.00

Depending on your computer architecture, you may or may not see similar results. For example, on some machines you may get the “correct” results by multiplying both arguments by 1, as the following example shows.

**Warning:** Never use this method in your applications. It is not an example of a trustworthy method!

```
mysql> SELECT i, ROUND(SUM(d1), 2)*1 AS a, ROUND(SUM(d2), 2)*1 AS b
-> FROM t1 GROUP BY i HAVING a <> b;
```

i	a	b
6	-51.40	0.00

The reason that the preceding example seems to work is that on the particular machine where the test was done, CPU floating-point arithmetic happens to round the numbers to the same value. However, there is no rule that any CPU should do so, so this method cannot be trusted.

The correct way to do floating-point number comparison is to first decide on an acceptable tolerance for differences between the numbers and then do the comparison against the tolerance value. For example, if we agree that floating-point numbers should be regarded the same if they are same within a precision of one in ten thousand (0.0001), the comparison should be written to find differences larger than the tolerance value:

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
-> GROUP BY i HAVING ABS(a - b) > 0.0001;
```

i	a	b
6	-51.40	0.00

1 row in set (0.00 sec)

Conversely, to get rows where the numbers are the same, the test should find differences within the

tolerance value:

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
-> GROUP BY i HAVING ABS(a - b) <= 0.0001;
```

i	a	b
1	21.40	21.40
2	76.80	76.80
3	7.40	7.40
4	15.40	15.40
5	7.20	7.20

## A.6. Optimizer-Related Issues

MySQL uses a cost-based optimizer to determine the best way to resolve a query. In many cases, MySQL can calculate the best possible query plan, but sometimes MySQL doesn't have enough information about the data at hand and has to make "educated" guesses about the data.

For the cases when MySQL does not do the "right" thing, tools that you have available to help MySQL are:

- Use the `EXPLAIN` statement to get information about how MySQL processes a query. To use it, just add the keyword `EXPLAIN` to the front of your `SELECT` statement:

```
mysql> EXPLAIN SELECT * FROM t1, t2 WHERE t1.i = t2.i;
```

`EXPLAIN` is discussed in more detail in Section 7.2.1, "Optimizing Queries with `EXPLAIN`".

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See Section 13.5.2.1, "ANALYZE TABLE Syntax".
- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index. See Section 13.2.7, "SELECT Syntax".

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

`USE INDEX` and `IGNORE INDEX` may also be useful.

- Global and table-level `STRAIGHT_JOIN`. See Section 13.2.7, "SELECT Syntax".
- You can tune global or thread-specific system variables. For example, Start `mysqld` with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.2.2, "Server System Variables".

## A.7. Table Definition-Related Issues

### A.7.1. Problems with `ALTER TABLE`

`ALTER TABLE` changes a table to the current character set. If you get a duplicate-key error during `ALTER TABLE`, the cause is either that the new character sets maps two keys to the same value or that the table is corrupted. In the latter case, you should run `REPAIR TABLE` on the table.

If `ALTER TABLE` dies with the following error, the problem may be that MySQL crashed during an

earlier ALTER TABLE operation and there is an old table named A-xxx or B-xxx lying around:

```
Error on rename of './database/name.frm'  
to './database/B-xxx.frm' (Errcode: 17)
```

In this case, go to the MySQL data directory and delete all files that have names starting with A- or B-. (You may want to move them elsewhere instead of deleting them.)

ALTER TABLE works in the following way:

- Create a new table named A-xxx with the requested structural changes.
- Copy all rows from the original table to A-xxx.
- Rename the original table to B-xxx.
- Rename A-xxx to your original table name.
- Delete B-xxx.

If something goes wrong with the renaming operation, MySQL tries to undo the changes. If something goes seriously wrong (although this shouldn't happen), MySQL may leave the old table as B-xxx. A simple rename of the table files at the system level should get your data back.

If you use ALTER TABLE on a transactional table or if you are using Windows or OS/2, ALTER TABLE unlocks the table if you had done a LOCK TABLE on it. This is done because InnoDB and these operating systems cannot drop a table that is in use.

## A.7.2. How to Change the Order of Columns in a Table

First, consider whether you really need to change the column order in a table. The whole point of SQL is to abstract the application from the data storage format. You should always specify the order in which you wish to retrieve your data. The first of the following statements returns columns in the order *col\_name1*, *col\_name2*, *col\_name3*, whereas the second returns them in the order *col\_name1*, *col\_name3*, *col\_name2*:

```
mysql> SELECT col_name1, col_name2, col_name3 FROM tbl_name;  
mysql> SELECT col_name1, col_name3, col_name2 FROM tbl_name;
```

If you decide to change the order of table columns anyway, you can do so as follows:

1. Create a new table with the columns in the new order.
2. Execute this statement:

```
mysql> INSERT INTO new_table  
-> SELECT columns-in-new-order FROM old_table;
```

3. Drop or rename *old\_table*.
4. Rename the new table to the original name:

```
mysql> ALTER TABLE new_table RENAME old_table;
```

SELECT \* is quite suitable for testing queries. However, in an application, you should *never* rely on using SELECT \* and retrieving the columns based on their position. The order and position in which columns are returned does not remain the same if you add, move, or delete columns. A simple

change to your table structure could cause your application to fail.

### A.7.3. TEMPORARY TABLE Problems

The following list indicates limitations on the use of TEMPORARY tables:

- A TEMPORARY table can only be of type HEAP, ISAM, MyISAM, MERGE, or InnoDB.
- You cannot refer to a TEMPORARY table more than once in the same query. For example, the following does not work:

```
mysql> SELECT * FROM temp_table, temp_table AS t2;  
ERROR 1137: Can't reopen table: 'temp_table'
```

- The SHOW TABLES statement does not list TEMPORARY tables.
- You cannot use RENAME to rename a TEMPORARY table. However, you can use ALTER TABLE instead:

```
mysql> ALTER TABLE orig_name RENAME new_name;
```

- There are known issues in using temporary tables with replication. See Section 6.7, “Replication Features and Known Problems”, for more information.

## A.8. Known Issues in MySQL

This section is a list of the known issues in recent versions of MySQL.

For information about platform-specific issues, see the installation and porting instructions in Section 2.13, “Operating System-Specific Notes”, and Appendix E, *Porting to Other Systems*.

### A.8.1. Open Issues in MySQL

The following problems are known and fixing them is a high priority:

- If you compare a NULL value to a subquery using ALL/ANY/SOME and the subquery returns an empty result, the comparison might evaluate to the non-standard result of NULL rather than to TRUE or FALSE. This will be fixed in MySQL 5.1.
- Subquery optimization for IN is not as effective as for =.
- Even if you use lower\_case\_table\_names=2 (which enables MySQL to remember the case used for databases and table names), MySQL does not remember the case used for database names for the function DATABASE() or within the various logs (on case-insensitive systems).
- Dropping a FOREIGN KEY constraint doesn't work in replication because the constraint may have another name on the slave.
- REPLACE (and LOAD DATA with the REPLACE option) does not trigger ON DELETE CASCADE.
- DISTINCT with ORDER BY doesn't work inside GROUP\_CONCAT() if you don't use all and only those columns that are in the DISTINCT list.
- If one user has a long-running transaction and another user drops a table that is updated in the transaction, there is small chance that the binary log may contain the DROP TABLE command before the table is used in the transaction itself. We plan to fix this by having the DROP TABLE command wait until the table is not being used in any transaction.

- When inserting a big integer value (between  $2^{63}$  and  $2^{64}-1$ ) into a decimal or string column, it is inserted as a negative value because the number is evaluated in a signed integer context.
- `FLUSH TABLES WITH READ LOCK` does not block `COMMIT` if the server is running without binary logging, which may cause a problem (of consistency between tables) when doing a full backup.
- `ANALYZE TABLE` on a BDB table may in some cases make the table unusable until you restart `mysqld`. If this happens, look for errors of the following form in the MySQL error file:  

```
001207 22:07:56 bdb: log_flush: LSN past current end-of-log
```
- Don't execute `ALTER TABLE` on a BDB table on which you are running multiple-statement transactions until all those transactions complete. (The transaction might be ignored.)
- `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` may cause problems on tables for which you are using `INSERT DELAYED`.
- Performing `LOCK TABLE ...` and `FLUSH TABLES ...` doesn't guarantee that there isn't a half-finished transaction in progress on the table.
- BDB tables are relatively slow to open. If you have many BDB tables in a database, it takes a long time to use the `mysql` client on the database if you are not using the `-A` option or if you are using `rehash`. This is especially noticeable when you have a large table cache.
- Replication uses query-level logging: The master writes the executed queries to the binary log. This is a very fast, compact, and efficient logging method that works perfectly in most cases.

It is possible for the data on the master and slave to become different if a query is designed in such a way that the data modification is non-deterministic (generally not a recommended practice, even outside of replication).

For example:

- `CREATE ... SELECT` or `INSERT ... SELECT` statements that insert zero or `NULL` values into an `AUTO_INCREMENT` column.
- `DELETE` if you are deleting rows from a table that has foreign keys with `ON DELETE CASCADE` properties.
- `REPLACE ... SELECT`, `INSERT IGNORE ... SELECT` if you have duplicate key values in the inserted data.

**If and only if the preceding queries have no `ORDER BY` clause guaranteeing a deterministic order.**

For example, for `INSERT ... SELECT` with no `ORDER BY`, the `SELECT` may return rows in a different order (which results in a row having different ranks, hence getting a different number in the `AUTO_INCREMENT` column), depending on the choices made by the optimizers on the master and slave.

A query is optimized differently on the master and slave only if:

- The table is stored using a different storage engine on the master than on the slave. (It is possible to use different storage engines on the master and slave. For example, you can use `InnoDB` on the master, but `MyISAM` on the slave if the slave has less available disk space.)
- MySQL buffer sizes (`key_buffer_size`, and so on) are different on the master and slave.
- The master and slave run different MySQL versions, and the optimizer code differs between these versions.

This problem may also affect database restoration using `mysqlbinlog|mysql`.

The easiest way to avoid this problem is to add an `ORDER BY` clause to the aforementioned non-deterministic queries to ensure that the rows are always stored or modified in the same order.

In future MySQL versions, we will automatically add an `ORDER BY` clause when needed.

The following issues are known and will be fixed in due time:

- Log filenames are based on the server hostname (if you don't specify a filename with the startup option). You have to use options such as `--log-bin=old_host_name-bin` if you change your hostname to something else. Another option is to rename the old files to reflect your hostname change (if these are binary logs, you need to edit the binary log index file and fix the bin-log names there as well). See Section 5.2.1, “`mysqld` Command Options”.
- `mysqlbinlog` does not delete temporary files left after a `LOAD DATA INFILE` command. See Section 8.9, “`mysqlbinlog` — Utility for Processing Binary Log Files”.
- `RENAME` doesn't work with `TEMPORARY` tables or tables used in a `MERGE` table.
- Due to the way table format (`.frm`) files are stored, you cannot use character 255 (`CHAR(255)`) in table names, column names, or enumerations. This is scheduled to be fixed in version 5.1 when we implement new table definition format files.
- When using `SET CHARACTER SET`, you can't use translated characters in database, table, and column names.
- You can't use `'_'` or `'%'` with `ESCAPE` in `LIKE ... ESCAPE`.
- If you have a `DECIMAL` column in which the same number is stored in different formats (for example, `+01.00`, `1.00`, `01.00`), `GROUP BY` may regard each value as a different value.
- You cannot build the server in another directory when using `MIT-pthreads`. Because this requires changes to `MIT-pthreads`, we are not likely to fix this. See Section 2.9.5, “`MIT-pthreads` Notes”.
- `BLOB` and `TEXT` values can't reliably be used in `GROUP BY`, `ORDER BY` or `DISTINCT`. Only the first `max_sort_length` bytes are used when comparing `BLOB` values in these cases. The default value of `max_sort_length` is 1024 and can be changed at server startup time or at runtime.
- Numeric calculations are done with `BIGINT` or `DOUBLE` (both are normally 64 bits long). Which precision you get depends on the function. The general rule is that bit functions are performed with `BIGINT` precision, `IF` and `ELT()` with `BIGINT` or `DOUBLE` precision, and the rest with `DOUBLE` precision. You should try to avoid using unsigned long long values if they resolve to be larger than 63 bits (9223372036854775807) for anything other than bit fields.
- You can have up to 255 `ENUM` and `SET` columns in one table.
- In `MIN()`, `MAX()`, and other aggregate functions, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set.
- `mysqld_safe` redirects all messages from `mysqld` to the `mysqld` log. One problem with this is that if you execute `mysqladmin refresh` to close and reopen the log, `stdout` and `stderr` are still redirected to the old log. If you use `--log` extensively, you should edit `mysqld_safe` to log to `host_name.err` instead of `host_name.log` so that you can easily reclaim the space for the old log by deleting it and executing `mysqladmin refresh`.
- In an `UPDATE` statement, columns are updated from left to right. If you refer to an updated column, you get the updated value instead of the original value. For example, the following

statement increments `KEY` by 2, not 1:

```
mysql> UPDATE tbl_name SET KEY=KEY+1,KEY=KEY+1;
```

- You can refer to multiple temporary tables in the same query, but you cannot refer to any given temporary table more than once. For example, the following doesn't work:

```
mysql> SELECT * FROM temp_table, temp_table AS t2;
ERROR 1137: Can't reopen table: 'temp_table'
```

- The optimizer may handle `DISTINCT` differently when you are using “hidden” columns in a join than when you are not. In a join, hidden columns are counted as part of the result (even if they are not shown), whereas in normal queries, hidden columns don't participate in the `DISTINCT` comparison. We will probably change this in the future to never compare the hidden columns when executing `DISTINCT`.

An example of this is:

```
SELECT DISTINCT mp3id FROM band_downloads
      WHERE userid = 9 ORDER BY id DESC;
```

and

```
SELECT DISTINCT band_downloads.mp3id
      FROM band_downloads,band_mp3
      WHERE band_downloads.userid = 9
      AND band_mp3.id = band_downloads.mp3id
      ORDER BY band_downloads.id DESC;
```

In the second case, using MySQL Server 3.23.x, you may get two identical rows in the result set (because the values in the hidden `id` column may differ).

Note that this happens only for queries where that do not have the `ORDER BY` columns in the result.

- If you execute a `PROCEDURE` on a query that returns an empty set, in some cases the `PROCEDURE` does not transform the columns.
- Creation of a table of type `MERGE` doesn't check whether the underlying tables are compatible types.
- If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table and then add a normal index on the `MERGE` table, the key order is different for the tables if there was an old, non-`UNIQUE` key in the table. This is because `ALTER TABLE` puts `UNIQUE` indexes before normal indexes to be able to detect duplicate keys as early as possible.

---

# Appendix B. Error Codes and Messages

This appendix lists the errors that may appear when you call MySQL from any host language. The first list displays server error messages. The second list displays client program messages.

## B.1. Server Error Codes and Messages

Server error information comes from the following source files. For details about the way that error information is defined, see the MySQL Internals manual, available at <http://dev.mysql.com/doc/>.

- Error message information is listed in the `share/errmsg.txt` file. `%d` and `%s` represent numbers and strings, respectively, that are substituted into the Message values when they are displayed.
- The Error values listed in `share/errmsg.txt` are used to generate the definitions in the `include/mysqld_error.h` and `include/mysqld_ename.h` MySQL source files.
- The SQLSTATE values listed in `share/errmsg.txt` are used to generate the definitions in the `include/sql_state.h` MySQL source file.

Because updates are frequent, it is possible that those files will contain additional error information not listed here.

- Error: 1000 SQLSTATE: HY000 (ER\_HASHCHK)  
Message: hashchk
- Error: 1001 SQLSTATE: HY000 (ER\_NISAMCHK)  
Message: isamchk
- Error: 1002 SQLSTATE: HY000 (ER\_NO)  
Message: NO
- Error: 1003 SQLSTATE: HY000 (ER\_YES)  
Message: YES
- Error: 1004 SQLSTATE: HY000 (ER\_CANT\_CREATE\_FILE)  
Message: Can't create file '%s' (errno: %d)
- Error: 1005 SQLSTATE: HY000 (ER\_CANT\_CREATE\_TABLE)  
Message: Can't create table '%s' (errno: %d)
- Error: 1006 SQLSTATE: HY000 (ER\_CANT\_CREATE\_DB)  
Message: Can't create database '%s' (errno: %d)
- Error: 1007 SQLSTATE: HY000 (ER\_DB\_CREATE\_EXISTS)  
Message: Can't create database '%s'; database exists
- Error: 1008 SQLSTATE: HY000 (ER\_DB\_DROP\_EXISTS)

- Message: Can't drop database '%s'; database doesn't exist
- Error: 1009 SQLSTATE: HY000 (ER\_DB\_DROP\_DELETE)  
Message: Error dropping database (can't delete '%s', errno: %d)
- Error: 1010 SQLSTATE: HY000 (ER\_DB\_DROP\_RMDIR)  
Message: Error dropping database (can't rmdir '%s', errno: %d)
- Error: 1011 SQLSTATE: HY000 (ER\_CANT\_DELETE\_FILE)  
Message: Error on delete of '%s' (errno: %d)
- Error: 1012 SQLSTATE: HY000 (ER\_CANT\_FIND\_SYSTEM\_REC)  
Message: Can't read record in system table
- Error: 1013 SQLSTATE: HY000 (ER\_CANT\_GET\_STAT)  
Message: Can't get status of '%s' (errno: %d)
- Error: 1014 SQLSTATE: HY000 (ER\_CANT\_GET\_WD)  
Message: Can't get working directory (errno: %d)
- Error: 1015 SQLSTATE: HY000 (ER\_CANT\_LOCK)  
Message: Can't lock file (errno: %d)
- Error: 1016 SQLSTATE: HY000 (ER\_CANT\_OPEN\_FILE)  
Message: Can't open file: '%s' (errno: %d)
- Error: 1017 SQLSTATE: HY000 (ER\_FILE\_NOT\_FOUND)  
Message: Can't find file: '%s' (errno: %d)
- Error: 1018 SQLSTATE: HY000 (ER\_CANT\_READ\_DIR)  
Message: Can't read dir of '%s' (errno: %d)
- Error: 1019 SQLSTATE: HY000 (ER\_CANT\_SET\_WD)  
Message: Can't change dir to '%s' (errno: %d)
- Error: 1020 SQLSTATE: HY000 (ER\_CHECKREAD)  
Message: Record has changed since last read in table '%s'
- Error: 1021 SQLSTATE: HY000 (ER\_DISK\_FULL)  
Message: Disk full (%s); waiting for someone to free some space...
- Error: 1022 SQLSTATE: 23000 (ER\_DUP\_KEY)  
Message: Can't write; duplicate key in table '%s'
- Error: 1023 SQLSTATE: HY000 (ER\_ERROR\_ON\_CLOSE)  
Message: Error on close of '%s' (errno: %d)
- Error: 1024 SQLSTATE: HY000 (ER\_ERROR\_ON\_READ)

- Message: Error reading file '%s' (errno: %d)
- Error: 1025 SQLSTATE: HY000 (ER\_ERROR\_ON\_RENAME)  
Message: Error on rename of '%s' to '%s' (errno: %d)
- Error: 1026 SQLSTATE: HY000 (ER\_ERROR\_ON\_WRITE)  
Message: Error writing file '%s' (errno: %d)
- Error: 1027 SQLSTATE: HY000 (ER\_FILE\_USED)  
Message: '%s' is locked against change
- Error: 1028 SQLSTATE: HY000 (ER\_FILSORT\_ABORT)  
Message: Sort aborted
- Error: 1029 SQLSTATE: HY000 (ER\_FORM\_NOT\_FOUND)  
Message: View '%s' doesn't exist for '%s'
- Error: 1030 SQLSTATE: HY000 (ER\_GET\_ERRNO)  
Message: Got error %d from storage engine
- Error: 1031 SQLSTATE: HY000 (ER\_ILLEGAL\_HA)  
Message: Table storage engine for '%s' doesn't have this option
- Error: 1032 SQLSTATE: HY000 (ER\_KEY\_NOT\_FOUND)  
Message: Can't find record in '%s'
- Error: 1033 SQLSTATE: HY000 (ER\_NOT\_FORM\_FILE)  
Message: Incorrect information in file: '%s'
- Error: 1034 SQLSTATE: HY000 (ER\_NOT\_KEYFILE)  
Message: Incorrect key file for table '%s'; try to repair it
- Error: 1035 SQLSTATE: HY000 (ER\_OLD\_KEYFILE)  
Message: Old key file for table '%s'; repair it!
- Error: 1036 SQLSTATE: HY000 (ER\_OPEN\_AS\_READONLY)  
Message: Table '%s' is read only
- Error: 1037 SQLSTATE: HY001 (ER\_OUTOFMEMORY)  
Message: Out of memory; restart server and try again (needed %d bytes)
- Error: 1038 SQLSTATE: HY001 (ER\_OUT\_OF\_SORTMEMORY)  
Message: Out of sort memory; increase server sort buffer size
- Error: 1039 SQLSTATE: HY000 (ER\_UNEXPECTED\_EOF)  
Message: Unexpected EOF found when reading file '%s' (errno: %d)
- Error: 1040 SQLSTATE: 08004 (ER\_CON\_COUNT\_ERROR)

Message: Too many connections

- Error: 1041 SQLSTATE: HY000 (ER\_OUT\_OF\_RESOURCES)

Message: Out of memory; check if mysqld or some other process uses all available memory; if not, you may have to use 'ulimit' to allow mysqld to use more memory or you can add more swap space

- Error: 1042 SQLSTATE: 08S01 (ER\_BAD\_HOST\_ERROR)

Message: Can't get hostname for your address

- Error: 1061 SQLSTATE: 42000 (ER\_DUP\_KEYNAME)  
Message: Duplicate key name '%s'
- Error: 1062 SQLSTATE: 23000 (ER\_DUP\_ENTRY)  
Message: Duplicate entry '%s' for key %d
- Error: 1063 SQLSTATE: 42000 (ER\_WRONG\_FIELD\_SPEC)  
Message: Incorrect column specifier for column '%s'
- Error: 1064 SQLSTATE: 42000 (ER\_PARSE\_ERROR)  
Message: %s near '%s' at line %d
- Error: 1065 SQLSTATE: 42000 (ER\_EMPTY\_QUERY)  
Message: Query was empty
- Error: 1066 SQLSTATE: 42000 (ER\_NONUNIQ\_TABLE)  
Message: Not unique table/alias: '%s'
- Error: 1067 SQLSTATE: 42000 (ER\_INVALID\_DEFAULT)  
Message: Invalid default value for '%s'
- Error: 1068 SQLSTATE: 42000 (ER\_MULTIPLE\_PRI\_KEY)  
Message: Multiple primary key defined
- Error: 1069 SQLSTATE: 42000 (ER\_TOO\_MANY\_KEYS)  
Message: Too many keys specified; max %d keys allowed
- Error: 1070 SQLSTATE: 42000 (ER\_TOO\_MANY\_KEY\_PARTS)  
Message: Too many key parts specified; max %d parts allowed
- Error: 1071 SQLSTATE: 42000 (ER\_TOO\_LONG\_KEY)  
Message: Specified key was too long; max key length is %d bytes
- Error: 1072 SQLSTATE: 42000 (ER\_KEY\_COLUMN\_DOES\_NOT\_EXISTS)

Message: Key column '%s' doesn't exist in table

- Error: 1073 SQLSTATE: 42000 (ER\_BLOB\_USED\_AS\_KEY)

Message: BLOB column '%s' can't be used in key specification with the used table type

- Error: 1074 SQLSTATE: 42000 (ER\_TOO\_BIG\_FIELDLENGTH)

Message: Column length too big for column '%s' (max = %d); use BLOB or TEXT instead

- Error: 1075 SQLSTATE: 42000 (ER\_WRONG\_AUTO\_KEY)

Message: Incorrect table definition; there can be only one auto column and it must be defined as a key

- Error: 1076 SQLSTATE: HY000 (ER\_READY)

Message: %s: ready for connections. Version: '%s' socket: '%s' port: %d

- Error: 1077 SQLSTATE: HY000 (ER\_NORMAL\_SHUTDOWN)

Message: %s: Normal shutdown

- Error: 1078 SQLSTATE: HY000 (ER\_GOT\_SIGNAL)

Message: %s: Got signal %d. Aborting!

- Error: 1079 SQLSTATE: HY000 (ER\_SHUTDOWN\_COMPLETE)

Message: %s: Shutdown complete

- Error: 1080 SQLSTATE: 08S01 (ER\_FORCING\_CLOSE)

Message: %s: Forcing close of thread %ld user: '%s'

- Error: 1081 SQLSTATE: 08S01 (ER\_IPSOCK\_ERROR)

Message: Can't create IP socket

- Error: 1082 SQLSTATE: 42S12 (ER\_NO\_SUCH\_INDEX)

Message: Table '%s' has no index like the one used in CREATE INDEX; recreate the table

- Error: 1083 SQLSTATE: 42000 (ER\_WRONG\_FIELD\_TERMINATORS)

Message: Field separator argument is not what is expected; check the manual

- Error: 1084 SQLSTATE: 42000 (ER\_BLOBS\_AND\_NO\_TERMINATED)

Message: You can't use fixed rowlength with BLOBs; please use 'fields terminated by'

- Error: 1085 SQLSTATE: HY000 (ER\_TEXTFILE\_NOT\_READABLE)

Message: The file '%s' must be in the database directory or be readable by all

- Error: 1086 SQLSTATE: HY000 (ER\_FILE\_EXISTS\_ERROR)

Message: File '%s' already exists

- Error: 1087 SQLSTATE: HY000 (ER\_LOAD\_INFO)

Message: Records: %ld Deleted: %ld Skipped: %ld Warnings: %ld

- Error: 1088 SQLSTATE: HY000 (ER\_ALTER\_INFO)

Message: Records: %ld Duplicates: %ld

- Error: 1089 SQLSTATE: HY000 (ER\_WRONG\_SUB\_KEY)

Message: Incorrect sub part key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique sub keys

- Error: 1090 SQLSTATE: 42000 (ER\_CANT\_REMOVE\_ALL\_FIELDS)

Message: You can't delete all columns with ALTER TABLE; use DROP TABLE instead

- Error: 1091 SQLSTATE: 42000 (ER\_CANT\_DROP\_FIELD\_OR\_KEY)

Message: Can't DROP '%s'; check that column/key exists

- Error: 1092 SQLSTATE: HY000 (ER\_INSERT\_INFO)

Message: Records: %ld Duplicates: %ld Warnings: %ld

- Error: 1093 SQLSTATE: HY000 (ER\_UPDATE\_TABLE\_USED)

Message: You can't specify target table '%s' for update in FROM clause

- Error: 1094 SQLSTATE: HY000 (ER\_NO\_SUCH\_THREAD)

Message: Unknown thread id: %lu

- Error: 1095 SQLSTATE: HY000 (ER\_KILL\_DENIED\_ERROR)

Message: You are not owner of thread %lu

- Error: 1096 SQLSTATE: HY000 (ER\_NO\_TABLES\_USED)

Message: No tables used

- Error: 1097 SQLSTATE: HY000 (ER\_TOO\_BIG\_SET)

Message: Too many strings for column %s and SET

- Error: 1098 SQLSTATE: HY000 (ER\_NO\_UNIQUE\_LOGFILE)

Message: Can't generate a unique log-filename %s.(1-999)

- Error: 1099 SQLSTATE: HY000 (ER\_TABLE\_NOT\_LOCKED\_FOR\_WRITE)

Message: Table '%s' was locked with a READ lock and can't be updated

- Error: 1100 SQLSTATE: HY000 (ER\_TABLE\_NOT\_LOCKED)

Message: Table '%s' was not locked with LOCK TABLES

- Error: 1101 SQLSTATE: 42000 (ER\_BLOB\_CANT\_HAVE\_DEFAULT)

Message: BLOB/TEXT column '%s' can't have a default value

- Error: 1102 SQLSTATE: 42000 (ER\_WRONG\_DB\_NAME)

Message: Incorrect database name '%s'

- Error: 1103 SQLSTATE: 42000 (ER\_WRONG\_TABLE\_NAME)

Message: Incorrect table name '%s'

- Error: 1104 SQLSTATE: 42000 (ER\_TOO\_BIG\_SELECT)

Message: The SELECT would examine more than MAX\_JOIN\_SIZE rows; check your WHERE and use SET SQL\_BIG\_SELECTS=1 or SET SQL\_MAX\_JOIN\_SIZE=# if the SELECT is okay

- Error: 1105 SQLSTATE: HY000 (ER\_UNKNOWN\_ERROR)

Message: Unknown error

- Error: 1106 SQLSTATE: 42000 (ER\_UNKNOWN\_PROCEDURE)

Message: Unknown procedure '%s'

- Error: 1107 SQLSTATE: 42000 (ER\_WRONG\_PARAMCOUNT\_TO\_PROCEDURE)

Message: Incorrect parameter count to procedure '%s'

- Error: 1108 SQLSTATE: HY000 (ER\_WRONG\_PARAMETERS\_TO\_PROCEDURE)

Message: Incorrect parameters to procedure '%s'

- Error: 1109 SQLSTATE: 42S02 (ER\_UNKNOWN\_TABLE)

Message: Unknown table '%s' in %s

- Error: 1110 SQLSTATE: 42000 (ER\_FIELD\_SPECIFIED\_TWICE)

Message: Column '%s' specified twice

- Error: 1111 SQLSTATE: HY000 (ER\_INVALID\_GROUP\_FUNC\_USE)

Message: Invalid use of group function

- Error: 1112 SQLSTATE: 42000 (ER\_UNSUPPORTED\_EXTENSION)

Message: Table '%s' uses an extension that doesn't exist in this MySQL version

- Error: 1113 SQLSTATE: 42000 (ER\_TABLE\_MUST\_HAVE\_COLUMNS)

Message: A table must have at least 1 column

- Error: 1114 SQLSTATE: HY000 (ER\_RECORD\_FILE\_FULL)

Message: The table '%s' is full

- Error: 1115 SQLSTATE: 42000 (ER\_UNKNOWN\_CHARACTER\_SET)

Message: Unknown character set: '%s'

- Error: 1116 SQLSTATE: HY000 (ER\_TOO\_MANY\_TABLES)

Message: Too many tables; MySQL can only use %d tables in a join

- Error: 1117 SQLSTATE: HY000 (ER\_TOO\_MANY\_FIELDS)

Message: Too many columns

- Error: 1118 SQLSTATE: 42000 (ER\_TOO\_BIG\_ROWSIZE)

Message: Row size too large. The maximum row size for the used table type, not counting BLOBs, is %ld. You have to change some columns to TEXT or BLOBs

- Error: 1119 SQLSTATE: HY000 (ER\_STACK\_OVERRUN)

Message: Thread stack overrun: Used: %ld of a %ld stack. Use 'mysqld -O thread\_stack=#' to

specify a bigger stack if needed

- Error: 1120 SQLSTATE: 42000 (ER\_WRONG\_OUTER\_JOIN)  
Message: Cross dependency found in OUTER JOIN; examine your ON conditions
- Error: 1121 SQLSTATE: 42000 (ER\_NULL\_COLUMN\_IN\_INDEX)  
Message: Column '%s' is used with UNIQUE or INDEX but is not defined as NOT NULL
- Error: 1122 SQLSTATE: HY000 (ER\_CANT\_FIND\_UDF)  
Message: Can't load function '%s'
- Error: 1123 SQLSTATE: HY000 (ER\_CANT\_INITIALIZE\_UDF)  
Message: Can't initialize function '%s'; %s
- Error: 1124 SQLSTATE: HY000 (ER\_UDF\_NO\_PATHS)  
Message: No paths allowed for shared library
- Error: 1125 SQLSTATE: HY000 (ER\_UDF\_EXISTS)  
Message: Function '%s' already exists
- Error: 1126 SQLSTATE: HY000 (ER\_CANT\_OPEN\_LIBRARY)  
Message: Can't open shared library '%s' (errno: %d %s)
- Error: 1127 SQLSTATE: HY000 (ER\_CANT\_FIND\_DL\_ENTRY)  
Message: Can't find function '%s' in library
- Error: 1128 SQLSTATE: HY000 (ER\_FUNCTION\_NOT\_DEFINED)  
Message: Function '%s' is not defined
- Error: 1129 SQLSTATE: HY000 (ER\_HOST\_IS\_BLOCKED)  
Message: Host '%s' is blocked because of many connection errors; unblock with 'mysqladmin flush-hosts'
- Error: 1130 SQLSTATE: HY000 (ER\_HOST\_NOT\_PRIVILEGED)  
Message: Host '%s' is not allowed to connect to this MySQL server
- Error: 1131 SQLSTATE: 42000 (ER\_PASSWORD\_ANONYMOUS\_USER)  
Message: You are using MySQL as an anonymous user and anonymous users are not allowed to change passwords
- Error: 1132 SQLSTATE: 42000 (ER\_PASSWORD\_NOT\_ALLOWED)  
Message: You must have privileges to update tables in the mysql database to be able to change passwords for others
- Error: 1133 SQLSTATE: 42000 (ER\_PASSWORD\_NO\_MATCH)  
Message: Can't find any matching row in the user table
- Error: 1134 SQLSTATE: HY000 (ER\_UPDATE\_INFO)  
Message: Rows matched: %ld Changed: %ld Warnings: %ld

- Error: 1135 SQLSTATE: HY000 (ER\_CANT\_CREATE\_THREAD)  
Message: Can't create a new thread (errno %d); if you are not out of available memory, you can consult the manual for a possible OS-dependent bug
- Error: 1136 SQLSTATE: 21S01 (ER\_WRONG\_VALUE\_COUNT\_ON\_ROW)  
Message: Column count doesn't match value count at row %ld
- Error: 1137 SQLSTATE: HY000 (ER\_CANT\_REOPEN\_TABLE)  
Message: Can't reopen table: '%s'
- Error: 1138 SQLSTATE: 22004 (ER\_INVALID\_USE\_OF\_NULL)  
Message: Invalid use of NULL value
- Error: 1139 SQLSTATE: 42000 (ER\_REGEXP\_ERROR)  
Message: Got error '%s' from regexp
- Error: 1140 SQLSTATE: 42000 (ER\_MIX\_OF\_GROUP\_FUNC\_AND\_FIELDS)  
Message: Mixing of GROUP columns (MIN(),MAX(),COUNT(),...) with no GROUP columns is illegal if there is no GROUP BY clause
- Error: 1141 SQLSTATE: 42000 (ER\_NONEXISTING\_GRANT)  
Message: There is no such grant defined for user '%s' on host '%s'
- Error: 1142 SQLSTATE: 42000 (ER\_TABLEACCESS\_DENIED\_ERROR)  
Message: %s command denied to user '%s'@'%s' for table '%s'
- Error: 1143 SQLSTATE: 42000 (ER\_COLUMNACCESS\_DENIED\_ERROR)  
Message: %s command denied to user '%s'@'%s' for column '%s' in table '%s'
- Error: 1144 SQLSTATE: 42000 (ER\_ILLEGAL\_GRANT\_FOR\_TABLE)  
Message: Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used
- Error: 1145 SQLSTATE: 42000 (ER\_GRANT\_WRONG\_HOST\_OR\_USER)  
Message: The host or user argument to GRANT is too long
- Error: 1146 SQLSTATE: 42S02 (ER\_NO\_SUCH\_TABLE)  
Message: Table '%s.%s' doesn't exist
- Error: 1147 SQLSTATE: 42000 (ER\_NONEXISTING\_TABLE\_GRANT)  
Message: There is no such grant defined for user '%s' on host '%s' on table '%s'
- Error: 1148 SQLSTATE: 42000 (ER\_NOT\_ALLOWED\_COMMAND)  
Message: The used command is not allowed with this MySQL version
- Error: 1149 SQLSTATE: 42000 (ER\_SYNTAX\_ERROR)  
Message: You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use
- Error: 1150 SQLSTATE: HY000 (ER\_DELAYED\_CANT\_CHANGE\_LOCK)

- Message: Delayed insert thread couldn't get requested lock for table %s

  - Error: 1151 SQLSTATE: HY000 (ER\_TOO\_MANY\_DELAYED\_THREADS)  
Message: Too many delayed threads in use
  - Error: 1152 SQLSTATE: 08S01 (ER\_ABORTING\_CONNECTION)  
Message: Aborted connection %ld to db: '%s' user: '%s' (%s)
  - Error: 1153 SQLSTATE: 08S01 (ER\_NET\_PACKET\_TOO\_LARGE)  
Message: Got a packet bigger than 'max\_allowed\_packet' bytes
  - Error: 1154 SQLSTATE: 08S01 (ER\_NET\_READ\_ERROR\_FROM\_PIPE)  
Message: Got a read error from the connection pipe
  - Error: 1155 SQLSTATE: 08S01 (ER\_NET\_FCNTL\_ERROR)  
Message: Got an error from fcntl()
  - Error: 1156 SQLSTATE: 08S01 (ER\_NET\_PACKETS\_OUT\_OF\_ORDER)  
Message: Got packets out of order
  - Error: 1157 SQLSTATE: 08S01 (ER\_NET\_UNCOMPRESS\_ERROR)  
Message: Couldn't uncompress communication packet
  - Error: 1158 SQLSTATE: 08S01 (ER\_NET\_READ\_ERROR)  
Message: Got an error reading communication packets
  - Error: 1159 SQLSTATE: 08S01 (ER\_NET\_READ\_INTERRUPTED)  
Message: Got timeout reading communication packets
  - Error: 1160 SQLSTATE: 08S01 (ER\_NET\_ERROR\_ON\_WRITE)  
Message: Got an error writing communication packets
  - Error: 1161 SQLSTATE: 08S01 (ER\_NET\_WRITE\_INTERRUPTED)  
Message: Got timeout writing communication packets
  - Error: 1162 SQLSTATE: 42000 (ER\_TOO\_LONG\_STRING)  
Message: Result string is longer than 'max\_allowed\_packet' bytes
  - Error: 1163 SQLSTATE: 42000 (ER\_TABLE\_CANT\_HANDLE\_BLOB)  
Message: The used table type doesn't support BLOB/TEXT columns
  - Error: 1164 SQLSTATE: 42000 (ER\_TABLE\_CANT\_HANDLE\_AUTO\_INCREMENT)  
Message: The used table type doesn't support AUTO\_INCREMENT columns
  - Error: 1165 SQLSTATE: HY000 (ER\_DELAYED\_INSERT\_TABLE\_LOCKED)  
Message: INSERT DELAYED can't be used with table '%s' because it is locked with LOCK TABLES
  - Error: 1166 SQLSTATE: 42000 (ER\_WRONG\_COLUMN\_NAME)

Message: Incorrect column name '%s'

- Error: 1167 SQLSTATE: 42000 (ER\_WRONG\_KEY\_COLUMN)

Message: The used storage engine can't index column '%s'

- Error: 1168 SQLSTATE: HY000 (ER\_WRONG\_MRG\_TABLE)

Message: All tables in the MERGE table are not identically defined

- Error: 1169 SQLSTATE: 23000 (ER\_DUP\_UNIQUE)

Message: Can't write, because of unique constraint, to table '%s'

- Error: 1170 SQLSTATE: 42000 (ER\_BLOB\_KEY\_WITHOUT\_LENGTH)

Message: BLOB/TEXT column '%s' used in key specification without a key length

- Error: 1171 SQLSTATE: 42000 (ER\_PRIMARY\_CANT\_HAVE\_NULL)

Message: All parts of a PRIMARY KEY must be NOT NULL; if you need NULL in a key, use UNIQUE instead

- Error: 1172 SQLSTATE: 42000 (ER\_TOO\_MANY\_ROWS)

Message: Result consisted of more than one row

- Error: 1173 SQLSTATE: 42000 (ER\_REQUIRES\_PRIMARY\_KEY)

Message: This table type requires a primary key

- Error: 1174 SQLSTATE: HY000 (ER\_NO\_RAID\_COMPILED)

Message: This version of MySQL is not compiled with RAID support

- Error: 1175 SQLSTATE: HY000 (ER\_UPDATE\_WITHOUT\_KEY\_IN\_SAFE\_MODE)

Message: You are using safe update mode and you tried to update a table without a WHERE that uses a KEY column

- Error: 1176 SQLSTATE: HY000 (ER\_KEY\_DOES\_NOT\_EXISTS)

Message: Key '%s' doesn't exist in table '%s'

- Error: 1177 SQLSTATE: 42000 (ER\_CHECK\_NO\_SUCH\_TABLE)

Message: Can't open table

- Error: 1178 SQLSTATE: 42000 (ER\_CHECK\_NOT\_IMPLEMENTED)

Message: The storage engine for the table doesn't support %s

- Error: 1179 SQLSTATE: 25000 (ER\_CANT\_DO\_THIS\_DURING\_AN\_TRANSACTION)

Message: You are not allowed to execute this command in a transaction

- Error: 1180 SQLSTATE: HY000 (ER\_ERROR\_DURING\_COMMIT)

Message: Got error %d during COMMIT

- Error: 1181 SQLSTATE: HY000 (ER\_ERROR\_DURING\_ROLLBACK)

Message: Got error %d during ROLLBACK

- Error: 1182 SQLSTATE: HY000 (ER\_ERROR\_DURING\_FLUSH\_LOGS)  
Message: Got error %d during FLUSH\_LOGS
- Error: 1183 SQLSTATE: HY000 (ER\_ERROR\_DURING\_CHECKPOINT)  
Message: Got error %d during CHECKPOINT
- Error: 1184 SQLSTATE: 08S01 (ER\_NEW\_ABORTING\_CONNECTION)  
Message: Aborted connection %ld to db: '%s' user: '%s' host: '%s' (%s)
- Error: 1185 SQLSTATE: HY000 (ER\_DUMP\_NOT\_IMPLEMENTED)  
Message: The storage engine for the table does not support binary table dump
- Error: 1186 SQLSTATE: HY000 (ER\_FLUSH\_MASTER\_BINLOG\_CLOSED)  
Message: Binlog closed, cannot RESET MASTER
- Error: 1187 SQLSTATE: HY000 (ER\_INDEX\_REBUILD)  
Message: Failed rebuilding the index of dumped table '%s'
- Error: 1188 SQLSTATE: HY000 (ER\_MASTER)  
Message: Error from master: '%s'
- Error: 1189 SQLSTATE: 08S01 (ER\_MASTER\_NET\_READ)  
Message: Net error reading from master
- Error: 1190 SQLSTATE: 08S01 (ER\_MASTER\_NET\_WRITE)  
Message: Net error writing to master
- Error: 1191 SQLSTATE: HY000 (ER\_FT\_MATCHING\_KEY\_NOT\_FOUND)  
Message: Can't find FULLTEXT index matching the column list
- Error: 1192 SQLSTATE: HY000 (ER\_LOCK\_OR\_ACTIVE\_TRANSACTION)  
Message: Can't execute the given command because you have active locked tables or an active transaction
- Error: 1193 SQLSTATE: HY000 (ER\_UNKNOWN\_SYSTEM\_VARIABLE)  
Message: Unknown system variable '%s'
- Error: 1194 SQLSTATE: HY000 (ER\_CRASHED\_ON\_USAGE)  
Message: Table '%s' is marked as crashed and should be repaired
- Error: 1195 SQLSTATE: HY000 (ER\_CRASHED\_ON\_REPAIR)  
Message: Table '%s' is marked as crashed and last (automatic?) repair failed
- Error: 1196 SQLSTATE: HY000 (ER\_WARNING\_NOT\_COMPLETE\_ROLLBACK)  
Message: Some non-transactional changed tables couldn't be rolled back
- Error: 1197 SQLSTATE: HY000 (ER\_TRANS\_CACHE\_FULL)  
Message: Multi-statement transaction required more than 'max\_binlog\_cache\_size' bytes of storage; increase this mysqld variable and try again

- Error: 1198 SQLSTATE: HY000 (ER\_SLAVE\_MUST\_STOP)  
Message: This operation cannot be performed with a running slave; run STOP SLAVE first
- Error: 1199 SQLSTATE: HY000 (ER\_SLAVE\_NOT\_RUNNING)  
Message: This operation requires a running slave; configure slave and do START SLAVE
- Error: 1200 SQLSTATE: HY000 (ER\_BAD\_SLAVE)  
Message: The server is not configured as slave; fix in config file or with CHANGE MASTER TO
- Error: 1201 SQLSTATE: HY000 (ER\_MASTER\_INFO)  
Message: Could not initialize master info structure; more error messages can be found in the MySQL error log
- Error: 1202 SQLSTATE: HY000 (ER\_SLAVE\_THREAD)  
Message: Could not create slave thread; check system resources
- Error: 1203 SQLSTATE: 42000 (ER\_TOO\_MANY\_USER\_CONNECTIONS)  
Message: User %s already has more than 'max\_user\_connections' active connections
- Error: 1204 SQLSTATE: HY000 (ER\_SET\_CONSTANTS\_ONLY)  
Message: You may only use constant expressions with SET
- Error: 1205 SQLSTATE: HY000 (ER\_LOCK\_WAIT\_TIMEOUT)  
Message: Lock wait timeout exceeded; try restarting transaction
- Error: 1206 SQLSTATE: HY000 (ER\_LOCK\_TABLE\_FULL)  
Message: The total number of locks exceeds the lock table size
- Error: 1207 SQLSTATE: 25000 (ER\_READ\_ONLY\_TRANSACTION)  
Message: Update locks cannot be acquired during a READ UNCOMMITTED transaction
- Error: 1208 SQLSTATE: HY000 (ER\_DROP\_DB\_WITH\_READ\_LOCK)

- Error: 1251 SQLSTATE: 08004 (ER\_NOT\_SUPPORTED\_AUTH\_MODE)

Message: Client does not support authentication protocol requested by server; consider upgrading MySQL client

- Error: 1252 SQLSTATE: 42000 (ER\_SPATIAL\_CANT\_HAVE\_NULL)

Message: All parts of a SPATIAL index must be NOT NULL

- Error: 1253 SQLSTATE: 42000 (ER\_COLLATION\_CHARSET\_MISMATCH)

Message: COLLATION '%s' is not valid for CHARACTER SET '%s'

- Error: 1254 SQLSTATE: HY000 (ER\_SLAVE\_WAS\_RUNNING)

Message: Slave is already running

- Error: 1255 SQLSTATE: HY000 (ER\_SLAVE\_WAS\_NOT\_RUNNING)

Message: Slave already has been stopped

- Error: 1256 SQLSTATE: HY000 (ER\_TOO\_BIG\_FOR\_UNCOMPRESS)

Message: Uncompressed data size too large; the maximum size is %d (probably, length of uncompressed data was corrupted)

- Error: 1257 SQLSTATE: HY000 (ER\_ZLIB\_Z\_MEM\_ERROR)

Message: ZLIB: Not enough memory

- Error: 1258 SQLSTATE: HY000 (ER\_ZLIB\_Z\_BUF\_ERROR)

Message: ZLIB: Not enough room in the output buffer (probably, length of uncompressed data was corrupted)

- Error: 1259 SQLSTATE: HY000 (ER\_ZLIB\_Z\_DATA\_ERROR)

Message: ZLIB: Input data corrupted

- Error: 1260 SQLSTATE: HY000 (ER\_CUT\_VALUE\_GROUP\_CONCAT)

Message: %d line(s) were cut by GROUP\_CONCAT()

- Error: 1261 SQLSTATE: 01000 (ER\_WARN\_TOO\_FEW\_RECORDS)

Message: Row %ld doesn't contain data for all columns

- Error: 1262 SQLSTATE: 01000 (ER\_WARN\_TOO\_MANY\_RECORDS)  
Message: Row %ld was truncated; it contained more data than there were input columns
- Error: 1263 SQLSTATE: 22004 (ER\_WARN\_NULL\_TO\_NOTNULL)  
Message: Column set to default value; NULL supplied to NOT NULL column '%s' at row %ld
- Error: 1264 SQLSTATE: 22003 (ER\_WARN\_DATA\_OUT\_OF\_RANGE)  
Message: Out of range value adjusted for column '%s' at row %ld
- Error: 1265 SQLSTATE: 01000 (WARN\_DATA\_TRUNCATED)  
Message: Data truncated for column '%s' at row %ld
- Error: 1266 SQLSTATE: HY000 (ER\_WARN\_USING\_OTHER\_HANDLER)  
Message: Using storage engine %s for table '%s'
- Error: 1267 SQLSTATE: HY000 (ER\_CANT\_AGGREGATE\_2COLLATIONS)  
Message: Illegal mix of collations (%s,%s) and (%s,%s) for operation '%s'
- Error: 1268 SQLSTATE: HY000 (ER\_DROP\_USER)  
Message: Cannot drop one or more of the requested users
- Error: 1269 SQLSTATE: HY000 (ER\_REVOKE\_GRANTS)  
Message: Can't revoke all privileges for one or more of the requested users
- Error: 1270 SQLSTATE: HY000 (ER\_CANT\_AGGREGATE\_3COLLATIONS)  
Message: Illegal mix of collations (%s,%s), (%s,%s), (%s,%s) for operation '%s'
- Error: 1271 SQLSTATE: HY000 (ER\_CANT\_AGGREGATE\_NCOLLATIONS)  
Message: Illegal mix of collations for operation '%s'
- Error: 1272 SQLSTATE: HY000 (ER\_VARIABLE\_IS\_NOT\_STRUCT)  
Message: Variable '%s' is not a variable component (can't be used as XXXX.variable\_name)
- Error: 1273 SQLSTATE: HY000 (ER\_UNKNOWN\_COLLATION)  
Message: Unknown collation: '%s'
- Error: 1274 SQLSTATE: HY000 (ER\_SLAVE\_IGNORED\_SSL\_PARAMS)  
Message: SSL parameters in CHANGE MASTER are ignored because this MySQL slave was compiled without SSL support; they can be used later if MySQL slave with SSL is started
- Error: 1275 SQLSTATE: HY000 (ER\_SERVER\_IS\_IN\_SECURE\_AUTH\_MODE)  
Message: Server is running in --secure-auth mode, but '%s'@'%s' has a password in the old format; please change the password to the new format
- Error: 1276 SQLSTATE: HY000 (ER\_WARN\_FIELD\_RESOLVED)  
Message: Field or reference '%s%s%s%s%s' of SELECT #%d was resolved in SELECT #%d
- Error: 1277 SQLSTATE: HY000 (ER\_BAD\_SLAVE\_UNTIL\_COND)  
Message: Incorrect parameter or combination of parameters for START SLAVE UNTIL

- Error: 1278 SQLSTATE: HY000 (ER\_MISSING\_SKIP\_SLAVE)  
Message: It is recommended to use --skip-slave-start when doing step-by-step replication with START SLAVE UNTIL; otherwise, you will get problems if you get an unexpected slave's mysqld restart
- Error: 1279 SQLSTATE: HY000 (ER\_UNTIL\_COND\_IGNORED)  
Message: SQL thread is not to be started so UNTIL options are ignored
- Error: 1280 SQLSTATE: 42000 (ER\_WRONG\_NAME\_FOR\_INDEX)  
Message: Incorrect index name '%s'
- Error: 1281 SQLSTATE: 42000 (ER\_WRONG\_NAME\_FOR\_CATALOG)  
Message: Incorrect catalog name '%s'
- Error: 1282 SQLSTATE: HY000 (ER\_WARN\_QC\_RESIZE)  
Message: Query cache failed to set size %lu; new query cache size is %lu
- Error: 1283 SQLSTATE: HY000 (ER\_BAD\_FT\_COLUMN)  
Message: Column '%s' cannot be part of FULLTEXT index
- Error: 1284 SQLSTATE: HY000 (ER\_UNKNOWN\_KEY\_CACHE)  
Message: Unknown key cache '%s'
- Error: 1285 SQLSTATE: HY000 (ER\_WARN\_HOSTNAME\_WONT\_WORK)  
Message: MySQL is started in --skip-name-resolve mode; you must restart it without this switch for this grant to work
- Error: 1286 SQLSTATE: 42000 (ER\_UNKNOWN\_STORAGE\_ENGINE)  
Message: Unknown table engine '%s'
- Error: 1287 SQLSTATE: HY000 (ER\_WARN\_DEPRECATED\_SYNTAX)  
Message: '%s' is deprecated; use '%s' instead
- Error: 1288 SQLSTATE: HY000 (ER\_NON\_UPDATABLE\_TABLE)  
Message: The target table %s of the %s is not updatable
- Error: 1289 SQLSTATE: HY000 (ER\_FEATURE\_DISABLED)  
Message: The '%s' feature is disabled; you need MySQL built with '%s' to have it working
- Error: 1290 SQLSTATE: HY000 (ER\_OPTION\_PREVENTS\_STATEMENT)  
Message: The MySQL server is running with the %s option so it cannot execute this statement
- Error: 1291 SQLSTATE: HY000 (ER\_DUPLICATED\_VALUE\_IN\_TYPE)  
Message: Column '%s' has duplicated value '%s' in %s
- Error: 1292 SQLSTATE: 22007 (ER\_TRUNCATED\_WRONG\_VALUE)  
Message: Truncated incorrect %s value: '%s'
- Error: 1293 SQLSTATE: HY000 (ER\_TOO\_MUCH\_AUTO\_TIMESTAMP\_COLS)

Message: Incorrect table definition; there can be only one `TIMESTAMP` column with `CURRENT_TIMESTAMP` in `DEFAULT` or `ON UPDATE` clause

- Error: 1294 SQLSTATE: HY000 (ER\_INVALID\_ON\_UPDATE)  
Message: Invalid `ON UPDATE` clause for '%s' column
- Error: 1295 SQLSTATE: HY000 (ER\_UNSUPPORTED\_PS)  
Message: This command is not supported in the prepared statement protocol yet
- Error: 1296 SQLSTATE: HY000 (ER\_GET\_ERRMSG)  
Message: Got error %d '%s' from %s
- Error: 1297 SQLSTATE: HY000 (ER\_GET\_TEMPORARY\_ERRMSG)  
Message: Got temporary error %d '%s' from %s
- Error: 1298 SQLSTATE: HY000 (ER\_UNKNOWN\_TIME\_ZONE)  
Message: Unknown or incorrect time zone: '%s'
- Error: 1299 SQLSTATE: HY000 (ER\_WARN\_INVALID\_TIMESTAMP)  
Message: Invalid `TIMESTAMP` value in column '%s' at row %ld
- Error: 1300 SQLSTATE: HY000 (ER\_INVALID\_CHARACTER\_STRING)  
Message: Invalid %s character string: '%s'
- Error: 1301 SQLSTATE: HY000 (ER\_WARN\_ALLOWED\_PACKET\_OVERFLOWED)  
Message: Result of %s() was larger than `max_allowed_packet` (%ld) - truncated
- Error: 1302 SQLSTATE: HY000 (ER\_CONFLICTING\_DECLARATIONS)

- Error: 1387 SQLSTATE: HY000 (ER\_LOGGING\_PROHIBIT\_CHANGING\_OF)

Message: Binary logging and replication forbid changing the global server %s

- Error: 1388 SQLSTATE: HY000 (ER\_NO\_FILE\_MAPPING)

Message: Can't map file: %s, errno: %d

- Error: 1389 SQLSTATE: HY000 (ER\_WRONG\_MAGIC)

Message: Wrong magic in %s

- Error: 1390 SQLSTATE: HY000 (ER\_PS\_MANY\_PARAM)

Message: Prepared statement contains too many placeholders

- Error: 1391 SQLSTATE: HY000 (ER\_KEY\_PART\_0)

Message: Key part '%s' length cannot be 0

- Error: 1392 SQLSTATE: HY000 (ER\_VIEW\_CHECKSUM)

Message: View text checksum failed

- Error: 1393 SQLSTATE: HY000 (ER\_VIEW\_MULTIUPDATE)

Message: Can not modify more than one base table through a join view '%s.%s'

- Error: 1394 SQLSTATE: HY000 (ER\_VIEW\_NO\_INSERT\_FIELD\_LIST)

Message: Can not insert into join view '%s.%s' without fields list

- Error: 1395 SQLSTATE: HY000 (ER\_VIEW\_DELETE\_MERGE\_VIEW)

Message: Can not delete from join view '%s.%s'

- Error: 1396 SQLSTATE: HY000 (ER\_CANNOT\_USER)

Message: Operation %s failed for %s

- Error: 1397 SQLSTATE: XAE04 (ER\_XAER\_NOTA)

Message: XAER\_NOTA: Unknown XID

- Error: 1398 SQLSTATE: XAE05 (ER\_XAER\_INVALID)

Message: XAER\_INVALID: Invalid arguments (or unsupported command)

- Error: 1399 SQLSTATE: XAE07 (ER\_XAER\_RMFAIL)

Message: XAER\_RMFAIL: The command cannot be executed when global transaction is in the %s state

- Error: 1400 SQLSTATE: XAE09 (ER\_XAER\_OUTSIDE)

Message: XAER\_OUTSIDE: Some work is done outside global transaction

- Error: 1401 SQLSTATE: XAE03 (ER\_XAER\_RMERR)

Message: XAER\_RMERR: Fatal error occurred in the transaction branch - check your data for consistency

- Error: 1402 SQLSTATE: XA100 (ER\_XA\_RBROLLBACK)

Message: XA\_RBROLLBACK: Transaction branch was rolled back

- Error: 1403 SQLSTATE: 42000 (ER\_NONEXISTING\_PROC\_GRANT)

Message: There is no such grant defined for user '%s' on host '%s' on routine '%s'

- Error: 1404 SQLSTATE: HY000 (ER\_PROC\_AUTO\_GRANT\_FAIL)

Message: Failed to grant EXECUTE and ALTER ROUTINE privileges

- Error: 1405 SQLSTATE: HY000 (ER\_PROC\_AUTO\_REVOKE\_FAIL)  
Message: Failed to revoke all privileges to dropped routine
- Error: 1406 SQLSTATE: 22001 (ER\_DATA\_TOO\_LONG)  
Message: Data too long for column '%s' at row %ld
- Error: 1407 SQLSTATE: 42000 (ER\_SP\_BAD\_SQLSTATE)  
Message: Bad SQLSTATE: '%s'
- Error: 1408 SQLSTATE: HY000 (ER\_STARTUP)  
Message: %s: ready for connections. Version: '%s' socket: '%s' port: %d %s
- Error: 1409 SQLSTATE: HY000 (ER\_LOAD\_FROM\_FIXED\_SIZE\_ROWS\_TO\_VAR)  
Message: Can't load value from file with fixed size rows to variable
- Error: 1410 SQLSTATE: 42000 (ER\_CANT\_CREATE\_USER\_WITH\_GRANT)  
Message: You are not allowed to create a user with GRANT
- Error: 1411 SQLSTATE: HY000 (ER\_WRONG\_VALUE\_FOR\_TYPE)  
Message: Incorrect %s value: '%s' for function %s
- Error: 1412 SQLSTATE: HY000 (ER\_TABLE\_DEF\_CHANGED)  
Message: Table definition has changed, please retry transaction
- Error: 1413 SQLSTATE: 42000 (ER\_SP\_DUP\_HANDLER)  
Message: Duplicate handler declared in the same block
- Error: 1414 SQLSTATE: 42000 (ER\_SP\_NOT\_VAR\_ARG)  
Message: OUT or INOUT argument %d for routine %s is not a variable
- Error: 1415 SQLSTATE: 0A000 (ER\_SP\_NO\_RESET)  
Message: Not allowed to return a result set from a %s
- Error: 1416 SQLSTATE: 22003 (ER\_CANT\_CREATE\_GEOMETRY\_OBJECT)  
Message: Cannot get geometry object from data you send to the GEOMETRY field
- Error: 1417 SQLSTATE: HY000 (ER\_FAILED\_ROUTINE\_BREAK\_BINLOG)  
Message: A routine failed and has neither NO SQL nor READS SQL DATA in its declaration and binary logging is enabled; if non-transactional tables were updated, the binary log will miss their changes
- Error: 1418 SQLSTATE: HY000 (ER\_BINLOG\_UNSAFE\_ROUTINE)  
Message: This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you \*might\* want to use the less safe log\_bin\_trust\_function\_creators variable)
- Error: 1419 SQLSTATE: HY000 (ER\_BINLOG\_CREATE\_ROUTINE\_NEED\_SUPER)  
Message: You do not have the SUPER privilege and binary logging is enabled (you \*might\* want to use the less safe log\_bin\_trust\_function\_creators variable)

- Error: 1420 SQLSTATE: HY000 (ER\_EXEC\_STMT\_WITH\_OPEN\_CURSOR)  
Message: You can't execute a prepared statement which has an open cursor associated with it. Reset the statement to re-execute it.
- Error: 1421 SQLSTATE: HY000 (ER\_STMT\_HAS\_NO\_OPEN\_CURSOR)  
Message: The statement (%lu) has no open cursor.
- Error: 1422 SQLSTATE: HY000 (ER\_COMMIT\_NOT\_ALLOWED\_IN\_SF\_OR\_TRG)  
Message: Explicit or implicit commit is not allowed in stored function or trigger.
- Error: 1423 SQLSTATE: HY000 (ER\_NO\_DEFAULT\_FOR\_VIEW\_FIELD)  
Message: Field of view '%s.%s' underlying table doesn't have a default value
- Error: 1424 SQLSTATE: HY000 (ER\_SP\_NO\_RECURSION)  
Message: Recursive stored functions and triggers are not allowed.
- Error: 1425 SQLSTATE: 42000 (ER\_TOO\_BIG\_SCALE)  
Message: Too big scale %d specified for column '%s'. Maximum is %d.
- Error: 1426 SQLSTATE: 42000 (ER\_TOO\_BIG\_PRECISION)  
Message: Too big precision %d specified for column '%s'. Maximum is %d.
- Error: 1427 SQLSTATE: 42000 (ER\_M\_BIGGER\_THAN\_D)  
Message: For float(M,D), double(M,D) or decimal(M,D), M must be >= D (column '%s').
- Error: 1428 SQLSTATE: HY000 (ER\_WRONG\_LOCK\_OF\_SYSTEM\_TABLE)  
Message: You can't combine write-locking of system '%s.%s' table with other tables
- Error: 1429 SQLSTATE: HY000 (ER\_CONNECT\_TO\_FOREIGN\_DATA\_SOURCE)  
Message: Unable to connect to foreign data source: %s
- Error: 1430 SQLSTATE: HY000 (ER\_QUERY\_ON\_FOREIGN\_DATA\_SOURCE)  
Message: There was a problem processing the query on the foreign data source. Data source error: %-.64
- Error: 1431 SQLSTATE: HY000 (ER\_FOREIGN\_DATA\_SOURCE\_DOESNT\_EXIST)  
Message: The foreign data source you are trying to reference does not exist. Data source error: %s
- Error: 1432 SQLSTATE: HY000 (ER\_FOREIGN\_DATA\_STRING\_INVALID\_CANT\_CREATE)  
Message: Can't create federated table. The data source connection string '%s' is not in the correct format
- Error: 1433 SQLSTATE: HY000 (ER\_FOREIGN\_DATA\_STRING\_INVALID)  
Message: The data source connection string '%s' is not in the correct format
- Error: 1434 SQLSTATE: HY000 (ER\_CANT\_CREATE\_FEDERATED\_TABLE)  
Message: Can't create federated table. Foreign data src error: %s

- Error: 1435 SQLSTATE: HY000 (ER\_TRG\_IN\_WRONG\_SCHEMA)  
Message: Trigger in wrong schema
- Error: 1436 SQLSTATE: HY000 (ER\_STACK\_OVERRUN\_NEED\_MORE)  
Message: Thread stack overrun: %ld bytes used of a %ld byte stack, and %ld bytes needed. Use 'mysqld -O thread\_stack=#' to specify a bigger stack.
- Error: 1437 SQLSTATE: 42000 (ER\_TOO\_LONG\_BODY)  
Message: Routine body for '%s' is too long
- Error: 1438 SQLSTATE: HY000 (ER\_WARN\_CANT\_DROP\_DEFAULT\_KEYCACHE)  
Message: Cannot drop default keycache
- Error: 1439 SQLSTATE: 42000 (ER\_TOO\_BIG\_DISPLAYWIDTH)  
Message: Display width out of range for column '%s' (max = %d)
- Error: 1440 SQLSTATE: XAE08 (ER\_XAER\_DUPID)  
Message: XAER\_DUPID: The XID already exists
- Error: 1441 SQLSTATE: 22008 (ER\_DATETIME\_FUNCTION\_OVERFLOW)  
Message: Datetime function: %s field overflow
- Error: 1442 SQLSTATE: HY000 (ER\_CANT\_UPDATE\_USED\_TABLE\_IN\_SF\_OR\_TRG)  
Message: Can't update table '%s' in stored function/trigger because it is already used by statement which invoked this stored function/trigger.
- Error: 1443 SQLSTATE: HY000 (ER\_VIEW\_PREVENT\_UPDATE)  
Message: The definition of table '%s' prevents operation %s on table '%s'.
- Error: 1444 SQLSTATE: HY000 (ER\_PS\_NO\_RECURSION)  
Message: The prepared statement contains a stored routine call that refers to that same statement. It's not allowed to execute a prepared statement in such a recursive manner
- Error: 1445 SQLSTATE: HY000 (ER\_SP\_CANT\_SET\_AUTOCOMMIT)  
Message: Not allowed to set autocommit from a stored function or trigger
- Error: 1446 SQLSTATE: HY000 (ER\_MALFORMED\_DEFINER)  
Message: Definer is not fully qualified
- Error: 1447 SQLSTATE: HY000 (ER\_VIEW\_FRM\_NO\_USER)  
Message: View '%s'.'%s' has no definer information (old table format). Current user is used as definer. Please recreate the view!
- Error: 1448 SQLSTATE: HY000 (ER\_VIEW\_OTHER\_USER)  
Message: You need the SUPER privilege for creation view with '%s'@'%s' definer
- Error: 1449 SQLSTATE: HY000 (ER\_NO\_SUCH\_USER)  
Message: There is no '%s'@'%s' registered
- Error: 1450 SQLSTATE: HY000 (ER\_FORBID\_SCHEMA\_CHANGE)

Message: Changing schema from '%s' to '%s' is not allowed.

- Error: 1451 SQLSTATE: 23000 (ER\_ROW\_IS\_REFERENCED\_2)

Message: Cannot delete or update a parent row: a foreign key constraint fails (%s)

- Error: 1452 SQLSTATE: 23000 (ER\_NO\_REFERENCED\_ROW\_2)

Message: Cannot add or update a child row: a foreign key constraint fails (%s)

- Error: 1453 SQLSTATE: 42000 (ER\_SP\_BAD\_VAR\_SHADOW)

Message: Variable '%s' must be quoted with `...`, or renamed

- Error: 1454 SQLSTATE: HY000 (ER\_TRG\_NO\_DEFINER)

Message: No definer attribute for trigger '%s'.%s'. The trigger will be activated under the authorization of the invoker, which may have insufficient privileges. Please recreate the trigger.

- Error: 1455 SQLSTATE: HY000 (ER\_OLD\_FILE\_FORMAT)

Message: '%s' has an old format, you should re-create the '%s' object(s)

- Error: 1456 SQLSTATE: HY000 (ER\_SP\_RECURSION\_LIMIT)

Message: Recursive limit %d (as set by the max\_sp\_recursion\_depth variable) was exceeded for routine %s

- Error: 1457 SQLSTATE: HY000 (ER\_SP\_PROC\_TABLE\_CORRUPT)

Message: Failed to load routine %s. The table mysql.proc is missing, corrupt, or contains bad data (internal code %d)

- Error: 1458 SQLSTATE: 42000 (ER\_SP\_WRONG\_NAME)

Message: Incorrect routine name '%s'

- Error: 1459 SQLSTATE: HY000 (ER\_TABLE\_NEEDS\_UPGRADE)

Message: Table upgrade required. Please do "REPAIR TABLE `%s`" to fix it!

- Error: 1460 SQLSTATE: 42000 (ER\_SP\_NO\_AGGREGATE)

Message: AGGREGATE is not supported for stored functions

- Error: 1461 SQLSTATE: 42000 (ER\_MAX\_PREPARED\_STMT\_COUNT\_REACHED)

Message: Can't create more than max\_prepared\_stmt\_count statements (current value: %lu)

- Error: 1462 SQLSTATE: HY000 (ER\_VIEW\_RECURSIVE)

Message: `%s`.`%s` contains view recursion

- Error: 1463 SQLSTATE: 42000 (ER\_NON\_GROUPING\_FIELD\_USED)

Message: non-grouping field '%s' is used in %s clause

- Error: 1464 SQLSTATE: HY000 (ER\_TABLE\_CANT\_HANDLE\_SPKEYS)

Message: The used table type doesn't support SPATIAL indexes

## B.2. Client Error Codes and Messages

---

Client error information comes from the following source files:

- The Error values and the symbols in parentheses correspond to definitions in the `include/er-rmsg.h` MySQL source file.
- The Message values correspond to the error messages that are listed in the `libmysql/er-rmsg.c` file. `%d` and `%s` represent numbers and strings, respectively, that are substituted into the messages when they are displayed.

Because updates are frequent, it is possible that those files will contain additional error information not listed here.

- Error: 2000 (CR\_UNKNOWN\_ERROR)  
Message: Unknown MySQL error
- Error: 2001 (CR\_SOCKET\_CREATE\_ERROR)  
Message: Can't create UNIX socket (%d)
- Error: 2002 (CR\_CONNECTION\_ERROR)  
Message: Can't connect to local MySQL server through socket '%s' (%d)
- Error: 2003 (CR\_CONN\_HOST\_ERROR)  
Message: Can't connect to MySQL server on '%s' (%d)
- Error: 2004 (CR\_IPSOCK\_ERROR)  
Message: Can't create TCP/IP socket (%d)
- Error: 2005 (CR\_UNKNOWN\_HOST)  
Message: Unknown MySQL server host '%s' (%d)
- Error: 2006 (CR\_SERVER\_GONE\_ERROR)  
Message: MySQL server has gone away
- Error: 2007 (CR\_VERSION\_ERROR)  
Message: Protocol mismatch; server version = %d, client version = %d
- Error: 2008 (CR\_OUT\_OF\_MEMORY)  
Message: MySQL client ran out of memory
- Error: 2009 (CR\_WRONG\_HOST\_INFO)  
Message: Wrong host info
- Error: 2010 (CR\_LOCALHOST\_CONNECTION)  
Message: Localhost via UNIX socket
- Error: 2011 (CR\_TCP\_CONNECTION)  
Message: %s via TCP/IP
- Error: 2012 (CR\_SERVER\_HANDSHAKE\_ERR)

Message: Error in server handshake

- Error: 2013 (CR\_SERVER\_LOST)

Message: Lost connection to MySQL server during query

- Error: 2014 (CR\_COMMANDS\_OUT\_OF\_SYNC)

Message: Commands out of sync; you can't run this command now

- Error: 2015 (CR\_NAMEDPIPE\_CONNECTION)

Message: Named pipe: %s

- Error: 2016 (CR\_NAMEDPIPEWAIT\_ERROR)

Message: Can't wait for named pipe to host: %s pipe: %s (%lu)

- Error: 2017 (CR\_NAMEDPIPEOPEN\_ERROR)

Message: Can't open named pipe to host: %s pipe: %s (%lu)

- Error: 2018 (CR\_NAMEDPIPESETSTATE\_ERROR)

Message: Can't set state of named pipe to host: %s pipe: %s (%lu)

- Error: 2019 (CR\_CANT\_READ\_CHARSET)

Message: Can't initialize character set %s (path: %s)

- Error: 2020 (CR\_NET\_PACKET\_TOO\_LARGE)

Message: Got packet bigger than 'max\_allowed\_packet' bytes

- Error: 2021 (CR\_EMBEDDED\_CONNECTION)

Message: Embedded server

- Error: 2022 (CR\_PROBE\_SLAVE\_STATUS)

Message: Error on SHOW SLAVE STATUS:

- Error: 2023 (CR\_PROBE\_SLAVE\_HOSTS)

Message: Error on SHOW SLAVE HOSTS:

- Error: 2024 (CR\_PROBE\_SLAVE\_CONNECT)

Message: Error connecting to slave:

- Error: 2025 (CR\_PROBE\_MASTER\_CONNECT)

Message: Error connecting to master:

- Error: 2026 (CR\_SSL\_CONNECTION\_ERROR)

Message: SSL connection error

- Error: 2027 (CR\_MALFORMED\_PACKET)

Message: Malformed packet

- Error: 2028 (CR\_WRONG\_LICENSE)

Message: This client library is licensed only for use with MySQL servers having '%s' license

- Error: 2029 (CR\_NULL\_POINTER)

Message: Invalid use of null pointer

- Error: 2030 (CR\_NO\_PREPARE\_STMT)

Message: Statement not prepared

- Error: 2031 (CR\_PARAMS\_NOT\_BOUND)

Message: No data supplied for parameters in prepared statement

- Error: 2032 (CR\_DATA\_TRUNCATED)

Message: Data truncated

- Error: 2033 (CR\_NO\_PARAMETERS\_EXISTS)

Message: No parameters exist in the statement

- Error: 2034 (CR\_INVALID\_PARAMETER\_NO)

Message: Invalid parameter number

- Error: 2035 (CR\_INVALID\_BUFFER\_USE)

Message: Can't send long data for non-string/non-binary data types (parameter: %d)

- Error: 2036 (CR\_UNSUPPORTED\_PARAM\_TYPE)

Message: Using unsupported buffer type: %d (parameter: %d)

- Error: 2037 (CR\_SHARED\_MEMORY\_CONNECTION)

Message: Shared memory: %s

- Error: 2038 (CR\_SHARED\_MEMORY\_CONNECT\_REQUEST\_ERROR)

Message: Can't open shared memory; client could not create request event (%lu)

- Error: 2039 (CR\_SHARED\_MEMORY\_CONNECT\_ANSWER\_ERROR)

Message: Can't open shared memory; no answer event received from server (%lu)

- Error: 2040 (CR\_SHARED\_MEMORY\_CONNECT\_FILE\_MAP\_ERROR)

Message: Can't open shared memory; server could not allocate file mapping (%lu)

- Error: 2041 (CR\_SHARED\_MEMORY\_CONNECT\_MAP\_ERROR)

Message: Can't open shared memory; server could not get pointer to file mapping (%lu)

- Error: 2042 (CR\_SHARED\_MEMORY\_FILE\_MAP\_ERROR)

Message: Can't open shared memory; client could not allocate file mapping (%lu)

- Error: 2043 (CR\_SHARED\_MEMORY\_MAP\_ERROR)

Message: Can't open shared memory; client could not get pointer to file mapping (%lu)

- Error: 2044 (CR\_SHARED\_MEMORY\_EVENT\_ERROR)

Message: Can't open shared memory; client could not create %s event (%lu)

- Error: 2045 (CR\_SHARED\_MEMORY\_CONNECT\_ABANDONED\_ERROR)

Message: Can't open shared memory; no answer from server (%lu)

- Error: 2046 (CR\_SHARED\_MEMORY\_CONNECT\_SET\_ERROR)

Message: Can't open shared memory; cannot send request event to server (%lu)

- Error: 2047 (CR\_CONN\_UNKNOW\_PROTOCOL)

Message: Wrong or unknown protocol

- Error: 2048 (CR\_INVALID\_CONN\_HANDLE)

Message: Invalid connection handle

- Error: 2049 (CR\_SECURE\_AUTH)

Message: Connection using old (pre-4.1.1) authentication protocol refused (client option 'secure\_auth' enabled)

- Error: 2050 (CR\_FETCH\_CANCELED)

Message: Row retrieval was canceled by mysql\_stmt\_close() call

- Error: 2051 (CR\_NO\_DATA)

Message: Attempt to read column without prior row fetch

- Error: 2052 (CR\_NO\_STMT\_METADATA)

Message: Prepared statement contains no metadata

- Error: 2053 (CR\_NO\_RESULT\_SET)

Message: Attempt to read a row while there is no result set associated with the statement

- Error: 2054 (CR\_NOT\_IMPLEMENTED)

Message: This feature is not implemented yet

---

# Appendix C. Credits

This appendix lists the developers, contributors, and supporters that have helped to make MySQL what it is today.

## C.1. Developers at MySQL AB

These are the developers that are or have been employed by MySQL AB to work on the MySQL database software, roughly in the order they started to work with us. Following each developer is a small list of the tasks that the developer is responsible for, or the accomplishments they have made. All developers are involved in support.

- Michael (Monty) Widenius
  - Lead developer and main author of the MySQL server (`mysqld`).
  - New functions for the string library.
  - Most of the `mysys` library.
  - The `ISAM` and `MyISAM` libraries (B-tree index file handlers with index compression and different record formats).
  - The `HEAP` library. A memory table system with our superior full dynamic hashing. In use since 1981 and published around 1984.
  - The `replace` program (take a look at it, it's **COOL!**).
  - Connector/ODBC (MyODBC), the ODBC driver for Windows.
  - Fixing bugs in MIT-pthreads to get it to work for MySQL Server. And also Unireg, a curses-based application tool with many utilities.
  - Porting of `mSQL` tools like `msqlperl`, `DBD/DBI`, and `DB2mysql`.
  - Most of `crash-me` and the foundation for the MySQL benchmarks.
- David Axmark
  - Initial main writer of the **Reference Manual**, including enhancements to `texi2html`.
  - Automatic Web site updating from the manual.
  - Initial Autoconf, Automake, and Libtool support.
  - Licensing.
  - Parts of all the text files. (Nowadays only the `README` is left. The rest ended up in the manual.)
  - Lots of testing of new features.
  - Our in-house Free Software legal expert.
  - Mailing list maintainer (who never has the time to do it right...).
  - Our original portability code (now more than 10 years old). Nowadays only some parts of `mysys` are left.
  - Someone for Monty to call in the middle of the night when he just got that new feature to work.

- Chief "Open Sourcerer" (MySQL community relations).
- Jani Tolonen
  - `mysqlimport`
  - A lot of extensions to the command-line clients.
  - `PROCEDURE ANALYSE()`
- Sinisa Milivojevic (now in support)
  - Compression (with `zlib`) in the client/server protocol.
  - Perfect hashing for the lexical analyzer phase.
  - Multi-row `INSERT`
  - `mysqldump -e` option
  - `LOAD DATA LOCAL INFILE`
  - `SQL_CALC_FOUND_ROWS SELECT` option
  - `--max-user-connections=...` option
  - `net_read` and `net_write_timeout`
  - `GRANT/REVOKE` and `SHOW GRANTS FOR`
  - New client/server protocol for 4.0
  - `UNION` in 4.0
  - Multiple-table `DELETE/UPDATE`
  - Subqueries in the `FROM` clause (4.1).
  - User resources management
  - Initial developer of the `MySQL++ C++ API` and the `MySQLGUI` client.
- Tonu Samuel (past developer)
  - VIO interface (the foundation for the encrypted client/server protocol).
  - MySQL Filesystem (a way to use MySQL databases as files and directories).
  - The `CASE` expression.
  - The `MD5()` and `COALESCE()` functions.
  - RAID support for `MyISAM` tables.
- Sasha Pachev (past developer)
  - Initial implementation of replication (up to version 4.0).
  - `SHOW CREATE TABLE`.
  - `mysql-bench`
- Matt Wagner

- MySQL test suite.
- Webmaster (until 2002).
- Miguel Solorzano (now in support)
  - Win32 development and release builds.
  - Windows NT server code.
  - WinMySQLAdmin
- Timothy Smith (now in support)
  - Dynamic character sets support.
  - configure, RPMs and other parts of the build system.
  - Initial developer of `libmysqld`, the embedded server.
- Sergei Golubchik
  - Full-text search.
  - Added keys to the MERGE library.
  - Precision math.
- Jeremy Cole (past developer)
  - Proofreading and editing this fine manual.
  - `ALTER TABLE ... ORDER BY ...`
  - `UPDATE ... ORDER BY ...`
  - `DELETE ... ORDER BY ...`
- Indrek Siitan
  - Designing/programming of our Web interface.
  - Author of our newsletter management system.
- Jorge del Conde (now in support)
  - MySQLCC (MySQL Control Center)
  - Win32 development
  - Initial implementation of the Web site portals.
- Venu Anuganti (past developer)
  - MyODBC 3.51
  - New client/server protocol for 4.1 (for prepared statements).
- Arjen Lentz (now handling community)
  - Maintainer of the MySQL Reference Manual.
  - Preparing the O'Reilly printed edition of the manual.

- Alexander (Bar) Barkov, Alexey (Holyfoot) Botchkov, and Ramil Kalimullin
  - Spatial data (GIS) and R-Trees implementation for 4.1
  - Unicode and character sets for 4.1; documentation for same
- Oleksandr (Sanja) Byelkin
  - Query cache in 4.0
  - Implementation of subqueries (4.1).
  - Implementation of views (5.0).
- Aleksey (Walrus) Kishkin and Alexey (Ranger) Stroganov
  - Benchmarks design and analysis.
  - Maintenance of the MySQL test suite.
- Zak Greant (past employee)
  - Open Source advocate, MySQL community relations.
- Carsten Pedersen
  - The MySQL Certification program.
- Lenz Grimmer
  - Production (build and release) engineering.
- Peter Zaitsev
  - `SHA1 ( )`, `AES_ENCRYPT ( )` and `AES_DECRYPT ( )` functions.
  - Debugging, cleaning up various features.
- Alexander (Salle) Keremidarski
  - Support.
  - Debugging.
- Per-Erik Martin
  - Lead developer for stored procedures (5.0).
- Jim Winstead
  - Former lead Web developer.
  - Improving server, fixing bugs.
- Mark Matthews
  - Connector/J driver (Java).
- Peter Gultzan
  - SQL standards compliance.
  - Documentation of existing MySQL code/algorithms.
  - Character set documentation.

- Guilhem Bichot
  - Replication, from MySQL version 4.0.
  - Fixed handling of exponents for DECIMAL.
  - Author of `mysql_tableinfo`.
  - Backup (in 5.1).
- Antony T. Curtis
  - Porting of the MySQL Database software to OS/2.
- Mikael Ronstrom
  - Much of the initial work on NDB Cluster until 2000. Roughly half the code base at that time. Transaction protocol, node recovery, system restart and restart code and parts of the API functionality.
  - Lead Architect, developer, debugger of NDB Cluster 1994-2004
  - Lots of optimizations
- Jonas Orelund
  - On-line Backup
  - The automatic test environment of MySQL Cluster
  - Portability Library for NDB Cluster
  - Lots of other things
- Pekka Nousiainen
  - Ordered index implementation of MySQL Cluster
  - BLOB support in MySQL Cluster
  - Charset support in MySQL Cluster
- Martin Skold
  - Unique index implementation of MySQL Cluster
  - Integration of NDB Cluster into MySQL
- Magnus Svensson
  - The test framework for MySQL Cluster
  - Integration of NDB Cluster into MySQL
- Tomas Ulin
  - Lots of work on configuration changes for simple installation and use of MySQL Cluster
- Konstantin Osipov
  - Prepared statements.
  - Cursors.
- Dmitri Lenev

- Time zone support.
- Triggers (in 5.0).

## C.2. Contributors to MySQL

Although MySQL AB owns all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize those who have made contributions of one kind or another to the `MySQL distribution`. Contributors are listed here, in somewhat random order:

- Gianmassimo Vigazzola <qwerg@mbx.vol.it> or <qwerg@tin.it>

The initial port to Win32/NT.

- Per Eric Olsson

For more or less constructive criticism and real testing of the dynamic record format.

- Irena Pancirov <irena@mail.yacc.it>

Win32 port with Borland compiler. `mysqlshutdown.exe` and `mysqlwatch.exe`

- David J. Hughes

For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with `mSQL`, but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder `Unireg`. `mysqladmin` and `mysql` client are programs that were largely influenced by their `mSQL` counterparts. We have put a lot of effort into making the MySQL syntax a superset of `mSQL`. Many of the API's ideas are borrowed from `mSQL` to make it easy to port free `mSQL` programs to the MySQL API. The MySQL software doesn't contain any code from `mSQL`. Two files in the distribution (`client/insert_test.c` and `client/select_test.c`) are based on the corresponding (non-copyrighted) files in the `mSQL` distribution, but are modified as examples showing the changes necessary to convert code from `mSQL` to MySQL Server. (`mSQL` is copyrighted David J. Hughes.)

- Patrick Lynch

For helping us acquire <http://www.mysql.com/>.

- Fred Lindberg

For setting up `qmail` to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

- Igor Romanenko <igor@frog.kiev.ua>

`mysqldump` (previously `msqldump`, but ported and enhanced by Monty).

- Yuri Dario

For keeping up and extending the MySQL OS/2 port.

- Tim Bunce

Author of `mysqlhotcopy`.

- Zarko Mocnik <zarko.mocnik@dem.si>

Sorting for Slovenian language.

- "TAMITO" <tommy@valley.ne.jp>  
The `_MB` character set macros and the `ujis` and `sjis` character sets.
- Joshua Chamas <joshua@chamas.com>  
Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.
- Yves Carlier <Yves.Carlier@rug.ac.be>  
`mysqlaccess`, a program to show the access rights for a user.
- Rhys Jones <rhys@wales.com> (And GWE Technologies Limited)  
For one of the early JDBC drivers.
- Dr Xiaokun Kelvin ZHU <X.Zhu@brad.ac.uk>  
Further development of one of the early JDBC drivers and other MySQL-related Java tools.
- James Cooper <pixel@organic.com>  
For setting up a searchable mailing list archive at his site.
- Rick Mehalick <Rick\_Mehalick@i-o.com>  
For `xmysql`, a graphical X client for MySQL Server.
- Doug Sisk <sisk@wix.com>  
For providing RPM packages of MySQL for Red Hat Linux.
- Diemand Alexander V. <axeld@vial.ethz.ch>  
For providing RPM packages of MySQL for Red Hat Linux-Alpha.
- Antoni Pamies Olive <toni@readysoft.es>  
For providing RPM versions of a lot of MySQL clients for Intel and SPARC.
- Jay Bloodworth <jay@pathways.sde.state.sc.us>  
For providing RPM versions for MySQL 3.21.
- David Sacerdote <davids@secnet.com>  
Ideas for secure checking of DNS hostnames.
- Wei-Jou Chen <jou@nematic.ieo.nctu.edu.tw>  
Some support for Chinese(BIG5) characters.
- Wei He <hewei@mail.ied.ac.cn>  
A lot of functionality for the Chinese(GBK) character set.
- Jan Pazdziora <adelton@fi.muni.cz>  
Czech sorting order.
- Zeev Suraski <bourbon@netvision.net.il>  
`FROM_UNIXTIME()` time formatting, `ENCRYPT()` functions, and `bison` advisor. Active mailing list member.

- Luuk de Boer <luuk@wxs.nl>  
Ported (and extended) the benchmark suite to DBI/DBD. Have been of great help with crash-me and running benchmarks. Some new date functions. The `mysql_setpermission` script.
- Alexis Mikhailov <root@medinf.chuvashia.su>  
User-defined functions (UDFs); `CREATE FUNCTION` and `DROP FUNCTION`.
- Andreas F. Bobak <bobak@relog.ch>  
The `AGGREGATE` extension to user-defined functions.
- Ross Wakelin <R.Wakelin@march.co.uk>  
Help to set up InstallShield for MySQL-Win32.
- Jethro Wright III <jetman@li.net>  
The `libmysql.dll` library.
- James Pereria <jpereira@iafrica.com>  
Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.
- Curt Sampson <cjs@portal.ca>  
Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.
- Martin Ramsch <m.ramsch@computer.org>  
Examples in the MySQL Tutorial.
- Steve Harvey  
For making `mysqlaccess` more secure.
- Konark IA-64 Centre of Persistent Systems Private Limited  
<http://www.pspl.co.in/konark/>. Help with the Win64 port of the MySQL server.
- Albert Chin-A-Young.  
Configure updates for Tru64, large file support and better TCP wrappers support.
- John Birrell  
Emulation of `pthread_mutex()` for OS/2.
- Benjamin Pflugmann  
Extended `MERGE` tables to handle `INSERTS`. Active member on the MySQL mailing lists.
- Jocelyn Fournier  
Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).
- Marc Liyanage  
Maintaining the Mac OS X packages and providing invaluable feedback on how to create Mac OS X PKGs.
- Robert Rutherford

Providing invaluable information and feedback about the QNX port.

- Previous developers of NDB Cluster

Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Atallah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, <jehamby@lightside>, <psmith@BayNetworks.com>, <duane@connect.com.au>, Ted Deppner <ted@psyber.com>, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

- Daniel Koch <dkoch@amcity.com>  
Irix setup.
- Luuk de Boer <luuk@wxs.nl>  
Benchmark questions.
- Tim Sailer <tps@users.buoy.com>  
DBD::mysql questions.
- Boyd Lynn Gerber <gerberb@zenez.com>  
SCO-related questions.
- Richard Mehalick <RM186061@shellus.com>  
xmysql-related questions and basic installation questions.
- Zeev Suraski <bourbon@netvision.net.il>  
Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.
- Francesc Guasch <frankie@citel.upc.es>  
General questions.
- Jonathan J Smith <jsmith@wtp.net>  
Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.
- David Sklar <sklar@student.net>  
Using MySQL from PHP and Perl.
- Alistair MacDonald <A.MacDonald@uel.ac.uk>

Is flexible and can handle Linux and perhaps HP-UX. Tries to get users to use `mysqlbug`.

- John Lyon <jlyon@imag.net>

Questions about installing MySQL on Linux systems, using either `.rpm` files or compiling from source.

- Lorvid Ltd. <lorvid@WOLFENET.com>

Simple billing/license/support/copyright issues.

- Patrick Sherrill <patrick@coconet.com>

ODBC and VisualC++ interface questions.

- Randy Harmon <rjharmon@uptimecomputers.com>

DBD, Linux, some SQL syntax questions.

## C.3. Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Paul DuBois

Ongoing help with making this manual correct and understandable. That includes rewriting Monty's and David's attempts at English into English as other people know it.

- Kim Aldale

Helped to rewrite Monty's and David's early attempts at English into English.

- Michael J. Miller Jr. <mke@terrapin.turbolift.com>

For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).

- Yan Cailin

First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded (<http://mysql.hitstar.com/>) versions were based. Personal home page at [linuxdb.yeah.net](http://linuxdb.yeah.net) [<http://linuxdb.yeah.net>].

- Jay Flaherty <fty@mediapulse.com>

Big parts of the Perl DBI/DBD section in the manual.

- Paul Southworth <pauls@etext.org>, Ray Loyzaga <yar@cs.su.oz.au>

Proof-reading of the Reference Manual.

- Therrien Gilbert <gilbert@ican.net>, Jean-Marc Pouyot <jmp@scalaire.fr>

French error messages.

- Petr Snajdr, <snajdr@pvt.net>

Czech error messages.

- Jaroslaw Lewandowski <jotel@itnet.com.pl>

Polish error messages.

- Miguel Angel Fernandez Roiz

Spanish error messages.

- Roy-Magne Mo <rmo@www.hivolda.no>

Norwegian error messages and testing of MySQL 3.21.xx.

- Timur I. Bakeyev <root@timur.tatarstan.ru>

Russian error messages.

- <brenno@dewinter.com> & Filippo Grassilli <phil@hyppo.com>

Italian error messages.

- Dirk Munzinger <dirk@trinity.saar.de>

German error messages.

- Billik Stefan <billik@sun.uniag.sk>

Slovak error messages.

- Stefan Saroiu <tzoompy@cs.washington.edu>

Romanian error messages.

- Peter Feher

Hungarian error messages.

- Roberto M. Serqueira

Portuguese error messages.

- Carsten H. Pedersen

Danish error messages.

- Arjen G. Lentz

Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

## C.4. Libraries used by and included with MySQL

The following is a list of the creators of the libraries we have included with the MySQL server source to make it easy to compile and install MySQL. We are very thankful to all individuals that have created these and it has made our life much easier.

- Fred Fish

For his excellent C debugging and trace library. Monty has made a number of smaller improvements to the library (speed and additional options).

- Richard A. O'Keefe  
For his public domain string library.
- Henry Spencer  
For his regex library, used in `WHERE column REGEXP regexp`.
- Chris Provenzano  
Portable user level pthreads. From the copyright: This product includes software developed by Chris Provenzano, the University of California, Berkeley, and contributors. We are currently using version 1\_60\_beta6 patched by Monty (see `mit-pthreads/Changes-mysql`).
- Jean-loup Gailly and Mark Adler  
For the zlib library (used on MySQL on Windows).
- Bjorn Benson  
For his `safe_malloc` (memory checker) package which is used in when you configure MySQL with `--debug`.
- Free Software Foundation  
The `readline` library (used by the `mysql` command-line client).
- The NetBSD foundation  
The `libedit` package (optionally used by the `mysql` command-line client).

## C.5. Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We can't list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at <http://solutions.mysql.com/software/>.

- Tim Bunce, Alligator Descartes  
For the DBD (Perl) interface.
- Andreas Koenig <a.koenig@mind.de>  
For the Perl interface for MySQL Server.
- Jochen Wiedmann <wiedmann@neckar-alb.de>  
For maintaining the Perl `DBD::mysql` module.
- Eugene Chan <eugene@acenet.com.sg>  
For porting PHP for MySQL Server.
- Georg Richter  
MySQL 4.1 testing and bug hunting. New PHP 5.0 `mysqli` extension (API) for use with MySQL 4.1 and up.
- Giovanni Maruzzelli <maruzz@matrice.it>

For porting iODBC (Unix ODBC).

- Xavier Leroy <Xavier.Leroy@inria.fr>

The author of LinuxThreads (used by the MySQL Server on Linux).

## C.6. Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- Free Software Foundation

From whom we got an excellent compiler (`gcc`), an excellent debugger (`gdb`) and the `libc` library (from which we have borrowed `strtoc` to get some code working in Linux).

- Free Software Foundation & The XEmacs development team

For a really great editor/environment used by almost everybody at MySQL AB.

- Julian Seward

Author of `valgrind`, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- Dorothea Lütkehaus and Andreas Zeller

For DDD (The Data Display Debugger) which is an excellent graphical front end to `gdb`.

## C.7. Supporters of MySQL

Although MySQL AB owns all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize the following companies, which helped us finance the development of the `MySQL server`, such as by paying us for developing a new feature or giving us hardware for development of the `MySQL server`.

- VA Linux / Andover.net

Funded replication.

- NuSphere

Editing of the MySQL manual.

- Stork Design studio

The MySQL Web site in use between 1998-2000.

- Intel

Contributed to development on Windows and Linux platforms.

- Compaq

Contributed to Development on Linux/Alpha.

- SWSoft  
Development on the embedded mysqld version.
- FutureQuest  
`--skip-show-database`

---

# Appendix D. MySQL Change History

This appendix lists the changes from version to version in the MySQL source code through the latest version of MySQL 5.0, which is currently MySQL 5.0.22. Starting with MySQL 5.0, we began offering a new version of the Manual for each new series of MySQL releases (5.0, 5.1, and so on). For information about changes in previous release series of the MySQL database software, see the corresponding version of this Manual. For information about legacy versions of the MySQL software through the 4.1 series, see *MySQL 3.23, 4.0, 4.1 Reference Manual*.

We update this section as we add new features in the 5.0 series, so that everybody can follow the development process.

Note that we tend to update the manual at the same time we make changes to MySQL. If you find a recent version of MySQL listed here that you can't find on our download page (<http://dev.mysql.com/downloads/>), it means that the version has not yet been released.

The date mentioned with a release version is the date of the last BitKeeper ChangeSet on which the release was based, not the date when the packages were made available. The binaries are usually made available a few days after the date of the tagged ChangeSet, because building and testing all packages takes some time.

The manual included in the source and binary distributions may not be fully accurate when it comes to the release changelog entries, because the integration of the manual happens at build time. For the most up-to-date release changelog, please refer to the online version instead.

## D.1. Changes in release 5.0.x (Production)

The following changelog shows what has been done in the 5.0 tree:

- Basic support for read-only server side cursors. For information about using cursors within stored routines, see Section 17.2.9, “Cursors”. For information about using cursors from within the C API, see Section 22.2.7.3, “`mysql_stmt_attr_set()`”.
- Basic support for (updatable) views. See, for example, Section 19.2, “CREATE VIEW Syntax”.
- Basic support for stored procedures and functions (SQL:2003 style). See Chapter 17, *Stored Procedures and Functions*.
- Initial support for rudimentary triggers.
- Added `SELECT INTO list_of_vars`, which can be of mixed (that is, global and local) types. See Section 17.2.7.3, “SELECT ... INTO Statement”.
- Removed the update log. It is fully replaced by the binary log. If the MySQL server is started with `--log-update`, it is translated to `--log-bin` (or ignored if the server is explicitly started with `--log-bin`), and a warning message is written to the error log. Setting `SQL_LOG_UPDATE` silently sets `SQL_LOG_BIN` instead (or do nothing if the server is explicitly started with `--log-bin`).
- Support for the ISAM storage engine has been removed. If you have ISAM tables, you should convert them before upgrading. See Section 2.11.2, “Upgrading from MySQL 4.1 to 5.0”.
- Support for RAID options in MyISAM tables has been removed. If you have tables that use these options, you should convert them before upgrading. See Section 2.11.2, “Upgrading from MySQL 4.1 to 5.0”.
- User variable names are now case insensitive: If you do `SET @a=10;` then `SELECT @A;` now returns 10. Case sensitivity of a variable's value depends on the collation of the value.
- Strict mode, which in essence means that you get an error instead of a warning when inserting an

incorrect value into a column. See Section 5.2.5, “The Server SQL Mode”.

- `VARCHAR` and `VARBINARY` columns remember end space. A `VARCHAR()` or `VARBINARY` column can contain up to 65,535 characters or bytes, respectively.
- `MEMORY (HEAP)` tables can have `VARCHAR()` columns.
- When using a constant string or a function that generates a string result in `CREATE ... SELECT`, MySQL creates the result field based on the maximum length of the string or expression:

Maximum Length	Data type
= 0	<code>CHAR(0)</code>
< 512	<code>VARCHAR(max_length)</code>
>= 512	<code>TEXT</code>

For a full list of changes, please refer to the changelog sections for each individual 5.0.x release.

## D.1.1. Changes in release 5.0.22 (Not yet released)

This is a bugfix release for the current production release family.

This section documents all changes and bug fixes that have been applied since the last official MySQL release. If you would like to receive more fine-grained and personalised *update alerts* about fixes that are relevant to the version and features you use, please consider subscribing to *MySQL Network* (a commercial MySQL offering). For more details please see <http://www.mysql.com/network/advisors.html>.

Functionality added or changed:

- The `mysql_upgrade` command has been converted from a shell script to a C program, so it is available on non-Unix systems such as Windows. This program should be run for each MySQL upgrade. See Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.
- The `ONLY_FULL_GROUP_BY` SQL mode now also applies to the `HAVING` clause. That is, columns not named in the `GROUP BY` clause cannot be used in the `HAVING` clause if not used in an aggregate function. (Bug#18739 [<http://bugs.mysql.com/18739>])
- SQL syntax for prepared statements now supports `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE`. (Bug#19308 [<http://bugs.mysql.com/19308>])
- The bundled `yaSSL` library was upgraded to version 1.3.0. This improves handling of certain problems with SSL-related command options. (Bug#17737 [<http://bugs.mysql.com/17737>])
- To prevent inadvertant loss of data, `ALTER TABLE` can no longer be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`. (Bug#10952 [<http://bugs.mysql.com/10952>])

Bugs fixed:

- A range access optimizer heuristic was invalid, causing some queries to be much slower in MySQL 5.0 than in 4.0. (Bug#17379 [<http://bugs.mysql.com/17379>])
- `IS_USED_LOCK()` could return an incorrect connection identifier. (Bug#16501 [<http://bugs.mysql.com/16501>])
- `mysql` displayed `NULL` for strings that are empty or contain only spaces. (Bug#16372 [<http://bugs.mysql.com/16372>])

- Concurrent reading and writing of privilege structures could crash the server. (Bug#16372 [<http://bugs.mysql.com/16372>])
- A NUL byte within a comment in a statement string caused the rest of the string not to be written to the query log, allowing logging to be bypassed. (CVE-2006-0903 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-0903>]) (Bug#17667 [<http://bugs.mysql.com/17667>])
- `mysql-test-run.pl` started NDB even for test cases that didn't need it. (Bug#19083 [<http://bugs.mysql.com/19083>])
- `SELECT DISTINCT` queries sometimes returned only the last row. (Bug#18068 [<http://bugs.mysql.com/18068>])
- Use of `CONVERT_TZ()` in a stored function or trigger (or in a stored procedure called from a stored function or trigger) caused an error. (Bug#11081 [<http://bugs.mysql.com/11081>])
- Some queries were slower in 5.0 than in 4.1 because some 4.1 cost-evaluation code had not been merged into 5.0. (Bug#14292 [<http://bugs.mysql.com/14292>])
- Index prefixes for `utf8 VARCHAR` columns did not work for `UPDATE` statements. (Bug#19080 [<http://bugs.mysql.com/19080>])
- InnoDB does not support `SPATIAL` indexes, but did not prevent creation of such an index. (Bug#15860 [<http://bugs.mysql.com/15860>])
- The configuration information for building the embedded server on Windows was missing a file. (Bug#18455 [<http://bugs.mysql.com/18455>])
- The parser leaked memory when its stack needed to be extended. (Bug#18930 [<http://bugs.mysql.com/18930>])
- When `myisamchk` needed to rebuild a table, `AUTO_INCREMENT` information was lost. (Bug#10405 [<http://bugs.mysql.com/10405>])
- `LOAD DATA FROM MASTER` would fail when trying to load the `INFORMATION_SCHEMA` database from the master, because the `INFORMATION_SCHEMA` system database would already exist on the slave. (Bug#18607 [<http://bugs.mysql.com/18607>])
- The binary log would create an incorrect `DROP` query when creating temporary tables during replication. (Bug#17263 [<http://bugs.mysql.com/17263>])
- NDB Cluster: Stopping multiple nodes could cause node failure handling not to be completed. (Bug#19039 [<http://bugs.mysql.com/19039>])
- NDB Cluster: `ndbd` could sometimes fail to start with the error Node failure handling not completed following a graceful restart. (Bug#18550 [<http://bugs.mysql.com/18550>])
- NDB Cluster: Backups could fail for large clusters with many tables, where the number of tables approached `MaxNoOfTables`. (Bug#17607 [<http://bugs.mysql.com/17607>])
- The `IN-to-EXISTS` transformation was making a reference to a parse tree fragment that was left out of the parse tree. This caused problems with prepared statements. (Bug#18492 [<http://bugs.mysql.com/18492>])
- In `mysqltest`, `--sleep=0` had no effect. Now it correctly causes `sleep` commands in test case files to sleep for 0 seconds. (Bug#18312 [<http://bugs.mysql.com/18312>])
- Attempting to set the default value of an `ENUM` or `SET` column to `NULL` caused a server crash. (Bug#19145 [<http://bugs.mysql.com/19145>])
- The `sql_notes` and `sql_warnings` system variables were not always displayed correctly by `SHOW VARIABLES` (for example, they were displayed as `ON` after being set to `OFF`). (Bug#16195 [<http://bugs.mysql.com/16195>])

- The `sql_big_selects` system variable was not displayed by `SHOW VARIABLES`. (Bug#17849 [<http://bugs.mysql.com/17849>])
- The `system_time_zone` and `version_*` system variables could not be accessed via `SELECT @@var_name` syntax. (Bug#12792 [<http://bugs.mysql.com/12792>], Bug#15684 [<http://bugs.mysql.com/15684>])
- Flushing the compression buffer (via `FLUSH TABLE`) no longer increases the size of an unmodified ARCHIVE table. (Bug#19204 [<http://bugs.mysql.com/19204>])

## D.1.2. Changes in release 5.0.21 (02 May 2006)

This is a bugfix release for the current production release family.

This MySQL 5.0.21 release includes the patches for recently reported security vulnerabilities in the MySQL client-server protocol. We would like to thank Stefano Di Paola <[stefano.dipaola@wisec.it](mailto:stefano.dipaola@wisec.it)> for finding and reporting these to us.

This section documents all changes and bug fixes that have been applied since the last official MySQL release. If you would like to receive more fine-grained and personalised *update alerts* about fixes that are relevant to the version and features you use, please consider subscribing to *MySQL Network* (a commercial MySQL offering). For more details please see <http://www.mysql.com/network/advisors.html>.

Functionality added or changed:

- **Security enhancement:** Added the global `max_prepared_stmt_count` system variable to limit the total number of prepared statements in the server. This limits the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. The current number of prepared statements is available through the `prepared_stmt_count` system variable. (Bug#16365 [<http://bugs.mysql.com/16365>])
- The `MySQL-shared-compat-5.0.X-i386.rpm` shared compatibility RPMs no longer contain libraries for MySQL 5.1. This avoids a conflict because the 5.0 and 5.1 libraries share the same soname number. It contains libraries for 3.23, 4.0, 4.1, and 5.0. (Bug#19288 [<http://bugs.mysql.com/19288>])
- Creating a table in an InnoDB database with a column name that matched the name of an internal InnoDB column (including `DB_ROW_ID`, `DB_TRX_ID`, `DB_ROLL_PTR` and `DB_MIX_ID`) would cause a crash. MySQL now returns error 1005 (cannot create table) with `errno` set to -1. (Bug#18934 [<http://bugs.mysql.com/18934>])
- NDB Cluster: It is now possible to perform a partial start of a cluster. That is, it is now possible to bring up the cluster without running `ndbd --initial` on all configured data nodes first. (Bug#18606 [<http://bugs.mysql.com/18606>])
- NDB Cluster: It is now possible to install MySQL with Cluster support to a non-default location and change the search path for font description files using either the `--basedir` or `--character-sets-dir` options. (Previously in MySQL 5.0, `ndbd` searched only the default path for character sets.)
- In result set metadata, the `MYSQL_FIELD.length` value for BIT columns now is reported in number of bits. For example, the value for a `BIT(9)` column is 9. (Formerly, the value was related to number of bytes.) (Bug#13601 [<http://bugs.mysql.com/13601>])
- The default for the `innodb_thread_concurrency` system variable was changed to 8. (Bug#15868 [<http://bugs.mysql.com/15868>])

Bugs fixed:

- **Security fix:** A malicious client, using specially crafted invalid login or COM\_TABLE\_DUMP packets was able to read uninitialized memory, which potentially, though unlikely in MySQL, could have led to an information disclosure. (CVE-2006-1516 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-1516>], CVE-2006-1517 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-1517>]) Thanks to Stefano Di Paola <[stefano.dipaola@wisec.it](mailto:stefano.dipaola@wisec.it)> for finding and reporting this bug.
- **Security fix:** A malicious client, using specially crafted invalid COM\_TABLE\_DUMP packets was able to trigger an exploitable buffer overflow on the server. (CVE-2006-1518 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2006-1518>]) Thanks to Stefano Di Paola <[stefano.dipaola@wisec.it](mailto:stefano.dipaola@wisec.it)> for finding and reporting this bug.
- NDB Cluster: A simultaneous DROP TABLE and table update operation utilising a table scan could trigger a node failure. (Bug#18597 [<http://bugs.mysql.com/18597>])
- mysql-test-run could not be run as root. (Bug#17002 [<http://bugs.mysql.com/17002>])
- MySQL-shared-compat-5.0.13-0.i386.rpm, MySQL-  
shared-compat-5.0.15-0.i386.rpm, MySQL-  
shared-compat-5.0.18-0.i386.rpm, MySQL-  
shared-compat-5.0.19-0.i386.rpm, MySQL-  
shared-compat-5.0.20-0.i386.rpm, and MySQL-  
shared-compat-5.0.20a-0.i386.rpm incorrectly depended on glibc 2.3 and could not be installed on a glibc 2.2 system. (Bug#16539 [<http://bugs.mysql.com/16539>])
- IA-64 RPM packages for Red Hat and SuSE Linux that were built with the icc compiler incorrectly depended on icc runtime libraries. (Bug#16662 [<http://bugs.mysql.com/16662>])
- Updates to a MEMORY table caused the size of BTREE indexes for the table to increase. (Bug#18610 [<http://bugs.mysql.com/18610>])
- REPAIR TABLE did not restore the length for packed keys in tables created under MySQL 4.x. (Bug#17810 [<http://bugs.mysql.com/17810>])
- After calling FLUSH STATUS, the max\_used\_connections variable did not increment for existing connections and connections which use the thread cache. (Bug#15933 [<http://bugs.mysql.com/15933>])
- MySQL would not compile on Linux distributions that use the tinfo library. (Bug#18912 [<http://bugs.mysql.com/18912>])
- Within a trigger, CONNECTION\_ID() did not return the connection ID of the thread that caused the trigger to be activated. (Bug#16461 [<http://bugs.mysql.com/16461>])
- The yaSSL library returned a cipher list in a manner incompatible with OpenSSL. (Bug#18399 [<http://bugs.mysql.com/18399>])
- For single-SELECT union constructs of the form (SELECT ... ORDER BY *order\_list1* [LIMIT *n*]) ORDER BY *order\_list2*, the ORDER BY lists were concatenated and the LIMIT clause was ignored. (Bug#18767 [<http://bugs.mysql.com/18767>])
- CREATE VIEW statements would not be replicated to the slave if the --replicate-wild-ignore-table rule was enabled. (Bug#18715 [<http://bugs.mysql.com/18715>])
- Index corruption could occur in cases when key\_cache\_block\_size was not a multiple of myisam\_block\_size (for example, with key\_cache\_block\_size=1536 and myisam\_block\_size=1024). (Bug#19079 [<http://bugs.mysql.com/19079>])
- LAST\_INSERT\_ID() in a stored function or trigger returned zero. . (Bug#15728 [<http://bugs.mysql.com/15728>])
- Use of CONVERT\_TZ() in a view definition could result in spurious syntax or access errors.

Bug#15153 [<http://bugs.mysql.com/15153>])

- UNCOMPRESS(NULL) could cause subsequent UNCOMPRESS( ) calls to return NULL for legal non-NULL arguments. (Bug#18643 [<http://bugs.mysql.com/18643>])
- Conversion of a number to a CHAR UNICODE string returned an invalid result. (Bug#18691 [<http://bugs.mysql.com/18691>])
- DELETE and UPDATE statements that used large NOT IN (*value\_list*) clauses could use large amounts of memory. (Bug#15872 [<http://bugs.mysql.com/15872>])
- Prevent recursive views caused by using RENAME TABLE on a view after creating it. (Bug#14308 [<http://bugs.mysql.com/14308>])
- A LOCK TABLES statement that failed could cause MyISAM not to update table statistics properly, causing a subsequent CHECK TABLE to report table corruption. (Bug#18544 [<http://bugs.mysql.com/18544>])
- For a reference to a non-existent stored function in a stored routine that had a CONTINUE handler, the server continued as though a useful result had been returned, possibly resulting in a server crash. (Bug#18787 [<http://bugs.mysql.com/18787>])
- InnoDB did not use a consistent read for CREATE ... SELECT when innodb\_locks\_unsafe\_for\_binlog was set. (Bug#18350 [<http://bugs.mysql.com/18350>])
- InnoDB could read a delete mark from its system tables incorrectly. (Bug#19217 [<http://bugs.mysql.com/19217>])
- Corrected a syntax error in mysql-test-run.sh. (Bug#19190 [<http://bugs.mysql.com/19190>])
- A missing DEBUG\_RETURN( ) caused the server to emit a spurious error message: missing DEBUG\_RETURN or DEBUG\_VOID\_RETURN macro in function "open\_table". (Bug#18964 [<http://bugs.mysql.com/18964>])
- DROP DATABASE did not drop stored routines associated with the database if the database name was longer than 21 characters. (Bug#18344 [<http://bugs.mysql.com/18344>])
- Avoid trying to include <asm/atomic.h> when it doesn't work in C++ code. (Bug#13621 [<http://bugs.mysql.com/13621>])
- Executing SELECT on a large table that had been compressed within myisampack could cause a crash. (Bug#17917 [<http://bugs.mysql.com/17917>])
- NDB Cluster: When attempting to create an index on a BIT or BLOB column, Error 743: Unsupported character set in table or index was returned instead of Error 906: Unsupported attribute type in index.
- Within stored routines, usernames were parsed incorrectly if they were enclosed within quotes. (Bug#13310 [<http://bugs.mysql.com/13310>])
- Casting a string to DECIMAL worked, but casting a trimmed string (using LTRIM( ) or RTRIM( )) resulted in loss of decimal digits. (Bug#17043 [<http://bugs.mysql.com/17043>])
- NDB Cluster: On slow networks or CPUs, the management client SHOW command could sometimes erroneously show all data nodes as being master nodes belonging to nodegroup 0. (Bug#15530 [<http://bugs.mysql.com/15530>])
- If the second or third argument to BETWEEN was a constant expression such as '2005-09-01 - INTERVAL 6 MONTH and the other two arguments were columns, BETWEEN was evaluated incorrectly. (Bug#18618 [<http://bugs.mysql.com/18618>])
- If the first argument to BETWEEN was a DATE or TIME column of a view and the other arguments were constants, BETWEEN did not perform conversion of the constants to the appropriate

temporary type, resulting in incorrect evaluation. (Bug#16069 [<http://bugs.mysql.com/16069>])

- Server and clients ignored the `--sysconfdir` option that was passed to `configure`. (Bug#15069 [<http://bugs.mysql.com/15069>])
  - NDB Cluster: In a 2-node cluster with a node failure, restarting the node with a low value for `StartPartialTimeout` could cause the cluster to come up partitioned (“split-brain” issue). (Bug#16447 [<http://bugs.mysql.com/16447>])
- A similar issue could occur when the cluster was first started with a sufficiently low value for this parameter. (Bug#18612 [<http://bugs.mysql.com/18612>])
- NDB Cluster: On systems with multiple network interfaces, data nodes would get “stuck” in startup phase 2 if the interface connecting them to the management server was working on node startup while the interface interconnecting the data nodes experienced a temporary outage. (Bug#15695 [<http://bugs.mysql.com/15695>])
  - NDB Cluster: Unused open handlers for tables in which the metadata had changed were not properly closed. This could result in stale results from Cluster tables following an `ALTER TABLE`. (Bug#13228 [<http://bugs.mysql.com/13228>])
  - NDB Cluster: Uninitialised internal variables could lead to unexpected results. (Bug#11033 [<http://bugs.mysql.com/11033>], Bug#11034 [<http://bugs.mysql.com/11034>])
  - For InnoDB tables, an expression of the form `col_name BETWEEN col_name2 - INTERVAL x DAY AND col_name2 + INTERVAL x DAY` when used in a join returned incorrect results. (Bug#14360 [<http://bugs.mysql.com/14360>])
  - `INSERT DELAYED` into a view caused an infinite loop. (Bug#13683 [<http://bugs.mysql.com/13683>])
  - Lettercase in database name qualifiers was not consistently handled properly in queries when `lower_case_table_names` was set to 1. (Bug#15917 [<http://bugs.mysql.com/15917>])
  - The optimizer could cause a server crash or use a non-optimal subset of indexes when evaluating whether to use `Index Merge/Intersection` variant of `index_merge` optimization. (Bug#19021 [<http://bugs.mysql.com/19021>])
  - The presence of multiple equalities in a condition after reading a constant table could cause the optimizer not to use an index. This resulted in certain queries being much slower than in MySQL 4.1. (Bug#16504 [<http://bugs.mysql.com/16504>])
  - A recent change caused the `mysql` client not to display `NULL` values correctly and to display numeric columns left-justified rather than right-justified. The problems have been corrected. (Bug#18265 [<http://bugs.mysql.com/18265>])
  - `mysql_reconnect()` sent a `SET NAMES` statement to the server, even for pre-4.1 servers that do not understand the statement. (Bug#18830 [<http://bugs.mysql.com/18830>])
  - `COUNT(*)` on a MyISAM table could return different results for the base table and a view on the base table. (Bug#18237 [<http://bugs.mysql.com/18237>])
  - `DELETE` with `LEFT JOIN` for InnoDB tables could crash the server if `innodb_locks_unsafe_for_binlog` was enabled. (Bug#15650 [<http://bugs.mysql.com/15650>])
  - InnoDB failure to release an adaptive hash index latch could cause a server crash if the query cache was enabled. (Bug#15758 [<http://bugs.mysql.com/15758>])
  - For `mysql.server`, if the `basedir` option was specified after `datadir` in an option file, the setting for `datadir` was ignored and assumed to be located under `basedir`. (Bug#16240 [<http://bugs.mysql.com/16240>])
  - The euro sign (€) was not stored correctly in columns using the `latin1_german1_ci` or

latin1\_general\_ci collation. (Bug#18321 [<http://bugs.mysql.com/18321>])

- `EXTRACT(QUARTER FROM date)` returned unexpected results. (Bug#18100 [<http://bugs.mysql.com/18100>])
- `TRUNCATE` did not reset the `AUTO_INCREMENT` counter for MyISAM tables when issued inside a stored procedure. (Bug#14945 [<http://bugs.mysql.com/14945>])  
**Note:** This bug did not affect InnoDB tables. Also, `TRUNCATE` does not reset the `AUTO_INCREMENT` counter for NDBCluster tables regardless of when it is called (see Bug#18864 [<http://bugs.mysql.com/18864>]).
- The server was always built as though `--with-extra-charsets=complex` had been specified. (Bug#12076 [<http://bugs.mysql.com/12076>])
- A query using `WHERE (column_1, column_2) IN ((value_1, value_2)[, (...), ...])` would return incorrect results. (Bug#16248 [<http://bugs.mysql.com/16248>])
- Queries of the form `SELECT DISTINCT timestamp_column WHERE date_function(timestamp_col) = constant` did not return all matching rows. (Bug#16710 [<http://bugs.mysql.com/16710>])
- When running a query that contained a `GROUP_CONCAT( SELECT GROUP_CONCAT(...))`, the result was `NULL` except in the `ROLLUP` part of the result, if there was one. (Bug#15560 [<http://bugs.mysql.com/15560>])
- For tables created in a MySQL 4.1 installation upgraded to MySQL 5.0 and up, multiple-table updates could update only the first matching row. (Bug#16281 [<http://bugs.mysql.com/16281>])
- NDB Cluster: When multiple node restarts were attempted without allowing each restart to complete, the error message returned was Array index out of bounds rather than Too many crashed replicas. (Bug#18349 [<http://bugs.mysql.com/18349>])
- `CAST(double AS SIGNED INT)` for large `double` values outside the signed integer range truncates the result to be within range, but the result sometimes had the wrong sign, and no warning was generated. (Bug#15098 [<http://bugs.mysql.com/15098>])
- Updating a field value when also requesting a lock with `GET_LOCK( )` would cause slave servers in a replication environment to terminate. (Bug#17284 [<http://bugs.mysql.com/17284>])

### D.1.3. Changes in release 5.0.20a (18 April 2006)

This is a bugfix release for the current production release family. It replaces MySQL 5.0.20.

Changes from 5.0.20 to 5.0.20a:

- The fix for “Command line options are ignored for mysql client” (Bug#16855 [<http://bugs.mysql.com/16855>]) has been revoked because it introduced an incompatible change in the way the `mysql` command-line client selects the server to connect to. In the worst case, this might have led to a client issuing commands to a server for which they were not intended, and this must not happen. To help all users in understanding this subject, Section 4.2, “Invoking MySQL Programs” now includes additional explanation of how command options with regard to host selection.
- The code of the `yaSSL` library has been improved to avoid the dependency on a C++ runtime library, so a link with pure C applications is now possible on additional (but not yet all) platforms. We are working on fixing the remaining issues.

Additional information about SSL support:

- With version 5.0.20a, SSL support is contained in all binaries for all Unix (including Linux) and Windows platforms except AIX, HP-UX, OpenServer 6, and the RPMs specific for RHAS3/RHAS4/SLES9 on Itanium CPUs (ia64); It is also not contained in those for Novell Netware. We are trying to add these platforms in future versions.
- Please note that the original 5.0.20 announcement included inexact wording: SSL support is “included” in both server and client, but by default not “enabled”. SSL can be enabled by passing the SSL-related options (`--ssl`, `--ssl-key=...`, `--ssl-cert=...`, `--ssl-ca=...`) when starting the server and the client or by specifying these options in an option file. For more information, see Section 5.9.7, “Using Secure Connections”.

## D.1.4. Changes in release 5.0.20 (31 March 2006)

Functionality added or changed:

- Added the `--sysdate-is-now` option to `mysqld` to enable `SYSDATE()` to be treated as an alias for `NOW()`. See Section 12.5, “Date and Time Functions”. (Bug#15101 [<http://bugs.mysql.com/15101>])
- InnoDB: The InnoDB storage engine now provides a descriptive error message if `ibdata` file information is omitted from `my.cnf`. (Bug#16827 [<http://bugs.mysql.com/16827>])
- The NDBCluster storage engine now supports `INSERT IGNORE` and `REPLACE` statements. Previously, these statements failed with an error. (Bug#17431 [<http://bugs.mysql.com/17431>])
- Builds for Windows, Linux, and Unix (except AIX) platforms now have SSL support enabled, in the server as well as in the client libraries. Because part of the SSL code is written in C++, this does introduce dependencies on the system's C++ runtime libraries in several cases, depending on compiler specifics. (Bug#18195 [<http://bugs.mysql.com/18195>])
- The syntax for `CREATE PROCEDURE` and `CREATE FUNCTION` statements now includes a `DEFINER` clause. The `DEFINER` value specifies the security context to be used when checking access privileges at routine invocation time if the routine has the `SQL SECURITY DEFINER` characteristic. See Section 17.2.1, “`CREATE PROCEDURE` and `CREATE FUNCTION` Syntax”, for more information.

When `mysqldump` is invoked with the `--routines` option, it now dumps the `DEFINER` value for stored routines.

- Large file support added to build for QNX platform. (Bug#17336 [<http://bugs.mysql.com/17336>])
- Large file support was re-enabled for the MySQL server binary for the AIX 5.2 platform. (Bug#13571 [<http://bugs.mysql.com/13571>])

Bugs fixed:

- If the `WHERE` condition of a query contained an OR-ed `FALSE` term, the set of tables whose rows cannot serve for null-complements in outer joins was determined incorrectly. This resulted in blocking possible conversions of outer joins into joins by the optimizer for such queries. (Bug#17164 [<http://bugs.mysql.com/17164>])
- `mysql_config` returned incorrect libraries on `x86_64` systems. (Bug#13158 [<http://bugs.mysql.com/13158>])
- Stored routine names longer than 64 characters were silently truncated. Now the limit is properly enforced and an error occurs. (Bug#17015 [<http://bugs.mysql.com/17015>])
- During conversion from one character set to `ucs2`, multi-byte characters with no `ucs2` equivalent were converted to multiple characters, rather than to `0x003F QUESTION MARK`.

Bug#15375 [<http://bugs.mysql.com/15375>])

- The `mysql_close()` C API function leaked handles for shared-memory connections on Windows. (Bug#15846 [<http://bugs.mysql.com/15846>])
- Checks for permissions on database operations could be performed in a case-insensitive manner (a user with permissions on database `MYDATABASE` could by accident get permissions on database `myDataBase`), if the privilege data were still cached from a previous check. (Bug#17279 [<http://bugs.mysql.com/17279>])
- If InnoDB ran out of buffer space for row locks and adaptive hashes, the server would crash. Now InnoDB rolls back the transaction. (Bug#18238 [<http://bugs.mysql.com/18238>])
- InnoDB tables with an adaptive hash blocked other queries during `CHECK TABLE` statements while the entire hash was checked. This could be a long time for a large hash. (Bug#17126 [<http://bugs.mysql.com/17126>])
- For InnoDB tables created in MySQL 4.1 or earlier, or created in 5.0 or later with compact format, updating a row so that a long column is updated or the length of some column changes, InnoDB later would fail to reclaim the BLOB storage space if the row was deleted. (Bug#18252 [<http://bugs.mysql.com/18252>])
- InnoDB had a memory leak for duplicate-key errors with tables having 90 columns or more. (Bug#18384 [<http://bugs.mysql.com/18384>])
- InnoDB: The `LATEST FOREIGN KEY ERROR` section in the output of `SHOW INNODB STATUS` was sometimes formatted incorrectly, causing problems with scripts that parsed the output of this statement. (Bug#16814 [<http://bugs.mysql.com/16814>])
- When using `ORDER BY` with a non-string column inside `GROUP_CONCAT()` the result's character set was converted to binary. (Bug#18281 [<http://bugs.mysql.com/18281>])

See also Bug#14169 [<http://bugs.mysql.com/14169>].

- `SELECT ... WHERE column LIKE 'A%'` when `column` had a key and used the `latin2_czech_cs` collation. (Bug#17374 [<http://bugs.mysql.com/17374>])
- Complex queries with nested joins could cause a server crash. (Bug#18279 [<http://bugs.mysql.com/18279>])
- The server could deadlock under heavy load while writing to the binary log. (Bug#18116 [<http://bugs.mysql.com/18116>])
- A `SELECT ... ORDER BY ...` from a view defined using a function could crash the server. An example of such a view might be `CREATE VIEW AS SELECT SQRT(c1) FROM t1`. (Bug#18386 [<http://bugs.mysql.com/18386>])
- A `DELETE` using a subquery could crash the server. (Bug#18306 [<http://bugs.mysql.com/18306>])
- `REPAIR TABLE`, `OPTIMIZE TABLE`, and `ALTER TABLE` operations on transactional tables (or on tables of any type on Windows) could corrupt triggers associated with those tables. (Bug#18153 [<http://bugs.mysql.com/18153>])
- MyISAM: Performing a bulk insert on a table referenced by a trigger would crash the table. (Bug#17764 [<http://bugs.mysql.com/17764>])
- MyISAM: Keys for which the first part of the key was a `CHAR` or `VARCHAR` column using the UTF-8 character set and longer than 254 bytes could become corrupted. (Bug#17705 [<http://bugs.mysql.com/17705>])
- Using `ORDER BY intvar` within a stored procedure (where `intvar` is an integer variable or expression) would crash the server. (Bug#16474 [<http://bugs.mysql.com/16474>])

**Note:** The use of an integer *i* in an `ORDER BY i` clause for sorting the result by the *i*<sup>th</sup> column is deprecated (and non-standard). It should *not* be used in new applications. See Section 13.2.7, “SELECT Syntax”.

- Triggers created in MySQL 5.0.16 and earlier could not be dropped after upgrading the server to 5.0.17 or later. (Bug#15921 [<http://bugs.mysql.com/15921>])
- A `SELECT` using a function against a nested view would crash the server. (Bug#15683 [<http://bugs.mysql.com/15683>])
- NDB Cluster: Certain queries using `ORDER BY ... ASC` in the `WHERE` clause could return incorrect results. (Bug#17729 [<http://bugs.mysql.com/17729>])
- NDB Cluster: A timeout in the handling of an `ABORT` condition with more than 32 operations could yield a node failure. (Bug#18414 [<http://bugs.mysql.com/18414>])
- NDB Cluster: A node restart immediately following a `CREATE TABLE` would fail. **Important:** This fix supports 2-node Clusters only. (Bug#18385 [<http://bugs.mysql.com/18385>])
- NDB Cluster: In event of a node failure during a rollback, a “false” lock could be established on the backup for that node, which lock could not be removed without restarting the node. (Bug#18352 [<http://bugs.mysql.com/18352>])
- NDB Cluster: The cluster created a crashed replica of a table having an ordered index — or when logging was not enabled, of a table having a table or unique index — leading to a crash of the cluster following 8 successive restarts. (Bug#18298 [<http://bugs.mysql.com/18298>])
- NDB Cluster: When replacing a failed master node, the replacement node could cause the cluster to crash from a buffer overflow if it had an excessively large amount of data to write to the cluster log. (Bug#18118 [<http://bugs.mysql.com/18118>])
- NDB Cluster: If a `mysql` or other client could not parse the result set returned from a `mysqld` process acting as an SQL node in a cluster, the client would crash instead of returning the appropriate error. For example, this could happen when the client attempted to use a character set was not available to the `mysqld`. (Bug#17380 [<http://bugs.mysql.com/17380>])
- NDB Cluster: Restarting nodes were allowed to start and join the cluster too early. (Bug#16772 [<http://bugs.mysql.com/16772>])
- If a row was inserted inside a stored procedure using the parameters passed to the procedure in the `INSERT` statement, the resulting binlog entry was not escaped properly. (Bug#18293 [<http://bugs.mysql.com/18293>])
- If InnoDB encountered a `HA_ERR_LOCK_TABLE_FULL` error and rolled-back a transaction, the transaction was still written to the binary log. (Bug#18283 [<http://bugs.mysql.com/18283>])
- Stored procedures that call UDFs and pass local string variables caused server crashes. (Bug#17261 [<http://bugs.mysql.com/17261>])
- Connecting to a server with a UCS2 default character set with a client using a non-UCS2 character set crashed the server. (Bug#18004 [<http://bugs.mysql.com/18004>])
- Loading of UDFs in a statically linked MySQL caused a server crash. UDF loading is now blocked if the MySQL server is statically linked. (Bug#11835 [<http://bugs.mysql.com/11835>])
- Views that incorporate tables from the `INFORMATION_SCHEMA` resulted in a server crash when queried. (Bug#18224 [<http://bugs.mysql.com/18224>])
- A `SELECT *` query on an `INFORMATION_SCHEMA` table by a user with limited privileges resulted in a server crash. (Bug#18113 [<http://bugs.mysql.com/18113>])
- Attempting to access an InnoDB table after starting the server with `--skip-innodb` caused a server crash. (Bug#14575 [<http://bugs.mysql.com/14575>])

- InnoDB used table locks (not row locks) within stored functions. (Bug#18077 [<http://bugs.mysql.com/18077>])
- Replication slaves could not replicate triggers from older servers that included no `DEFINER` clause in the trigger definition. Now the trigger executes with the privileges of the invoker (which on the slave is the slave SQL thread). (Bug#16266 [<http://bugs.mysql.com/16266>])
- Character set conversion of string constants for `UNION` of constant and table column was not done when it was safe to do so. (Bug#15949 [<http://bugs.mysql.com/15949>])
- The `DEFINER` value for stored routines was not replicated. (Bug#15963 [<http://bugs.mysql.com/15963>])
- Use of stored functions with `DISTINCT` or `GROUP BY` can produce incorrect results when `ORDER BY` is also used. (Bug#13575 [<http://bugs.mysql.com/13575>])
- Use of `TRUNCATE TABLE` for a `TEMPORARY` table on a master server was propagated to slaves properly, but slaves did not decrement the `Slave_open_temp_tables` counter properly. (Bug#17137 [<http://bugs.mysql.com/17137>])
- `SELECT COUNT(*)` for a `MyISAM` table could return different results depending on whether an index was used. (Bug#14980 [<http://bugs.mysql.com/14980>])
- A `LEFT JOIN` with a `UNION` that selects literal values could crash the server. (Bug#17366 [<http://bugs.mysql.com/17366>])
- Large file support did not work in AIX server binaries. (Bug#10776 [<http://bugs.mysql.com/10776>])
- Updating a view that filters certain rows to set a filtered out row to be included in the table caused infinite loop. For example, if the view has a `WHERE` clause of `salary > 100` then issuing an `UPDATE` statement of `SET salary = 200 WHERE id = 10`, caused an infinite loop. (Bug#17726 [<http://bugs.mysql.com/17726>])
- Certain combinations of joins with mixed `ON` and `USING` clauses caused unknown column errors. (Bug#15229 [<http://bugs.mysql.com/15229>])
- NDB Cluster: Inserting and deleting BLOB column values while a backup was in process could cause the loss of an `ndbd` node. (Bug#14028 [<http://bugs.mysql.com/14028>])
- If the server was started with the `--skip-grant-tables` option, it was impossible to create a trigger or a view without explicitly specifying a `DEFINER` clause. (Bug#16777 [<http://bugs.mysql.com/16777>])
- `COUNT(DISTINCT col1, col2)` and `COUNT(DISTINCT CONCAT(col1, col2))` operations produced different results if one of the columns was an indexed `DECIMAL` column. (Bug#15745 [<http://bugs.mysql.com/15745>])
- The server displayed garbage in the error message warning about bad assignments to `DECIMAL` columns or routine variables. (Bug#15480 [<http://bugs.mysql.com/15480>])
- The server would execute stored routines that had a non-existent definer. (Bug#13198 [<http://bugs.mysql.com/13198>])
- For `FEDERATED` tables, a `SELECT` statement with an `ORDER BY` clause did not return rows in the proper order. (Bug#17377 [<http://bugs.mysql.com/17377>])
- The `FORMAT()` function returned an incorrect result when the client's `character_set_connection` value was `utf8`. (Bug#16678 [<http://bugs.mysql.com/16678>])
- NDB Cluster: Some query cache statistics were not always correctly reported for Cluster tables. (Bug#16795 [<http://bugs.mysql.com/16795>])
- Updating the value of a Unicode `VARCHAR` column with the result returned by a stored function

would cause the insertion of ASCII characters into the column instead of Unicode, even where the function's return type was also declared as Unicode. (Bug#17615 [<http://bugs.mysql.com/17615>])

## D.1.5. Changes in release 5.0.19 (04 March 2006)

Functionality added or changed:

- **Incompatible change:** The InnoDB storage engine no longer ignores trailing spaces when comparing BINARY or VARBINARY column values. This means that (for example) the binary values 'a' and 'a ' are now regarded as *unequal* any time they are compared, as they are in MyISAM tables. (Bug#14189 [<http://bugs.mysql.com/14189>])

See Section 11.4.2, “The BINARY and VARBINARY Types” for more information about the BINARY and VARBINARY types.

- Several changes were made to make upgrades easier:
  - Added the `mysql_upgrade` program that checks all tables for incompatibilities with the current version of MySQL Server and repairs them if necessary. This program should be run for each MySQL upgrade (rather than `mysql_fix_privilege_tables`). See Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.
  - Added the `FOR UPGRADE` option for the `CHECK TABLE` statement. This option checks whether tables are incompatible with the current version of MySQL Server.
  - Added the `--check-upgrade` to `mysqlcheck` that invokes `CHECK TABLE` with the `FOR UPGRADE` option.
- NDB Cluster: The `ndb_mgm` client commands `node_id START` and `node_id STOP` now work with management nodes as well as data nodes. (However, using `ALL` for the `node_id` continues to affect all data nodes only.)
- When using the `GROUP_CONCAT()` function where the `group_concat_max_len` system variable was greater than 512, the type of the result was BLOB only if the query included an `ORDER BY` clause; otherwise the result was a VARCHAR.

The result type of the `GROUP_CONCAT()` function is now VARCHAR only if the value of the `group_concat_max_len` system variable is less than or equal to 512. Otherwise, this function returns a BLOB. (Bug#14169 [<http://bugs.mysql.com/14169>])

- `mysql` no longer terminates data value display when it encounters a NUL byte. Instead, it displays NUL bytes as spaces. (Bug#16859 [<http://bugs.mysql.com/16859>])
- Added the `--wait-timeout` option to `mysqlmanager` to allow configuration of the timeout for dropping an inactive connection, and increased the default timeout from 30 seconds to 28,800 seconds (8 hours). (Bug#12674 [<http://bugs.mysql.com/12674>], Bug#15980 [<http://bugs.mysql.com/15980>])
- A number of performance issues were resolved that had previously been encountered when using statements that repeatedly invoked stored functions. For example, calling `BENCHMARK()` using a stored function executed much more slowly than when invoking it with inline code that accomplished the same task. In most cases the two should now execute with approximately the same speed. (Bug#15014 [<http://bugs.mysql.com/15014>], Bug#14946 [<http://bugs.mysql.com/14946>])
- `libmysqlclient` now uses versioned symbols with GNU ld. (Bug#3074 [<http://bugs.mysql.com/3074>])
- NDB Cluster: More descriptive warnings are now issued when inappropriate logging parameters are set in `config.ini`. (Formerly, the warning issued was simply `Could not add log-`

file destination.) (Bug#11331 [<http://bugs.mysql.com/11331>])

- Added the `--port-open-timeout` option to `mysqld` to control how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. (Bug#15591 [<http://bugs.mysql.com/15591>])
- Repeated invocation of `my_init()` and `my_end()` caused corruption of character set data and connection failure. (Bug#6536 [<http://bugs.mysql.com/6536>])
- Two new Hungarian collations are included: `utf8_hungarian_ci` and `ucs2_hungarian_ci`. These support the correct sort order for Hungarian vowels. However, they do not support the correct order for sorting Hungarian consonant contractions; this issue will be fixed in a future release.
- Wording of error 1329 changed to No data - zero rows fetched, selected, or processed. (Bug#15206 [<http://bugs.mysql.com/15206>])
- The `INFORMATION_SCHEMA` now skips data contained in unlistable/unreadable directories rather than returning an error. (Bug#15851 [<http://bugs.mysql.com/15851>])
- InnoDB now caches a list of unflushed files instead of scanning for unflushed files during a table flush operation. This improves performance when `--innodb-file-per-table` is set on a system with a large number of InnoDB tables. (Bug#15653 [<http://bugs.mysql.com/15653>])
- The message for error 1109 changed from Unknown table ... in order clause to Unknown table ... in field list. (Bug#15091 [<http://bugs.mysql.com/15091>])
- The `mysqltest` utility now converts all CR/LF combinations to LF to allow test cases intended for Windows to work properly on UNIX-like systems. (Bug#13809 [<http://bugs.mysql.com/13809>])
- The `mysql_ping` function will now retry if the `reconnect` flag is set and error `CR_SERVER_LOST` is encountered during the first attempt to ping the server. (Bug#14057 [<http://bugs.mysql.com/14057>])
- `mysqldump` now surrounds the `DEFINER`, `SQL SECURITY DEFINER` and `WITH CHECK OPTION` clauses of a `CREATE VIEW` statement with "not in version" comments to prevent errors in earlier versions of MySQL. (Bug#14871 [<http://bugs.mysql.com/14871>])
- New `charset` command added to `mysql` command-line client. By typing `charset name` or `\C name` (such as `\C UTF8`), the client character set can be changed without reconnecting. (Bug#16217 [<http://bugs.mysql.com/16217>])
- Client API will now attempt reconnect on TCP/IP if the `reconnect` flag is set, as is the case with sockets. (Bug#2845 [<http://bugs.mysql.com/2845>])

Bugs fixed:

- Cursors in stored routines could cause a server crash. (Bug#16887 [<http://bugs.mysql.com/16887>])
- Setting the `myisam_repair_threads` system variable to a value larger than 1 could cause corruption of large MyISAM tables. (Bug#11527 [<http://bugs.mysql.com/11527>])
- The length of a `VARCHAR()` column that used the `utf8` character set would increase each time the table was re-created in a stored procedure or prepared statement, eventually causing the `CREATE TABLE` statement to fail. (Bug#13134 [<http://bugs.mysql.com/13134>])
- `type_decimal` failed with the prepared statement protocol. (Bug#17826 [<http://bugs.mysql.com/17826>])
- The MySQL server could crash with out of memory errors when performing aggregate functions

on a DECIMAL column. (Bug#17602 [<http://bugs.mysql.com/17602>])

- A stored procedure failed to return data the first time it was called per connection. (Bug#17476 [<http://bugs.mysql.com/17476>])
- Using DROP FUNCTION IF EXISTS *func\_name* to drop a user-defined function caused a server crash if the server was running with the --skip-grant-tables option. (Bug#17595 [<http://bugs.mysql.com/17595>])
- Using ALTER TABLE to increase the length of a BINARY(*M*) column caused column values to be padded with spaces rather than 0x00 bytes. (Bug#16857 [<http://bugs.mysql.com/16857>])
- A large BIGINT value specified in a WHERE clause could be treated differently depending on whether it is specified as a quoted string. (For example, WHERE bigint\_col = 17666000000000000000 versus WHERE bigint\_col = '17666000000000000000'). (Bug#9088 [<http://bugs.mysql.com/9088>])
- A natural join between INFORMATION\_SCHEMA tables failed. (Bug#17523 [<http://bugs.mysql.com/17523>])
- A memory leak caused warnings on slaves for certain statements that executed without warning on the master. (Bug#16175 [<http://bugs.mysql.com/16175>])
- The embedded server did not allow binding of columns to the MYSQL\_TYPE\_VAR\_STRING data type in prepared statements. (Bug#12070 [<http://bugs.mysql.com/12070>])
- The embedded server failed various tests in the automated test suite. (Bug#9630 [<http://bugs.mysql.com/9630>], Bug#9631 [<http://bugs.mysql.com/9631>], Bug#9633 [<http://bugs.mysql.com/9633>], Bug#10801 [<http://bugs.mysql.com/10801>], Bug#10911 [<http://bugs.mysql.com/10911>], Bug#10924 [<http://bugs.mysql.com/10924>], Bug#10925 [<http://bugs.mysql.com/10925>], Bug#10926 [<http://bugs.mysql.com/10926>], Bug#10930 [<http://bugs.mysql.com/10930>], Bug#15433 [<http://bugs.mysql.com/15433>])
- Instance Manager erroneously accepted a list of instance identifiers for the START INSTANCE and STOP INSTANCE commands (should accept only a single identifier). (Bug#12813 [<http://bugs.mysql.com/12813>])
- For a transaction that used MyISAM and InnoDB tables, interruption of the transaction due to a dropped connection on a master server caused slaves to lose synchrony. (Bug#16559 [<http://bugs.mysql.com/16559>])
- SELECT with GROUP BY on a view can cause a server crash. (Bug#16382 [<http://bugs.mysql.com/16382>])
- If the query optimizer transformed a GROUP BY clause in a subquery, it did not also transform the HAVING clause if there was one, producing incorrect results. (Bug#16603 [<http://bugs.mysql.com/16603>])
- SUBSTRING\_INDEX() could yield inconsistent results when applied with the same arguments to consecutive rows in a query. (Bug#14676 [<http://bugs.mysql.com/14676>])
- The parser allowed CREATE AGGREGATE FUNCTION for creating stored functions, even though AGGREGATE does not apply. (It is used only for CREATE FUNCTION only when creating user-defined functions.) (Bug#16896 [<http://bugs.mysql.com/16896>])
- Data truncations on non-UNIQUE indexes could crash InnoDB when using multi-byte character sets. (Bug#17530 [<http://bugs.mysql.com/17530>])
- Triggers created without BEGIN and END clauses could not be properly restored from a mysqldump file. (Bug#16878 [<http://bugs.mysql.com/16878>])
- The RENAME TABLE statement did not move triggers to the new table. (Bug#13525 [<http://bugs.mysql.com/13525>])

- Clients compiled from source with the `--without-readline` did not save command history from session to session. (Bug#16557 [<http://bugs.mysql.com/16557>])
- Stored routines that contained only a single statement were not written properly to the dumpfile when using `mysqldump`. (Bug#14857 [<http://bugs.mysql.com/14857>])
- For certain `MERGE` tables, the optimizer wrongly assumed that using `index_merge/intersection` was too expensive. (Bug#17314 [<http://bugs.mysql.com/17314>])
- Executing a `SHOW CREATE VIEW` query of an invalid view caused the `mysql_next_result` function of `libMySQL.dll` to hang. (Bug#15943 [<http://bugs.mysql.com/15943>])
- `BIT` fields were not properly handled when using row-based replication. (Bug#13418 [<http://bugs.mysql.com/13418>])
- Issuing `GRANT EXECUTE` on a procedure would display any warnings related to the creation of the procedure. (Bug#7787 [<http://bugs.mysql.com/7787>])
- NDB Cluster: `ndb_delete_all` would run out of memory on tables containing `BLOB` columns. (Bug#16693 [<http://bugs.mysql.com/16693>])
- NDB Cluster: `UNIQUE` keys in Cluster tables were limited to 225 bytes in length. (Bug#15918 [<http://bugs.mysql.com/15918>])
- In a highly concurrent environment, a server crash or deadlock could result from execution of a statement that used stored functions or activated triggers coincident with alteration of the tables used by these functions or triggers. (Bug#16593 [<http://bugs.mysql.com/16593>])
- Previously, a stored function invocation was written to the binary log as `DO func_name()` if the invocation changes data and occurs within a non-logged statement, or if the function invokes a stored procedure that produces an error. These invocations now are logged as `SELECT func_name()` instead for better control over error code checking (slave servers could stop due to detecting a different error than occurred on the master). (Bug#14769 [<http://bugs.mysql.com/14769>])
- `CHECKSUM TABLE` returned different values on `MyISAM` table depending on whether the `QUICK` or `EXTENDED` options were used. (Bug#8841 [<http://bugs.mysql.com/8841>])
- MySQL server dropped client connection for certain `SELECT` statements against views defined that used `MERGE` algorithm. (Bug#16260 [<http://bugs.mysql.com/16260>])
- A call to the `IF()` function using decimal arguments could return incorrect results. (Bug#16272 [<http://bugs.mysql.com/16272>])
- A statement containing `GROUP BY` and `HAVING` clauses could return incorrect results when the `HAVING` clause contained logic that returned `FALSE` for every row. (Bug#14927 [<http://bugs.mysql.com/14927>])
- Using `GROUP BY` on column used in `WHERE` clause could cause empty set to be returned. (Bug#16203 [<http://bugs.mysql.com/16203>])
- For a MySQL 5.0 server, using MySQL 4.1 tables in queries with a `GROUP BY` clause could result in buffer overrun or a server crash. (Bug#16752 [<http://bugs.mysql.com/16752>])
- `SET sql_mode = N`, where  $N > 31$ , did not work properly. (Bug#13897 [<http://bugs.mysql.com/13897>])
- NDB Cluster: Cluster log file paths were truncated to 128 characters. They may now be as long as `MAX_PATH` (the maximum path length permitted by the operating system). (Bug#17411 [<http://bugs.mysql.com/17411>])
- The `mysql_stmt_store_result()` C API function could not be used for a prepared state-

- ment if a cursor had been opened for the statement. (Bug#14013 [<http://bugs.mysql.com/14013>])
- The `mysql_stmt_sqlstate()` C API function incorrectly returned an empty string rather than '00000' when no error occurred. (Bug#16143 [<http://bugs.mysql.com/16143>])
  - Using the `TRUNCATE()` function with a negative number for the second argument on a `BIGINT` column returned incorrect results. (Bug#8461 [<http://bugs.mysql.com/8461>])
  - Instance Manager searched wrong location for password file on some platforms. (Bug#16499 [<http://bugs.mysql.com/16499>])
  - NDB Cluster: Following multiple forced shutdowns and restarts of data nodes, `DROP DATABASE` could fail. (Bug#17325 [<http://bugs.mysql.com/17325>])
  - NDB Cluster: An `UPDATE` with an inner join failed to match any records if both tables in the join did not have a primary key. (Bug#17257 [<http://bugs.mysql.com/17257>])
  - NDB Cluster: A `DELETE` with a join in the `WHERE` clause failed to retrieve any records if both tables in the join did not have a primary key. (Bug#17249 [<http://bugs.mysql.com/17249>])
  - The error message returned by `pererror --ndb` was prefixed with OS error code: instead of NDB error code:. (Bug#17235 [<http://bugs.mysql.com/17235>])
  - NDB Cluster: In some cases, `LOAD DATA INFILE` did not load all data into NDB tables. (Bug#17081 [<http://bugs.mysql.com/17081>])
  - NDB Cluster: The `REDO` log would become corrupted (and thus unreadable) in some circumstances, due to a failure in the query handler. (Bug#17295 [<http://bugs.mysql.com/17295>])
  - NDB Cluster: No error message was generated for setting `NoOfFragmentLogFiles` too low. (Bug#13966 [<http://bugs.mysql.com/13966>])
  - NDB Cluster: No error message was generated for setting `MaxNoOfAttributes` too low. (Bug#13965 [<http://bugs.mysql.com/13965>])
  - Binary distributions for Solaris contained files with group ownership set to the non-existing `wheel` group. Now the `bin` group is used. (Bug#15562 [<http://bugs.mysql.com/15562>])
  - The `DECIMAL` data type was not being handled correctly with prepared statements. (Bug#16511 [<http://bugs.mysql.com/16511>])
  - The `SELECT` privilege was required for triggers that performed no selects. (Bug#15196 [<http://bugs.mysql.com/15196>])
  - The `UPDATE` privilege was required for triggers that performed no updates. (Bug#15166 [<http://bugs.mysql.com/15166>])
  - `CAST(... AS TIME)` operations returned different results when using versus not using prepared-statement protocol. (Bug#15805 [<http://bugs.mysql.com/15805>])
  - Improper memory handling for stored routine variables could cause memory overruns and binary log corruption. (Bug#15588 [<http://bugs.mysql.com/15588>])
  - Killing a long-running query containing a subquery could cause a server crash. (Bug#14851 [<http://bugs.mysql.com/14851>])
  - A `FULLTEXT` query in a prepared statement could result in unexpected behavior. (Bug#14496 [<http://bugs.mysql.com/14496>])
  - A `RETURN` statement within a trigger caused a server crash. `RETURN` now is disallowed within triggers. To exit immediately, use `LEAVE`. (Bug#16829 [<http://bugs.mysql.com/16829>])
  - `STR_TO_DATE(1, NULL)` caused a server crash. (Bug#15828 [<http://bugs.mysql.com/15828>])

- An invalid stored routine could not be dropped. (Bug#16303 [<http://bugs.mysql.com/16303>])
- When evaluation of the test in a CASE failed in a stored procedure that contained a CONTINUE handler, execution resumed at the beginning of the CASE statement instead of at the end. (Bug#16568 [<http://bugs.mysql.com/16568>])
- An INSERT statement in a stored procedure corrupted the binary log. (Bug#16621 [<http://bugs.mysql.com/16621>])
- When MyODBC or any other client called `my_init()/my_end()` several times, it caused corruption of charset data stored in `once_mem_pool`. (Bug#11892 [<http://bugs.mysql.com/11892>])
- When multiple handlers are created for the same MySQL error number within nested blocks, the outermost handler took precedence. (Bug#15011 [<http://bugs.mysql.com/15011>])
- Certain LEAVE statements in stored procedures were not properly optimized. (Bug#15737 [<http://bugs.mysql.com/15737>])
- Setting InnoDB path settings to an empty string caused InnoDB storage engine to crash upon server startup. (Bug#16157 [<http://bugs.mysql.com/16157>])
- InnoDB used full explicit table locks in trigger processing. (Bug#16229 [<http://bugs.mysql.com/16229>])
- Server crash when dropping InnoDB constraints named `TABLENAME_ibfk_0`. (Bug#16387 [<http://bugs.mysql.com/16387>])
- Corrected race condition when dropping the adaptive hash index for a B-tree page in InnoDB. (Bug#16582 [<http://bugs.mysql.com/16582>])
- The `mysql_real_connect()` C API function incorrectly reset the `MYSQL_OPT_RECONNECT` option to its default value. (Bug#15719 [<http://bugs.mysql.com/15719>])
- InnoDB: After upgrading an InnoDB table having a VARCHAR BINARY column created in MySQL 4.0 to MySQL 5.0, update operations on the table would cause the server to crash. (Bug#16298 [<http://bugs.mysql.com/16298>])
- Trying to compile the server on Windows generated a stack overflow warning due to a recursive definition of the internal `Field_date::store()` method. (Bug#15634 [<http://bugs.mysql.com/15634>])
- The use of LOAD INDEX within a stored routine was permitted and caused the server to crash. **Note:** LOAD INDEX statements within stored routines *are not supported*, and now yield an error if attempted. This behavior is intended. (Bug#14270 [<http://bugs.mysql.com/14270>])
- The `mysqlbinlog` utility did not output DELIMITER statements, causing syntax errors for stored routine creation statements. (Bug#11312 [<http://bugs.mysql.com/11312>])
- NDB Cluster returned incorrect Can't find file error for OS error 24, changed to Too many open files. (Bug#15020 [<http://bugs.mysql.com/15020>])
- Performing a RENAME TABLE on an InnoDB table when the server is started with the `--innodb-file-per-table` and the data directory is a symlink caused a server crash. (Bug#15991 [<http://bugs.mysql.com/15991>])
- Multi-byte path names for LOAD DATA and SELECT ... INTO OUTFILE caused errors. Added the `character_set_filesystem` system variable, which controls the interpretation of string literals that refer to filenames. (Bug#12448 [<http://bugs.mysql.com/12448>])
- Certain subqueries where the inner query is the result of an aggregate function would return different results on MySQL 5.0 than on MySQL 4.1. (Bug#15347 [<http://bugs.mysql.com/15347>])

- Attempts to create FULLTEXT indexes on VARCHAR columns larger than 1000 bytes resulted in error. (Bug#13835 [<http://bugs.mysql.com/13835>])
- Characters in the gb2312 and euckr character sets which did not have Unicode mappings were truncated. (Bug#15377 [<http://bugs.mysql.com/15377>])
- Certain nested LEFT JOIN operations were not properly optimized. (Bug#16393 [<http://bugs.mysql.com/16393>])
- GRANT statements specifying schema names that included underscore characters (i.e. my\_schema) did not match if the underscore was escaped in the GRANT statement (i.e. GRANT ALL ON `my\\_schema` . . .). (Bug#14834 [<http://bugs.mysql.com/14834>])
- Running out of disk space in the location specified by the tmpdir option resulted in incorrect error message. (Bug#14634 [<http://bugs.mysql.com/14634>])
- Test suite sp test left behind tables when the test failed that could cause future tests to fail. (Bug#15866 [<http://bugs.mysql.com/15866>])
- UPDATE statement crashed multi-byte character set FULLTEXT index if update value was almost identical to initial value only differing in some spaces being changed to &nbsp;. (Bug#16489 [<http://bugs.mysql.com/16489>])
- A SELECT query which contained a GROUP\_CONCAT() and an ORDER BY clause against the INFORMATION\_SCHEMA resulted in an empty result set. (Bug#15307 [<http://bugs.mysql.com/15307>])
- The --replicate-do and --replicate-ignore options were not being enforced on multiple-table statements. (Bug#15699 [<http://bugs.mysql.com/15699>], Bug#16487 [<http://bugs.mysql.com/16487>])
- A prepared statement created from a SELECT . . . LIKE query (such as PREPARE stmt1 FROM 'SELECT col\_1 FROM tedd\_test WHERE col\_1 LIKE ?';) would begin to produce erratic results after being executed repeatedly numerous (thousands) of times. (Bug#12734 [<http://bugs.mysql.com/12734>])
- The server would crash when the size of an ARCHIVE table grew beyond 2GB. (Bug#15787 [<http://bugs.mysql.com/15787>])
- Created a user function with an empty string (that is, CREATE FUNCTION ''()), was accepted by the server. Following this, calling SHOW FUNCTION STATUS would cause the server to crash. (Bug#15658 [<http://bugs.mysql.com/15658>])
- In some cases the query optimizer did not properly perform multiple joins where inner joins followed left joins, resulting in corrupted result sets. (Bug#15633 [<http://bugs.mysql.com/15633>])
- The absence of a table in the left part of a left or right join was not checked prior to name resolution, which resulted in a server crash. (Bug#15538 [<http://bugs.mysql.com/15538>])
- NDBCluster: A bitfield whose offset and length totaled 32 would crash the cluster. (Bug#16125 [<http://bugs.mysql.com/16125>])
- NDBCluster: Upon the completion of a scan where a key request remained outstanding on the primary replica and a starting node died, the scan did not terminate. This caused incomplete error handling of the failed node. (Bug#15908 [<http://bugs.mysql.com/15908>])
- NDBCluster: The ndb\_autodiscover test failed sporadically due to a node not being permitted to connect to the cluster. (Bug#15619 [<http://bugs.mysql.com/15619>])
- NDBCluster: When running more than one management process in a cluster:
  - `ndb_mgm -c host:port -e "node_id stop"` would stop a management process running only on the same system on which the command was issued.

- `ndb_mgm -e "shutdown"` failed to shut down any management processes at all. (Bug#12045 [<http://bugs.mysql.com/12045>], Bug#12124 [<http://bugs.mysql.com/12124>])
- The contents of `fill_help_tables.sql` could not be loaded in strict SQL mode. (Bug#15760 [<http://bugs.mysql.com/15760>])
- `fill_help_tables.sql` was not included in binary distributions for several platforms. (Bug#15759 [<http://bugs.mysql.com/15759>])
- An `INSERT ... SELECT` statement between tables in a `MERGE` set can return errors when statement involves insert into child table from merge table or vice-versa. (Bug#5390 [<http://bugs.mysql.com/5390>])
- Certain permission management statements could create a `NULL` hostname for a user, resulting in a server crash. (Bug#15598 [<http://bugs.mysql.com/15598>])
- A `COMMIT` statement followed by a `ALTER TABLE` statement on a BDB table caused server crash. (Bug#14212 [<http://bugs.mysql.com/14212>])
- A `DELETE` statement involving a `LEFT JOIN` and an `IS NULL` test on the right-hand table of the join crashed the server when the `innodb_locks_unsafe_for_binlog` option was enabled. (Bug#15650 [<http://bugs.mysql.com/15650>])
- Performing an `ORDER BY` on an indexed `ENUM` column returned error. (Bug#15308 [<http://bugs.mysql.com/15308>])
- The `NOT FOUND` condition handler for stored procedures did not distinguish between a `NOT FOUND` condition and an exception or warning. (Bug#15231 [<http://bugs.mysql.com/15231>])
- A stored procedure with an undefined variable and an exception handler would hang the client when called. (Bug#14498 [<http://bugs.mysql.com/14498>])
- Subselect could return wrong results when records cache and grouping was involved. (Bug#15347 [<http://bugs.mysql.com/15347>])
- Temporary table aliasing did not work inside stored functions. (Bug#12198 [<http://bugs.mysql.com/12198>])
- `MIN()` and `MAX()` operations were not optimized for views. (Bug#16016 [<http://bugs.mysql.com/16016>])
- Using an aggregate function as the argument for a `HAVING` clause would result in the aggregate function always returning `FALSE`. (Bug#14274 [<http://bugs.mysql.com/14274>])
- Parallel builds occasionally failed on Solaris. (Bug#16282 [<http://bugs.mysql.com/16282>])
- The `FORCE INDEX` keyword in a query would prevent an index merge from being used where an index merge would normally be chosen by the optimizer. (Bug#16166 [<http://bugs.mysql.com/16166>])
- The `COALESCE()` function truncated data in a `TINYTEXT` column. (Bug#15581 [<http://bugs.mysql.com/15581>])
- InnoDB: Comparison of indexed `VARCHAR CHARACTER SET ucs2 COLLATE ucs2_bin` columns using `LIKE` could fail. (Bug#14583 [<http://bugs.mysql.com/14583>])
- An attempt to open a table that requires a disabled storage engine could cause a server crash. (Bug#15185 [<http://bugs.mysql.com/15185>])
- Issuing a `DROP USER` command could cause some users to encounter a `hostname is not allowed to connect to this MySQL server` error. (Bug#15775 [<http://bugs.mysql.com/15775>])

- Setting `innodb_log_file_size` to a value greater than 4G crashed the server. (Bug#15108 [<http://bugs.mysql.com/15108>])
- A `SELECT` of a stored function that references the `INFORMATION_SCHEMA` could crash the server. (Bug#15533 [<http://bugs.mysql.com/15533>])
- Tarball install package was missing a proper `fill_help_tables.sql` file. (Bug#15151 [<http://bugs.mysql.com/15151>])

## D.1.6. Changes in release 5.0.18 (21 December 2005)

Functionality added or changed:

- It is now possible to build the server such that `MyISAM` tables can support up to 128 keys rather than the standard 64. This can be done by configuring the build using the option `--with-max-indexes=N`, where  $N \leq 128$  is the maximum number of indexes to permit per table. (Bug#10932 [<http://bugs.mysql.com/10932>])
- The server treats stored routine parameters and local variables (and stored function return values) according to standard SQL. Previously, parameters, variables, and return values were treated as items in expressions and were subject to automatic (silent) conversion and truncation. Now the data type is observed. Data type conversion and overflow problems that occur in assignments result in warnings, or errors in strict mode. The `CHARACTER SET` clause for character data type declarations is used. Parameters, variables, and return values must be scalars; it is no longer possible to assign a row value. Also, stored functions execute using the `sql_mode` value in force at function creation time rather than ignoring it. For more information, see Section 17.2.1, “`CREATE PROCEDURE` and `CREATE FUNCTION` Syntax”. (Bug#8702 [<http://bugs.mysql.com/8702>], Bug#8768 [<http://bugs.mysql.com/8768>], Bug#8769 [<http://bugs.mysql.com/8769>], Bug#9078 [<http://bugs.mysql.com/9078>], Bug#9572 [<http://bugs.mysql.com/9572>], Bug#12903 [<http://bugs.mysql.com/12903>], Bug#13705 [<http://bugs.mysql.com/13705>], Bug#13808 [<http://bugs.mysql.com/13808>], Bug#13909 [<http://bugs.mysql.com/13909>], Bug#14161 [<http://bugs.mysql.com/14161>], Bug#15148 [<http://bugs.mysql.com/15148>])

Bugs fixed:

- API function `mysql_stmt_prepare` returned wrong field length for `TEXT` columns. (Bug#15613 [<http://bugs.mysql.com/15613>])
- The output of `mysqldump --triggers` did not contain the `DEFINER` clause in dumped trigger definitions. (Bug#15110 [<http://bugs.mysql.com/15110>])
- The output of `SHOW TRIGGERS` contained extraneous whitespace. (Bug#15103 [<http://bugs.mysql.com/15103>])
- Creating a trigger caused a server crash if the table or trigger database was not known because no default database had been selected. (Bug#14863 [<http://bugs.mysql.com/14863>])
- `SHOW [FULL] COLUMNS` and `SHOW INDEX FROM` did not function with temporary tables. (Bug#14271 [<http://bugs.mysql.com/14271>], Bug#14387 [<http://bugs.mysql.com/14387>], Bug#15224 [<http://bugs.mysql.com/15224>])
- The `INFORMATION_SCHEMA.COLUMNS` table did not report the size of `BINARY` or `VARBINARY` columns. (Bug#14271 [<http://bugs.mysql.com/14271>])
- The server would not compile under Cygwin. (Bug#13640 [<http://bugs.mysql.com/13640>])
- `DESCRIBE` did not function with temporary tables. (Bug#12770 [<http://bugs.mysql.com/12770>])

- Reversing the order of operands in a WHERE clause testing a simple equality (such as WHERE `t1.col1 = t2.col2`) would produce different output from EXPLAIN. (Bug#15106 [<http://bugs.mysql.com/15106>])
- Column aliases were displayed incorrectly in a SELECT from a view following an update to a base table of the view. (Bug#14861 [<http://bugs.mysql.com/14861>])
- Set functions could not be aggregated in outer subqueries. (Bug#12762 [<http://bugs.mysql.com/12762>])
- When a connection using yaSSL was aborted, the server would continue to try to read the closed socket, and the thread continued to appear in the output of SHOW PROCESSLIST. Note that this issue did not affect secure connection attempts using OpenSSL. (Bug#15772 [<http://bugs.mysql.com/15772>])
- InnoDB: Having two tables in a parent-child relationship enforced by a foreign key where one table used ROW\_FORMAT=COMPACT and the other used ROW\_FORMAT=REDUNDANT could result in a MySQL server crash. Note that this problem did not exist prior to MySQL 5.0.3, when the compact row format for InnoDB was introduced. (Bug#15550 [<http://bugs.mysql.com/15550>])
- BDB: A DELETE, INSERT, or UPDATE of a BDB table could cause the server to crash where the query contained a subquery using an index read. (Bug#15536 [<http://bugs.mysql.com/15536>])
- A left join on a column that having a NULL value could cause the server to crash. (Bug#15268 [<http://bugs.mysql.com/15268>])
- A replication slave server could sometimes crash on a BEFORE UPDATE trigger if the UPDATE query was not executed in the same database as the table with the trigger. (Bug#14614 [<http://bugs.mysql.com/14614>])
- A race condition when creating temporary files caused a deadlock on Windows with threads in Opening tables or Waiting for table states. (Bug#12071 [<http://bugs.mysql.com/12071>])
- InnoDB: If FOREIGN\_KEY\_CHECKS was 0, InnoDB allowed inconsistent foreign keys to be created. (Bug#13778 [<http://bugs.mysql.com/13778>])
- NDB Cluster: Under some circumstances, it was possible for a restarting node to undergo a forced shutdown. (Bug#15632 [<http://bugs.mysql.com/15632>])
- NDB Cluster: If an abort by the Transaction Coordinator timed out, the abort condition was incorrectly handled, causing the transaction record to be released prematurely. (Bug#15685 [<http://bugs.mysql.com/15685>])
- NDB Cluster: The `ndb_read_multi_range.test` script failed to drop a table, causing the test to fail. (Bug#15675 [<http://bugs.mysql.com/15675>]) (See also Bug#15401 [<http://bugs.mysql.com/15401>].)
- NDB Cluster: A node which failed during cluster startup was sometimes not removed from the internal list of active nodes. (Bug#15587 [<http://bugs.mysql.com/15587>])
- Resolution of the argument to the VALUES() function to a variable inside a stored routine caused a server crash. The argument must be a table column. (Bug#15441 [<http://bugs.mysql.com/15441>])

## D.1.7. Changes in release 5.0.17 (14 December 2005)

Functionality added or changed:

- The original Linux RPM packages (5.0.17-0) had an issue with a `zlib` dependency that would result in an error during an install or upgrade. They were replaced by new binaries, 5.0.17-1. (Bug#15223 [<http://bugs.mysql.com/15223>]) Here is a list of the new RPM binaries:
  - `MySQL-{Max,client,devel,server,shared,ndb*}-5.0.17-1.i386.rpm`
  - `MySQL-*-standard-5.0.17-1.rhel3.i386.rpm`, `MySQL-*-standard-5.0.17-1.rhel3.ia64.rpm`,  
`MySQL-*-standard-5.0.17-1.rhel3.x86_64.rpm`
  - `MySQL-*-pro-5.0.17-1.rhel3.i386.rpm`, `MySQL-*-pro-5.0.17-1.rhel3.ia64.rpm`, `MySQL-*-pro-5.0.17-1.rhel3.x86_64.rpm`
  - `MySQL-*-pro-gpl-5.0.17-1.rhel3.i386.rpm`, `MySQL-*-pro-gpl-5.0.17-1.rhel3.ia64.rpm`,  
`MySQL-*-pro-gpl-5.0.17-1.rhel3.x86_64.rpm`
- The syntax for `CREATE TRIGGER` now includes a `DEFINER` clause for specifying which access privileges to check at trigger invocation time. See Section 18.1, “`CREATE TRIGGER Syntax`”, for more information.

**Known issue:** If you attempt to replicate from a master server older than MySQL 5.0.17 to a slave running MySQL 5.0.17 through 5.0.19, replication of `CREATE TRIGGER` statements fails on the slave with a `Definer not fully qualified` error. A workaround is to create triggers on the master using a version-specific comment embedded in each `CREATE TRIGGER` statement:

```
CREATE /*!50017 DEFINER = 'root'@'localhost' */ TRIGGER ... ;
```

`CREATE TRIGGER` statements written this way will replicate to newer slaves, which pick up the `DEFINER` clause from the comment and execute successfully. (Bug#16266 [<http://bugs.mysql.com/16266>])

- Added a `DEFINER` column to the `INFORMATION_SCHEMA.TRIGGERS` table.
- Invoking a stored function or trigger creates a new savepoint level. When the function or trigger finishes, the previous savepoint level is restored. (See Bug#13825 [<http://bugs.mysql.com/13825>] for more information.)
- Recursion is allowed in stored procedures. Recursive stored functions and triggers still are disallowed. (Bug#10100 [<http://bugs.mysql.com/10100>])
- In the `latin5_turkish_ci` collation, the order of the characters `A WITH CIRCUMFLEX`, `I WITH CIRCUMFLEX`, and `U WITH CIRCUMFLEX` was changed. If you have used these characters in any indexed columns, you should rebuild those indexes. (Bug#13421 [<http://bugs.mysql.com/13421>])
- Support files for compiling with Visual Studio 6 have been removed. (Bug#15094 [<http://bugs.mysql.com/15094>])

Bugs fixed:

- RPM packages had an incorrect `zlib` dependency. (Bug#15223 [<http://bugs.mysql.com/15223>])
- NDB Cluster: `REPLACE` failed when attempting to update a primary key value in a Cluster table. (Bug#14007 [<http://bugs.mysql.com/14007>])
- `make` failed when attempting to build MySQL in different directory than source. (Bug#11827 [<http://bugs.mysql.com/11827>])
- Corrected an error-handling problem within stored routines on 64-bit platforms. (Bug#15630 [<http://bugs.mysql.com/15630>])

- Slave SQL thread cleanup was not handled properly on Mac OS X when a statement was killed, resulting in a slave crash. (Bug#15623 [<http://bugs.mysql.com/15623>], Bug#15668 [<http://bugs.mysql.com/15668>])
- Symbolic links did not function properly on Windows platforms. (Bug#14960 [<http://bugs.mysql.com/14960>], Bug#14310 [<http://bugs.mysql.com/14310>])
- `mysqld` would not start on Windows 9X operating systems including Windows Me. (Bug#15209 [<http://bugs.mysql.com/15209>])
- InnoDB: During replication, There was a failure to record events in the binary log that still occurred even in the event of a ROLLBACK. For example, this sequence of commands:

```
BEGIN;
CREATE TEMPORARY TABLE t1 (a INT) ENGINE=INNODB;
ROLLBACK;
INSERT INTO t1 VALUES (1);
```

would succeed on the replication master as expected. However, the INSERT would fail on the slave because the ROLLBACK would (erroneously) cause the CREATE TEMPORARY TABLE statement not to be written to the binlog. (Bug#7947 [<http://bugs.mysql.com/7947>])

- A bug in `mysql-test/t/mysqltest.test` caused that test to fail. (Bug#15605 [<http://bugs.mysql.com/15605>])
- The CREATE test case in `mysql-test-run.pl` failed on AIX and SCO. (Bug#15607 [<http://bugs.mysql.com/15607>])
- NDB Cluster: Creating a table with packed keys failed silently. NDB now supports the PACK\_KEYS option to CREATE TABLE correctly. (Bug#14514 [<http://bugs.mysql.com/14514>])
- NDB Cluster: Using ORDER BY *primary\_key\_column* when selecting from a table having the primary key on a VARCHAR column caused a forced shutdown of the cluster. (Bug#14828 [<http://bugs.mysql.com/14828>], Bug#15240 [<http://bugs.mysql.com/15240>], Bug#15682 [<http://bugs.mysql.com/15682>], Bug#15517 [<http://bugs.mysql.com/15517>])
- NDB Cluster: Under certain circumstances, when `mysqld` connects to a cluster management server, the connection would fail before a node ID could be allocated. (Bug#15215 [<http://bugs.mysql.com/15215>])
- NDB Cluster: There was a small window for a node failure to occur during a backup without an error being reported. (Bug#15425 [<http://bugs.mysql.com/15425>])
- `mysql --help` was missing a newline after the version string when the bundled readline library was not used. (Bug#15097 [<http://bugs.mysql.com/15097>])
- Implicit versus explicit conversion of float to integer (such as inserting a float value into an integer column versus using CAST( . . . AS UNSIGNED before inserting the value) could produce different results. Implicit and explicit typecasts now are done the same way, with a value equal to the nearest integer according to the prevailing rounding mode. (Bug#12956 [<http://bugs.mysql.com/12956>])
- GROUP BY on a view column did not correctly account for the possibility that the column could contain NULL values. (Bug#14850 [<http://bugs.mysql.com/14850>])
- ANALYZE TABLE did not properly update table statistics for a MyISAM table with a FULLTEXT index containing stopwords, so a subsequent ANALYZE TABLE would not recognize the table as having already been analyzed. (Bug#14902 [<http://bugs.mysql.com/14902>])
- The maximum value of MAX\_ROWS was handled incorrectly on 64-bit systems. (Bug#14155 [<http://bugs.mysql.com/14155>])

- NDB Cluster: A forced cluster shutdown occurred when the management daemon was restarted with a changed `config.ini` file that added an API/SQL node. (Bug#15512 [<http://bugs.mysql.com/15512>])
- Multiple-table update operations were counting updates and not updated rows. As a result, if a row had several updates it was counted several times for the “rows matched” value but updated only once. (Bug#15028 [<http://bugs.mysql.com/15028>])
- A statement that produced a warning, when fetched via `mysql_stmt_fetch()`, did not produce a warning count according to `mysql_warning_count()`. (Bug#15510 [<http://bugs.mysql.com/15510>])
- Manual manipulation of the `mysql.proc` table could cause a server crash. This should not happen, but it is also not supported that the server will notice such changes. (Bug#14233 [<http://bugs.mysql.com/14233>])
- Revised table locking to allow proper assessment of view security. (Bug#11555 [<http://bugs.mysql.com/11555>])
- Within a stored procedure, inserting with `INSERT ... SELECT` into a table with an `AUTO_INCREMENT` column did not generate the correct sequence number. (Bug#14304 [<http://bugs.mysql.com/14304>])
- `SELECT` queries that began with an opening parenthesis were not being placed in the query cache. (Bug#14652 [<http://bugs.mysql.com/14652>])
- Space truncation was being ignored when inserting into `BINARY` or `VARBINARY` columns. Now space truncation results in a warning, or an error in strict mode. (Bug#14299 [<http://bugs.mysql.com/14299>])
- The database-changing code for stored routine handling caused an error-handling problem resulting in a server crash. (Bug#15392 [<http://bugs.mysql.com/15392>])
- Selecting from a view processed with the temptable algorithm caused a server crash if the query cache was enabled. (Bug#15119 [<http://bugs.mysql.com/15119>])
- `REPAIR TABLES`, `BACKUP TABLES`, `RESTORE TABLES` within a stored procedure caused a server crash. (Bug#13012 [<http://bugs.mysql.com/13012>])
- Creating a view that referenced a stored function that selected from a view caused a crash upon selection from the view. (Bug#15096 [<http://bugs.mysql.com/15096>])
- `ALTER TABLE ... SET DEFAULT` had no effect. (Bug#14693 [<http://bugs.mysql.com/14693>])
- Creating a view within a stored procedure could result in an out of memory error or a server crash. (Bug#14885 [<http://bugs.mysql.com/14885>])
- InnoDB: A race condition allowed two threads to drop a hash index simultaneously. (Bug#14747 [<http://bugs.mysql.com/14747>])
- `mysqlhotcopy` tried to copy `INFORMATION_SCHEMA` tables. (Bug#14610 [<http://bugs.mysql.com/14610>])
- `CHAR(... USING ...)` and `CONVERT(CHAR(...) USING ...)`, though logically equivalent, could produce different results. (Bug#14146 [<http://bugs.mysql.com/14146>])
- The value of `INFORMATION_SCHEMA.TABLES.TABLE_TYPE` sometimes was reported as empty. (Bug#14476 [<http://bugs.mysql.com/14476>])
- InnoDB: Activity on an InnoDB table caused execution time for `SHOW CREATE TABLE` for the table to increase. (Bug#13762 [<http://bugs.mysql.com/13762>])
- `DELETE` from CSV tables reported an incorrect rows-affected value. (Bug#13406

[<http://bugs.mysql.com/13406>])

- The server crashed if compiled without any transactional storage engines. (Bug#15047 [<http://bugs.mysql.com/15047>])
- Declaring a stored routine variable to have a DEFAULT value that referred to a variable of the same name caused a server crash. (For example: DECLARE x INT DEFAULT x) Now the DEFAULT variable is interpreted as referring to a variable in an outer scope, if there is one. (Bug#14376 [<http://bugs.mysql.com/14376>])
- Perform character set conversion of constant values whenever possible without data loss. (Bug#10446 [<http://bugs.mysql.com/10446>])
- mysql ignored the MYSQL\_TCP\_PORT environment variable. (Bug#5792 [<http://bugs.mysql.com/5792>])
- ROW\_COUNT() returned an incorrect result after EXECUTE of a prepared statement. (Bug#14956 [<http://bugs.mysql.com/14956>])
- A UNION of DECIMAL columns could produce incorrect results. (Bug#14216 [<http://bugs.mysql.com/14216>])
- Queries that select records based on comparisons to a set of column could crash the server if there was one index covering the columns, and a set of other non-covering indexes that taken together cover the columns. (Bug#15204 [<http://bugs.mysql.com/15204>])
- When using an aggregate function to select from a table that has a multiple-column primary key, adding ORDER BY to the query could produce an incorrect result. (Bug#14920 [<http://bugs.mysql.com/14920>])
- SHOW CREATE TABLE for a view could fail if the client had locked the view. (Bug#14726 [<http://bugs.mysql.com/14726>])
- For binary string data types, mysqldump --hex-blob produced an illegal output value of 0x rather than ' '. (Bug#13318 [<http://bugs.mysql.com/13318>])
- Some comparisons for the IN( ) operator were inconsistent with equivalent comparisons for the = operator. (Bug#12612 [<http://bugs.mysql.com/12612>])
- In a stored procedure, continuing (via a condition handler) after a failed variable initialization caused a server crash. (Bug#14643 [<http://bugs.mysql.com/14643>])
- Within a stored procedure, exception handling for UPDATE statements that caused a duplicate-key error caused a Packets out of order error for the following statement. (Bug#13729 [<http://bugs.mysql.com/13729>])
- Creating a table containing an ENUM or SET column from within a stored procedure or prepared statement caused a server crash later when executing the procedure or statement. (Bug#14410 [<http://bugs.mysql.com/14410>])
- Selecting from a view used filesort retrieval when faster retrieval was possible. (Bug#14816 [<http://bugs.mysql.com/14816>])
- Warnings from a previous command were not being reset when fetching from a cursor. (Bug#13524 [<http://bugs.mysql.com/13524>])
- RESET MASTER failed to delete log files on Windows. (Bug#13377 [<http://bugs.mysql.com/13377>])
- Using ORDER BY on a column from a view, when also selecting the column normally, and via an alias, caused a mistaken Column 'x' in order clause is ambiguous error. (Bug#14662 [<http://bugs.mysql.com/14662>])
- Invoking a stored procedure within another stored procedure caused the server to crash.

Bug#13549 [<http://bugs.mysql.com/13549>])

- Stored functions making use of cursors were not replicated. (Bug #)
- `CAST(expr AS BINARY(N))` did not pad with 0x00 to a length of *N* bytes. (Bug#14255 [<http://bugs.mysql.com/14255>])
- Casting a `FLOAT` or `DOUBLE` whose value was less than `1.0E-06` to `DECIMAL` would yield an inappropriate value. (Bug#14268 [<http://bugs.mysql.com/14268>])
- In some cases, a left outer join could yield an invalid result or cause the server to crash, due to a `MYSQL_DATA_TRUNCATED` error. (Bug#13488 [<http://bugs.mysql.com/13488>])
- For a invalid view definition, selecting from the `INFORMATION_SCHEMA.VIEWS` table or using `SHOW CREATE VIEW` failed, making it difficult to determine what part of the definition was invalid. Now the server returns the definition and issues a warning. (Bug#13818 [<http://bugs.mysql.com/13818>])
- The server could misinterpret old trigger definition files created before MySQL 5.0.17. Now they are interpreted correctly, but this takes more time and the server issues a warning that the trigger should be re-created. (Bug#14090 [<http://bugs.mysql.com/14090>])
- `mysqldump --triggers` did not account for the SQL mode and could dump trigger definitions with missing whitespace if the `IGNORE_SPACE` mode was enabled. (Bug#14554 [<http://bugs.mysql.com/14554>])
- Within a trigger definition the `CURRENT_USER()` function evaluated to the user whose actions caused the trigger to be activated. Now that triggers have a `DEFINER` value, `CURRENT_USER()` evaluates to the trigger definer. (Bug#5861 [<http://bugs.mysql.com/5861>])
- `CREATE TABLE tbl_name (...) SELECT ...` could crash the server and write invalid data into the `.frm` file if the `CREATE TABLE` and `SELECT` both contained a column with the same name. Also, if a default value is specified in the column definition, it is now actually used. (Bug#14480 [<http://bugs.mysql.com/14480>])
- A newline character in a column alias in a view definition caused an error when selecting from the view later. (Bug#13622 [<http://bugs.mysql.com/13622>])
- `mysql_fix_privilege_tables.sql` contained an erroneous comment that resulted in an error when the file contents were processed. (Bug#14469 [<http://bugs.mysql.com/14469>])
- On Windows, the server could crash during shutdown if both replication threads and normal client connection threads were active. (Re-fix of Bug#11796 [<http://bugs.mysql.com/11796>])
- The grammar for supporting the `DEFINER = CURRENT_USER` clause in `CREATE VIEW` and `ALTER VIEW` was incorrect. (Bug#14719 [<http://bugs.mysql.com/14719>])
- Queries on `ARCHIVE` tables that used the `filesort` sorting method could result in a server crash. (Bug#14433 [<http://bugs.mysql.com/14433>])
- The `mysql_stmt_fetch()` C APP function could return `MYSQL_NO_DATA` for a `SELECT COUNT(*) FROM tbl_name WHERE 1 = 0` statement, which should return 1 row. (Bug#14845 [<http://bugs.mysql.com/14845>])
- A `LIMIT`-related optimization failed to take into account that `MyISAM` table indexes can be disabled, causing Error 124 when it tried to use such an index. (Bug#14616 [<http://bugs.mysql.com/14616>])
- A server crash resulted from the following sequence of events: 1) With no default database selected, create a stored procedure with the procedure name explicitly qualified with a database name (`CREATE PROCEDURE db_name.proc_name ...`). 2) Create another stored procedure with no database name qualifier. 3) Execute `SHOW PROCEDURE STATUS`. (Bug#14569 [<http://bugs.mysql.com/14569>])

- Complex subqueries could cause improper internal query execution environment initialization and crash the server. (Bug#14342 [<http://bugs.mysql.com/14342>])
- For a table that had been opened with `HANDLER OPEN`, issuing `OPTIMIZE TABLE`, `ALTER TABLE`, or `REPAIR TABLE` caused a server crash. (Bug#14397 [<http://bugs.mysql.com/14397>])
- A server crash could occur if a prepared statement invoked a stored procedure that existed when the statement was prepared but had been dropped and re-created prior to statement execution. (Bug#12329 [<http://bugs.mysql.com/12329>])
- A server crash could occur if a prepared statement updated a table for which a trigger existed when the statement was prepared but had been dropped prior to statement execution. (Bug#13399 [<http://bugs.mysql.com/13399>])
- Statements that implicitly commit a transaction are prohibited in stored functions and triggers. An attempt to create a function or trigger containing such a statement produces an error. (Bug#13627 [<http://bugs.mysql.com/13627>]) (The originally reported symptom was that a trigger that dropped another trigger could cause a server crash. That problem was fixed by the patch for Bug#13343 [<http://bugs.mysql.com/13343>].)

## D.1.8. Changes in release 5.0.16 (10 November 2005)

Functionality added or changed:

- When trying to run the server with yaSSL enabled, MySQL now tries to open `/dev/random` automatically if `/dev/urandom` is not available. (Bug#13164 [<http://bugs.mysql.com/13164>])
- The `read_only` system variable no longer applies to `TEMPORARY` tables. (Bug#4544 [<http://bugs.mysql.com/4544>])
- Due to changes in binary logging, the restrictions on which stored routine creators can be trusted not to create unsafe routines have been lifted for stored procedures (but not stored functions). Consequently, the `log_bin_trust_routine_creators` system variable and the corresponding `--log-bin-trust-routine-creators` server option were renamed to `log_bin_trust_function_creators` and `--log-bin-trust-function-creators`. For backward compatibility, the old names are recognized but result in a warning. See Section 17.4, “Binary Logging of Stored Routines and Triggers”.
- Added the `Compression` status variable, which indicates whether the client connection uses compression in the client/server protocol.
- In MySQL 5.0.13, syntax for `DEFINER` and `SQL SECURITY` clauses was added to the `CREATE VIEW` and `ALTER VIEW` statements, but the clauses had no effect. They now are enabled. They specify the security context to be used when checking access privileges at view invocation time. See Section 19.2, “CREATE VIEW Syntax”, for more information.
- The `InnoDB`, `NDB`, `BDB`, and `ARCHIVE` storage engines now support spatial columns. See Chapter 16, *Spatial Extensions*.
- The `CHECK TABLE` statement now works for `ARCHIVE` tables.
- You must now declare a prefix for an index on any column of any `Geometry` class, the only exception being when the column is a `POINT`. (Bug#12267 [<http://bugs.mysql.com/12267>])
- Added a `--hexdump` option to `mysqlbinlog` that displays a hex dump of the log in comments. This output can be helpful for replication debugging.
- MySQL 5.0 now supports character set conversion for seven additional cp950 characters into the big5 character set: 0xF9D6, 0xF9D7, 0xF9D8, 0xF9D9, 0xF9DA, 0xF9DB, and

0xF9DC. **Note:** If you move data containing these additional characters to an older MySQL installation which does not support them, you may encounter errors. (Bug#12476 [<http://bugs.mysql.com/12476>])

- When a date column is set NOT NULL and contains 0000-00-00, it will be updated for UPDATE statements that contains `columnname IS NULL` in the WHERE clause. (Bug#14186 [<http://bugs.mysql.com/14186>])

Bugs fixed:

- When the DATE\_FORMAT() function appeared in both the SELECT and ORDER BY clauses of a query but with arguments that differ by case (i.e. %m and %M), incorrect sorting may have occurred. (Bug#14016 [<http://bugs.mysql.com/14016>])
- For InnoDB tables, using a column prefix for a utf8 column in a primary key caused Cannot find record errors when attempting to locate records. (Bug#14056 [<http://bugs.mysql.com/14056>])
- NDB Cluster: A memory leak occurred when performing ordered index scans using indexes a columns larger than 32 bytes, which would eventually lead to the forced shutdown of all mysqld server processes used with the cluster. (Bug#13078 [<http://bugs.mysql.com/13078>])
- InnoDB: Large innobase\_buffer\_pool\_size and innobase\_log\_file\_size values were displayed incorrectly on 64-bit systems. (Bug#12701 [<http://bugs.mysql.com/12701>])
- InnoDB: When dropping and adding a PRIMARY KEY, if a loose index scan using only the second part of multiple-part index was chosen, incorrect keys were created and an endless loop resulted. (Bug#13293 [<http://bugs.mysql.com/13293>])
- NDB Cluster: Repeated transactions using unique index lookups could cause a memory leak leading to error 288, Out of index operations in transaction coordinator. (Bug#14199 [<http://bugs.mysql.com/14199>])
- Selecting from a table in both an outer query and a subquery could cause a server crash. (Bug#14482 [<http://bugs.mysql.com/14482>])
- SHOW CREATE TABLE did not display the CONNECTION string for FEDERATED tables. (Bug#13724 [<http://bugs.mysql.com/13724>])
- For some stored functions dumped by mysqldump --routines, the function definition could not be reloaded later due to a parsing error. (Bug#14723 [<http://bugs.mysql.com/14723>])
- For a MyISAM table originally created in MySQL 4.1, INSERT DELAYED could cause a server crash. (Bug#13707 [<http://bugs.mysql.com/13707>])
- The --exit-info=65536 option conflicted with --temp-pool and caused problems with the server's use of temporary files. Now --temp-pool is ignored if --exit-info=65536 is specified. (Bug#9551 [<http://bugs.mysql.com/9551>])
- ORDER BY DESC within the GROUP\_CONCAT() function was not honored when used in a view. (Bug#14466 [<http://bugs.mysql.com/14466>])
- A comparison with an invalid date (such as WHERE col\_name > '2005-09-31') caused any index on col\_name not to be used and a string comparison for each row, resulting in slow performance. (Bug#14093 [<http://bugs.mysql.com/14093>])
- Within stored routines, REPLACE() could return an empty string (rather than the original string) when no replacement was done, and IFNULL() could return garbage results. (Bug#13941 [<http://bugs.mysql.com/13941>])
- Inserts of too-large DECIMAL values were handled inconsistently (sometimes set to the maximum DECIMAL value, sometimes set to 0). (Bug#13573 [<http://bugs.mysql.com/13573>])

- Executing `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE` on a view for which an underlying table had been dropped caused a server crash. (Bug#14540 [<http://bugs.mysql.com/14540>])
- A prepared statement that selected from a view processed using the merge algorithm could crash on the second execution. (Bug#14026 [<http://bugs.mysql.com/14026>])
- Deletes from a CSV table could cause table corruption. (Bug#14672 [<http://bugs.mysql.com/14672>])
- An update of a CSV table could cause a server crash. (Bug#13894 [<http://bugs.mysql.com/13894>])
- For queries with nested outer joins, the optimizer could choose join orders that query execution could not handle. The fix is that now the optimizer avoids choosing such join orders. (Bug#13126 [<http://bugs.mysql.com/13126>])
- Starting `mysqld` with the `--skip-innodb` and `--default-storage-engine=innodb` (or `--default-table-type=innodb`) caused a server crash. (Bug#9815 [<http://bugs.mysql.com/9815>], re-fix of bug from 5.0.5)
- `mysqlmanager` did not start up correctly on Windows 2003. (Bug#14537 [<http://bugs.mysql.com/14537>])
- The parser did not correctly recognize wildcards in the host part of the `DEFINER` user in `CREATE VIEW` statements. (Bug#14256 [<http://bugs.mysql.com/14256>])
- Memory corruption and a server crash could be caused by statements that used a cursor and generated a result set larger than `max_heap_table_size`. (Bug#14210 [<http://bugs.mysql.com/14210>])
- `mysqld_safe` did not correctly start the `-max` version of the server (if it was present) if the `-ledir` option was given. (Bug#13774 [<http://bugs.mysql.com/13774>])
- The `mysql` parser did not properly strip the delimiter from input lines less than nine characters long. For example, this could cause `USE abc;` to result in an `Unknown database: abc;` error. (Bug#14358 [<http://bugs.mysql.com/14358>])
- Statements of the form `CREATE TABLE ... SELECT ...` that created a column with a multi-byte character set could incorrectly calculate the maximum length of the column, resulting in a `Specified key was too long error`. (Bug#14139 [<http://bugs.mysql.com/14139>])
- Some updatable views could not be updated. (Bug#14027 [<http://bugs.mysql.com/14027>])
- Running `OPTIMIZE TABLE` and other data-updating statements concurrently on an InnoDB table could cause a crash or the following warnings in the error log: `Warning: Found locks from different threads in write: enter write_lock`, `Warning: Found locks from different threads in write: start of release lock`. (Bug#11704 [<http://bugs.mysql.com/11704>])
- Indexes for BDB tables were being limited incorrectly to 255 bytes. (Bug#14381 [<http://bugs.mysql.com/14381>])
- Use of `col_name = VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause of an `INSERT` statement failed with an `Column 'col_name' in field list is ambiguous error`. (Bug#13392 [<http://bugs.mysql.com/13392>])
- On Windows, the server was not ignoring hidden or system directories that Windows may have created in the data directory, and would treat them as available databases. (Bug#4375 [<http://bugs.mysql.com/4375>])
- `mysqldump` could not dump views if the `-x` option was given. (Bug#12838 [<http://bugs.mysql.com/12838>])

- `mysqlimport` now issues a `SET @@character_set_database = binary` statement before loading data so that a file containing mixed character sets (columns with different character sets) can be loaded properly. (Bug#12123 [<http://bugs.mysql.com/12123>])
- Use of the deprecated `--sql-bin-update-same` option caused a server crash. (Bug#12974 [<http://bugs.mysql.com/12974>])
- Maximum values were handled incorrectly for command-line options of type `GET_LL`. (Bug#12925 [<http://bugs.mysql.com/12925>])
- For a user that has the `SELECT` privilege on a view, the server erroneously was also requiring the user to have the `EXECUTE` privilege at view execution time for stored functions used in the view definition. (Bug#9505 [<http://bugs.mysql.com/9505>])
- Use of `WITH ROLLUP PROCEDURE ANALYSE()` could hang the server. (Bug#14138 [<http://bugs.mysql.com/14138>])
- `TIMEDIFF()`, `ADDTIME()`, and `STR_TO_DATE()` were not reporting that they could return `NULL`, so functions that invoked them might misinterpret their results. (Bug#14009 [<http://bugs.mysql.com/14009>])
- The example configuration files supplied with MySQL distributions listed the `thread_cache_size` variable as `thread_cache`. (Bug#13811 [<http://bugs.mysql.com/13811>])
- Using `ALTER TABLE` to add an index could fail if the operation ran out of temporary file space. Now it automatically makes a second attempt that uses a slower method but no temporary file. In this case, problems that occurred during the first attempt can be displayed with `SHOW WARNINGS`. (Bug#12166 [<http://bugs.mysql.com/12166>])
- The input polling loop for Instance Manager did not sleep properly. Instance Manager used up too much CPU as a result. (Bug#14388 [<http://bugs.mysql.com/14388>])
- Trying to take the logarithm of a negative value is now handled in the same fashion as division by zero. That is, it produces a warning when `ERROR_FOR_DIVISION_BY_ZERO` is set, and an error in strict mode. (Bug#13820 [<http://bugs.mysql.com/13820>])
- `LOAD DATA INFILE` would not accept the same character for both the `ESCAPED BY` and the `ENCLOSED BY` clauses. (Bug#11203 [<http://bugs.mysql.com/11203>])
- The value of `Last_query_cost` was not updated for queries served from the query cache. (Bug#10303 [<http://bugs.mysql.com/10303>])
- `TIMESTAMPDIFF()` returned an incorrect result if one argument but not the other was a leap year and a date was from March or later. (Bug#13534 [<http://bugs.mysql.com/13534>])
- The server incorrectly accepted column definitions of the form `DECIMAL(0,D)` for `D` less than 11. (Bug#13667 [<http://bugs.mysql.com/13667>])
- The displayed value for the `CHARACTER_MAXIMUM_LENGTH` column in the `INFORMATION_SCHEMA.COLUMNS` table was not adjusted for multi-byte character sets. (Bug#14290 [<http://bugs.mysql.com/14290>])
- A bugfix in MySQL 5.0.15 caused the displayed values for the `CHARACTER_MAXIMUM_LENGTH` and `CHARACTER_OCTET_LENGTH` columns in the `INFORMATION_SCHEMA.COLUMNS` table to be reversed. (Bug#14207 [<http://bugs.mysql.com/14207>])
- On Windows, the value of `character_sets_dir` in `SHOW VARIABLES` output was displayed inconsistently (using both `'/'` and `'\'` as pathname component separators). (Bug#14137 [<http://bugs.mysql.com/14137>])
- Subqueries in the `FROM` clause failed if the current database was `INFORMATION_SCHEMA`. (Bug#14089 [<http://bugs.mysql.com/14089>])

- Corrected a parser precedence problem that resulted in an `Unknown column ... in 'on clause'` error for some joins. (Bug#13832 [<http://bugs.mysql.com/13832>])
- For `LIKE ... ESCAPE`, an escape sequence longer than one character was accepted as valid. Now the sequence must be empty or one character long. If the `NO_BACKSLASH_ESCAPES SQL` mode is enabled, the sequence must be one character long. (Bug#12595 [<http://bugs.mysql.com/12595>])
- `SELECT DISTINCT CHAR(col_name)` returned incorrect results after `SET NAMES utf8`. (Bug#13233 [<http://bugs.mysql.com/13233>])
- A prepared statement failed with `Illegal mix of collations` if the client character set was `utf8` and the statement used a table that had a character set of `latin1`. (Bug#12371 [<http://bugs.mysql.com/12371>])
- Inserting a new row into an InnoDB table could cause `DATETIME` values already stored in the table to change. (Bug#13900 [<http://bugs.mysql.com/13900>])
- The default value of `query_prealloc_size` was set to 8192, lower than its minimum of 16384. The minimum has been lowered to 8192. (Bug#13334 [<http://bugs.mysql.com/13334>])
- The server did not take character set into account in checking the width of the `mysql.user.Password` column. As a result, it could incorrectly generate long password hashes even if the column was not long enough to hold them. (Bug#13064 [<http://bugs.mysql.com/13064>])
- Inserting `cp932` strings into a `VARCHAR` column caused a server crash rather than string truncation if the string was longer than the column definition. (Bug#12547 [<http://bugs.mysql.com/12547>])
- Two threads that were creating triggers on an InnoDB table at the same time could deadlock. (Bug#12739 [<http://bugs.mysql.com/12739>])
- `mysqladmin` and `mysqldump` would hang on SCO OpenServer. (Bug#13238 [<http://bugs.mysql.com/13238>])
- Where one stored procedure called another stored procedure: If the second stored procedure generated an exception, the exception was not caught by the calling stored procedure. For example, if stored procedure A used an `EXIT` statement to handle an exception, subsequent statements in A would be executed regardless when A was called by another stored procedure B, even if an exception that should have been handled by the `EXIT` was generated in A. (Bug#7049 [<http://bugs.mysql.com/7049>])
- Trying to create a stored routine with no database selected would crash the server. (Bug#13514 [<http://bugs.mysql.com/13514>], Bug#13587 [<http://bugs.mysql.com/13587>])
- Specifying `--default-character-set=cp-932` for `mysqld` would cause SQL scripts containing comments written using that character set to fail with a syntax error. (Bug#13487 [<http://bugs.mysql.com/13487>])
- Trying to compile the server using the `--without-geometry` option caused the build to fail. (Bug#12991 [<http://bugs.mysql.com/12991>])

## D.1.9. Changes in release 5.0.15 (19 October 2005: Production)

Functionality added or changed:

- **Warning: Incompatible change.** For `BINARY` columns, the pad value and how it is handled has changed. The pad value for inserts now is `0x00` rather than space, and there is no stripping

of the pad value for selects. For details, see Section 11.4.2, “The BINARY and VARBINARY Types”.

- **Warning: Incompatible change.** The CHAR( ) function now returns a binary string rather than a string in the connection character set. An optional USING *charset* clause may be used to produce a result in a specific character set instead. Also, arguments larger than 256 produce multiple characters. They are no longer interpreted modulo 256 to produce a single character each. These changes may cause some incompatibilities, as noted in Section 2.11.2, “Upgrading from MySQL 4.1 to 5.0”.
- NDB Cluster: The `pererror` utility included with the MySQL-Server RPM now provides support for the `--ndb` option, and so can be used to obtain error message text for MySQL Cluster error codes. (Bug#13740 [<http://bugs.mysql.com/13740>])
- NDB Cluster: The `ndb_mgm` client now reports node startup phases automatically. (Bug#16197 [<http://bugs.mysql.com/16197>])
- When executing single-table UPDATE or DELETE queries containing an ORDER BY ... LIMIT *N* clause, but not having any WHERE clause, MySQL can now take advantage of an index to read the first *N* rows in the ordering specified in the query. If an index is used, only the first *N* records will be read, as opposed to scanning the entire table. (Bug#12915 [<http://bugs.mysql.com/12915>])
- The MySQL-server RPM now explicitly assigns the `mysql` system user to the `mysql` user group during the postinstallation process. This corrects an issue with upgrading the server on some Linux distributions whereby a previously existing `mysql` user was not changed to the `mysql` group, resulting in wrong groups for files created following the installation. (Bug#12823 [<http://bugs.mysql.com/12823>])
- Added the `--tz-utc` option to `mysqldump`. This option adds SET TIME\_ZONE='+00:00' to the dump file so that TIMESTAMP columns can be dumped and reloaded between servers in different time zones and protected from changes due to daylight saving time. (Bug#13052 [<http://bugs.mysql.com/13052>])
- When declaring a local variable (or parameter) named `password` or `name`, and setting it with SET (for example, SET `password` = ''), the new error message ERROR 42000: Variable '`nnn`' must be quoted with ``...``, or renamed is returned (where '`nnn`' is '`password`' or '`names`'). This means there is a syntax conflict with special sentences like SET PASSWORD = PASSWORD( ... ) (for setting a user's password) and set names default (for setting charset and collation).

This must be resolved either by quoting the variable name: SET ``password`` = ..., which will set the local variable ``password``, or by renaming the variable to something else (if setting the user's password is the desired effect).

- The following statements now cause an implicit COMMIT:
  - CREATE VIEW
  - ALTER VIEW
  - DROP VIEW
  - CREATE TRIGGER
  - DROP TRIGGER
  - CREATE USER
  - RENAME USER
  - DROP USER

(Bug#13343 [<http://bugs.mysql.com/13343>])

- NDBCluster: A number of new or improved error messages have been implemented in this release in order to provide better and more accurate diagnostic information regarding cluster configuration issues and problems. (Bug#11739 [<http://bugs.mysql.com/11739>], Bug#11749 [<http://bugs.mysql.com/11749>], Bug#12044 [<http://bugs.mysql.com/12044>], Bug#12786 [<http://bugs.mysql.com/12786>], Bug#13197 [<http://bugs.mysql.com/13197>])
- NDBCluster: A new “smart” node allocation algorithm means that it is no longer necessary to use sequential IDs for cluster nodes, and that nodes not explicitly assigned IDs should now have IDs allocated automatically in most cases. In practical terms, this means that it is now possible to assign a set of node IDs such as 1, 2, 4, 5 without an error being generated due to the missing 3. (Bug#13009 [<http://bugs.mysql.com/13009>])

Bugs fixed:

- Issuing `STOP SLAVE` after having acquired a global read lock with `FLUSH TABLES WITH READ LOCK` caused a deadlock. Now `STOP SLAVE` generates an error in such circumstances. (Bug#10942 [<http://bugs.mysql.com/10942>])
- An expression in an `ORDER BY` clause failed with `Unknown column 'col_name' in 'order clause'` if the expression referred to a column alias. (Bug#11694 [<http://bugs.mysql.com/11694>])
- `mysqldump` could not dump views. (Bug#14061 [<http://bugs.mysql.com/14061>])
- Using an undefined variable in an `IF` or `SET` clause inside a stored routine produced an incorrect `unknown column ... in 'order clause'` error message. (Bug#13037 [<http://bugs.mysql.com/13037>])
- Trying to create a view dynamically using a prepared statement within a stored procedure failed with error 1295. (Bug#13095 [<http://bugs.mysql.com/13095>])
- `mysqldump --triggers` did not quote identifiers properly if the `--compatible` option was given, so the dump output could not be reloaded. (Bug#13146 [<http://bugs.mysql.com/13146>])
- Character set conversion was not being done for `FIND_IN_SET()`. (Bug#13751 [<http://bugs.mysql.com/13751>])
- `CAST(1E+300 TO SIGNED INT)` produced an incorrect result on little-endian machines. (Bug#13344 [<http://bugs.mysql.com/13344>])
- Corrected a memory-copying problem for `big5` values when using `icc` compiler on Linux IA-64 systems. (Bug#10836 [<http://bugs.mysql.com/10836>])
- On BSD systems, the system `crypt()` call could return an error for some salt values. The error was not handled, resulting in a server crash. (Bug#13619 [<http://bugs.mysql.com/13619>])
- Character set file parsing during `mysql_real_connect()` read past the end of a memory buffer. (Bug#6413 [<http://bugs.mysql.com/6413>])
- InnoDB: Queries that were executed using an `index_merge` union or intersection could produce incorrect results if the underlying table used the InnoDB storage engine and had a primary key containing `VARCHAR` members. (Bug#13484 [<http://bugs.mysql.com/13484>])
- `CREATE DEFINER=... VIEW ...` caused the server to crash when run with `--skip-grant-tables`. (Bug#13504 [<http://bugs.mysql.com/13504>])
- The `--interactive-timeout` and `--slave-net-timeout` options for `mysqld` were not being obeyed on Mac OS X and other BSD-based platforms. (Bug#8731 [<http://bugs.mysql.com/8731>])
- Queries of the form `(SELECT ...) ORDER BY ...` were being treated as a UNION. This

improperly resulted in only distinct values being returned (because UNION by default eliminates duplicate results). Also, references to column aliases in ORDER BY clauses following parenthesized SELECT statements were not resolved properly. (Bug#7672 [<http://bugs.mysql.com/7672>])

- If special characters such as '\_', '%', or the escape character were included within the prefix of a column index, LIKE pattern matching on the indexed column did not return the correct result. (Bug#13046 [<http://bugs.mysql.com/13046>], Bug#13919 [<http://bugs.mysql.com/13919>])
- An UPDATE query using a join would be executed incorrectly on a replication slave. (Bug#12618 [<http://bugs.mysql.com/12618>])
- Server crashed during a SELECT statement, writing a message like this to the error log:
 

```
InnoDB: Error: MySQL is trying to perform a SELECT
InnoDB: but it has not locked any tables in ::external_lock()!
```

 (Bug#12736 [<http://bugs.mysql.com/12736>])
- NDBCluster: ndb\_mgmd would allow a node to be stopped or restarted while another node was still starting up, which could crash the cluster. It should now not be possible to issue a node stop or restart while a different node is still restarting, and the cluster management client issues an error if an attempt is made to do so. (Bug#13461 [<http://bugs.mysql.com/13461>])
- NDBCluster: Placing multiple [TCP DEFAULT] sections in the cluster config.ini file crashed ndb\_mgmd. (The ndb\_mgmd process now exits gracefully with an appropriate error message instead.) (Bug#13611 [<http://bugs.mysql.com/13611>])
- NDBCluster: Trying to run ndbd as system root when connecting to a mysqld process running as the mysql system user via SHM caused the ndbd process to crash. (ndbd should now exit gracefully with an appropriate error message instead.) (Bug#9249 [<http://bugs.mysql.com/9249>])
- Server may over-allocate memory when performing a FULLTEXT search for stopwords only. (Bug#13582 [<http://bugs.mysql.com/13582>])
- Queries that use indexes in normal SELECT statements may cause range scans in VIEWS. (Bug#13327 [<http://bugs.mysql.com/13327>])
- When calling a stored procedure with the syntax CALL *schema.procedurename* and no default schema selected, ERROR 1046 was displayed after the procedure returned. (Bug#13616 [<http://bugs.mysql.com/13616>])
- With --log-slave-updates Exec\_master\_log\_pos of SQL thread lagged IO (Bug#13023 [<http://bugs.mysql.com/13023>])
- SHOW CREATE TABLE did not display any FOREIGN KEY clauses if a temporary file could not be created. Now SHOW CREATE TABLE displays an error message in an SQL comment if this occurs. (Bug#13002 [<http://bugs.mysql.com/13002>])
- A column in the ON condition of a join that referenced a table in a nested join could not be resolved if the nested join was a right join. (Bug#13597 [<http://bugs.mysql.com/13597>])
- A qualified reference to a view column in the HAVING clause could not be resolved. (Bug#13410 [<http://bugs.mysql.com/13410>])
- comp\_err did not detect when multiple error messages for a language were given for an error symbol. (Bug#13071 [<http://bugs.mysql.com/13071>])
- For XA transaction IDs (*gtrid.bqual.formatID*), uniqueness is supposed to be assessed based on *gtrid* and *bqual*. MySQL was also including *formatID* in the uniqueness check. (Bug#13143 [<http://bugs.mysql.com/13143>])
- Local (non-XA) and XA transactions are supposed to be mutually exclusive within a given client connection, but this prohibition was not always enforced. (Bug#12935

[<http://bugs.mysql.com/12935>])

- `mysqlcheck --all-databases --analyze --optimize` failed because it also tried to analyze and optimize the `INFORMATION_SCHEMA` tables which it can't. (Bug#13783 [<http://bugs.mysql.com/13783>])
- `SELECT * INTO OUTFILE ... FROM INFORMATION_SCHEMA.schemata` failed with an `Access denied` error. (Bug#13202 [<http://bugs.mysql.com/13202>])
- A table or view named `Ç` (C-cedilla) couldn't be dropped. (Bug#13145 [<http://bugs.mysql.com/13145>])
- Tests containing `SHOW TABLE STATUS` or `INFORMATION_SCHEMA` failed on `opnsrv6c`. (Bug, #14064, Bug#14065 [<http://bugs.mysql.com/14065>])

## D.1.10. Changes in release 5.0.14 (Not released)

Functionality added or changed:

The limit of 255 characters on the input buffer for `mysql` on Windows has been lifted. The exact limit depends on what the system allows, but can be up to 64K characters. A typical limit is 16K characters. (Bug#12929 [<http://bugs.mysql.com/12929>])

Re-enabled the `--delayed-inserts` option for `mysqldump`, which now checks for each table dumped whether its storage engine supports `DELAYED` inserts. (Bug#7815 [<http://bugs.mysql.com/7815>])

Added the `myisam_stats_method`, which controls whether `NULL` values in indexes are considered the same or different when collecting statistics for `MyISAM` tables. This influences the query optimizer as described in Section 7.4.7, "MyISAM Index Statistics Collection". (Bug#12232 [<http://bugs.mysql.com/12232>])

- When an `InnoDB` foreign key constraint is violated, the error message now indicates which table, column, and constraint names are involved. (Bug#3443 [<http://bugs.mysql.com/3443>])
- Configure-time checking for the availability of multi-byte macros and functions in the bundled `readline` library. This improves handling of multi-byte character sets in the `mysql` client. (Bug#3982 [<http://bugs.mysql.com/3982>])
- The `CHAR()` function now takes into account the character set and collation given by the `character_set_connection` and `collation_connection` system variables. For an argument `n` to `CHAR()`, the result is `n mod 256` for single-byte character sets. For multi-byte character sets, `n` must be a valid code point in the character set. Also, the result string from `CHAR()` is checked for well-formedness. For invalid arguments, or a result that is not well-formed, MySQL generates a warning (or, in strict SQL mode, an error). (Bug#10504 [<http://bugs.mysql.com/10504>])
- `RENAME TABLE` now works for views as well, as long as you do not try to rename a view into a different database. (Bug#5508 [<http://bugs.mysql.com/5508>])
- Multiple-table `UPDATE` and `DELETE` statements that do not affect any rows are now written to the binary log and will replicate. (Bug#13348 [<http://bugs.mysql.com/13348>], Bug#12844 [<http://bugs.mysql.com/12844>])
- Range scans can now be performed for queries on `VIEWS` such as `column IN (<constants>)` and `column BETWEEN ConstantA AND ConstantB`. (Bug#13317 [<http://bugs.mysql.com/13317>])

Bugs fixed:

- NDBCluster: A trigger updating the value of an AUTO\_INCREMENT column in a Cluster table would insert an error code rather than the expected value into the column. (Bug#13961 [<http://bugs.mysql.com/13961>])
- NDBCluster: When performing a delete of a great many (tens of thousands of) rows at once from a Cluster table, an improperly dereferenced pointer could cause the mysqld process to crash. (Bug#9282 [<http://bugs.mysql.com/9282>])
- CHECKSUM TABLE locked InnoDB tables and did not use a consistent read. (Bug#12669 [<http://bugs.mysql.com/12669>])
- The --skip-innodb-doublewrite option disables use of the InnoDB doublewrite buffer. However, having this option in effect when creating a new MySQL installation prevented the buffer from even being created, resulting in a server crash later. (Bug#13367 [<http://bugs.mysql.com/13367>])
- MySQL programs in binary distributions for Solaris 8/9/10 x86 systems would not run on Pentium III machines. (Bug#6772 [<http://bugs.mysql.com/6772>])
- When SELECT ... FOR UPDATE or SELECT ... LOCK IN SHARE MODE for an InnoDB table were executed from within a stored function or a trigger, they were converted to a non-locking consistent read. (Bug#11238 [<http://bugs.mysql.com/11238>])
- NDB Cluster: If ndb\_restore could not find a free mysqld process, it crashed. (Bug#13512 [<http://bugs.mysql.com/13512>])
- NDB Cluster: Receipt of several enter single user mode commands by multiple ndb\_mgmd processes within a short period of time resulted in cluster shutdown. (Bug#13053 [<http://bugs.mysql.com/13053>])
- NDB Cluster: Multiple ndb\_mgmd processes in a cluster would not know each other's IP addresses. (Bug#12037 [<http://bugs.mysql.com/12037>])
- NDB Cluster: With two mgmd processes in a cluster, ndb\_mgmd output for SHOW would display the same IP address for both processes, even when they were on different hosts. (Bug#11595 [<http://bugs.mysql.com/11595>])
- NDB Cluster: Queries on NDB tables that are executed using index\_merge/union or index\_merge/intersection could produce incorrect results. (Bug#13081 [<http://bugs.mysql.com/13081>])
- The --replicate-rewrite-db and --replicate-do-table options did not work for statements in which tables were aliased to names other than those listed by the options. (Bug#11139 [<http://bugs.mysql.com/11139>])
- After running configure with the --with-embedded-privilege-control option, the embedded server failed to build. (Bug#13501 [<http://bugs.mysql.com/13501>])
- Nested handlers within stored procedures didn't work. (Bug#6127 [<http://bugs.mysql.com/6127>])
- The optimizer chose a less efficient execution plan for *col\_name* BETWEEN *const* AND *const* than for *col\_name* = *const*, even though the two expressions are logically equivalent. Now the optimizer can use the *ref* access method for both expressions. (Bug#13455 [<http://bugs.mysql.com/13455>])
- Incorrect creation of DECIMAL local variables in a stored procedure could cause a server crash. (Bug#12589 [<http://bugs.mysql.com/12589>])
- Queries against a MERGE table that has a composite index could produce incorrect results. (Bug#9112 [<http://bugs.mysql.com/9112>])
- The server was not rejecting FLOAT(*M*,*D*) or DOUBLE(*M*,*D*) columns specifications when *M* was less than *D*. (Bug#12694 [<http://bugs.mysql.com/12694>])

- After running `configure` with the `--without-server` option, the distribution failed to build. (Bug#11680 [<http://bugs.mysql.com/11680>], Bug#13550 [<http://bugs.mysql.com/13550>])
- Joins nested under `NATURAL` or `USING` joins were sometimes not initialized properly, causing a server crash. (Bug#13545 [<http://bugs.mysql.com/13545>])
- Locking a view with the query cache enabled and `query_cache_wlock_invalidate` enabled could cause a server crash. (Bug#13424 [<http://bugs.mysql.com/13424>])
- A `HAVING` clause that references an unqualified view column name could crash the server. (Bug#13411 [<http://bugs.mysql.com/13411>])
- Comparisons involving row constructors containing constants could cause a server crash. (Bug#13356 [<http://bugs.mysql.com/13356>])
- NDB Cluster: `LOAD DATA INFILE` with a large data file failed. (Bug#10694 [<http://bugs.mysql.com/10694>])
- NDB Cluster: Adding an index to a table with a large number of columns (more than 100) crashed the storage node. (Bug#13316 [<http://bugs.mysql.com/13316>])
- Calling the `FORMAT( )` function with a `DECIMAL` column value caused a server crash when the value was `NULL`. (Bug#13361 [<http://bugs.mysql.com/13361>])
- Aggregate functions sometimes incorrectly were allowed in the `WHERE` clause of `UPDATE` and `DELETE` statements. (Bug#13180 [<http://bugs.mysql.com/13180>])
- It was possible to create a view that executed a stored function for which you did not have the `EXECUTE` privilege. (Bug#12812 [<http://bugs.mysql.com/12812>])
- `BIT` columns and following columns in NDB tables were corrupt when dumped by `mysqldump`. (Bug#13152 [<http://bugs.mysql.com/13152>])
- `NATURAL` joins and joins with `USING` against a view could return `NULL` rather than the correct value. (Bug#13127 [<http://bugs.mysql.com/13127>])
- Use of a user-defined function within the `HAVING` clause of a query resulted in an `Unknown column` error. (Bug#11553 [<http://bugs.mysql.com/11553>])
- For queries for which the optimizer determined a join type of “Range checked for each record” (as shown by `EXPLAIN`, the query sometimes could cause a server crash, depending on the data distribution. (Bug#12291 [<http://bugs.mysql.com/12291>])
- For queries with `DISTINCT` and `WITH ROLLUP`, the `DISTINCT` should be applied after the rollup operation, but was not always. (Bug#12887 [<http://bugs.mysql.com/12887>])
- The server crashed when processing a view that invoked the `CONVERT_TZ( )` function. (Bug#11416 [<http://bugs.mysql.com/11416>])
- Shared-memory connections were not working on Windows. (Bug#12723 [<http://bugs.mysql.com/12723>])

## D.1.11. Changes in release 5.0.13 (22 September 2005: Release Candidate)

Functionality added or changed:

- The syntax for `CREATE VIEW` and `ALTER VIEW` statements now includes `DEFINER` and `SQL SECURITY` clauses for specifying the security context to be used when checking access privileges at view invocation time. (The syntax is present in 5.0.13, but these clauses have no ef-

fect until 5.0.16.) See Section 19.2, “CREATE VIEW Syntax”, for more information.

- The `--hex-dump` option for `mysqldump` now also applies to `BIT` columns.
- Added a `--routines` option for `mysqldump` that enables dumping of stored routines. (Bug#9056 [<http://bugs.mysql.com/9056>])
- The connection string for `FEDERATED` tables now is specified using a `CONNECTION` table option rather than a `COMMENT` table option.
- Better detection of connection timeout for replication servers on Windows allows elimination of extraneous `Lost connection errors` in the error log. (Bug#5588 [<http://bugs.mysql.com/5588>])
- The counters for the `Key_read_requests`, `Key_reads`, `Key_write_requests`, and `Key_writes` status variables were changed from unsigned long to unsigned longlong to accommodate larger values before the variables roll over and restart from 0. (Bug#12920 [<http://bugs.mysql.com/12920>])
- The restriction on the use of `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` within stored procedures was lifted. The restriction still applies to stored functions and triggers. (Bug#10975 [<http://bugs.mysql.com/10975>], Bug#7115 [<http://bugs.mysql.com/7115>], Bug#10605 [<http://bugs.mysql.com/10605>])
- A new command line argument was added to `mysqld` to ignore client character set information sent during handshake, and use server side settings instead, to reproduce 4.0 behavior (Bug#9948 [<http://bugs.mysql.com/9948>]):

```
mysqld --skip-character-set-client-handshake
```

- `OPTIMIZE TABLE` and `HANDLER` now are prohibited in stored procedures and functions and in triggers. (Bug#12953 [<http://bugs.mysql.com/12953>], Bug#12995 [<http://bugs.mysql.com/12995>])
- InnoDB: The `TRUNCATE TABLE` statement for InnoDB tables always resets the counter for an `AUTO_INCREMENT` column now, regardless of whether there is a foreign key constraint on the table. (Beginning with 5.0.3, `TRUNCATE TABLE` reset the counter, but only if there was no such constraint.) (Bug#11946 [<http://bugs.mysql.com/11946>])
- The `LEAST()` and `GREATEST()` functions used to return `NULL` only if all arguments were `NULL`. Now they return `NULL` if any argument is `NULL`, the same as Oracle. (Bug#12791 [<http://bugs.mysql.com/12791>])
- Two new collations have been added for Esperanto: `utf8_esperanto_ci` and `ucs2_esperanto_ci`.
- Reorder network startup to come after all other initialization, particularly storage engine startup which can take a long time. This also prevents MySQL from being run on a privileged port (any port under 1024) unless run as the root user. (Bug#11707 [<http://bugs.mysql.com/11707>])
- The Windows binary packages are now compiled with the Microsoft Visual Studio 2003 compiler instead of Microsoft Visual C++ 6.0.
- The binaries compiled with the Intel `icc` compiler are now built using `icc 9.0` instead of `icc 8.1`. You will have to install new versions of the Intel `icc` runtime libraries, which are available from here: (<http://dev.mysql.com/downloads/os-linux.html>) [<http://dev.mysql.com/downloads/os-linux.html>])

Bugs fixed:

- **Incompatible change:** A lock wait timeout caused InnoDB to roll back the entire current trans-

action. Now it rolls back only the most recent SQL statement. (Bug#12308 [<http://bugs.mysql.com/12308>])

- The FEDERATED storage engine does not support ALTER TABLE, but no appropriate error message was issued. (Bug#13108 [<http://bugs.mysql.com/13108>])
- mysqldump did not dump triggers properly. (Bug#12597 [<http://bugs.mysql.com/12597>])
- NDBCluster: The average row size for Cluster tables was being calculated incorrectly. This affected the values shown for the Data\_length and Avg\_row\_length columns in the output generated by SHOW TABLE STATUS as well as the values for the data\_length and data\_length/table\_rows columns shown in the TABLES table of the INFORMATION\_SCHEMA database with respect to Cluster tables (tables using other storage engines were not affected by this bug). (Bug#9896 [<http://bugs.mysql.com/9896>])
- Within a stored procedure, fetching a large number of rows in a loop using a cursor could result in a server crash or an out of memory error. Also, values inserted within a stored procedure using a cursor were interpreted as latin1 even if character set variables had been set to a different character set. (Bug#6513 [<http://bugs.mysql.com/6513>], Bug#9819 [<http://bugs.mysql.com/9819>])
- For a server compiled with yaSSL, clients that used MySQL Connector/J were not able to establish SSH connections. (Bug#13029 [<http://bugs.mysql.com/13029>])
- When used in view definitions, DAYNAME(*expr*), DAYOFWEEK(*expr*), WEEKDAY(*expr*) were incorrectly treated as though the expression was TO\_DAYS(*expr*) or TO\_DAYS(TO\_DAYS(*expr*)). (Bug#13000 [<http://bugs.mysql.com/13000>])
- Incorrect implicit nesting of joins caused the parser to fail on queries of the form SELECT ... FROM t1 JOIN t2 JOIN t3 ON t1.t1col = t3.t3col with an Unknown column 't1.t1col' in 'on clause' error. (Bug#12943 [<http://bugs.mysql.com/12943>])
- NDB: A cluster shutdown following the crash of a data node would fail to terminate the remaining node processes, even though ndb\_mgm showed the shutdown request as having been completed. (Bug#10938 [<http://bugs.mysql.com/10938>], Bug#9996 [<http://bugs.mysql.com/9996>], Bug#11623 [<http://bugs.mysql.com/11623>])
- A column that can be NULL was not handled properly for WITH ROLLUP in a subquery or view. (Bug#12885 [<http://bugs.mysql.com/12885>])
- Within a transaction, the following statements now cause an implicit commit: CREATE FUNCTION, DROP FUNCTION, DROP PROCEDURE, ALTER FUNCTION, ALTER PROCEDURE, CREATE PROCEDURE. This corrects a problem where these statements followed by ROLLBACK might not be replicated properly. (Bug#12870 [<http://bugs.mysql.com/12870>])
- Simultaneous execution of DML statements and CREATE TRIGGER or DROP TRIGGER statements on the same table could cause server crashes or errors. (Bug#12704 [<http://bugs.mysql.com/12704>])
- If a stored function invoked from a SELECT failed with an error, it could cause the client connection to be dropped. Now such errors generate warnings instead so as not to interrupt the SELECT. (Bug#12379 [<http://bugs.mysql.com/12379>])
- A concurrency problem for CREATE ... SELECT could cause a server crash. (Bug#12845 [<http://bugs.mysql.com/12845>])
- The server incorrectly generated an Unknown table error message when for attempts to drop tables in the INFORMATION\_SCHEMA database. Now it issues an Access denied message. (Bug#9846 [<http://bugs.mysql.com/9846>])
- The server allowed privileges to be granted explicitly for the INFORMATION\_SCHEMA database. Such privileges are always implicit and should not be grantable. (Bug#10734

[<http://bugs.mysql.com/10734>])

- The server allowed `TEMPORARY` tables and stored procedures to be created in the `INFORMATION_SCHEMA` database. (Bug#9683 [<http://bugs.mysql.com/9683>], Bug#10708 [<http://bugs.mysql.com/10708>])
- The server failed to disallow `SET AUTOCOMMIT` in stored functions and triggers. It is allowed to change the value of `AUTOCOMMIT` in stored procedures, but a runtime error might occur if the procedure is invoked from a stored function or trigger. (Bug#12712 [<http://bugs.mysql.com/12712>])
- Using an `INOUT` parameter with a `DECIMAL` data type in a stored procedure caused a server crash. (Bug#12979 [<http://bugs.mysql.com/12979>])
- Performing an `IS NULL` check on the `MIN()` or `MAX()` of an indexed column in a complex query could produce incorrect results. (Bug#12695 [<http://bugs.mysql.com/12695>])
- The `mysql.server` script contained incorrect path for the `libexec` directory. (Bug#12550 [<http://bugs.mysql.com/12550>])
- The `NDB START BACKUP` command could be interrupted by a `SHOW` command. (Bug#13054 [<http://bugs.mysql.com/13054>])
- The `LIKE ... ESCAPE` syntax produced invalid results when escape character was larger than one byte. (Bug#12611 [<http://bugs.mysql.com/12611>])
- A client connection thread cleanup problem caused the server to crash when closing the connection if the binary log was enabled. (Bug#12517 [<http://bugs.mysql.com/12517>])
- Using `AS` to rename a column selected from a view in a subquery made it not possible to refer to that column in the outer query. (Bug#12993 [<http://bugs.mysql.com/12993>])
- The `character_set_system` system variable could not be selected with `SELECT @@character_set_system`. (Bug#11775 [<http://bugs.mysql.com/11775>])
- A view-creation statement of the form `CREATE VIEW name AS SELECT ... FROM tbl_name AS name` failed with a `Not unique table/alias: 'name'` error. (Bug#6808 [<http://bugs.mysql.com/6808>])
- `UNION [DISTINCT]` was not removing all duplicates for multi-byte character values. (Bug#12891 [<http://bugs.mysql.com/12891>])
- Multiplying a `DECIMAL` value within a loop in a stored routine could incorrectly result in a value of `NULL`. (Bug#12938 [<http://bugs.mysql.com/12938>])
- `mysql` and `mysqldump` were ignoring the `--defaults-extra-file` option. (Bug#12917 [<http://bugs.mysql.com/12917>])
- Columns named in the `USING()` clause of `JOIN ... USING()` were incorrectly resolved in case-sensitive fashion. (Bug#13067 [<http://bugs.mysql.com/13067>])
- Local variables in stored routines were not always initialized correctly. (Bug#13133 [<http://bugs.mysql.com/13133>])
- `SHOW FIELDS FROM schemaname.viewname` caused error 1046 when no default schema was set. (Bug#12905 [<http://bugs.mysql.com/12905>])
- The value of `character_set_results` could be set to `NULL`, but returned the string `"NULL"` when retrieved. (Bug#12363 [<http://bugs.mysql.com/12363>])
- InnoDB: Limit recursion depth to 200 in deadlock detection to avoid running out of stack space. (Bug#12588 [<http://bugs.mysql.com/12588>])
- `GROUP_CONCAT()` ignored an empty string if it was the first value to occur in the result.

Bug#12863 [<http://bugs.mysql.com/12863>])

- Outer join elimination was erroneously applied for some queries that used a NOT BETWEEN condition, an IN(*value\_list*) condition, or an IF() condition. (Bug#12101 [<http://bugs.mysql.com/12101>], Bug#12102 [<http://bugs.mysql.com/12102>])
- SHOW FIELDS truncated the TYPE column to 40 characters. (Bug#7142 [<http://bugs.mysql.com/7142>])
- Use of PREPARE and EXECUTE with a statement that selected from a view in a subquery could cause a server crash. (Bug#12651 [<http://bugs.mysql.com/12651>])
- On HP-UX 11.x (PA-RISC), the -L option caused mysqlimport to crash. (Bug#12958 [<http://bugs.mysql.com/12958>])
- If the binary log is enabled, execution of a stored procedure that modifies table data and uses user variables could cause a server crash or incorrect information to be written to the binary log. (Bug#12637 [<http://bugs.mysql.com/12637>])
- Queries with subqueries, where the inner subquery uses the range or index\_merge access method, could return incorrect results. (Bug#12720 [<http://bugs.mysql.com/12720>])
- After changing the character set with SET CHARACTER SET, the result of the GROUP\_CONCAT() function was not converted to the proper character set. (Bug#12829 [<http://bugs.mysql.com/12829>])
- A bug introduced in MySQL 5.0.12 caused SHOW TABLE STATUS to display an Auto\_increment value of 0 for InnoDB tables. (Bug#12973 [<http://bugs.mysql.com/12973>])
- Foreign keys were not properly enforced in TEMPORARY tables. Foreign keys now are disallowed in TEMPORARY tables. (Bug#12084 [<http://bugs.mysql.com/12084>])
- Replication of LOAD DATA INFILE failed between systems that use different pathname syntax (such as delimiter characters). (Bug#11815 [<http://bugs.mysql.com/11815>])
- Within a stored procedure, a server crash was caused by assigning to a VARCHAR INOUT parameter the value of an expression that included the variable itself. (For example, SET c = c.) (Bug#12849 [<http://bugs.mysql.com/12849>])
- SELECT ... JOIN ... ON ... JOIN ... USING caused a server crash. (Bug#12977 [<http://bugs.mysql.com/12977>])
- Using GROUP BY when selecting from a view in some cases could cause incorrect results to be returned. (Bug#12922 [<http://bugs.mysql.com/12922>])
- myisampack did not properly pack BLOB values larger than 2<sup>24</sup> bytes. (Bug#4214 [<http://bugs.mysql.com/4214>])
- Incorrect results could be returned from a view processed using a temporary table. (Bug#12941 [<http://bugs.mysql.com/12941>])
- The server crashed when one thread resized the query cache while another thread was using it. (Bug#12848 [<http://bugs.mysql.com/12848>])
- mysqld\_multi now quotes arguments on command lines that it constructs to avoid problems with arguments that contain shell metacharacters. (Bug#11280 [<http://bugs.mysql.com/11280>])
- InnoDB: A consistent read could return inconsistent results due to a bug introduced in MySQL 5.0.5. (Bug#12947 [<http://bugs.mysql.com/12947>])
- Deadlock occurred when several account management statements were run (particularly between FLUSH PRIVILEGES/SET PASSWORD and GRANT/REVOKE statements). (Bug#12423 [<http://bugs.mysql.com/12423>])

- The Windows installer made a change to one of the `mysql.proc` table files, causing stored routine functionality to be compromised. The Windows installer now never overwrites files in the MySQL data directory. During an upgrade from one version to another, a file in the data directory will not be overwritten even if it has not been modified since it was put there by an older installer.

If you have already lost access to stored routines because of this problem, you can get them back using the following procedure:

- Stop the server.
- In the `mysql\data` directory under your MySQL installation directory, and replace the `proc.frm` file with corresponding file from the version of MySQL that you were using before you upgraded.
- Start the server
- Start the `mysql` command-line client (use the `root` account or another account that has full database privileges) and execute the `mysql_fix_privilege_tables.sql` script that upgrades the grant tables to the current structure. Instructions for doing this are given in Section 5.6.1, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.

After this, all stored routine functionality should work. (Bug#12820 [<http://bugs.mysql.com/12820>])

- On Windows, the server was preventing tables from being created if the table name was a prefix of a forbidden name. For example, `nul` is a forbidden name because it's the same as a Windows device name, but a table with the name of `n` or `nu` was being forbidden as well. (Bug#12325 [<http://bugs.mysql.com/12325>])
- InnoDB was too permissive with `LOCK TABLE ... READ LOCAL` and allowed new inserts into the table. Now `READ LOCAL` is equivalent to `READ` for InnoDB. This will cause slightly more locking in `mysqldump`, but makes InnoDB table dumps consistent with MyISAM table dumps. (Bug#12410 [<http://bugs.mysql.com/12410>])
- Use of the `mysql` client `HELP` command from within a stored routine caused a “packets out of order” error and a lost connection. Now `HELP` is detected and disallowed within stored routines. (Bug#12490 [<http://bugs.mysql.com/12490>])
- Use of `yaSSL` for a secure client connection caused `LOAD DATA LOCAL INFILE` to fail. (Bug#11286 [<http://bugs.mysql.com/11286>])
- `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` no longer qualify the routine name with the database name, for consistency with the behavior of `SHOW CREATE TABLE`. (Bug#10362 [<http://bugs.mysql.com/10362>])
- A `UNION` of long `utf8` `VARCHAR` columns was sometimes returned as a column with a `LONGTEXT` data type rather than `VARCHAR`. This could prevent such queries from working at all if selected into a `MEMORY` table because the `MEMORY` storage engine does not support the `TEXT` data types. (Bug#12537 [<http://bugs.mysql.com/12537>])
- If a client has opened an InnoDB table for which the `.ibd` file is missing, InnoDB would not honor a `DROP TABLE` statement for the table. (Bug#12852 [<http://bugs.mysql.com/12852>])
- `ALTER TABLE ... DISCARD TABLESPACE` for non-InnoDB table caused the client to lose the connection. (The server was not returning the error properly.) (Bug#12207 [<http://bugs.mysql.com/12207>])
- `DO IFNULL(NULL, NULL)` and `SELECT CAST(IFNULL(NULL, NULL) AS DECIMAL)` caused a server crash. (Bug#12841 [<http://bugs.mysql.com/12841>])
- When using a cursor, a `SELECT` statement that uses a `GROUP BY` clause could return incorrect results. (Bug#11904 [<http://bugs.mysql.com/11904>])

- The `SYSDATE()` function now returns the time at which it was invoked. In particular, within a stored routine or trigger, `SYSDATE()` returns the time at which it executes, not the time at which the stored routine or triggering statement began to execute. (Bug#12480 [<http://bugs.mysql.com/12480>])
- `CREATE VIEW` inside a stored procedure caused a server crash if the table underlying the view had been deleted. (Bug#12468 [<http://bugs.mysql.com/12468>])
- A memory leak resulting from repeated `SELECT . . . INTO` statements inside a stored procedure could cause the server to crash. (Bug#11333 [<http://bugs.mysql.com/11333>])

## D.1.12. Changes in release 5.0.12 (02 September 2005)

Functionality added or changed:

- **Incompatible change:** Beginning with MySQL 5.0.12, natural joins and joins with `USING`, including outer join variants, are processed according to the SQL:2003 standard. The changes include elimination of redundant output columns for `NATURAL` joins and joins specified with a `USING` clause and proper ordering of output columns. (Bug#6136 [<http://bugs.mysql.com/6136>], Bug#6276 [<http://bugs.mysql.com/6276>], Bug#6489 [<http://bugs.mysql.com/6489>], Bug#6495 [<http://bugs.mysql.com/6495>], Bug#6558 [<http://bugs.mysql.com/6558>], Bug#9067 [<http://bugs.mysql.com/9067>], Bug#9978 [<http://bugs.mysql.com/9978>], Bug#10428 [<http://bugs.mysql.com/10428>], Bug#10646 [<http://bugs.mysql.com/10646>], Bug#10972 [<http://bugs.mysql.com/10972>].) The precedence of the comma operator also now is lower compared to `JOIN`. (Bug#4789 [<http://bugs.mysql.com/4789>], Bug#12065 [<http://bugs.mysql.com/12065>], Bug#13551 [<http://bugs.mysql.com/13551>].)

These changes make MySQL more compliant with standard SQL. However, they can result in different output columns for some joins. Also, some queries that appeared to work correctly prior to 5.0.12 must be rewritten to comply with the standard. For details about the scope of the changes and examples that show what query rewrites are necessary, see Section 13.2.7.1, “`JOIN Syntax`”.

- Recursive triggers are detected and disallowed. Also, within a stored function or trigger, it is not allowable to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger. (Bug#11896 [<http://bugs.mysql.com/11896>], Bug#12644 [<http://bugs.mysql.com/12644>])
- `SHOW TABLE STATUS` for a view now shows `VIEW` in uppercase, consistent with `SHOW TABLES` and `INFORMATION_SCHEMA`. (Bug#5501 [<http://bugs.mysql.com/5501>])
- An optimizer estimate of zero rows for a non-empty `InnoDB` table used in a left or right join could cause incomplete rollback for the table. (Bug#12779 [<http://bugs.mysql.com/12779>])
- Calls to stored procedures were written to the binary log even within transactions that were rolled back, causing them to be executed on replication slaves. (Bug#12334 [<http://bugs.mysql.com/12334>])
- Interleaved execution of stored procedures and functions could be written to the binary log incorrectly, causing replication slaves to get out of sync. (Bug#12335 [<http://bugs.mysql.com/12335>])
- A query of the form `SHOW TABLE STATUS FROM db_name WHERE name IN (select_query)` would crash the server. (Bug#12636 [<http://bugs.mysql.com/12636>])
- Users created using an IP address or other alias rather than a hostname listed in `/etc/hosts` could not set their own passwords. (Bug#12302 [<http://bugs.mysql.com/12302>])
- Using `DESCRIBE` on a view after renaming a column in one of the view's base tables caused the server to crash. (Bug#12533 [<http://bugs.mysql.com/12533>])

- `SHOW OPEN TABLES` now supports `FROM` and `LIKE` clauses. (Bug#12183 [<http://bugs.mysql.com/12183>])
- `SHOW TABLE STATUS FROM INFORMATION_SCHEMA` now sorts output by table name the same as it does for other databases. (Bug#12315 [<http://bugs.mysql.com/12315>])
- `SHOW ENGINE INNODB STATUS` now can display longer query strings. (Bug#7819 [<http://bugs.mysql.com/7819>])
- Added the `SLEEP( )` function, which pauses for the number of seconds given by its argument. (Bug#6760 [<http://bugs.mysql.com/6760>])
- Trying to drop the default keycache by setting `@@global.key_buffer_size` to zero now returns a warning that the default keycache cannot be dropped. (Bug#10473 [<http://bugs.mysql.com/10473>])
- The stability of cursors when used with InnoDB tables was greatly improved. (Bug#11832 [<http://bugs.mysql.com/11832>], Bug#12243 [<http://bugs.mysql.com/12243>], Bug#11309 [<http://bugs.mysql.com/11309>])
- It is no longer possible to issue `FLUSH` commands from within stored functions or triggers. See Section I.1, “Restrictions on Stored Routines and Triggers”, for details. (Bug#12280 [<http://bugs.mysql.com/12280>], Bug#12307 [<http://bugs.mysql.com/12307>])
- `INFORMATION_SCHEMA` objects are now reported as a `SYSTEM VIEW` table type. (Bug#11711 [<http://bugs.mysql.com/11711>])

Bugs fixed:

- `CHECKSUM TABLE` command returned incorrect results for tables with deleted rows. After upgrading, users who used stored checksum information to detect table changes should rebuild their checksum data. (Bug#12296 [<http://bugs.mysql.com/12296>])
- A data type of `CHAR BINARY` was not recognized as valid for stored routine parameters. (Bug#9048 [<http://bugs.mysql.com/9048>])
- `SET GLOBAL TRANSACTION ISOLATION LEVEL` was not working. (Bug#11207 [<http://bugs.mysql.com/11207>])
- NDB Cluster: Corrected the parsing of the `CLUSTERLOG` command by `ndb_mgm` to allow multiple items. (Bug#12833 [<http://bugs.mysql.com/12833>])
- NDB Cluster: Improved error messages related to filesystem issues. (Bug#11218 [<http://bugs.mysql.com/11218>])
- NDB Cluster: When a schema was detected to be corrupt, `ndb` neglected to close it, resulting in a “file already open” error if the schema was opened again later. (Bug#12027 [<http://bugs.mysql.com/12027>])
- NDB Cluster: When it could not copy a fragment, `ndbd` exited without printing a message about the condition to the error log. Now the message is written. (Bug#12900 [<http://bugs.mysql.com/12900>])
- NDB Cluster: When a disk full condition occurred, `ndbd` exited without printing a message about the condition to the error log. Now the message is written. (Bug#12716 [<http://bugs.mysql.com/12716>])
- `mysql_fix_privilege_tables.sql` was missing a comma, causing a syntax error when executed. (Bug#12705 [<http://bugs.mysql.com/12705>])
- `STRCMP( )` was not handled correctly in views. (Bug#12489 [<http://bugs.mysql.com/12489>])

- NDB Cluster: Bad values in `config.ini` caused `ndb_mgmd` to crash. (Bug#12043 [<http://bugs.mysql.com/12043>])
- `TRUNCATE TABLE` did not work with `TEMPORARY` InnoDB tables. (Bug#11816 [<http://bugs.mysql.com/11816>])
- Built-in commands for the `mysql` client, such as `delimiter` and `\d` are now always parsed within files that are read using the `\.` and `source` commands. (Bug#11523 [<http://bugs.mysql.com/11523>])
- `ALTER TABLE db_name.t RENAME t` did not move the table to default database unless the new name was qualified with the database name. (Bug#11493 [<http://bugs.mysql.com/11493>])
- It was not possible to create a stored function with a spatial return value data type. (Bug#10499 [<http://bugs.mysql.com/10499>])
- The only valid values for the `PACK_KEYS` table option are 0 and 1, but other values were being accepted. (Bug#10056 [<http://bugs.mysql.com/10056>])
- If a `DROP DATABASE` fails on a master server due to the presence of a non-database file in the database directory, the master have the database tables deleted, but not the slaves. To deal with failed database drops, we now write `DROP TABLE` statements to the binary log for the tables so that they are dropped on slaves. (Bug#4680 [<http://bugs.mysql.com/4680>])
- Improper use of loose index scan in InnoDB sometimes caused incorrect query results. (Bug#12672 [<http://bugs.mysql.com/12672>])
- `DELETE` or `UPDATE` for an indexed MyISAM table could fail. This was due to a change in end-space comparison behavior from 4.0 to 4.1. (Bug#12565 [<http://bugs.mysql.com/12565>])
- Joins on `VARCHAR` columns of different lengths could produce incorrect results. (Bug#11398 [<http://bugs.mysql.com/11398>])
- A “Duplicate column name” error no longer occurs when selecting from a view defined as `SELECT * from a join that uses a USING clause on tables that have a common column name.` (Bug#6558 [<http://bugs.mysql.com/6558>])
- Invocations of the `SLEEP()` function incorrectly could get optimized away for statements in which it occurs. Statements containing `SLEEP()` incorrectly could be stored in the query cache. (Bug#12689 [<http://bugs.mysql.com/12689>])
- NDB Cluster: An `ALTER TABLE` command caused loss of data stored prior to the issuing of the command. (Bug#12118 [<http://bugs.mysql.com/12118>])
- Query cache is switched off if a thread (connection) has tables locked. This prevents invalid results where the locking thread inserts values between a second thread connecting and selecting from the table. (Bug#12385 [<http://bugs.mysql.com/12385>])
- `NOW()`, `CURRENT_TIME` and values generated by timestamp columns are now constant for the duration of a stored function or trigger. This prevents the breaking of statements-based replication. (Bug#12480 [<http://bugs.mysql.com/12480>], Bug#12481 [<http://bugs.mysql.com/12481>])
- Some statements executed on a master server caused the SQL thread on a slave to run out of memory. (Bug#12532 [<http://bugs.mysql.com/12532>])
- A `SELECT DISTINCT` query with a constant value for one of the columns would return only a single row. (Bug#12625 [<http://bugs.mysql.com/12625>])
- NDB Cluster: Cluster failed to take character set data into account when recomputing hashes (and thus could not locate records for updating or deletion) following a configuration change and node restart. (Bug#12220 [<http://bugs.mysql.com/12220>])
- NDB Cluster: Wrong error message displayed when cluster management server closed port

while mysqld was connecting. (Bug#10950 [<http://bugs.mysql.com/10950>])

- A view was allowed to depend on a function that referred to a temporary table. (Bug#10970 [<http://bugs.mysql.com/10970>])
- Prepared statement parameters could cause errors in the binary log if the character set was cp932. (Bug#11338 [<http://bugs.mysql.com/11338>])
- The CREATE\_OPTIONS column of INFORMATION\_SCHEMA.TABLES showed incorrect options for tables in INFORMATION\_SCHEMA. (Bug#12397 [<http://bugs.mysql.com/12397>])
- MEMORY tables using B-Tree index on 64-bit platforms could produce false table is full errors. (Bug#12460 [<http://bugs.mysql.com/12460>])
- Issuing FLUSH INSTANCES followed by STOP INSTANCE caused instance manager to crash. (Bug#10957 [<http://bugs.mysql.com/10957>])
- Duplicate instructions in stored procedures resulted in incorrect execution when the optimizer optimized the duplicate code away. (Bug#12168 [<http://bugs.mysql.com/12168>])
- SHOW TABLES FROM returned wrong error message if the schema specified did not exist. (Bug#12591 [<http://bugs.mysql.com/12591>])
- The ROW() function returned an incorrect result when comparison involved NULL values. (Bug#12509 [<http://bugs.mysql.com/12509>])
- Views with multiple UNION and UNION ALL produced incorrect results. (Bug#10624 [<http://bugs.mysql.com/10624>])
- Stored procedures with particularly long loops could crash server due to memory leak. (Bug#12297 [<http://bugs.mysql.com/12297>], Bug#11247 [<http://bugs.mysql.com/11247>])
- Trigger and stored procedure execution could break replication. (Bug#12482 [<http://bugs.mysql.com/12482>])
- A server crash could result from an update of a view defined as a join, even though the update updated only a single table. (Bug#12569 [<http://bugs.mysql.com/12569>])
- On Windows when the --innodb\_buffer\_pool\_ave\_mem\_mb option has been given, the server detects whether AWE support is available and has been compiled into the server, and displays an appropriate error message if not. (Bug#6581 [<http://bugs.mysql.com/6581>])
- The NUMERIC\_SCALE column of the INFORMATION\_SCHEMA.COLUMNS table should be returned as 0 for integer columns. It was being returned as NULL. (Bug#12301 [<http://bugs.mysql.com/12301>])
- The COLUMN\_DEFAULT column of the INFORMATION\_SCHEMA.COLUMNS table should be returned as NULL if a column has no default value. An empty string was being returned if the column was defined as NOT NULL. (Bug#12518 [<http://bugs.mysql.com/12518>])
- Slave I/O threads were considered to be in the running state when launched (rather than after successfully connecting to the master server), resulting in incorrect SHOW SLAVE STATUS output. (Bug#10780 [<http://bugs.mysql.com/10780>])
- Column names in subqueries must be unique, but were not being checked for uniqueness. (Bug#11864 [<http://bugs.mysql.com/11864>])
- On Windows, the server could crash during shutdown if both replication threads and normal client connection threads were active. (Bug#11796 [<http://bugs.mysql.com/11796>])
- Some subqueries of the form SELECT ... WHERE ROW(...) IN (subquery) were being handled incorrectly. (Bug#11867 [<http://bugs.mysql.com/11867>])
- Selecting from a view after INSERT statements for the view's underlying table yielded different

results than subsequent selects. (Bug#12382 [<http://bugs.mysql.com/12382>])

- The `mysql_info()` C API function could return incorrect data when executed as part of a multi-statement that included a mix of statements that do and do not return information. (Bug#11688 [<http://bugs.mysql.com/11688>])
- When restoring `INFORMATION_SCHEMA` as the default database after failing to execute a stored procedure in an inaccessible database, the server returned a spurious `ERROR 42000: Unknown database 'information_schema'` message. (Bug#12318 [<http://bugs.mysql.com/12318>])
- Renamed the `rest()` macro in `my_list.h` to `list_rest()` to avoid name clashes with user code. (Bug#12327 [<http://bugs.mysql.com/12327>])
- `DATE_ADD()` and `DATE_SUB()` were converting invalid dates to `NULL` in `TRADITIONAL SQL` mode rather than rejecting them with an error. (Bug#10627 [<http://bugs.mysql.com/10627>])
- A trigger that included a `SELECT` statement could cause a server crash. (Bug#11587 [<http://bugs.mysql.com/11587>])
- An incorrect conversion from `double` to `ulonglong` caused indexes not to be used for BDB tables on HP-UX. (Bug#10802 [<http://bugs.mysql.com/10802>])
- `myisampack` failed to delete `.TMD` temporary files when run with `-T` option. (Bug#12235 [<http://bugs.mysql.com/12235>])
- Added portability check for Intel compiler to address a problem compiling `InnoDB` code. (Bug#11510 [<http://bugs.mysql.com/11510>])
- `XA` allowed two active transactions to be started with the same `XID`. (Bug#12162 [<http://bugs.mysql.com/12162>])
- Concatenating `USER()` or `DATEBASE()` with a column produced invalid results. (Bug#12351 [<http://bugs.mysql.com/12351>])
- Creating a view that included the `TIMESTAMPDIFF()` function resulted in a invalid view. (Bug#12298 [<http://bugs.mysql.com/12298>])
- Comparison of `InnoDB` multi-part primary keys that include `VARCHAR` columns can result in incorrect results. (Bug#12340 [<http://bugs.mysql.com/12340>])
- For `PKG` installs on Mac OS X, the preinstallation and postinstallation scripts were being run only for new installations and not for upgrade installations, resulting in an incomplete installation process. (Bug#11380 [<http://bugs.mysql.com/11380>])
- Using cursors and nested queries for the same table, corrupted results were returned for the outer query. (Bug#11909 [<http://bugs.mysql.com/11909>])
- User variables were not automatically cast for comparisons, causing queries to fail if the column and connection character sets differed. Now when mixing strings with different character sets but the same coercibility, allow conversion if one character set is a superset of the other. (Bug#10892 [<http://bugs.mysql.com/10892>])
- Selecting from a view defined as a join over many tables could result in a server crash due to miscalculation of the number of conditions in the `WHERE` clause. (Bug#12470 [<http://bugs.mysql.com/12470>])
- Pathame values for options such as `---basedir` or `--datadir` didn't work on Japanese Windows machines for directory names containing multi-byte characters having a second byte of `0x5C ('\\')`. (Bug#5439 [<http://bugs.mysql.com/5439>])
- A race condition between server threads could cause a crash if one thread deleted a stored routine while another thread was executing a stored routine. (Bug#12228 [<http://bugs.mysql.com/12228>])

- Mishandling of comparison for rows containing NULL values against rows produced by an IN subquery could cause a server crash. (Bug#12392 [<http://bugs.mysql.com/12392>])
- Inserting NULL into a GEOMETRY column for a table that has a trigger could result in a server crash if the table was subsequently dropped. (Bug#12281 [<http://bugs.mysql.com/12281>])
- A failure to obtain a lock for an IN SHARE MODE query could result in a server crash. (Bug#12082 [<http://bugs.mysql.com/12082>])
- SELECT ... INTO var\_name within a trigger could cause a server crash. (Bug#11973 [<http://bugs.mysql.com/11973>])
- INSERT ... SELECT ... ON DUPLICATE KEY UPDATE could fail with an erroneous "Column 'col\_name' specified twice" error. (Bug#10109 [<http://bugs.mysql.com/10109>])
- SHOW TABLE STATUS sometimes reported a Row\_format value of Dynamic for MEMORY tables, though such tables always have a format of Fixed. (Bug#3094 [<http://bugs.mysql.com/3094>])
- A query using a LEFT JOIN, an IN subquery on the outer table, and an ORDER BY clause, caused the server to crash when cursors were enabled. (Bug#11901 [<http://bugs.mysql.com/11901>])
- Using a stored procedure that referenced tables in the INFORMATION\_SCHEMA database would return an empty result set. (Bug#10055 [<http://bugs.mysql.com/10055>], Bug#12278 [<http://bugs.mysql.com/12278>])
- Columns defined as TINYINT(1) were redefined as TINYINT(4) when incorporated into a VIEW. (Bug#11335 [<http://bugs.mysql.com/11335>])
- ISO-8601 formatted dates were not being parsed correctly. (Bug#7308 [<http://bugs.mysql.com/7308>])
- FLUSH TABLES WITH READ LOCK combined with LOCK TABLE .. WRITE caused deadlock. (Bug#9459 [<http://bugs.mysql.com/9459>])
- NULL column definitions read incorrectly for inner tables of nested outer joins. (Bug#12154 [<http://bugs.mysql.com/12154>])
- GROUP\_CONCAT ignores the DISTINCT modifier when used in a query joining multiple tables where one of the tables has a single row. (Bug#12095 [<http://bugs.mysql.com/12095>])
- UNION query with FULLTEXT could cause server crash. (Bug#11869 [<http://bugs.mysql.com/11869>])

## D.1.13. Changes in release 5.0.11 (06 August 2005)

Functionality added or changed:

- Security improvement: Applied a patch that addresses a potential zlib data vulnerability that could result in an application crash. (CVE-2005-1849 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-1849>]) This only affects the binaries for platforms that are linked statically against the bundled zlib (most notably Microsoft Windows and HP-UX).
- SHOW CHARACTER SET and INFORMATION\_SCHEMA now properly report the Latin1 character set as cp1252. (Bug#11216 [<http://bugs.mysql.com/11216>])
- mysqldump now dumps triggers for each dumped table. This can be suppressed with the --skip-triggers option. (Bug#10431 [<http://bugs.mysql.com/10431>])

- Added new `ER_STACK_OVERRUN_NEED_MORE` error message to indicate that, while the stack is not completely full, more stack space is required. (Bug#11213 [<http://bugs.mysql.com/11213>])
- NDB: Improved handling of the configuration variables `NoOfPagesToDiskDuringRestartACC`, `NoOfPagesToDiskAfterRestartACC`, `NoOfPagesToDiskDuringRestartTUP`, and `NoOfPagesToDiskAfterRestartTUP` should result in noticeably faster startup times for MySQL Cluster. (Bug#12149 [<http://bugs.mysql.com/12149>])
- Added support of where clause for queries with `FROM DUAL`. (Bug#11745 [<http://bugs.mysql.com/11745>])
- Added an optimization that avoids key access with `NULL` keys for the `ref` method when used in outer joins. (Bug#12144 [<http://bugs.mysql.com/12144>])
- Maximum size of stored procedures increased from 64k to 4Gb. (Bug#11602 [<http://bugs.mysql.com/11602>])
- Added error message for users who attempt `CREATE TABLE ... LIKE` and specify a non-table in the `LIKE` clause. (Bug#6859 [<http://bugs.mysql.com/6859>])

Bugs fixed:

- DDL statements now are allowed in stored procedures if the procedure is not invoked from a stored function or a trigger. Also fixed problems where a `TEMPORARY` statement created by one stored routine was inaccessible to another routine invoked during the same connection. (Bug#11126 [<http://bugs.mysql.com/11126>])
- Creation of the `mysql` group account failed during the RPM installation. (Bug#12348 [<http://bugs.mysql.com/12348>])
- `big5` strings were not being stored in `FULLTEXT` index. (Bug#12075 [<http://bugs.mysql.com/12075>])
- When `DROP DATABASE` was called concurrently with a `DROP TABLE` of any table the MySQL Server crashed. (Bug#12212 [<http://bugs.mysql.com/12212>])
- `max_connections_per_hour` setting was being capped by unrelated `max_user_connections` setting. (Bug#9947 [<http://bugs.mysql.com/9947>])
- `SELECT @@local...` returned `@@session...` in the column header. (Bug#10724 [<http://bugs.mysql.com/10724>])
- Multiplying `ABS()` output by a negative number would return incorrect results. (Bug#11402 [<http://bugs.mysql.com/11402>])
- Updated dependency list for RPM builds to include missing dependencies such as `useradd` and `groupadd`. (Bug#12233 [<http://bugs.mysql.com/12233>])
- `mysql_install_db` used static `localhost` value in `GRANT` tables even when server host-name is not `localhost`, such as `localhost.localdomain`. This change is applied to version 5.0.10b on Windows. (Bug#11822 [<http://bugs.mysql.com/11822>])
- Multiple `SELECT SQL_CACHE` queries in a stored procedure causes error and client hang. (Bug#6897 [<http://bugs.mysql.com/6897>])
- Added checks to prevent error when allocating memory when there was insufficient memory available. (Bug#7003 [<http://bugs.mysql.com/7003>])
- Character data truncated when GBK characters `0xA3A0` and `0xA1` are present. (Bug#11987 [<http://bugs.mysql.com/11987>])

- Comparisons like `SELECT "A\\" LIKE "A\\";` fail when using `SET NAMES utf8;`. (Bug#11754 [<http://bugs.mysql.com/11754>])
- When used in a `SELECT` query against a view, the `GROUP_CONCAT()` function returned only a single row. (Bug#11412 [<http://bugs.mysql.com/11412>])
- Calling the C API function `mysql_stmt_fetch()` after all rows of a result set were exhausted would return an error instead of `MYSQL_NO_DATA`. (Bug#11037 [<http://bugs.mysql.com/11037>])
- Information about a trigger was not displayed in the output of `SELECT ... FROM INFORMATION_SCHEMA.TRIGGERS` when the selected database was `INFORMATION_SCHEMA`, prior to the trigger's first invocation. (Bug#12127 [<http://bugs.mysql.com/12127>])
- Issuing successive `FLUSH TABLES WITH READ LOCK` would cause the `mysql` client to hang. (Bug#11934 [<http://bugs.mysql.com/11934>])
- In stored procedures, a cursor that fetched an empty string into a variable would set the variable to `NULL` instead. (Bug#8692 [<http://bugs.mysql.com/8692>])
- A trigger dependent on a feature of one `SQL_MODE` setting would cause an error when invoked after the `SQL_MODE` was changed. (Bug#5891 [<http://bugs.mysql.com/5891>])
- A delayed insert that would duplicate an existing record crashed the server instead. (Bug#12226 [<http://bugs.mysql.com/12226>])
- `ALTER TABLE` when `SQL_MODE = 'TRADITIONAL'` gave rise to an invalid error message. (Bug#11964 [<http://bugs.mysql.com/11964>])
- Attempting to repair a table having a fulltext index on a column containing words whose length exceeded 21 characters and where `myisam_repair_threads` was greater than 1 would crash the server. (Bug#11684 [<http://bugs.mysql.com/11684>])
- The MySQL Cluster backup log was invalid where the number of Cluster nodes was not equal to a power of 2. (Bug#11675 [<http://bugs.mysql.com/11675>])
- `GROUP_CONCAT()` sometimes returned a result with a different collation from that of its arguments. (Bug#10201 [<http://bugs.mysql.com/10201>])
- The `LPAD()` and `RPAD()` functions returned the wrong length to `mysql_fetch_fields()`. (Bug#11311 [<http://bugs.mysql.com/11311>])
- A `UNIQUE VARCHAR` column would be mis-identified as `MUL` in table descriptions. (Bug#11227 [<http://bugs.mysql.com/11227>])
- Incorrect error message displayed if user attempted to create a table in a non-existing database using `CREATE database_name.table_name` syntax. (Bug#10407 [<http://bugs.mysql.com/10407>])
- InnoDB: Do not flush after each write, not even before setting up the doublewrite buffer. Flushing can be extremely slow on some systems. (Bug#12125 [<http://bugs.mysql.com/12125>])
- InnoDB: True `VARCHAR`: Return `NULL` columns in the format expected by MySQL. (Bug#12186 [<http://bugs.mysql.com/12186>])
- Two threads could potentially initialize different characters sets and overwrite each other. (Bug#12109 [<http://bugs.mysql.com/12109>])
- Unsigned `LONG` system variables may return incorrect value when retrieved with a `SELECT` for certain values. (Bug#10351 [<http://bugs.mysql.com/10351>])
- Prepared statements were not being written to the Slow Query log. (Bug#9968 [<http://bugs.mysql.com/9968>])

## D.1.14. Changes in release 5.0.10 (27 July 2005)

Functionality added or changed:

- Security improvement: Applied a patch that addresses a `zlib` data vulnerability that could result in a buffer overflow and code execution. (CVE-2005-2096 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-2096>] (Bug#11844 [<http://bugs.mysql.com/11844>]))
- **Incompatible change:** The namespace for triggers has changed. Previously, trigger names had to be unique per table. Now they must be unique within the schema (database). An implication of this change is that `DROP TRIGGER` syntax now uses a schema name instead of a table name (schema name is optional and, if omitted, the current schema will be used). (Bug#5892 [<http://bugs.mysql.com/5892>]))

*Note:* When upgrading from a previous version of MySQL 5 to MySQL 5.0.10 or newer, you must drop all triggers and re-create them or `DROP TRIGGER` will not work after the upgrade. A suggested procedure for doing this is given in Section 2.11.2, “Upgrading from MySQL 4.1 to 5.0”.

- The viewing of triggers and trigger metadata has been enhanced as follows:
  - An extension to the `SHOW` command has been added: `SHOW TRIGGERS` can be used to view a listing of triggers. See Section 13.5.4.23, “`SHOW TRIGGERS` Syntax”, for details.
  - The `INFORMATION_SCHEMA` database now includes a `TRIGGERS` table. See Section 20.16, “The `INFORMATION_SCHEMA TRIGGERS` Table”, for details. (Bug#9586 [<http://bugs.mysql.com/9586>]))
- Triggers can now reference tables by name. See Section 18.1, “`CREATE TRIGGER` Syntax”, for more information.
- The output of `peror --help` now displays the `--ndb` option. (Bug#11999 [<http://bugs.mysql.com/11999>]))
- On Windows, the search path used by MySQL applications for `my.ini` now includes `..my.ini` (that is, the application's parent directory, and hence, the installation directory). (Bug#10419 [<http://bugs.mysql.com/10419>]))
- Add the `--defaults-group-suffix` option. See Section 4.3.2, “Using Option Files”.
- Added `mysql_get_character_set_info()` C API function for obtaining information about the default character set of the current connection.
- The bundled version of the `readline` library was upgraded to version 5.0.
- It is no longer necessary to issue an explicit `LOCK TABLES` for any tables accessed by a trigger prior to executing any statements that might invoke the trigger. (Bug#9581 [<http://bugs.mysql.com/9581>], Bug#8406 [<http://bugs.mysql.com/8406>]))
- MySQL Cluster: A new `-P` option is available for use with the `ndb_mgmd` client. When called with this option, `ndb_mgmd` prints all configuration data to `stdout`, then exits.
- Add `table_lock_wait_timeout` global server system variable.

Bugs fixed:

- NDB: Trying to use a greater number of tables than specified by the value of `MaxNoOfTables` caused table corruption such that data nodes could not be restarted. (Bug#9994 [<http://bugs.mysql.com/9994>]))

- NDB: Attempting to create or drop tables during a backup would cause the cluster to shut down. (Bug#11942 [<http://bugs.mysql.com/11942>])
- When attempting to drop a table with a broken unique index, NDB failed to drop the table and erroneously report that the table was unknown. (Bug#11355 [<http://bugs.mysql.com/11355>])
- `SELECT ... NOT IN()` gave unexpected results when only static value present between the `()`. (Bug#11885 [<http://bugs.mysql.com/11885>])
- Fixed compile error when using GCC4 on AMD64. (Bug#12040 [<http://bugs.mysql.com/12040>])
- NDB ignored the `Hostname` option in the `NDBD DEFAULT` section of the Cluster configuration file. (Bug#12028 [<http://bugs.mysql.com/12028>])
- `SHOW PROCEDURE/FUNCTION STATUS` didn't work for users with limited access. (Bug#11577 [<http://bugs.mysql.com/11577>])
- MySQL server would crash is a fetch was performed after a `ROLLBACK` when cursors were involved. (Bug#10760 [<http://bugs.mysql.com/10760>])
- The temporary tables created by an `ALTER TABLE` on a cluster table were visible to all MySQL servers. (Bug#12055 [<http://bugs.mysql.com/12055>])
- `NDB_MGMD` was leaking file descriptors. (Bug#11898 [<http://bugs.mysql.com/11898>])
- IP addresses not shown in `ndb_mgm SHOW` command on second `ndb_mgmd` (or on `ndb_mgmd` restart). (Bug#11596 [<http://bugs.mysql.com/11596>])
- Functions that evaluate to constants (such as `NOW()` and `CURRENT_USER()`) were being evaluated in the definition of a `VIEW` rather than included verbatim. (Bug#4663 [<http://bugs.mysql.com/4663>])
- Execution of `SHOW TABLES` failed to increment the `Com_show_tables` status variable. (Bug#11685 [<http://bugs.mysql.com/11685>])
- For execution of a stored procedure that refers to a view, changes to the view definition were not seen. The procedure continued to see the old contents of the view. (Bug#6120 [<http://bugs.mysql.com/6120>])
- For prepared statements, the SQL parser did not disallow '?' parameter markers immediately adjacent to other tokens, which could result in malformed statements in the binary log. (For example, `SELECT * FROM t WHERE? = 1` could become `SELECT * FROM t WHERE0 = 1.`) (Bug#11299 [<http://bugs.mysql.com/11299>])
- When two threads compete for the same table, a deadlock could occur if one thread has also a lock on another table through `LOCK TABLES` and the thread is attempting to remove the table in some manner and the other thread want locks on both tables. (Bug#10600 [<http://bugs.mysql.com/10600>])
- Aliasing the column names in a `VIEW` did not work when executing a `SELECT` query on the `VIEW`. (Bug#11399 [<http://bugs.mysql.com/11399>])
- Performing an `ORDER BY` on a `SELECT` from a `VIEW` produced unexpected results when `VIEW` and underlying table had the same column name on different columns. Bug#11709 [<http://bugs.mysql.com/11709>])
- The C API function `mysql_statement_reset()` did not clear error information. (Bug#11183 [<http://bugs.mysql.com/11183>])
- When used within a subquery, `SUBSTRING()` returned an empty string. (Bug#10269 [<http://bugs.mysql.com/10269>])
- Multiple-table `UPDATE` queries using `CONVERT_TZ()` would fail with an error. (Bug#9979)

[<http://bugs.mysql.com/9979>])

- `mysql_fetch_fields()` returned incorrect length information for MEDIUM and LONG TEXT and BLOB columns. (Bug#9735 [<http://bugs.mysql.com/9735>])
- `mysqlbinlog` was failing the test suite on Windows due to BOOL being incorrectly cast to INT. (Bug#11567 [<http://bugs.mysql.com/11567>])
- NDBCluster: Server left core files following shutdown if data nodes had failed. (Bug#11516 [<http://bugs.mysql.com/11516>])
- Creating a trigger in one database that references a table in another database was being allowed without generating errors. (Bug#8751 [<http://bugs.mysql.com/8751>])
- Duplicate trigger names were allowed within a single schema. (Bug#6182 [<http://bugs.mysql.com/6182>])
- Server did not accept some fully-qualified trigger names. (Bug#8758 [<http://bugs.mysql.com/8758>])
- The traditional SQL mode accepted invalid dates if the date value provided was the result of an implicit type conversion. (Bug#5906 [<http://bugs.mysql.com/5906>])
- The MySQL server had issues with certain combinations of basedir and datadir. (Bug#7249 [<http://bugs.mysql.com/7249>])
- INFORMATION\_SCHEMA.COLUMNS had some inaccurate values for some data types. (Bug#11057 [<http://bugs.mysql.com/11057>])
- LIKE pattern matching using prefix index didn't return correct result. (Bug#11650 [<http://bugs.mysql.com/11650>])
- For several character sets, MySQL incorrectly converted the character code for the division sign to the euc\_jpms character set. (Bug#11717 [<http://bugs.mysql.com/11717>])
- When invoked within a view, SUBTIME() returned incorrect values. (Bug#11760 [<http://bugs.mysql.com/11760>])
- SHOW BINARY LOGS displayed a file size of 0 for all log files but the current one if the files were not located in the data directory. (Bug#12004 [<http://bugs.mysql.com/12004>])
- Server-side prepared statements failed for columns with a character set of ucs2. (Bug#9442 [<http://bugs.mysql.com/9442>])
- References to system variables in an SQL statement prepared with PREPARE were evaluated during EXECUTE to their values at prepare time, not to their values at execution time. (Bug#9359 [<http://bugs.mysql.com/9359>])
- For server shutdown on Windows, error messages of the form Forcing close of thread *n* user: '*name*' were being written to the error log. Now connections are closed more gracefully without generating error messages. (Bug#7403 [<http://bugs.mysql.com/7403>])
- Increased the version number of the libmysqlclient shared library from 14 to 15 because it is binary incompatible with the MySQL 4.1 client library. (Bug#11893 [<http://bugs.mysql.com/11893>])
- A recent optimizer change caused DELETE ... WHERE ... NOT LIKE and DELETE ... WHERE ... NOT BETWEEN to not properly identify the rows to be deleted. (Bug#11853 [<http://bugs.mysql.com/11853>])
- Within a stored procedure that selects from a table, invoking another procedure that requires a write lock for the table caused that procedure to fail with a message that the table was read-locked. (Bug#9565 [<http://bugs.mysql.com/9565>])

- Within a stored procedure, selecting from a table through a view caused subsequent updates to the table to fail with a message that the table was read-locked. (Bug#9597 [<http://bugs.mysql.com/9597>])
- For a stored procedure defined with `SQL SECURITY DEFINER` characteristic, `CURRENT_USER()` incorrectly reported the user invoking the procedure, not the user who defined it. (Bug#7291 [<http://bugs.mysql.com/7291>])
- Creating a table with a `SET` or `ENUM` column with the `DEFAULT 0` clause caused a server crash if the table's character set was `utf8`. (Bug#11819 [<http://bugs.mysql.com/11819>])
- With strict SQL mode enabled, `ALTER TABLE` reported spurious "Invalid default value" messages for columns that had no `DEFAULT` clause. (Bug#9881 [<http://bugs.mysql.com/9881>])
- In SQL prepared statements, comparisons could fail for values not equally space-padded. For example, `SELECT 'a' = 'a ';` returns 1, but `PREPARE s FROM 'SELECT ?=?'; SET @a = 'a', @b = 'a '; PREPARE s FROM 'SELECT ?=?'; EXECUTE s USING @a, @b;` incorrectly returned 0. (Bug#9379 [<http://bugs.mysql.com/9379>])
- Labels in stored routines did not work if the character set was not `latin1`. (Bug#7088 [<http://bugs.mysql.com/7088>])
- Invoking the `DES_ENCRYPT()` function could cause a server crash if the server was started without the `--des-key-file` option. (Bug#11643 [<http://bugs.mysql.com/11643>])
- The server crashed upon execution of a statement that used a stored function indirectly (via a view) if the function was not yet in the connection-specific stored routine cache and the statement would update a `Handler_xxx` status variable. This fix allows the use of stored routines under `LOCK TABLES` without explicitly locking the `mysql.lock` table. However, you cannot use `mysql.proc` in statements that will combine locking of it with modifications for other tables. (Bug#11554 [<http://bugs.mysql.com/11554>])
- The server crashed when dropping a trigger that invoked a stored procedure, if the procedure was not yet in the connection-specific stored routine cache. (Bug#11889 [<http://bugs.mysql.com/11889>])
- Selecting the result of an aggregate function for an `ENUM` or `SET` column within a subquery could result in a server crash. (Bug#11821 [<http://bugs.mysql.com/11821>])
- Incorrect column values could be retrieved from views defined using statements of the form `SELECT * FROM tbl_name`. (Bug#11771 [<http://bugs.mysql.com/11771>])
- The `mysql.proc` table was not being created properly with the proper `utf8` character set and collation, causing server crashes for stored procedure operations if the server was using a multi-byte character set. To take advantage of the bug fix, `mysql_fix_privilege_tables` should be run to correct the structure of the `mysql.proc` table. (Bug#11365 [<http://bugs.mysql.com/11365>])

Note that it is *necessary* to run `mysql_fix_privileges_tables` when upgrading from a previous installation that contains the `mysql.proc` table (that is, from a previous 5.0 installation). Otherwise, creating stored procedures might not work.

- Execution of a prepared statement that invoked a non-existent or dropped stored routine would crash the server. (Bug#11834 [<http://bugs.mysql.com/11834>])
- Executing a statement that invoked a trigger would cause problems unless a `LOCK TABLES` was first issued for any tables accessed by the trigger. **Note:** The exact nature of the problem depended upon the MySQL 5.0 release being used: prior to 5.0.3, this resulted in a crash; from 5.0.3 to 5.0.7, MySQL would issue a warning; in 5.0.9, the server would issue an error. (Bug#8406 [<http://bugs.mysql.com/8406>])

The same issue caused `LOCK TABLES` to fail following `UNLOCK TABLES` if triggers were involved. (Bug#9581 [<http://bugs.mysql.com/9581>])

- In a shared Windows environment, MySQL could not find its configuration file unless the file was in the C:\ directory. (Bug#5354 [<http://bugs.mysql.com/5354>])

## D.1.15. Changes in release 5.0.9 (15 July 2005)

Functionality added or changed:

- An attempt to create a `TIMESTAMP` column with a display width (for example, `TIMESTAMP(6)`) now results in a warning. Display widths have not been supported for `TIMESTAMP` since MySQL 4.1. (Bug#10466 [<http://bugs.mysql.com/10466>])
- InnoDB: When creating or extending an InnoDB data file, at most one megabyte at a time is allocated for initializing the file. Previously, InnoDB allocated and initialized 1 or 8 megabytes of memory, even if only a few 16-kilobyte pages were to be written. This improves the performance of `CREATE TABLE` in `innodb_file_per_table` mode.
- InnoDB: Various optimizations. Removed unreachable debug code from non-debug builds. Added hints for the branch predictor in `gcc`. Made assertions occupy less space.
- InnoDB: Make `innodb_thread_concurrency=20` by default. Bypass the concurrency checking if the setting is greater than or equal to 20.
- InnoDB: Make `CHECK TABLE` killable. (Bug#9730 [<http://bugs.mysql.com/9730>])
- Recursion in stored routines is now disabled because it was crashing the server. We plan to modify stored routines to allow this to operate safely in a future release. (Bug#11394 [<http://bugs.mysql.com/11394>])
- The handling of `BIT` columns has been improved, and should now be much more reliable in a number of cases. (Bug#10617 [<http://bugs.mysql.com/10617>], Bug#11091 [<http://bugs.mysql.com/11091>], Bug#11572 [<http://bugs.mysql.com/11572>])
- `mysql_real_escape_string()` API function now respects `NO_BACKSLASH_ESCAPES` SQL mode. (Bug#10214 [<http://bugs.mysql.com/10214>])

Bugs fixed:

- `SHOW CREATE VIEW` did not take the `ANSI MODE` into account when quoting identifiers. (Bug#6903 [<http://bugs.mysql.com/6903>])
- The `mysql_config` script did not handle symbolic linking properly. (Bug#10986 [<http://bugs.mysql.com/10986>])
- Incorrect results when using `GROUP BY ... WITH ROLLUP` on a `VIEW`. (Bug#11639 [<http://bugs.mysql.com/11639>])
- Instances of the `VAR_SAMP()` function in view definitions were converted to `VARIANCE()`. This is incorrect because `VARIANCE()` is the same as `VAR_POP()`, not `VAR_SAMP()`. (Bug#10651 [<http://bugs.mysql.com/10651>])
- `mysqldump` failed when reloading a view if the view was defined in terms of a different view that had not yet been reloaded. `mysqldump` now creates a dummy table to handle this case. (Bug#10927 [<http://bugs.mysql.com/10927>])
- `mysqldump` could crash for illegal or non-existent table names. (Bug#9358 [<http://bugs.mysql.com/9358>])
- The `--no-data` option for `mysqldump` was being ignored if table names were given after the database name. (Bug#9558 [<http://bugs.mysql.com/9558>])

- The `--master-data` option for `mysqldump` resulted in no error if the binary log was not enabled. Now an error occurs unless the `--force` option is given. (Bug#11678 [<http://bugs.mysql.com/11678>])
- `DES_ENCRYPT()` and `DES_DECRYPT()` require SSL support to be enabled, but were not checking for it. Checking for incorrect arguments or resource exhaustion was also improved for these functions. (Bug#10589 [<http://bugs.mysql.com/10589>])
- When used in joins, `SUBSTRING()` failed to truncate to zero any string values that could not be converted to numbers. (Bug#10124 [<http://bugs.mysql.com/10124>])
- `mysqldump --xml` did not format `NULL` column values correctly. (Bug#9657 [<http://bugs.mysql.com/9657>])
- There was a compression algorithm issue with `myisampack` for very large datasets (where the total size of all records in a single column was on the order of 3 GB or more) on 64-bit platforms. (A fix for other platforms was made in MySQL 5.0.6.) (Bug#8321 [<http://bugs.mysql.com/8321>])
- Temporary tables were created in the data directory instead of `tmpdir`. (Bug#11440 [<http://bugs.mysql.com/11440>])
- MySQL would not compile correctly on QNX due to missing `rint()` function. (Bug#11544 [<http://bugs.mysql.com/11544>])
- A `SELECT DISTINCT col_name` would work correctly with a MyISAM table only when there was an index on `col_name`. (Bug#11484 [<http://bugs.mysql.com/11484>])
- The server would lose table-level `CREATE VIEW` and `SHOW VIEW` privileges following a `FLUSH PRIVILEGES` or server restart. (Bug#9795 [<http://bugs.mysql.com/9795>])
- In strict mode, an `INSERT` into a view that did not include a value for a `NOT NULL` column but that did include a `WHERE` test on the same column would succeed, This happened even though the `INSERT` should have been prevented due to the failure to supply a value for the `NOT NULL` column. (Bug#6443 [<http://bugs.mysql.com/6443>])
- Running a `CHECK TABLES` on multiple views crashed the server. (Bug#11337 [<http://bugs.mysql.com/11337>])
- When a table had a primary key containing a `BLOB` column, creation of another index failed with the error `BLOB/TEXT column used in key specification without keylength`, even when the new index did not contain a `BLOB` column. (Bug#11657 [<http://bugs.mysql.com/11657>])
- NDB Cluster: When trying to open a table that could not be discovered or unpacked, cluster would return error codes which the MySQL server falsely interpreted as operating system errors. (Bug#103651 [<http://bugs.mysql.com/103651>])
- Manually inserting a row with `host=''` into `mysql.tables_priv` and performing a `FLUSH PRIVILEGES` would cause the server to crash. (Bug#11330 [<http://bugs.mysql.com/11330>])
- A cursor using a query with a filter on a `DATE` or `DATETIME` column would cause the server to crash server after the data was fetched. (Bug#11172 [<http://bugs.mysql.com/11172>])
- Closing a cursor that was already closed would cause MySQL to hang. (Bug#9814 [<http://bugs.mysql.com/9814>])
- Using `CONCAT_WS` on a column set `NOT NULL` caused incorrect results when used in a `LEFT JOIN`. (Bug#11469 [<http://bugs.mysql.com/11469>])
- Signed `BIGINT` would not accept `-9223372036854775808` as a `DEFAULT` value. (Bug#11215 [<http://bugs.mysql.com/11215>])

- Views did not use indexes on all appropriate queries. (Bug#10031 [<http://bugs.mysql.com/10031>])
- For MEMORY tables, it was possible for updates to be performed using outdated key statistics when the updates involved only very small changes in a very few rows. This resulted in the random failures of queries such as `UPDATE t SET col = col + 1 WHERE col_key = 2;` where the same query with no WHERE clause would succeed. (Bug#10178 [<http://bugs.mysql.com/10178>])
- Optimizer performed range check when comparing unsigned integers to negative constants, could cause errors. (Bug#11185 [<http://bugs.mysql.com/11185>])
- Wrong comparison method used in VIEW when relaxed date syntax used (for example, `2005.06.10`). (Bug#11325 [<http://bugs.mysql.com/11325>])
- The `ENCRYPT()` and `SUBSTRING_INDEX()` functions would cause errors when used with a VIEW. (Bug#7024 [<http://bugs.mysql.com/7024>])
- Clients would hang following some errors with stored procedures. (Bug#9503 [<http://bugs.mysql.com/9503>])
- Combining cursors and subqueries could cause server crash or memory leaks. (Bug#10736 [<http://bugs.mysql.com/10736>])
- If a prepared statement cursor is opened but not completely fetched, attempting to open a cursor for a second prepared statement will fail. (Bug#10794 [<http://bugs.mysql.com/10794>])

## D.1.16. Changes in release 5.0.8 (Not released)

**Note:** Starting with version 5.0.8, changes for MySQL Cluster can be found in the combined Change History.

Functionality added or changed:

- **Warning: Incompatible change:** Previously, conversion of DATETIME values to numeric form by adding zero produced a result in YYYYMMDDHHMMSS format. The result of DATETIME+0 is now in YYYYMMDDHHMMSS.000000 format. (Bug#12268 [<http://bugs.mysql.com/12268>])
- MEMORY tables now support indexes of up to 500 bytes. See Section 14.4, “The MEMORY (HEAP) Storage Engine”. (Bug#10566 [<http://bugs.mysql.com/10566>])
- New SQL\_MODE - NO\_ENGINE\_SUBSTITUTION Prevents automatic substitution of storage engine when the requested storage engine is disabled or not compiled in. (Bug#6877 [<http://bugs.mysql.com/6877>])
- The statements CREATE TABLE, TRUNCATE TABLE, DROP DATABASE, and CREATE DATABASE cause an implicit commit. (Bug#6883 [<http://bugs.mysql.com/6883>])
- Expanded on information provided in general log and slow query log for prepared statements. (Bug#8367 [<http://bugs.mysql.com/8367>], Bug#9334 [<http://bugs.mysql.com/9334>])
- Where a GROUP BY query uses a grouping column from the query's SELECT clause, MySQL now issues a warning. This is done because the SQL standard states that any grouping column must unambiguously reference a column of the table resulting from the query's FROM clause, and allowing columns from the SELECT clause to be used as grouping columns is a MySQL extension to the standard.

By way of example, consider the following table:

```
CREATE TABLE users (  
  userid INT NOT NULL PRIMARY KEY,
```

```
username VARCHAR(25),
usergroupid INT NOT NULL
);
```

MySQL allows you to use the alias in this query:

```
SELECT usergroupid AS id, COUNT(userid) AS number_of_users
FROM users
GROUP BY id;
```

However, the SQL standard requires that the column name be used, as shown here:

```
SELECT usergroupid AS id, COUNT(userid) AS number_of_users
FROM users
GROUP BY usergroupid;
```

Queries such as the first of the two shown above will continue to be supported in MySQL; however, beginning with MySQL 5.0.8, using a column alias in this fashion will generate a warning. Note that in the event of a collision between column names and/or aliases used in joins, MySQL attempts to resolve the conflict by giving preference to columns arising from tables named in the query's FROM clause. (Bug#11211 [<http://bugs.mysql.com/11211>])

- The granting or revocation of privileges on a stored routine is no longer performed when running the server with `--skip-grant-tables` even after the statement `SET @@global.automatic_sp_privileges=1;` has been executed. (Bug#9993 [<http://bugs.mysql.com/9993>])
- Added support for `B'10'` syntax for bit literal. (Bug#10650 [<http://bugs.mysql.com/10650>])

Bugs fixed:

- **Security fix:** On Windows systems, a user with any of the following privileges
  - REFERENCES
  - CREATE TEMPORARY TABLES
  - GRANT OPTION
  - CREATE
  - SELECT

on `*.*` could crash `mysqld` by issuing a `USE LPT1;` or `USE PRN;` command. In addition, any of the commands `USE NUL;`, `USE CON;`, `USE COM1;`, or `USE AUX;` would report success even though the database was not in fact changed. **Note:** Although this bug was thought to be fixed previously, it was later discovered to be present in the MySQL 5.0.7-beta release for Windows. (Bug#9148 [<http://bugs.mysql.com/9148>], CVE-2005-0799 [<http://cve.mitre.org/cvename.cgi?name=CVE-2005-0799>])

- A `CREATE TABLE db_name.tbl_name LIKE ...` statement would crash the server when no database was selected. (Bug#11028 [<http://bugs.mysql.com/11028>])
- `SELECT DISTINCT` queries or `GROUP BY` queries without `MIN()` or `MAX()` could return inconsistent results for indexed columns. (Bug#11044 [<http://bugs.mysql.com/11044>])
- The `SHOW INSTANCE OPTIONS` command in MySQL Instance Manager displayed option values incorrectly for options for which no value had been given. (Bug#11200 [<http://bugs.mysql.com/11200>])

- An outer join with an empty derived table (a result from a subquery) returned no result. (Bug#11284 [<http://bugs.mysql.com/11284>])
- An outer join with an ON condition that evaluated to false could return an incorrect result. (Bug#11285 [<http://bugs.mysql.com/11285>])
- `mysqld_safe` would sometimes fail to remove the pid file for the old `mysql` process after a crash. As a result, the server would fail to start due to a false `A mysqld process already exists...` error. (Bug#11122 [<http://bugs.mysql.com/11122>])
- `CAST( ... AS DECIMAL)` didn't work for strings. (Bug#11283 [<http://bugs.mysql.com/11283>])
- `NULLIF()` function could produce incorrect results if first argument is `NULL`. (Bug#11142 [<http://bugs.mysql.com/11142>])
- Setting `@SQL_MODE = NULL` caused an erroneous error message. (Bug#10732 [<http://bugs.mysql.com/10732>])
- Converting a `VARCHAR` column having an index to a different type (such as `TINYTEXT`) gave rise to an incorrect error message. (Bug#10543 [<http://bugs.mysql.com/10543>])

Note that this bugfix induces a slight change in the behavior of indexes: If an index is defined to be the same length as a field (or is left to default to that field's length), and the length of the field is later changed, then the index will adopt the new length of the field. Previously, the size of the index did not change for some field types (such as `VARCHAR`) when the field type was changed.

- `sql_data_access` column of `routines` table of `INFORMATION_SCHEMA` was empty. (Bug#11055 [<http://bugs.mysql.com/11055>])
- A `CAST()` value could not be included in a `VIEW`. (Bug#11387 [<http://bugs.mysql.com/11387>])
- Server crashed when using `GROUP BY` on the result of a `DIV` operation on a `DATETIME` value. (Bug#11385 [<http://bugs.mysql.com/11385>])
- Possible `NULL` values in `BLOB` columns could crash the server when a `BLOB` was used in a `GROUP BY` query. (Bug#11295 [<http://bugs.mysql.com/11295>])
- Fixed 64 bit compiler warning for packet length in replication. (Bug#11064 [<http://bugs.mysql.com/11064>])
- Multiple range accesses in a subquery cause server crash. (Bug#11487 [<http://bugs.mysql.com/11487>])
- An issue with index merging could cause suboptimal index merge plans to be chosen when searching by indexes created on `DATE` columns. The same issue caused the InnoDB storage engine to issue the warning using a partial-field key prefix in search. (Bug#8441 [<http://bugs.mysql.com/8441>])
- The `mysqlhotcopy` script was not parsing the output of `SHOW SLAVE STATUS` correctly when called with the `--record_log_pos` option. (Bug#7967 [<http://bugs.mysql.com/7967>])
- `SELECT * FROM table` returned incorrect results when called from a stored procedure, where `table` had a primary key. (Bug#10136 [<http://bugs.mysql.com/10136>])
- When used in defining a view, the `TIME_FORMAT()` function failed with calculated values, for example, when passed the value returned by `SEC_TO_TIME()`. (Bug#7521 [<http://bugs.mysql.com/7521>])
- `SELECT DISTINCT ... GROUP BY constant` returned multiple rows (it should return a single row). (Bug#8614 [<http://bugs.mysql.com/8614>])
- `INSERT INTO SELECT FROM view` produced incorrect result when using `ORDER BY`. (Bug#11298 [<http://bugs.mysql.com/11298>])

- Fixed hang/crash with Boolean full-text search where a query contained more query terms that one-third of the query length (it could be achieved with truncation operator: 'a\*b\*c\*d\*'). (Bug#7858 [<http://bugs.mysql.com/7858>])
- Fixed column name generation in VIEW creation to ensure there are no duplicate column names. (Bug#7448 [<http://bugs.mysql.com/7448>])
- An ORDER BY clause sometimes had no effect on the ordering of a result when selecting specific columns (as opposed to using SELECT \*) from a view. (Bug#7422 [<http://bugs.mysql.com/7422>])
- Some data definition statements (CREATE TABLE where the table was not a temporary table, TRUNCATE TABLE, DROP DATABASE, and CREATE DATABASE) were not being written to the binary log after a ROLLBACK. This also caused problems with replication. (Bug#6883 [<http://bugs.mysql.com/6883>])
- Calling a stored procedure that made use of an INSERT ... SELECT ... UNION SELECT ... query caused a server crash. (Bug#11060 [<http://bugs.mysql.com/11060>])
- Selecting from a view defined using SELECT SUM(DISTINCT ...) caused an error; attempting to execute a SELECT \* FROM INFORMATION\_SCHEMA.TABLES query after defining such a view crashed the server. (Bug#7015 [<http://bugs.mysql.com/7015>])
- The mysql client would output a prompt twice following input of very long strings, because it incorrectly assumed that a call to the \_cgets() function would clear the input buffer. (Bug#10840 [<http://bugs.mysql.com/10840>])
- A three byte buffer overflow in the client functions caused improper exiting of the client when reading a command from the user. (Bug#10841 [<http://bugs.mysql.com/10841>])
- Fixed a problem where a stored procedure caused a server crash if the query cache was enabled. (Bug#9715 [<http://bugs.mysql.com/9715>])
- SHOW CREATE DATABASE INFORMATION\_SCHEMA returned an “unknown database” error. (Bug#9434 [<http://bugs.mysql.com/9434>])
- Corrected a problem with IFNULL() returning an incorrect result on 64-bit systems. (Bug#11235 [<http://bugs.mysql.com/11235>])
- Fixed a problem resolving table names with lower\_case\_table\_names=2 when the table name lettercase differed in the FROM and WHERE clauses. (Bug#9500 [<http://bugs.mysql.com/9500>])
- Fixed server crash due to some internal functions not taking into account that for multi-byte character sets, CHAR columns could exceed 255 bytes and VARCHAR columns could exceed 65,535 bytes. (Bug#11167 [<http://bugs.mysql.com/11167>])
- Fixed locking problems for multiple-statement DELETE statements performed within a stored routine, such as incorrectly locking a to-be-modified table with a read lock rather than a write lock. (Bug#11158 [<http://bugs.mysql.com/11158>])
- Fixed a portability problem testing for crypt() support that caused compilation problems when using OpenSSL/yaSSL on HP-UX and Mac OS X. (Bug#10675 [<http://bugs.mysql.com/10675>], Bug#11150 [<http://bugs.mysql.com/11150>])
- The hostname cache was not working. (Bug#10931 [<http://bugs.mysql.com/10931>])
- On Windows, mysqlshow did not interpret wildcard characters properly if they were given in the table name argument. (Bug#10947 [<http://bugs.mysql.com/10947>])
- The default hostname for MySQL server was always mysql. (Bug#11174 [<http://bugs.mysql.com/11174>])
- Using PREPARE to prepare a statement that invoked a stored routine that deallocated the pre-

pared statement caused a server crash. This is prevented by disabling dynamic SQL within stored routines. (Bug#10975 [<http://bugs.mysql.com/10975>]) (Note: This restriction was lifted in 5.0.13 for stored procedures, but not stored functions or triggers.)

- Using `PREPARE` to prepare a statement that invoked a stored routine that executed the prepared statement caused a `Packets out of order` error the second time the routine was invoked. This is prevented by disabling dynamic SQL within stored routines. (Bug#7115 [<http://bugs.mysql.com/7115>]) (Note: This restriction was lifted in 5.0.13 for stored procedures, but not stored functions or triggers.)
- Using prepared statements within a stored routine (`PREPARE`, `EXECUTE`, `DEALLOCATE`) could cause the client connection to be dropped after the routine returned. This is prevented by disabling dynamic SQL within stored routines. (Bug#10605 [<http://bugs.mysql.com/10605>]) (Note: This restriction was lifted in 5.0.13 for stored procedures, but not stored functions or triggers.)
- When using a cursor with a prepared statement, the first execution returned the correct result but was not cleaned up properly, causing subsequent executions to return incorrect results. (Bug#10729 [<http://bugs.mysql.com/10729>])
- MySQL Cluster: Connections between data nodes and management nodes were not being closed following shutdown of `ndb_mgmd`. (Bug#11132 [<http://bugs.mysql.com/11132>])
- MySQL Cluster: `mysqld` processes would not reconnect to cluster following restart of `ndb_mgmd`. (Bug#11221 [<http://bugs.mysql.com/11221>])
- MySQL Cluster: Fixed problem whereby data nodes would fail to restart on 64-bit Solaris (Bug#9025 [<http://bugs.mysql.com/9025>])
- MySQL Cluster: Calling `ndb_select_count()` crashed the cluster when running on Red Hat Enterprise 4/64-bit/Opteron. (Bug#10058 [<http://bugs.mysql.com/10058>])
- MySQL Cluster: Insert records were incorrectly applied by `ndb_restore`, thus making restoration from backup inconsistent if the binlog contained inserts. (Bug#11166 [<http://bugs.mysql.com/11166>])
- MySQL Cluster: Cluster would time out and crash after first query on 64-bit Solaris 9. (Bug#8918 [<http://bugs.mysql.com/8918>])
- MySQL Cluster: `ndb_mgm` client `show` command displayed incorrect output after master data node failure. (Bug#11050 [<http://bugs.mysql.com/11050>])
- MySQL Cluster: A delete performed as part of a transaction caused an erroneous result. (Bug#11133 [<http://bugs.mysql.com/11133>])
- MySQL Cluster: Not allowing sufficient parallelism in cluster configuration (for example, `NoOfTransactions` too small) caused `ndb_restore` to fail without providing any error messages. (Bug#10294 [<http://bugs.mysql.com/10294>])
- MySQL Cluster: When using dynamically allocated ports on Linux, cluster would hang on initial startup. (Bug#10893 [<http://bugs.mysql.com/10893>])
- MySQL Cluster: Setting `TransactionInactiveTimeout= 0` did not result in an infinite timeout. (Bug#11290 [<http://bugs.mysql.com/11290>])
- InnoDB: Enforce maximum `CHAR_LENGTH()` of UTF-8 data in `ON UPDATE CASCADE`. (Bug#10409 [<http://bugs.mysql.com/10409>])
- InnoDB: Pad UTF-8 `VARCHAR` columns with `0x20`. Pad UCS2 `CHAR` columns with `0x0020`. (Bug#10511 [<http://bugs.mysql.com/10511>])

## D.1.17. Changes in release 5.0.7 (10 June 2005)

Functionality added or changed:

- Security improvement: Applied a patch to fix a UDF library-loading vulnerability that could result in a buffer overflow and code execution. (<http://www.appsecinc.com/resources/alerts/mysql/2005-002.html>)
- Added `mysql_set_character_set()` C API function for setting the default character set of the current connection. This allows clients to affect the character set used by `mysql_real_escape_string()`. (Bug#8317 [<http://bugs.mysql.com/8317>])
- The behavior of the `Last_query_cost` system variable has been changed. The default value is now 0 (rather than -1) and it now has session-level scope (rather than being global). See Section 5.2.4, “Server Status Variables”, for additional information.
- All characters occurring on the same line following the `DELIMITER` keyword will be set as delimiter. For example, `DELIMITER ;;` will set `;;` as the delimiter. This behavior is now consistent between MySQL 5.1 and MySQL 5.0. (Bug#9879 [<http://bugs.mysql.com/9879>])
- The `table`, `type`, and `rows` columns of `EXPLAIN` output can now be `NULL`. This is required for using `EXPLAIN` on `SELECT` queries that use no tables (for example, `EXPLAIN SELECT 1`). (Bug#9899 [<http://bugs.mysql.com/9899>])
- Placeholders now can be used for `LIMIT` in prepared statements. (Bug#7306 [<http://bugs.mysql.com/7306>])
- `SHOW BINARY LOGS` now displays a `File_size` column that indicates the size of each file.
- The `--delayed-insert` option for `mysqldump` has been disabled to avoid causing problems with storage engines that do not support `INSERT DELAYED`. (Bug#7815 [<http://bugs.mysql.com/7815>])
- Improved the optimizer to be able to use indexes for expressions of the form `indexed_col NOT IN (val1, val2, ...)` and `indexed_col NOT BETWEEN val1 AND val2..` (Bug#10561 [<http://bugs.mysql.com/10561>])
- Removed `mysqlshutdown.exe` and `mysqlwatch.exe` from the Windows “No Installer” distribution (they had already been removed from the “With Installer” distribution before). Removed those programs from the source distribution.
- Removed `WinMySQLAdmin` from the source distribution and from the “No Installer” Windows distribution (it had already been removed from the “With Installer” distribution before).
- InnoDB: In stored procedures and functions, InnoDB no longer takes full explicit table locks for every involved table. Only ‘intention’ locks are taken, similar to those in the execution of an ordinary SQL statement. This greatly reduces the number of deadlocks.

Bugs fixed:

- **Security update:** A user with limited privileges could obtain information about the privileges of other users by querying objects in the `INFORMATION_SCHEMA` database for which that user did not have the requisite privileges. (Bug#10964 [<http://bugs.mysql.com/10964>])
- Triggers with dropped functions caused crashes. (Bug#5893 [<http://bugs.mysql.com/5893>])
- Failure of a `BEFORE` trigger did not prevent the triggering statement from performing its operation on the row for which the trigger error occurred. Now the triggering statement fails as described in Section 18.3, “Using Triggers”. (Bug#10902 [<http://bugs.mysql.com/10902>])
- Issuing a write lock for a table from one client prevented other clients from accessing the table's metadata. For example, if one client issued a `LOCK TABLES mydb.mytable WRITE`, then a second client attempting to execute a `USE mydb;` would hang. (Bug#9998)

[<http://bugs.mysql.com/9998>])

- The `LAST_DAY()` failed to return `NULL` when supplied with an invalid argument. See Section 12.5, “Date and Time Functions”. (Bug#10568 [<http://bugs.mysql.com/10568>])
- The functions `COALESCE()`, `IF()`, and `IFNULL()` performed incorrect conversions of their arguments. (Bug#9939 [<http://bugs.mysql.com/9939>])
- The `TIME_FORMAT()` function returned incorrect results with some format specifiers. See Section 12.5, “Date and Time Functions”. (Bug#10590 [<http://bugs.mysql.com/10590>])
- Dropping stored routines when the MySQL server had been started with `-skip-grant-tables` generated extraneous warnings. (Bug#9993 [<http://bugs.mysql.com/9993>])
- A problem with the `my_global.h` file caused compilation of MySQL to fail on single-processor Linux systems running 2.6 kernels. (Bug#10364 [<http://bugs.mysql.com/10364>])
- The `ucs2_turkish_ci` collation failed with `upper('i')`. `UPPER/LOWER` now can return a string with different length. (Bug#8610 [<http://bugs.mysql.com/8610>])
- `OPTIMIZE` of InnoDB table does not return 'Table is full' if out of tablespace. (Bug#8135 [<http://bugs.mysql.com/8135>])
- `GROUP BY` queries with `ROLLUP` returned wrong results for expressions containing group by columns. (Bug#7894 [<http://bugs.mysql.com/7894>])
- Fixed bug in `FIELD()` function where value list contains `NULL`. (Bug#10944 [<http://bugs.mysql.com/10944>])
- Corrected a problem where an incorrect data type was returned in the result set metadata when using a prepared `SELECT DISTINCT` statement to select from a view. (Bug#11111 [<http://bugs.mysql.com/11111>])
- Fixed bug in the MySQL Instance manager that caused the version to always be unknown when `SHOW INSTANCE STATUS` was issued. (Bug#10229 [<http://bugs.mysql.com/10229>])
- Using `ORDER BY` to sort the results of an `IF()` that contained a `FROM_UNIXTIME()` expression returned incorrect results due to integer overflow. (Bug#9669 [<http://bugs.mysql.com/9669>])
- Fixed a server crash resulting from accessing InnoDB tables within stored functions. This is handled by prohibiting statements that do an implicit or explicit commit or rollback within stored functions or triggers. (Bug#10015 [<http://bugs.mysql.com/10015>])
- Fixed a server crash resulting from the second invocation of a stored procedure that selected from a view defined as a join that used `ON` in the join conditions. (Bug#6866 [<http://bugs.mysql.com/6866>])
- Using `ALTER TABLE` for a table that had a trigger caused a crash when executing a statement that activated the trigger, and also a crash later with `USE db_name` for the database containing the table. (Bug#5894 [<http://bugs.mysql.com/5894>])
- Fixed a server crash resulting from an attempt to allocate too much memory when `GROUP BY blob_col` and `COUNT(DISTINCT)` were used. (Bug#11088 [<http://bugs.mysql.com/11088>])
- Fixed a portability problem for compiling on Windows with Visual Studio 6. (Bug#11153 [<http://bugs.mysql.com/11153>])
- The incorrect sequence of statements `HANDLER tbl_name READ index_name NEXT` without a preceding `HANDLER tbl_name READ index_name = (value_list)` for an InnoDB table resulted in a server crash rather than an error. (Bug#5373 [<http://bugs.mysql.com/5373>])

- On Windows, with `lower_case_table_names` set to 2, using `ALTER TABLE` to alter a MEMORY or InnoDB table that had a mixed-case name also improperly changed the name to lowercase. (Bug#9660 [<http://bugs.mysql.com/9660>])
- The server timed out SSL connections too quickly on Windows. (Bug#8572 [<http://bugs.mysql.com/8572>])
- Executing `LOAD INDEX INTO CACHE` for a table while other threads were selecting from the table caused a deadlock. (Bug#10602 [<http://bugs.mysql.com/10602>])
- Fixed a server crash resulting from `CREATE TABLE ... SELECT` that selected from a table being altered by `ALTER TABLE`. (Bug#10224 [<http://bugs.mysql.com/10224>])
- The FEDERATED storage engine properly handled outer joins, but not inner joins. (Bug#10848 [<http://bugs.mysql.com/10848>])
- Consistently report `INFORMATION_SCHEMA` table names in uppercase in `SHOW TABLE STATUS` output. (Bug#10059 [<http://bugs.mysql.com/10059>])
- Fixed a failure of `WITH ROLLUP` to sum values properly. (Bug#10982 [<http://bugs.mysql.com/10982>])
- Triggers were not being activated for multiple-table `UPDATE` or `DELETE` statements. (Bug#5860 [<http://bugs.mysql.com/5860>])
- `INSERT BEFORE` triggers were not being activated for `INSERT ... SELECT` statements. (Bug#6812 [<http://bugs.mysql.com/6812>])
- `INSERT BEFORE` triggers were not being activated for implicit inserts (`LOAD DATA`). (Bug#8755 [<http://bugs.mysql.com/8755>])
- If a stored function contained a `FLUSH` statement, the function crashed when invoked. `FLUSH` now is disallowed within stored functions. (Bug#8409 [<http://bugs.mysql.com/8409>])
- Multiple-row `REPLACE` could fail on a duplicate-key error when having one `AUTO_INCREMENT` key and one unique key. (Bug#11080 [<http://bugs.mysql.com/11080>])
- Fixed a server crash resulting from invalid string pointer when inserting into the `mysql.host` table. (Bug#10181 [<http://bugs.mysql.com/10181>])
- Multiple-table `DELETE` did always delete on the fly from the first table that was to be deleted from. In some cases, when using many tables and it was necessary to access the same row twice in the first table, we could miss some rows-to-be-deleted from other tables. This is now fixed.
- The `mysql_next_result()` function could hang if you were executing many statements in a `mysql_real_query()` call and one of those statements raised an error. (Bug#9992 [<http://bugs.mysql.com/9992>])
- The combination of `COUNT()`, `DISTINCT`, and `CONCAT()` sometimes triggered a memory deallocation bug on Windows resulting in a server crash. (Bug#9593 [<http://bugs.mysql.com/9593>])
- InnoDB: Do very fast shutdown only if `innodb_fast_shutdown=2`, but wait for threads to exit and release allocated memory if `innodb_fast_shutdown=1`. Starting with MySQL/InnoDB 5.0.5, InnoDB would do brutal shutdown also when `innodb_fast_shutdown=1`. (Bug#9673 [<http://bugs.mysql.com/9673>])
- InnoDB: Fixed InnoDB: Error: `stored_select_lock_type` is 0 inside `::start_stmt()`! in a stored procedure call if `innodb_locks_unsafe_for_binlog` was set in `my.cnf`. (Bug#10746 [<http://bugs.mysql.com/10746>])
- InnoDB: Fixed a duplicate key error that occurred with `REPLACE` in a table with an `AUTO-INC` column. (Bug#11005 [<http://bugs.mysql.com/11005>])

- MySQL would pass an incorrect key length to storage engines for `MIN()`. This could cause warnings `InnoDB: Warning: using a partial-field key prefix in search.` in the `.err` log. (Bug#11039 [<http://bugs.mysql.com/11039>], same as Bug#13218 [<http://bugs.mysql.com/13218>] in MySQL 4.1.15)
- Fixed a server crash for `INSERT` or `UPDATE` when the `WHERE` clause contained a correlated subquery that referred to a column of the table being modified. (Bug#6384 [<http://bugs.mysql.com/6384>])
- Fixed a problem causing an incorrect result for columns that include an aggregate function as part of an expression when `WITH ROLLUP` is added to `GROUP BY`. (Bug#7914 [<http://bugs.mysql.com/7914>])
- Fixed a problem with returning an incorrect result from a view that selected a `COALESCE()` expression from the result of an outer join. (Bug#9938 [<http://bugs.mysql.com/9938>])
- MySQL was adding a `DEFAULT` clause to `ENUM` columns that included no explicit `DEFAULT` and were defined as `NOT NULL`. (This is supposed to happen only for columns that are `NULL`.) (Bug#6267 [<http://bugs.mysql.com/6267>])
- Corrected inappropriate error messages that were displayed when attempting to set the read-only `warning_count` and `error_count` system variables. (Bug#10339 [<http://bugs.mysql.com/10339>])

## D.1.18. Changes in release 5.0.6 (26 May 2005)

Functionality added or changed:

- **Incompatible change:** MyISAM and InnoDB tables created with `DECIMAL` columns in MySQL 5.0.3 to 5.0.5 will appear corrupt after an upgrade to MySQL 5.0.6. Dump such tables with `mysqldump` before upgrading, and then reload them after upgrading. (The same incompatibility will occur for these tables created in MySQL 5.0.6 after a downgrade to MySQL 5.0.3 to 5.0.5.) (Bug#10465 [<http://bugs.mysql.com/10465>], Bug#10625 [<http://bugs.mysql.com/10625>])
- **Incompatible change:** The behavior of `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` has changed when the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values both are empty. Formerly, a column was read or written the display width of the column. For example, `INT(4)` was read or written using a field with a width of 4. Now columns are read and written using a field width wide enough to hold all values in the field. However, data files written before this change was made might not be reloaded correctly with `LOAD DATA INFILE` for MySQL 4.1.12 and up. This change also affects data files read by `mysqlimport` and written by `mysqldump --tab`, which use `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`. For more information, see Section 13.2.5, “LOAD DATA INFILE Syntax”. (Bug#12564 [<http://bugs.mysql.com/12564>])
- The precision of the `DECIMAL` data type has been increased from 64 to 65 decimal digits.
- Added the `div_precision_increment` system variable, which indicates the number of digits of precision by which to increase the result of division operations performed with the `/` operator.
- Added the `log_bin_trust_routine_creators` system variable, which applies when binary logging is enabled. It controls whether stored routine creators can be trusted not to create stored routines that will cause unsafe events to be written to the binary log.
- Added the `--log-bin-trust-routine-creators` server option for setting the `log_bin_trust_routine_creators` system variable from the command line.
- Implemented the `STMT_ATTR_PREFETCH_ROWS` option for the `mysql_stmt_attr_set()` C API function. This sets how many rows to fetch at a time

when using cursors with prepared statements.

- The GRANT and REVOKE statements now support an *object\_type* clause to be used for disambiguating whether the grant object is a table, a stored function, or a stored procedure. Use of this clause requires that you upgrade your grant tables. See Section 5.6.1, “mysql\_fix\_privilege\_tables — Upgrade MySQL System Tables”. (Bug#10246 [<http://bugs.mysql.com/10246>])
- Added REFERENCED\_TABLE\_SCHEMA, REFERENCED\_TABLE\_NAME, and REFERENCED\_COLUMN\_NAME columns to the KEY\_COLUMN\_USAGE table of INFORMATION\_SCHEMA. (Bug#9587 [<http://bugs.mysql.com/9587>])
- Added a --show-warnings option to mysql to cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode. In interactive mode, \w and \W may be used to enable and disable warning display. (Bug#8684 [<http://bugs.mysql.com/8684>])
- Removed a limitation that prevented use of FIFOs as logging targets (such as for the general query log). This modification *does not apply* to the binary log and the relay log. (Bug#8271 [<http://bugs.mysql.com/8271>])
- Added a --debug option to my\_print\_defaults.
- When the server cannot read a table because it cannot read the .frm file, print a message that the table was created with a different version of MySQL. (This can happen if you create tables that use new features and then downgrade to an older version of MySQL.) (Bug#10435 [<http://bugs.mysql.com/10435>])
- SHOW VARIABLES now shows the slave\_compressed\_protocol, slave\_load\_tmpdir and slave\_skip\_errors system variables. (Bug#7800 [<http://bugs.mysql.com/7800>])
- Removed unused system variable myisam\_max\_extra\_sort\_file\_size.
- Changed default value of myisam\_data\_pointer\_size from 4 to 6. This allows us to avoid table is full errors for most cases.
- The variable concurrent\_insert now takes 3 values. Setting this to 2 changes MyISAM to do concurrent inserts to end of table if table is in use by another thread.
- New /\*> prompt for mysql. This prompt indicates that a /\* ... \*/ comment was begun on an earlier line and the closing \*/ sequence has not yet been seen. (Bug#9186 [<http://bugs.mysql.com/9186>])
- If strict SQL mode is enabled, VARCHAR and VARBINARY columns with a length greater than 65,535 no longer are silently converted to TEXT or BLOB columns. Instead, an error occurs. (Bug#8295 [<http://bugs.mysql.com/8295>], Bug#8296 [<http://bugs.mysql.com/8296>])
- The INFORMATION\_SCHEMA.SCHEMATA table now has a DEFAULT\_COLLATION\_NAME column. (Bug#8998 [<http://bugs.mysql.com/8998>])
- InnoDB: When the maximum length of SHOW INNODB STATUS output would be exceeded, truncate the beginning of the list of active transactions, instead of truncating the end of the output. (Bug#5436 [<http://bugs.mysql.com/5436>])
- InnoDB: If innodb\_locks\_unsafe\_for\_binlog option is set and the isolation level of the transaction is not set to serializable then InnoDB uses a consistent read for select in clauses like INSERT INTO ... SELECT and UPDATE ... (SELECT) that do not specify FOR UPDATE or IN SHARE MODE. Thus no locks are set to rows read from selected table.
- Updated version of libedit to 2.9. (Bug#2596 [<http://bugs.mysql.com/2596>])
- Removed mysqlshutdown.exe and mysqlwatch.exe from the Windows “With In-

staller” distribution.

Bugs fixed:

- An error in the implementation of the MyISAM compression algorithm caused `myisampack` to fail with very large sets of data (total size of all the records in a single column needed to be  $\geq 3$  GB in order to trigger this issue). (Bug#8321 [<http://bugs.mysql.com/8321>])
- Statements that create and use stored routines were not being written to the binary log, which affects replication and data recovery options. (Bug#2610 [<http://bugs.mysql.com/2610>]) Stored routine-related statements now are logged, subject to the issues and limitations discussed in Section 17.4, “Binary Logging of Stored Routines and Triggers”.
- Disabled binary logging within stored routines to avoid writing spurious extra statements to the binary log. For example, if a routine `p()` executes an `INSERT` statement, then for `CALL p()`, the `CALL` statement appears in the binary log, but not the `INSERT` statement. (Bug#9100 [<http://bugs.mysql.com/9100>])
- Statements that create and drop triggers were not being written to the binary log, which affects replication and data recovery options. (Bug#10417 [<http://bugs.mysql.com/10417>]) Trigger-related statements now are logged, subject to the issues and limitations discussed in Section 17.4, “Binary Logging of Stored Routines and Triggers”.
- The `mysql_stmt_execute()` and `mysql_stmt_reset()` C API functions now close any cursor that is open for the statement, which prevents a server crash. (Bug#9478 [<http://bugs.mysql.com/9478>])
- The `mysql_stmt_attr_set()` C API function now returns an error for option values that are defined in `mysql.h` but not yet implemented, such as `CURSOR_TYPE_SCROLLABLE`. (Bug#9643 [<http://bugs.mysql.com/9643>])
- MERGE tables could fail on Windows due to incorrect interpretation of pathname separator characters for filenames in the `.MRG` file. (Bug#10687 [<http://bugs.mysql.com/10687>])
- Fixed a server crash for `INSERT ... ON DUPLICATE KEY UPDATE` with MERGE tables, which do not have unique indexes. (Bug#10400 [<http://bugs.mysql.com/10400>])
- Fix `FORMAT()` to do better rounding for double values (for example, `FORMAT(4.55, 1)` returns `4.6`, not `4.5`). (Bug#9060 [<http://bugs.mysql.com/9060>])
- Disallow use of `SESSION` or `GLOBAL` for user variables or local variables in stored routines. (Bug#9286 [<http://bugs.mysql.com/9286>])
- Fixed a server crash when using `GROUP BY ... WITH ROLLUP` on an indexed column in an InnoDB table. (Bug#9798 [<http://bugs.mysql.com/9798>])
- In strict SQL mode, some assignments to numeric columns that should have been rejected were not (such as the result of an arithmetic expression or an explicit `CAST()` operation). (Bug#6961 [<http://bugs.mysql.com/6961>])
- `CREATE TABLE t AS SELECT UUID()` created a `VARCHAR(12)` column, which is too small to hold the 36-character result from `UUID()`. (Bug#9535 [<http://bugs.mysql.com/9535>])
- Fixed a server crash in the BLACKHOLE storage engine. (Bug#10175 [<http://bugs.mysql.com/10175>])
- Fixed a server crash resulting from repeated calls to `ABS()` when the argument evaluated to `NULL`. (Bug#10599 [<http://bugs.mysql.com/10599>])
- For a user-defined function invoked from within a prepared statement, the UDF's initialization routine was invoked for each execution of the statement, but the deinitialization routine was not. (It was invoked only when the statement was closed.) Similarly, when invoking a UDF from

within a trigger, the initialization routine was invoked but the deinitialization routine was not. For UDFs that have an expensive deinit function (such as `myperl`, this bugfix will have negative performance consequences. (Bug#9913 [<http://bugs.mysql.com/9913>])

- Portability fix for Cygwin: Don't use `#pragma interface` in source files. (Bug#10241 [<http://bugs.mysql.com/10241>])
- Fix `CREATE TABLE ... LIKE` to work when `lower_case_table_names` is set on a case-sensitive filesystem and the source table name is not given in lowercase. (Bug#9761 [<http://bugs.mysql.com/9761>])
- Fixed a server crash resulting from a `CHECK TABLE` statement where the arguments were a view name followed by a table name. (Bug#9897 [<http://bugs.mysql.com/9897>])
- Within a stored procedure, attempting to update a view defined as an inner join failed with a `Table 'tbl_name' was locked with a READ lock and can't be updated` error. (Bug#9481 [<http://bugs.mysql.com/9481>])
- Fixed a problem with `INFORMATION_SCHEMA` tables being inaccessible depending on letter-case used to refer to them. (Bug#10018 [<http://bugs.mysql.com/10018>])
- `my_print_defaults` was ignoring the `--defaults-extra-file` option or crashing when the option was given. (Bug#9136 [<http://bugs.mysql.com/9136>], Bug#9851 [<http://bugs.mysql.com/9851>])
- The `INFORMATION_SCHEMA.COLUMNS` table was missing columns of views for which the user has access. (Bug#9838 [<http://bugs.mysql.com/9838>])
- Fixed a `mysqldump` crash that occurred with the `--complete-insert` option when dumping tables with a large number of long column names. (Bug#10286 [<http://bugs.mysql.com/10286>])
- Corrected a problem where `DEFAULT` values were not assigned properly to `BIT(1)` or `CHAR(1)` columns if certain other columns preceded them in the table definition. (Bug#10179 [<http://bugs.mysql.com/10179>])
- For `MERGE` tables, avoid writing absolute pathnames in the `.MRG` file for the names of the constituent `MyISAM` tables so that if the data directory is moved, `MERGE` tables will not break. For `mysqld`, write just the `MyISAM` table name if it is in the same database as the `MERGE` table, and a path relative to the data directory otherwise. For the embedded servers, absolute pathnames may still be used. (Bug#5964 [<http://bugs.mysql.com/5964>])
- Corrected a problem resolving outer column references in correlated subqueries when using the prepared statements. (Bug#10041 [<http://bugs.mysql.com/10041>])
- Corrected the error message for exceeding the `MAX_CONNECTIONS_PER_HOUR` limit to say `max_connections_per_hour` instead of `max_connections`. (Bug#9947 [<http://bugs.mysql.com/9947>])
- Fixed incorrect memory block allocation for the query cache in the embedded server. (Bug#9549 [<http://bugs.mysql.com/9549>])
- Corrected an inability to select from a view within a stored procedure. (Bug#9758 [<http://bugs.mysql.com/9758>])
- Fixed a server crash resulting from use of `AVG(DISTINCT)` with `GROUP BY ... WITH ROLLUP`. (Bug#9799 [<http://bugs.mysql.com/9799>])
- Fixed a server crash resulting from use of `DISTINCT AVG()` with `GROUP BY ... WITH ROLLUP`. (Bug#9800 [<http://bugs.mysql.com/9800>])
- Fixed a server crash resulting from use of a `CHAR` or `VARCHAR` column with `MIN()` or `MAX()` and `GROUP BY ... WITH ROLLUP`. (Bug#9820 [<http://bugs.mysql.com/9820>])

- Fixed a server crash resulting from use of `SELECT DISTINCT` with a prepared statement that uses a cursor. (Bug#9520 [<http://bugs.mysql.com/9520>])
- Fixed server crash resulting from multiple calls to a stored procedure that assigned the result of a subquery to a variable or compared it to a value with `IN`. (Bug#5963 [<http://bugs.mysql.com/5963>])
- Selecting from a single-table view defined on multiple-table views caused a server crash. (Bug#8528 [<http://bugs.mysql.com/8528>])
- If the file named by a `--defaults-extra-file` option does not exist or is otherwise inaccessible, an error now occurs. (Bug#5056 [<http://bugs.mysql.com/5056>])
- `net_read_timeout` and `net_write_timeout` were not being respected on Windows. (Bug#9721 [<http://bugs.mysql.com/9721>])
- `SELECT` from `INFORMATION_SCHEMA` tables failed if the statement has a `GROUP BY` clause and an aggregate function in the select list. (Bug#9404 [<http://bugs.mysql.com/9404>])
- Corrected some failures of prepared statements for SQL (`PREPARE` plus `EXECUTE`) to return all rows for some `SELECT` statements. (Bug#9096 [<http://bugs.mysql.com/9096>], Bug#9777 [<http://bugs.mysql.com/9777>])
- Remove extra slashes in `--tmpdir` value (for example, convert `/var//tmp` to `/var/tmp`, because they caused various errors. (Bug#8497 [<http://bugs.mysql.com/8497>])
- Added `Create_routine_priv`, `Alter_routine_priv`, and `Execute_priv` privileges to the `mysql.host` privilege table. (They had been added to `mysql.db` in MySQL 5.0.3 but not to the `host` table.) (Bug#8166 [<http://bugs.mysql.com/8166>])
- Fixed `configure` to properly recognize whether NTPL is available on Linux. (Bug#2173 [<http://bugs.mysql.com/2173>])
- Incomplete results were returned from `INFORMATION_SCHEMA.COLUMNS` for `INFORMATION_SCHEMA` tables for non-root users. (Bug#10261 [<http://bugs.mysql.com/10261>])
- Fixed a portability problem in compiling `mysql.cc` with VC++ on Windows. (Bug#10245 [<http://bugs.mysql.com/10245>])
- `SELECT 0/0` returned 0 rather than `NULL`. (Bug#10404 [<http://bugs.mysql.com/10404>])
- `MAX()` for an `INT UNSIGNED` (unsigned 4-byte integer) column could return negative values if the column contained values larger than  $2^{31}$ . (Bug#9298 [<http://bugs.mysql.com/9298>])
- `SHOW CREATE VIEW` got confused and could not find the view if there was a temporary table with the same name as the view. (Bug#8921 [<http://bugs.mysql.com/8921>])
- Fixed a deadlock resulting from use of `FLUSH TABLES WITH READ LOCK` while an `INSERT DELAYED` statement is in progress. (Bug#7823 [<http://bugs.mysql.com/7823>])
- The optimizer was choosing suboptimal execution plans for certain outer joins where the right table of a left join (or left table of a right join) had both `ON` and `WHERE` conditions. (Bug#10162 [<http://bugs.mysql.com/10162>])
- `RENAME TABLE` for an `ARCHIVE` table failed if the `.arn` file was not present. (Bug#9911 [<http://bugs.mysql.com/9911>])
- Invoking a stored function that executed a `SHOW` statement resulted in a server crash. (Bug#8408 [<http://bugs.mysql.com/8408>])
- Fixed problems with static variables and do not link with `libsupc++` to allow building on FreeBSD 5.3. (Bug#9714 [<http://bugs.mysql.com/9714>])
- Fixed some `awk` script portability problems in `cmd-`

line-utils/libedit/makelist.sh. (Bug#9954 [<http://bugs.mysql.com/9954>])

- Fixed a problem with mishandling of NULL key parts in hash indexes on VARCHAR columns, resulting in incorrect query results. (Bug#9489 [<http://bugs.mysql.com/9489>], Bug#10176 [<http://bugs.mysql.com/10176>])
- InnoDB: Fixed a critical bug in InnoDB AUTO\_INCREMENT: it could assign the same value for several rows. (Bug#10359 [<http://bugs.mysql.com/10359>]) InnoDB: All InnoDB bug fixes from 4.1.12 and earlier versions, and also the fixes to bugs #10335 and #10607 listed in the 4.1.13 change notes.

## D.1.19. Changes in release 5.0.5 (Not released)

No public release of MySQL 5.0.5 was made. The changes described in this section are available in MySQL 5.0.6.

Functionality added or changed:

- Added support for the BIT data type to the MEMORY, InnoDB, and BDB storage engines.
- SHOW VARIABLES no longer displays the deprecated log\_update system variable. (Bug#9738 [<http://bugs.mysql.com/9738>])
- The behavior controlled by the --innodb-fast-shutdown option now can be changed at runtime by setting the value of the global innodb\_fast\_shutdown system variable. It now accepts values 0, 1 and 2 (except on Netware where 2 is disabled). If set to 2, then when the MySQL server shuts down, InnoDB will just flush its logs and shut down brutally (and quickly) as if a MySQL crash had occurred; no committed transaction will be lost, but a crash recovery will be done at next startup.

Bugs fixed:

- **Security fix:** If mysqld was started with --user=non\_existent\_user, it would run using the privileges of the account it was invoked from, even if that was root. (Bug#9833 [<http://bugs.mysql.com/9833>])
- Corrected a failure to resolve a column reference correctly for a LEFT JOIN that compared a join column to an IN subquery. (Bug#9338 [<http://bugs.mysql.com/9338>])
- Fixed a problem where, after an internal temporary table in memory became too large and had to be converted to an on-disk table, the error indicator was not cleared and the query failed with error 1023 (Can't find record in '). (Bug#9703 [<http://bugs.mysql.com/9703>])
- Multiple-table updates could produce spurious data-truncation warnings if they used a join across columns that are indexed using a column prefix. (Bug#9103 [<http://bugs.mysql.com/9103>])
- Fixed a string-length comparison problem that caused mysql to fail loading dump files containing certain '\'-sequences. (Bug#9756 [<http://bugs.mysql.com/9756>])
- Fixed a failure to resolve a column reference properly when an outer join involving a view contained a subquery and the column was used in the subquery and the outer query. (Bug#6106 [<http://bugs.mysql.com/6106>], Bug#6107 [<http://bugs.mysql.com/6107>])
- Use of a subquery that used WITH ROLLUP in the FROM clause of the main query sometimes resulted in a Column cannot be null error. (Bug#9681 [<http://bugs.mysql.com/9681>])
- Fixed a memory leak that occurred when selecting from a view that contained a subquery. (Bug#10107 [<http://bugs.mysql.com/10107>])

- Fixed an optimizer bug in computing the union of two ranges for the OR operator. (Bug#9348 [<http://bugs.mysql.com/9348>])
- Fixed a segmentation fault in `mysqlcheck` that occurred when the last table checked in `--auto-repair` mode returned an error (such as the table being a MERGE table). (Bug#9492 [<http://bugs.mysql.com/9492>])
- `SET @var= CAST(NULL AS [INTEGER|CHAR])` now sets the result type of the variable to INTEGER/CHAR. (Bug#6598 [<http://bugs.mysql.com/6598>])
- Incorrect results were returned for queries of the form `SELECT ... LEFT JOIN ... WHERE EXISTS (subquery)`, where the subquery selected rows based on an IS NULL condition. (Bug#9516 [<http://bugs.mysql.com/9516>])
- Executing `LOCK TABLES` and then calling a stored procedure caused an error and resulting in the server thinking that no stored procedures exist. (Bug#9566 [<http://bugs.mysql.com/9566>])
- Selecting from a view containing a subquery caused the server to hang. (Bug#8490 [<http://bugs.mysql.com/8490>])
- Within a stored procedure, attempting to execute a multiple-table UPDATE failed with a Table '`tbl_name`' was locked with a READ lock and can't be updated error. (Bug#9486 [<http://bugs.mysql.com/9486>])
- Starting `mysqld` with the `--skip-innodb` and `--default-storage-engine=innodb` (or `--default-table-type=innodb`) caused a server crash. (Bug#9815 [<http://bugs.mysql.com/9815>])
- Queries containing `CURRENT_USER()` incorrectly were registered in the query cache. (Bug#9796 [<http://bugs.mysql.com/9796>])
- Setting the `storage_engine` system variable to MEMORY succeeded, but retrieving the variable resulted in a value of HEAP (the old name for the MEMORY storage engine) rather than MEMORY. (Bug#10039 [<http://bugs.mysql.com/10039>])
- `mysqlshow` displayed an incorrect row count for tables. (Bug#9391 [<http://bugs.mysql.com/9391>])
- The server died with signal 11 if a non-existent location was specified for the location of the binary log. Now the server exits after printing an appropriate error message. (Bug#9542 [<http://bugs.mysql.com/9542>])
- Fixed a problem in the client/server protocol where the server closed the connection before sending the final error message. The problem could show up as a `Lost connection to MySQL server during query` when attempting to connect to access a non-existent database. (Bug#6387 [<http://bugs.mysql.com/6387>], Bug#9455 [<http://bugs.mysql.com/9455>])
- Fixed a readline-related crash in `mysql` when the user pressed Control-R. (Bug#9568 [<http://bugs.mysql.com/9568>])
- For stored functions that should return a YEAR value, corrected a failure of the value to be in YEAR format. (Bug#8861 [<http://bugs.mysql.com/8861>])
- Fixed a server crash resulting from invocation of a stored function that returned a value having an ENUM or SET data type. (Bug#9775 [<http://bugs.mysql.com/9775>])
- Fixed a server crash resulting from invocation of a stored function that returned a value having a BLOB data type. (Bug#9102 [<http://bugs.mysql.com/9102>])
- Fixed a server crash resulting from invocation of a stored function that returned a value having a BIT data type. (Bug#7648 [<http://bugs.mysql.com/7648>])
- `TIMEDIFF()` with a negative time first argument and positive time second argument produced incorrect results. (Bug#8068 [<http://bugs.mysql.com/8068>])

- Fixed a problem with `OPTIMIZE TABLE` for InnoDB tables being written twice to the binary log. (Bug#9149 [<http://bugs.mysql.com/9149>])
- InnoDB: Prevent `ALTER TABLE` from changing the storage engine if there are foreign key constraints on the table. (Bug#5574 [<http://bugs.mysql.com/5574>], Bug#5670 [<http://bugs.mysql.com/5670>])
- InnoDB: Fixed a bug where next-key locking doesn't allow the insert which does not produce a phantom. (Bug#9354 [<http://bugs.mysql.com/9354>]) If the range is of type 'a' <= unique-column, InnoDB lock only the RECORD, if the record with the column value 'a' exists in a CLUSTERED index. This allows inserts before a range.
- InnoDB: When `FOREIGN_KEY_CHECKS=0`, `ALTER TABLE` and `RENAME TABLE` will ignore any type incompatibilities between referencing and referenced columns. Thus, it will be possible to convert the character sets of columns that participate in a foreign key. Be sure to convert all tables before modifying any data! (Bug#9802 [<http://bugs.mysql.com/9802>])
- Provide more informative error messages in clustered setting when a query is issued against a table that has been modified by another mysqld server. (Bug#6762 [<http://bugs.mysql.com/6762>])

## D.1.20. Changes in release 5.0.4 (16 April 2005)

Functionality added or changed:

- Added `ENGINE=MyISAM` table option when creating `mysql.proc` table in `mysql_create_system_tables` script to make sure the table is created as a MyISAM table even if the default storage engine has been changed. (Bug#9496 [<http://bugs.mysql.com/9496>])
- `SHOW CREATE TABLE` for an `INFORMATION_SCHEMA` table no longer prints a `MAX_ROWS` value because the value has no meaning. (Bug#8941 [<http://bugs.mysql.com/8941>])
- Invalid `DEFAULT` values for `CREATE TABLE` now generate errors. (Bug#5902 [<http://bugs.mysql.com/5902>])
- Added `--show-table-type` option to `mysqlshow`, to display a column indicating the table type, as in `SHOW FULL TABLES`. (Bug#5036 [<http://bugs.mysql.com/5036>])
- The way the time zone information is stored in the binary log was changed, so that it is now possible to have a replication master and slave running with different global time zones. A drawback is that replication from 5.0.4 masters to pre-5.0.4 slaves is impossible.
- Added `--with-big-tables` compilation option to `configure`. (Previously it was necessary to pass `-DBIG_TABLES` to the compiler manually in order to enable large table support.) See Section 2.9.2, “Typical configure Options”, for details.
- New configuration directives `!include` and `!includedir` implemented for including option files and searching directories for option files. See Section 4.3.2, “Using Option Files”, for usage.

Bugs fixed:

- The use of `XOR` together with `NOT ISNULL( )` erroneously resulted in some outer joins being converted to inner joins by the optimizer. (Bug#9017 [<http://bugs.mysql.com/9017>])
- Fixed an optimizer problem where extraneous comparisons between `NULL` values in indexed columns were being done for operators such as `=` that are never true for `NULL`. (Bug#8877 [<http://bugs.mysql.com/8877>])

- Fixed the client/server protocol for prepared statements so that reconnection works properly when the connection is killed while `reconnect` is enabled. (Bug#8866 [<http://bugs.mysql.com/8866>])
- A server installed as a Windows service and started with `--shared-memory` could not be stopped. (Bug#9665 [<http://bugs.mysql.com/9665>])
- Fixed a server crash resulting from multiple executions of a prepared statement involving a join of an `INFORMATION_SCHEMA` table with another table. (Bug#9383 [<http://bugs.mysql.com/9383>])
- Fixed `utf8_spanish2_ci` and `ucs2_spanish2_ci` collations to not consider 'r' equal to 'rr'. If you upgrade to this version from an earlier version, you should rebuild the indexes of affected tables. (Bug#9269 [<http://bugs.mysql.com/9269>])
- `mysqldump` dumped core when invoked with `--tmp` and `--single-transaction` options and a non-existent table name. (Bug#9175 [<http://bugs.mysql.com/9175>])
- Allow extra HKSCS and cp950 characters (`big5` extension characters) to be accepted in `big5` columns. (Bug#9357 [<http://bugs.mysql.com/9357>])
- `mysql.server` no longer uses non-portable `alias` command or `LSB` functions. (Bug#9852 [<http://bugs.mysql.com/9852>])
- Fixed a server crash resulting from `GROUP BY` on a decimal expression. (Bug#9210 [<http://bugs.mysql.com/9210>])
- In prepared statements, subqueries containing parameters were erroneously treated as `const` tables during preparation, resulting in a server crash. (Bug#8807 [<http://bugs.mysql.com/8807>])
- InnoDB: `ENUM` and `SET` columns were treated incorrectly as character strings. This bug did not manifest itself with `latin1` collations if there were less than about 100 elements in an `ENUM`, but it caused malfunction with `UTF-8`. Old tables will continue to work. In new tables, `ENUM` and `SET` will be internally stored as unsigned integers. (Bug#9526 [<http://bugs.mysql.com/9526>])
- InnoDB: Avoid test suite failures caused by a locking conflict between two server instances at server shutdown/startup. This conflict on advisory locks appears to be the result of a bug in the operating system; these locks should be released when the files are closed, but somehow that does not always happen immediately in Linux. (Bug#9381 [<http://bugs.mysql.com/9381>])
- InnoDB: True `VARCHAR`: InnoDB stored the 'position' of a row wrong in a column prefix primary key index; this could cause MySQL to complain `ERROR 1032: Can't find record ...` in an update of the primary key, and also some `ORDER BY` or `DISTINCT` queries. (Bug#9314 [<http://bugs.mysql.com/9314>])
- InnoDB: Fix bug in MySQL/InnoDB 5.0.3: SQL statements were not rolled back on error. (Bug#8650 [<http://bugs.mysql.com/8650>])
- Fixed a `Commands out of sync` error when two prepared statements for single-row result sets were open simultaneously. (Bug#8880 [<http://bugs.mysql.com/8880>])
- Fixed a server crash after a call to `mysql_stmt_close()` for single-row result set. (Bug#9159 [<http://bugs.mysql.com/9159>])
- Fixed server crashes for `CREATE TABLE ... SELECT` or `INSERT INTO ... SELECT` when selecting from multiple-table view. (Bug#8703 [<http://bugs.mysql.com/8703>], Bug#9398 [<http://bugs.mysql.com/9398>])
- `TRADITIONAL SQL` mode should prevent inserts where a column with no default value is omitted or set to a value of `DEFAULT`. Fixed cases where this restriction was not enforced. (Bug#5986 [<http://bugs.mysql.com/5986>])

- Fixed a server crash when creating a `PRIMARY KEY` for a table, if the table contained a `BIT` column. (Bug#9571 [<http://bugs.mysql.com/9571>])
- Warning message from `GROUP_CONCAT()` did not always indicate correct number of lines. (Bug#8681 [<http://bugs.mysql.com/8681>])
- The commit count cache for NDB was not properly invalidated when deleting a record using a cursor. (Bug#8585 [<http://bugs.mysql.com/8585>])
- Fixed option-parsing code for the embedded server to understand `K`, `M`, and `G` suffixes for the `net_buffer_length` and `max_allowed_packet` options. (Bug#9472 [<http://bugs.mysql.com/9472>])
- Selecting a `BIT` column failed if the binary client/server protocol was used. (Bug#9608 [<http://bugs.mysql.com/9608>])
- Fixed a permissions problem whereby information in `INFORMATION_SCHEMA` could be exposed to a user with insufficient privileges. (Bug#7214 [<http://bugs.mysql.com/7214>])
- An error now occurs if you try to insert an invalid value via a stored procedure in `STRICT` mode. (Bug#5907 [<http://bugs.mysql.com/5907>])
- Link with `libsupc++` on Fedora Core 3 to get language support functions. (Bug#6554 [<http://bugs.mysql.com/6554>])
- The value of the `CHARACTER_MAXIMUM_LENGTH` and `CHARACTER_OCTET_LENGTH` columns of the `INFORMATION_SCHEMA.COLUMNS` table must be `NULL` for numeric columns, but were not. (Bug#9344 [<http://bugs.mysql.com/9344>])
- `DROP TABLE` did not drop triggers that were defined for the table. `DROP DATABASE` did not drop triggers in the database. (Bug#5859 [<http://bugs.mysql.com/5859>], Bug#6559 [<http://bugs.mysql.com/6559>])
- `CREATE OR REPLACE VIEW` and `ALTER VIEW` now require the `CREATE VIEW` and `DROP` privileges, not `CREATE VIEW` and `DELETE`. (`DELETE` is a row-level privilege, not a table-level privilege.) (Bug#9260 [<http://bugs.mysql.com/9260>])
- Some user variables were not being handled with “implicit” coercibility. (Bug#9425 [<http://bugs.mysql.com/9425>])
- Setting the `max_error_count` system variable to 0 resulted in a setting of 1. (Bug#9072 [<http://bugs.mysql.com/9072>])
- Fixed a collation coercibility problem that caused a union between binary and non-binary columns to fail. (Bug#6519 [<http://bugs.mysql.com/6519>])
- Fixed a bug in division of floating point numbers. It could cause nine zeroes (000000000) to be inserted in the middle of the quotient. (Bug#9501 [<http://bugs.mysql.com/9501>])
- `INFORMATION_SCHEMA` tables had an implicit upper limit for the number of rows. As a result, not all data could be returned for some queries. (Bug#9317 [<http://bugs.mysql.com/9317>])
- Fixed a problem with the `tee` command in `mysql` that resulted in `mysql` crashing. (Bug#8499 [<http://bugs.mysql.com/8499>])
- `CAST()` now produces warnings when casting incorrect `INTEGER` and `CHAR` values. This also applies to implicit `string` to `number` casts. (Bug#5912 [<http://bugs.mysql.com/5912>])
- `ALTER TABLE` now fails in `STRICT` mode if the alteration generates warnings.
- Using `CONVERT('0000-00-00', date)` or `CAST('0000-00-00' as date)` with the `NO_ZERO_DATE SQL` mode enabled now produces a warning. (Bug#6145 [<http://bugs.mysql.com/6145>])

- Inserting a zero date in a DATE, DATETIME or TIMESTAMP column during TRADITIONAL mode now produces an error. (Bug#5933 [<http://bugs.mysql.com/5933>])
- Inserting a zero date into a DATETIME column in TRADITIONAL mode now produces an error.
- STR\_TO\_DATE ( ) now produces errors in strict mode (and warnings otherwise) when given an illegal argument. (Bug#5902 [<http://bugs.mysql.com/5902>])
- Fixed a problem with ORDER BY that sometimes caused incorrect sorting of utf8 data. (Bug#9309 [<http://bugs.mysql.com/9309>])
- Fixed server crash resulting from queries that combined SELECT DISTINCT, SUM ( ), and ROLLUP. (Bug#8615 [<http://bugs.mysql.com/8615>])
- Incorrect results were returned from queries that combined SELECT DISTINCT, GROUP BY , and ROLLUP. (Bug#8616 [<http://bugs.mysql.com/8616>])
- Too many rows were returned from queries that combined ROLLUP and LIMIT if SQL\_CALC\_FOUND\_ROWS was given. (Bug#8617 [<http://bugs.mysql.com/8617>])
- If on replication master a LOAD DATA INFILE is interrupted in the middle (integrity constraint violation, killed connection...), the slave used to skip this LOAD DATA INFILE entirely, thus missing some changes if this command permanently inserted/updated some table records before being interrupted. This is now fixed. (Bug#3247 [<http://bugs.mysql.com/3247>])

## D.1.21. Changes in release 5.0.3 (23 March 2005: Beta)

**Note:** This Beta release, as any other pre-production release, should not be installed on “production” level systems or systems with critical data. It is good practice to back up your data before installing any new version of software. Although MySQL worked very hard to ensure a high level of quality, protect your data by making a backup as you would for any software beta release.

Functionality added or changed:

- Security improvement: The server creates .frm, .MYD, .MYI, .MRG, .ISD, and .ISM table files only if a file with the same name does not already exist. Thanks to Stefano Di Paola <[stefano.dipaola@wisec.it](mailto:stefano.dipaola@wisec.it)> for finding and informing us about this issue. (CVE-2005-0711 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0711>])
- Security improvement: User-defined functions should have at least one symbol defined in addition to the xxx symbol that corresponds to the main xxx ( ) function. These auxiliary symbols correspond to the xxx\_init ( ), xxx\_deinit ( ), xxx\_reset ( ), xxx\_clear ( ), and xxx\_add ( ) functions. mysqld by default no longer loads UDFs unless they have at least one auxiliary symbol defined in addition to the main symbol. The --allow-suspicious-udfs option controls whether UDFs that have only an xxx symbol can be loaded. By default, the option is off. mysqld also checks UDF filenames when it reads them from the mysql . func table and rejects those that contain directory pathname separator characters. (It already checked names as given in CREATE FUNCTION statements.) See Section 24.2.4.1, “UDF Calling Sequences for Simple Functions”, Section 24.2.4.2, “UDF Calling Sequences for Aggregate Functions”, and Section 24.2.4.6, “User-Defined Function Security Precautions”. Thanks to Stefano Di Paola <[stefano.dipaola@wisec.it](mailto:stefano.dipaola@wisec.it)> for finding and informing us about this issue. (CVE-2005-0709 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0709>], CVE-2005-0710 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0710>])
- The DECIMAL and NUMERIC data types now are handled with a fixed-point library that allows for precision math handling that results in more accurate results. See Chapter 21, *Precision Math*.

**Warning: Incompatible change:** A consequence of the change in handling of the DECIMAL and NUMERIC fixed-point data types is that the server is more strict to follow standard SQL. For example, a data type of DECIMAL ( 3 , 1 ) stores a maximum value of 99.9. Previously, the serv-

er allowed larger numbers to be stored. That is, it stored a value such as 100.0 as 100.0. Now the server clips 100.0 to the maximum allowable value of 99.9. If you have tables that were created before MySQL 5.0.3 and that contain floating-point data not strictly legal for the data type, you should alter the data types of those columns. For example:

```
ALTER TABLE tbl_name MODIFY col_name DECIMAL(4,1);
```

- **Incompatible change:** The C API `ER_WARN_DATA_TRUNCATED` warning symbol was renamed to `WARN_DATA_TRUNCATED`.
- **InnoDB: Upgrading from 4.1:** The sorting order for end-space in `TEXT` columns for InnoDB tables has changed. Starting from 5.0.3, InnoDB compares `TEXT` columns as space-padded at the end. If you have a non-unique index on a `TEXT` column, you should run `CHECK TABLE` on it, and run `OPTIMIZE TABLE` if the check reports errors. If you have a `UNIQUE INDEX` on a `TEXT` column, you should rebuild the table with `OPTIMIZE TABLE`.
- Implemented support for XA transactions. See Section 13.4.7, “XA Transactions”. The implementation make the `innodb_safe_binlog` system variable obsolete, so it has been removed.
- `mysqlbinlog` now prints a `ROLLBACK` statement at the end of its output, in case the server crashed while it was in the process of writing the final entry into the last binary log named on the command line. This causes any half-written transaction to be rolled back when the output is executed. The `ROLLBACK` is harmless if the binary log file was written and closed normally.
- Added the `engine_condition_pushdown` system variable. For NDB, setting this variable to 1 allows processing of some `WHERE` clause conditions to be processed in NDB nodes before rows are sent to the MySQL server, rather than having rows sent to the server for evaluation.
- Additional control over transaction completion was implemented. The `COMMIT` and `ROLLBACK` statements support `AND [NO] CHAIN` and `RELEASE` clauses. There is a new `RELEASE SAVEPOINT` statement. The `completion_type` system variable was added for setting the global and session default completion type.
- A new `CREATE USER` privilege was added.
- `my.cnf` in the compile-time `datadir` (usually `/usr/local/mysql/data/` in the binary tarball distributions) is not being read anymore. The value of the environment variable `MYSQL_HOME` is used instead of the hard-coded path.
- Support for the `ISAM` storage engine has been removed. If you have `ISAM` tables, you should convert them before upgrading. See Section 2.11.2, “Upgrading from MySQL 4.1 to 5.0”.
- Support for `RAID` options in `MyISAM` tables has been removed. If you have tables that use these options, you should convert them before upgrading. See Section 2.11.2, “Upgrading from MySQL 4.1 to 5.0”.
- Added support for `AVG(DISTINCT)`.
- `ONLY_FULL_GROUP_BY` no longer is included in the `ANSI` composite `SQL` mode. (Bug#8510 [<http://bugs.mysql.com/8510>])
- `mysqld_safe` will create the directory where the `UNIX` socket file is to be located if the directory does not exist. This applies only to the last component of the directory pathname. (Bug#8513 [<http://bugs.mysql.com/8513>])
- The coercibility for the return value of functions such as `USER()` or `VERSION()` now is “system constant” rather than “implicit.” This makes these functions more coercible than column values so that comparisons of the two do not result in `Illegal mix of collations` errors. `COERCIBILITY()` was modified to accommodate this new coercibility value. See Section 12.9.3, “Information Functions”.
- User variable coercibility has been changed from “coercible” to “implicit.” That is, user vari-

ables have the same coercibility as column values.

- Boolean full-text phrase searching now requires only that matches contain exactly the same words as the phrase and in the same order. Non-word characters no longer need match exactly.
- CHECKSUM TABLE returns a warning for non-existing tables. The checksum value remains NULL as before. (Bug#8256 [<http://bugs.mysql.com/8256>])
- The server now includes a timestamp in the Ready for connections message that is written to the error log at startup. (Bug#8444 [<http://bugs.mysql.com/8444>])
- Added SQL\_NOTES session variable to cause Note-level warnings not to be recorded. (Bug#6662 [<http://bugs.mysql.com/6662>])
- Allowed the service-installation command for Windows servers to specify a single option other than --defaults-file following the service name. This is for compatibility with MySQL 4.1. (Bug#7856 [<http://bugs.mysql.com/7856>])
- InnoDB: Commit after every 10,000 copied rows when executing ALTER TABLE, CREATE INDEX, DROP INDEX or OPTIMIZE TABLE. This makes it much faster to recover from an aborted operation.
- Added VAR\_POP() and STDDEV\_POP() as standard SQL aliases for the VARIANCE() and STDDEV() functions that compute population variance and standard deviation. Added new VAR\_SAMP() and STDDEV\_SAMP() functions to compute sample variance and standard deviation. (Bug#3190 [<http://bugs.mysql.com/3190>])
- Fixed a problem with out-of-order packets being sent (ERROR after OK or EOF) following a KILL QUERY statement. (Bug#6804 [<http://bugs.mysql.com/6804>])
- Retrieving from a view defined as a SELECT that mixed UNION ALL and UNION DISTINCT resulted in a different result than retrieving from the original SELECT. (Bug#6565 [<http://bugs.mysql.com/6565>])
- Fixed a problem with non-optimal index\_merge query execution plans being chosen on IRIX. (Bug#8578 [<http://bugs.mysql.com/8578>])
- BIT in column definitions now is a distinct data type; it no longer is treated as a synonym for TINYINT(1).
- Bit-field values can be written using b'value' notation. value is a binary value written using 0s and 1s.
- From the Windows distribution, predefined accounts without passwords for remote users ("root@", "@%") were removed (other distributions never had them).
- Added mysql\_library\_init() and mysql\_library\_end() as synonyms for the mysql\_server\_init() and mysql\_server\_end() C API functions. mysql\_library\_init() and mysql\_library\_end() are #define symbols, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL C API library no matter whether the application uses libmysqlclient or libmysqld. (Bug#6149 [<http://bugs.mysql.com/6149>])
- SHOW COLUMNS now displays NO rather than blank in the Null output column if the corresponding table column cannot be NULL.
- Changed XML format for mysql from <col\_name>col\_value</col\_name> to <field name="col\_name">col\_value</field> to allow for proper encoding of column names that are not legal as element names. (Bug#7811 [<http://bugs.mysql.com/7811>])
- Added --innodb-checksums and --innodb-doublewrite options for mysqld.
- Added --large-pages option for mysqld.

- Added `multi_read_range` system variable.
- `SHOW DATABASES`, `SHOW TABLES`, `SHOW COLUMNS`, and so forth display information about the `INFORMATION_SCHEMA` database. Also, several `SHOW` statements now accept a `WHERE` clause specifying which output rows to display. See Chapter 20, *The INFORMATION\_SCHEMA Database*.
- Added the `CREATE ROUTINE` and `ALTER ROUTINE` privileges, and made the `EXECUTE` privilege operational.
- InnoDB: Corrected a bug in the crash recovery of `ROW_FORMAT=COMPACT` tables that caused corruption. (Bug#7973 [<http://bugs.mysql.com/7973>]) There may still be bugs in the crash recovery, especially in `COMPACT` tables.
- When the `MyISAM` storage engine detects corruption of a `MyISAM` table, a message describing the problem now is written to the error log.
- InnoDB: When MySQL/InnoDB is compiled on Mac OS X 10.2 or earlier, detect the operating system version at run time and use the `fcntl()` file flush method on Mac OS X versions 10.3 and later. In Mac OS X, `fsync()` does not flush the write cache in the disk drive, but the special `fcntl()` does; however, the flush request is ignored by some external devices. Failure to flush the buffers may cause severe database corruption at power outages.
- InnoDB: Implemented fast `TRUNCATE TABLE`. The old approach (deleting rows one by one) may be used if the table is being referenced by foreign keys. (Bug#7150 [<http://bugs.mysql.com/7150>])
- Added `cp932` (SJIS for Windows Japanese) and `ujis` (UJIS for Windows Japanese) character sets.
- Added several InnoDB status variables. See Section 5.2.4, “Server Status Variables”.
- Added the `FEDERATED` storage engine. See Section 14.7, “The FEDERATED Storage Engine”.
- `SHOW CREATE TABLE` now uses `USING index_type` rather than `TYPE index_type` to specify an index type. (Bug#7233 [<http://bugs.mysql.com/7233>])
- InnoDB now supports a fast `TRUNCATE TABLE`. One visible change from this is that auto-increment values for this table are reset on `TRUNCATE`.
- Added an `error` member to the `MYSQL_BIND` data structure that is used in the C API for prepared statements. This member is used for reporting data truncation errors. Truncation reporting is enabled via the new `MYSQL_REPORT_DATA_TRUNCATION` option for the `mysql_options()` C API function.
- API change: the `reconnect` flag in the `MYSQL` structure is now set to 0 by `mysql_real_connect()`. Only those client programs which didn't explicitly set this flag to 0 or 1 after `mysql_real_connect()` experience a change. Having automatic reconnection enabled by default was considered too dangerous (after reconnection, table locks, temporary tables, user and session variables are lost).
- `FLUSH TABLES WITH READ LOCK` is now killable while it's waiting for running `COMMIT` statements to finish.
- `MEMORY (HEAP)` can have `VARCHAR()` fields.
- `VARCHAR` columns now remember end space. A `VARCHAR()` column can now contain up to 65535 bytes. For more details, see Section D.1, “Changes in release 5.0.x (Production)”. If the table handler doesn't support the new `VARCHAR` type, then it's converted to a `CHAR` column. Currently this happens for NDB tables.
- InnoDB: Introduced a compact record format that does not store the number of columns or the lengths of fixed-size columns. The old format can be requested by specifying

ROW\_FORMAT=REDUNDANT. The new format (ROW\_FORMAT=COMPACT) is the default. The new format typically saves 20 % of disk space and memory.

- InnoDB: Setting the initial AUTO\_INCREMENT value for an InnoDB table using CREATE TABLE ... AUTO\_INCREMENT = *n* now works, and ALTER TABLE ... AUTO\_INCREMENT = *n* resets the current value.
- Seconds\_Behind\_Master is NULL (which means “unknown”) if the slave SQL thread is not running, or if the slave I/O thread is not running or not connected to master. It is zero if the SQL thread has caught up to the I/O thread. It no longer grows indefinitely if the master is idle.
- The MySQL server aborts immediately instead of simply issuing a warning if it is started with the --log-bin option but cannot initialize the binary log at startup (that is, an error occurs when writing to the binary log file or binary log index file).
- The binary log file and binary log index file now are handled the same way as MyISAM tables when there is a “disk full” or “quota exceeded” error. See Section A.4.3, “How MySQL Handles a Full Disk”.
- The MySQL server now aborts when started with the option --log-bin-index and without --log-bin, and when started with --log-slave-updates and without --log-bin.
- If the MySQL server is started without an argument to --log-bin and without --log-bin-index, thus not providing a name for the binary log index file, a warning is issued because MySQL falls back to using the hostname for that name, and this is prone to replication issues if the server's hostname's gets changed later. See Section A.8.1, “Open Issues in MySQL”.
- Added account-specific MAX\_USER\_CONNECTIONS limit, which allows you to specify the maximum number of concurrent connections for the account. Also, all limited resources now are counted per account (instead of being counted per user + host pair as it was before). Use the --old-style-user-limits option to get the old behavior.
- InnoDB: A shared record lock (LOCK\_REC\_NOT\_GAP) is now taken for a matching record in the foreign key check because inserts can be allowed into gaps.
- InnoDB: Relaxed locking in INSERT...SELECT, single table UPDATE...SELECT and single table DELETE...SELECT clauses when innodb\_locks\_unsafe\_for\_binlog is used and isolation level of the transaction is not serializable. InnoDB uses consistent read in these cases for a selected table.
- Added a new global system variable slave\_transaction\_retries: if the replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or exceeded InnoDB's innodb\_lock\_wait\_timeout or NDBCluster's TransactionDeadlockDetectionTimeout or TransactionInactiveTimeout, it automatically retries slave\_transaction\_retries times before stopping with an error. The default is 10. (Bug#8325 [<http://bugs.mysql.com/8325>])
- When a client releases a user-level lock, DO RELEASE\_LOCK( ) will not be written to the binary log anymore (this makes the binary log smaller); as a counterpart, the slave does not actually take the lock when it executes GET\_LOCK( ). This is mainly an optimization and should not affect existing setups. (Bug#7998 [<http://bugs.mysql.com/7998>])
- The way the character set information is stored into the binary log was changed, so that it's now possible to have a replication master and slave running with different global character sets. A drawback is that replication from 5.0.3 masters to pre-5.0.3 slaves is impossible.
- The LOAD DATA statement was extended to support user variables in the target column list, and an optional SET clause. Now one can perform some transformations on data after they have been read and before they are inserted into the table. For example:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

Also, replication of `LOAD DATA` was changed, so you can't replicate such statements from a 5.0.3 master to pre-5.0.3 slaves.

- `NDB Cluster`: When using this storage engine, the output of `SHOW TABLE STATUS` now displays properly-calculated values in the `Avg_row_length` and `Data_length` columns. (Note that `BLOB` columns are not yet taken into account.) In addition, the number of replicas is now shown in the `Comment` column (as `number_of_replicas`).

Bugs fixed:

- If a `MyISAM` table on Windows had `INDEX DIRECTORY` or `DATA DIRECTORY` table options, `mysqldump` dumped the directory pathnames with single-backslash pathname separators. This would cause syntax errors when importing the dump file. `mysqldump` now changes `'\'` to `'/'` in the pathnames on Windows. (Bug#6660 [<http://bugs.mysql.com/6660>])
- `mysql_fix_privilege_tables` now fixes that the `mysql` privilege tables can be used in MySQL 4.1. This allows one to easily downgrade to 4.1 or run MySQL 5.0 and 4.1 with the same privilege files for testing purposes.
- Fixed bug creating user with `GRANT` fails with password but works without, (Bug#7905 [<http://bugs.mysql.com/7905>])
- `mysqldump` misinterpreted `'_'` and `'%'` characters in the names of tables to be dumped as wildcard characters. (Bug#9123 [<http://bugs.mysql.com/9123>])
- The definition of the enumeration-valued `sql_mode` column of the `mysql.proc` table was missing some of the current allowable SQL modes, so stored routines would not necessarily execute with the SQL mode in effect at the time of routine definition. (Bug#8902 [<http://bugs.mysql.com/8902>])
- `REPAIR TABLE` did not invalidate query results in the query cache that were generated from the table. (Bug#8480 [<http://bugs.mysql.com/8480>])
- In strict or traditional SQL mode, too-long string values assigned to string columns (`CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `TEXT`, or `BLOB`) were correctly truncated, but the server returned an `SQLSTATE` value of `01000` (should be `22001`). (Bug#6999 [<http://bugs.mysql.com/6999>], Bug#9029 [<http://bugs.mysql.com/9029>])
- Stored functions that used cursors could return incorrect results. (Bug#8386 [<http://bugs.mysql.com/8386>])
- `AES_DECRYPT(col_name, key)` could fail to return `NULL` for invalid values in `col_name`, if `col_name` was declared as `NOT NULL`. (Bug#8669 [<http://bugs.mysql.com/8669>])
- Ordering by unsigned expression (more complex than a column reference) was treating the value as signed, producing incorrectly sorted results. (Bug#7425 [<http://bugs.mysql.com/7425>])
- `HAVING` was treating unsigned columns as signed. (Bug#7425 [<http://bugs.mysql.com/7425>])
- Fixed a problem with boolean full-text searches on `utf8` columns where a double quote in the search string caused a server crash. (Bug#8351 [<http://bugs.mysql.com/8351>])
- For a query with both `GROUP BY` and `COUNT(DISTINCT)` clauses and a `FROM` clause with a subquery, `NULL` was returned for any `VARCHAR` column selected by the subquery. (Bug#8218 [<http://bugs.mysql.com/8218>])
- Fixed a bug in `TRUNCATE`, which did not work within stored procedures. A workaround has been made so that within stored procedures, `TRUNCATE` is executed like `DELETE`. This was ne-

cessary because `TRUNCATE` is implicitly locking tables. (Bug#8850 [<http://bugs.mysql.com/8850>])

- Fixed an optimizer bug that caused incorrectly ordered result from a query that used a `FULLTEXT` index to retrieve rows and there was another index that was usable for `ORDER BY`. For such a query, `EXPLAIN` showed `fulltext` join type, but regular (not `FULLTEXT`) index in the `Key` column. (Bug#6635 [<http://bugs.mysql.com/6635>])
- If `SELECT DISTINCT` named an index column multiple times in the select list, the server tried to access different key fields for each instance of the column, which could result in a crash. (Bug#8532 [<http://bugs.mysql.com/8532>])
- For a stored function that refers to a given table, invoking the function while selecting from the same table resulted in a server crash. (Bug#8405 [<http://bugs.mysql.com/8405>])
- Comparison of a `DECIMAL` column containing `NULL` to a subquery that produced `DECIMAL` values resulted in a server crash. (Bug#8397 [<http://bugs.mysql.com/8397>])
- The `--set-character-set` option for `myisamchk` was changed to `--set-collation`. The value needed for specifying how to sort indexes is a collation name, not a character set name. (Bug#8349 [<http://bugs.mysql.com/8349>])
- Hostname matching didn't work if a netmask was specified for table-specific privileges. (Bug#3309 [<http://bugs.mysql.com/3309>])
- Corruption of `MyISAM` table indexes could occur with `TRUNCATE TABLE` if the table had already been opened. For example, this was possible if the table had been opened implicitly by selecting from a `MERGE` table that mapped to the `MyISAM` table. The server now issues an error message for `TRUNCATE TABLE` under these conditions. (Bug#8306 [<http://bugs.mysql.com/8306>])
- Setting the connection collation to a value different from the server collation followed by a `CREATE TABLE` statement that included a quoted default value resulted in a server crash. (Bug#8235 [<http://bugs.mysql.com/8235>])
- Fixed handling of table-name matching in `mysqlhotcopy` to accommodate `DBD::mysql 2.9003` and up (which implement identifier quoting). (Bug#8136 [<http://bugs.mysql.com/8136>])
- Selecting from a view defined as a join caused a server crash if the query cache was enabled. (Bug#8054 [<http://bugs.mysql.com/8054>])
- Results in the query cache generated from a view were not properly invalidated after `ALTER VIEW` or `DROP VIEW` on that view. (Bug#8050 [<http://bugs.mysql.com/8050>])
- `FOUND_ROWS()` returned an incorrect value after a `SELECT SQL_CALC_FOUND_ROWS DISTINCT` statement that selected constants and included `GROUP BY` and `LIMIT` clauses. (Bug#7945 [<http://bugs.mysql.com/7945>])
- Selecting from an `INFORMATION_SCHEMA` table combined with a subquery on an `INFORMATION_SCHEMA` table caused an error with the message `Table 'tbl_name' is corrupted`. (Bug#8164 [<http://bugs.mysql.com/8164>])
- Fixed a problem with equality propagation optimization for prepared statements and stored procedures that caused a server crash upon re-execution of the prepared statement or stored procedure. (Bug#8115 [<http://bugs.mysql.com/8115>], Bug#8849 [<http://bugs.mysql.com/8849>])
- `LEFT OUTER JOIN` between an empty base table and a view on an empty base table caused a server crash. (Bug#7433 [<http://bugs.mysql.com/7433>])
- Use of `GROUP_CONCAT()` in the select list when selecting from a view caused a server crash. (Bug#7116 [<http://bugs.mysql.com/7116>])
- Use of a view in a correlated subquery that contains `HAVING` but no `GROUP BY` caused a server

crash. (Bug#6894 [<http://bugs.mysql.com/6894>])

- Handling by `mysql_list_fields()` of references to stored functions within views was incorrect and could result in a server crash. (Bug#6814 [<http://bugs.mysql.com/6814>])
- `mysqldump` now avoids writing `SET NAMES` to the dump output if the server is older than version 4.1 and would not understand that statement. (Bug#7997 [<http://bugs.mysql.com/7997>])
- Fixed problems when selecting from a view that had an `EXISTS` or `NOT EXISTS` subquery. Selecting columns by name caused a server crash. With `SELECT *`, a crash did not occur, but columns in outer query were not resolved properly. (Bug#6394 [<http://bugs.mysql.com/6394>])
- DDL statements for views were not being written to the binary log (and thus not subject to replication). (Bug#4838 [<http://bugs.mysql.com/4838>])
- The `CHAR()` function was not ignoring `NULL` arguments, contrary to the documentation. (Bug#6317 [<http://bugs.mysql.com/6317>])
- Creating a table using a name containing a character that is illegal in `character_set_client` resulted in the character being stripped from the name and no error. The character now is considered an error. (Bug#8041 [<http://bugs.mysql.com/8041>])
- Fixed a problem with the Cyrillic letters `I` and `SHORT I` being treated the same by the `utf8_general_ci` collation. (Bug#8385 [<http://bugs.mysql.com/8385>])
- Some `INFORMATION_SCHEMA` columns that contained catalog identifiers were of type `LONGTEXT`. These were changed to `VARCHAR(N)`, where `N` is the appropriate maximum identifier length. (Bug#7215 [<http://bugs.mysql.com/7215>])
- Some `INFORMATION_SCHEMA` columns that contained timestamp values were of type `VARBINARY`. These were changed to `TIMESTAMP`. (Bug#7217 [<http://bugs.mysql.com/7217>])
- An expression that tested a case-insensitive character column against string constants that differed in lettercase could fail because the constants were treated as having a binary collation. (For example, `WHERE city='London' AND city='london'` could fail.) (Bug#7098 [<http://bugs.mysql.com/7098>], Bug#8690 [<http://bugs.mysql.com/8690>])
- The output of the `STATUS (\s)` command in `mysql` had the values for the server and client character sets reversed. (Bug#7571 [<http://bugs.mysql.com/7571>])
- If the slave was running with `--replicate-*-table` options which excluded one temporary table and included another, and the two tables were used in a single `DROP TEMPORARY TABLE IF EXISTS` statement, as the ones the master automatically writes to its binary log upon client's disconnection when client has not explicitly dropped these, the slave could forget to delete the included replicated temporary table. Only the slave needs to be upgraded. (Bug#8055 [<http://bugs.mysql.com/8055>])
- When setting integer system variables to a negative value with `SET VARIABLES`, the value was treated as a positive value modulo  $2^{32}$ . (Bug#6958 [<http://bugs.mysql.com/6958>])
- Corrected a problem with references to `DUAL` where statements such as `SELECT 1 AS a FROM DUAL` would succeed but statements such as `SELECT 1 AS a FROM DUAL LIMIT 1` would fail. (Bug#8023 [<http://bugs.mysql.com/8023>])
- Fixed a server crash caused by `DELETE FROM tbl_name ... WHERE ... ORDER BY tbl_name.col_name` when the `ORDER BY` column was qualified with the table name. (Bug#8392 [<http://bugs.mysql.com/8392>])
- Fixed a bug in `MATCH ... AGAINST` in natural language mode that could cause a server crash if the `FULLTEXT` index was not used in a join (`EXPLAIN` did not show `fulltext` join mode) and the search query matched no rows in the table (Bug#8522 [<http://bugs.mysql.com/8522>]).

- InnoDB: Honor the `--tmpdir` startup option when creating temporary files. Previously, InnoDB temporary files were always created in the temporary directory of the operating system. On Netware, InnoDB will continue to ignore `--tmpdir`. (Bug#5822 [<http://bugs.mysql.com/5822>])
- Platform and architecture information in version information produced for `--version` option on Windows was always Win95/Win98 (i32). More accurately determine platform as Win32 or Win64 for 32-bit or 64-bit Windows, and architecture as ia32 for x86, ia64 for Itanium, and axp for Alpha. (Bug#4445 [<http://bugs.mysql.com/4445>])
- If multiple semicolon-separated statements were received in a single packet, they were written to the binary log as a single event rather than as separate per-statement events. For a server serving as a replication master, this caused replication to fail when the event was sent to slave servers. (Bug#8436 [<http://bugs.mysql.com/8436>])
- Fixed `LOAD INDEX` statement to actually load index in memory. (Bug#8452 [<http://bugs.mysql.com/8452>])
- Fixed a failure of multiple-table updates to replicate properly on slave servers when `--replicate-*-table` options had been specified. (Bug#7011 [<http://bugs.mysql.com/7011>])
- Fixed failure of `CREATE TABLE ... LIKE` Windows when the source or destination table was located in a symlinked database directory. (Bug#6607 [<http://bugs.mysql.com/6607>])
- With `lower_case_table_names` set to 1, `mysqldump` on Windows could write the same table name in different lettercase for different SQL statements. Fixed so that consistent lettercase is used. (Bug#5185 [<http://bugs.mysql.com/5185>])
- `mysqld_safe` now understands the `--help` option. Previously, it ignored the option and attempted to start the server anyway. (Bug#7931 [<http://bugs.mysql.com/7931>])
- Fixed problem in `NO_BACKSLASH_ESCAPES` SQL mode for strings that contained both the string quoting character and backslash. (Bug#6368 [<http://bugs.mysql.com/6368>])
- Fixed some portability issues with overflow in floating point values.
- Prepared statements now gives warnings on prepare.
- Fixed bug in prepared statements with `SUM(DISTINCT...)`.
- Fixed bug in prepared statements with `OUTER JOIN`.
- Fixed a bug in `CONV()` function returning unsigned `BIGINT` number (third argument is positive, and return value does not fit in 32 bits). (Bug#7751 [<http://bugs.mysql.com/7751>])
- Fixed a failure of the `IN()` operator to return correct result if all values in the list were constants and some of them were using substring functions, for example, `LEFT()`, `RIGHT()`, or `MID()`. (Bug#7716 [<http://bugs.mysql.com/7716>])
- Fixed a crash in `CONVERT_TZ()` function when its second or third argument was from a `const` table (see Section 7.2.1, “Optimizing Queries with `EXPLAIN`”). (Bug#7705 [<http://bugs.mysql.com/7705>])
- Fixed a problem with calculation of number of columns in row comparison against subquery. (Bug#8020 [<http://bugs.mysql.com/8020>])
- Fixed erroneous output resulting from `SELECT DISTINCT` combined with a subquery and `GROUP BY`. (Bug#7946 [<http://bugs.mysql.com/7946>])
- Fixed server crash in comparing a nested row expression (for example `row(1, (2, 3))`) with a subquery. (Bug#8022 [<http://bugs.mysql.com/8022>])
- Fixed server crash resulting from certain correlated subqueries with forward references

(references to an alias defined later in the outer query). (Bug#8025 [<http://bugs.mysql.com/8025>])

- Fixed server crash resulting from re-execution of prepared statements containing subqueries. (Bug#8125 [<http://bugs.mysql.com/8125>])
- Fixed a bug where ALTER TABLE improperly would accept an index on a TIMESTAMP column that CREATE TABLE would reject. (Bug#7884 [<http://bugs.mysql.com/7884>])
- SHOW CREATE TABLE now reports ENGINE=MEMORY rather than ENGINE=HEAP for a MEMORY table (unless the MYSQL323 SQL mode is enabled). (Bug#6659 [<http://bugs.mysql.com/6659>])
- Fixed a bug where the use of GROUP\_CONCAT() with HAVING caused a server crash. (Bug#7769 [<http://bugs.mysql.com/7769>])
- Fixed a bug where comparing the result of a subquery to a non-existent column caused a server crash on Windows. (Bug#7885 [<http://bugs.mysql.com/7885>])
- Fixed a bug in a combination of -not and trunc\* operators of full-text search. Using more than one truncated negative search term, was causing empty result set.
- InnoDB: Corrected the handling of trailing spaces in the UCS2 character set. (Bug#7350 [<http://bugs.mysql.com/7350>], Bug#8771 [<http://bugs.mysql.com/8771>])
- InnoDB: Use native tmpfile() function on Netware. All InnoDB temporary files are created under sys:\tmp. Previously, InnoDB temporary files were never deleted on Netware.
- Fixed a bug in max\_heap\_table\_size handling, that resulted in Table is full error when the table was still smaller than the limit. (Bug#7791 [<http://bugs.mysql.com/7791>]).
- Fixed a symlink vulnerability in the mysqlaccess script. Reported by Javier Fernandez-Sanguino Pena and Debian Security Audit Team [<http://www.debian.org/security/audit>]. (CVE-2005-0004 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2005-0004>])
- Fixed a bug that caused server crash if some error occurred during filling of temporary table created for derived table or view handling. (Bug#7413 [<http://bugs.mysql.com/7413>])
- Fixed a bug which caused server crash if query containing CONVERT\_TZ() function with constant arguments was prepared. (Bug#6849 [<http://bugs.mysql.com/6849>])
- Prevent adding CREATE TABLE .. SELECT query to the binary log when the insertion of new records partially failed. (Bug#6682 [<http://bugs.mysql.com/6682>])
- Fixed a bug which caused a crash when only the slave I/O thread was stopped and started. (Bug#6148 [<http://bugs.mysql.com/6148>])
- Giving mysqld a SIGHUP caused it to crash.
- Changed semantics of CREATE/ALTER/DROP DATABASE statements so that replication of CREATE DATABASE is possible when using --binlog-do-db and --binlog-ignore-db. (Bug#6391 [<http://bugs.mysql.com/6391>])
- A sequence of BEGIN (or SET AUTOCOMMIT=0), FLUSH TABLES WITH READ LOCK, transactional update, COMMIT, FLUSH TABLES WITH READ LOCK could hang the connection forever and possibly the MySQL server itself. This happened for example when running the innobackup script several times. (Bug#6732 [<http://bugs.mysql.com/6732>])
- mysqlbinlog did not print SET PSEUDO\_THREAD\_ID statements in front of LOAD DATA INFILE statements inserting into temporary tables, thus causing potential problems when rolling forward these statements after restoring a backup. (Bug#6671 [<http://bugs.mysql.com/6671>])
- InnoDB: Fixed a bug no error message for ALTER with InnoDB and AUTO\_INCREMENT

Bug#7061 [<http://bugs.mysql.com/7061>]). InnoDB now supports ALTER TABLE . . . AUTO\_INCREMENT = x query to set auto increment value for a table.

- Made the MySQL server accept executing SHOW CREATE DATABASE even if the connection has an open transaction or locked tables; refusing it made mysqldump --single-transaction sometimes fail to print a complete CREATE DATABASE statement for some dumped databases. (Bug#7358 [<http://bugs.mysql.com/7358>])
- Fixed that, when encountering a “disk full” or “quota exceeded” write error, MyISAM sometimes didn't sleep and retry the write, thus resulting in a corrupted table. (Bug#7714 [<http://bugs.mysql.com/7714>])
- Fixed that --expire-log-days was not honored if using only transactions. (Bug#7236 [<http://bugs.mysql.com/7236>])
- Fixed that a slave could crash after replicating many ANALYZE TABLE, OPTIMIZE TABLE, or REPAIR TABLE statements from the master. (Bug#6461 [<http://bugs.mysql.com/6461>], Bug#7658 [<http://bugs.mysql.com/7658>])
- mysqldbinnlog forgot to add backquotes around the collation of user variables (causing later parsing problems as BINARY is a reserved word). (Bug#7793 [<http://bugs.mysql.com/7793>])
- Ensured that mysqldump --single-transaction sets its transaction isolation level to REPEATABLE READ before proceeding (otherwise if the MySQL server was configured to run with a default isolation level lower than REPEATABLE READ it could give an inconsistent dump). (Bug#7850 [<http://bugs.mysql.com/7850>])
- Fixed that when using the RPAD( ) function (or any function adding spaces to the right) in a query that had to be resolved by using a temporary table, all resulting strings had rightmost spaces removed (that is, RPAD( ) did not work) (Bug#4048 [<http://bugs.mysql.com/4048>])
- Fixed that a 5.0.3 slave can connect to a master < 3.23.50 without hanging (the reason for the hang is a bug in these quite old masters -- SELECT @@unknown\_var hangs them -- which was fixed in MySQL 3.23.50). (Bug#7965 [<http://bugs.mysql.com/7965>])
- InnoDB: Fixed a deadlock without any locking, simple select and update (Bug#7975 [<http://bugs.mysql.com/7975>]). InnoDB now takes an exclusive lock when INSERT ON DUPLICATE KEY UPDATE is checking duplicate keys.
- Fixed a bug where MySQL was allowing concurrent updates (inserts, deletes) to a table if binary logging is enabled. Changed to ensure that all updates are executed in a serialized fashion, because they are executed serialized when binlog is replayed. (Bug#7879 [<http://bugs.mysql.com/7879>])
- Fixed a rare race condition which could lead to FLUSH TABLES WITH READ LOCK hanging. (Bug#8682 [<http://bugs.mysql.com/8682>])
- Fixed a bug in replication that caused the master to stamp generated statements (such as SET commands) with an error\_code intended only for another statement. This could happen, for example, when a statements generates a duplicate key error on the master but must be replicated. (Bug#8412 [<http://bugs.mysql.com/8412>])

## D.1.22. Changes in release 5.0.2 (01 December 2004)

Functionality added or changed:

- **Warning: Incompatible change!** The precedence of NOT operator has changed so that expressions such as NOT a BETWEEN b AND c are parsed correctly as NOT (a BETWEEN b AND c) rather than as (NOT a) BETWEEN b AND c. The pre-5.0 higher-precedence behavior can be obtained by enabling the new HIGH\_NOT\_PRECEDENCE SQL mode.

- `SHOW STATUS` now shows the thread specific status variables and `SHOW GLOBAL STATUS` shows the status variables for the whole server.
- Added support for the `INFORMATION_SCHEMA` “information database” that provides database metadata. See Chapter 20, *The INFORMATION\_SCHEMA Database*.
- A `HAVING` clause in a `SELECT` statement now can refer to columns in the `GROUP BY` clause, as required by standard SQL.
- Added the `CREATE USER` and `RENAME USER` statements.
- Modify `DROP USER` so that it drops the account, including all its privileges. Formerly, it removed the account record only for an account that had had all privileges revoked.
- Added `IS [NOT] boolean_value` syntax, where `boolean_value` is `TRUE`, `FALSE`, or `UNKNOWN`.
- Added several InnoDB status variables. See Section 5.2.4, “Server Status Variables”.
- Implemented the `WITH CHECK OPTION` clause for `CREATE VIEW`.
- `CHECK TABLE` now works for views.
- The `SCHEMA` and `SCHEMAS` keywords are now accepted as synonyms for `DATABASE` and `DATABASES`.
- Added initial support for rudimentary triggers (the `CREATE TRIGGER` and `DROP TRIGGER` statements).
- Added basic support for read-only server side cursors.
- `mysqldump --single-transaction --master-data` is now able to take an online (non-blocking) dump of InnoDB and report the corresponding binary log coordinates, which makes a backup suitable for point-in-time recovery, roll-forward or replication slave creation. See Section 8.11, “mysqldump — A Database Backup Program”.
- Added `--start-datetime`, `--stop-datetime`, `--start-position`, `--stop-position` options to `mysqlbinlog` (makes point-in-time recovery easier).
- Made the MySQL server not react to signals `SIGHUP` and `SIGQUIT` on Mac OS X 10.3. This is needed because under this OS, the MySQL server receives lots of these signals (reported as Bug#2030 [<http://bugs.mysql.com/2030>]).
- New `--auto-increment-increment` and `--auto-increment-offset` startup options. These allow you to set up a server to generate auto-increment values that don't conflict with another server.
- MySQL now by default checks dates and in strict mode allows only fully correct dates. If you want MySQL to behave as before, you should enable the new `ALLOW_INVALID_DATES` SQL mode.
- Added `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, and `TRADITIONAL SQL` modes. The `TRADITIONAL` mode is shorthand for all the preceding modes. When using mode `TRADITIONAL`, MySQL generates an error if you try to insert a wrong value in a column. It does not adjust the value to the closest possible legal value.
- MySQL now remembers which columns were declared to have default values. In `STRICT_TRANS_TABLES/STRICT_ALL_TABLES` mode, you now get an error if you do an `INSERT` without specifying all columns that don't have a default value. A side effect of this is that when you do `SHOW CREATE` for a new table, you no longer see a `DEFAULT` value for a column for which you didn't specify a default value.
- The compilation flag `DONT_USE_DEFAULT_FIELDS` was removed because you can get the

same behavior by setting the `sql_mode` system variable to `STRICT_TRANS_TABLES`.

- Added `NO_AUTO_CREATE_USER` SQL mode to prevent `GRANT` from automatically creating new users if it would otherwise do so, unless a password also is specified.
- We now detect too-large floating point numbers during statement parsing and generate an error messages for them.
- Renamed the `sql_updatable_view_key` system variable to `updatable_views_with_limit`. This variable now can have only two values:
  - 1 or YES: Don't issue an error message (warning only) if a `VIEW` without presence of a key in the underlying table is used in queries with a `LIMIT` clause for updating. (This is the default value.)
  - 0 or NO: Prohibit update of a `VIEW`, which does not contain a key in the underlying table and the query uses a `LIMIT` clause (usually get from GUI tools).
- Reverted output format of `SHOW TABLES` to old pre-5.0.1 format that did not include a table type column. To get the additional column that lists the table type, use `SHOW FULL TABLES NOW`.
- The `mysql_fix_privilege_tables` script now initializes the global `CREATE VIEW` and `SHOW VIEW` privileges in the `user` table to the value of the `CREATE` privilege in that table.
- If the server finds that the `user` table has not been upgraded to include the view-related privilege columns, it treats each account as having view privileges that are the same as its `CREATE` privilege.
- InnoDB: If you specify the option `innodb_locks_unsafe_for_binlog` in `my.cnf`, InnoDB in an `UPDATE` or a `DELETE` only locks the rows that it updates or deletes. This greatly reduces the probability of deadlocks.
- A connection doing a rollback now displays "Rolling back" in the `State` column of `SHOW PROCESSLIST`.
- `mysqlbinlog` now prints an informative commented line (thread id, timestamp, server id, and so forth) before each `LOAD DATA INFILE`, like it does for other queries; unless `-short-form` is used.
- Two new server system variables were introduced. `auto_increment_increment` and `auto_increment_offset` can be set locally or globally, and are intended for use in controlling the behavior of `AUTO_INCREMENT` columns in master-to-master replication. Note that these variables are not intended to take the place of sequences. See Section 5.2.2, "Server System Variables".

Bugs fixed:

- Fixed that `mysqlbinlog --read-from-remote-server` sometimes couldn't accept two binary log files on the command line. (Bug#4507 [<http://bugs.mysql.com/4507>])
- Fixed that `mysqlbinlog --position --read-from-remote-server` had incorrect # at lines. (Bug#4506 [<http://bugs.mysql.com/4506>])
- Fixed that `CREATE TABLE ... TYPE=HEAP ... AS SELECT...` caused replication slave to stop. (Bug#4971 [<http://bugs.mysql.com/4971>])
- Fixed that `mysql_options(...,MYSQL_OPT_LOCAL_INFILE,...)` failed to disable `LOAD DATA LOCAL INFILE`. (Bug#5038 [<http://bugs.mysql.com/5038>])
- Fixed that `disable-local-infile` option had no effect if client read it from a configuration file using `mysql_options(...,MYSQL_READ_DEFAULT,...)`. (Bug#5073)

[<http://bugs.mysql.com/5073>])

- Fixed that `SET GLOBAL SYNC_BINLOG` did not work on some platforms (Mac OS X). (Bug#5064 [<http://bugs.mysql.com/5064>])
- Fixed that `mysql-test-run` failed on the `rpl_trunc_binlog` test if running test from the installed (the target of 'make install') directory. (Bug#5050 [<http://bugs.mysql.com/5050>])
- Fixed that `mysql-test-run` failed on the `grant_cache` test when run as Unix user 'root'. (Bug#4678 [<http://bugs.mysql.com/4678>])
- Fixed an unlikely deadlock which could happen when using `KILL`. (Bug#4810 [<http://bugs.mysql.com/4810>])
- Fixed a crash when one connection got KILLED while it was doing `START SLAVE`. (Bug#4827 [<http://bugs.mysql.com/4827>])
- Made `FLUSH TABLES WITH READ LOCK` block `COMMIT` if server is running with binary logging; this ensures that the binary log position can be trusted when doing a full backup of tables and the binary log. (Bug#4953 [<http://bugs.mysql.com/4953>])
- Fixed that the counter of an `auto_increment` column was not reset by `TRUNCATE TABLE` is the table was a temporary one. (Bug#5033 [<http://bugs.mysql.com/5033>])
- Fixed slave SQL thread so that the `SET COLLATION_SERVER...` statements it replicates don't advance its position (so that if it gets interrupted before the actual update query, it later re-does the `SET`). (Bug#5705 [<http://bugs.mysql.com/5705>])
- Fixed that if the slave SQL thread found a syntax error in a query (which should be rare, as the master parsed it successfully), it stops. (Bug#5711 [<http://bugs.mysql.com/5711>])
- Fixed that if a write to a MyISAM table fails because of a full disk or an exceeded disk quota, it prints a message to the error log every 10 minutes, and waits until disk becomes free. (Bug#3248 [<http://bugs.mysql.com/3248>])
- Fixed problem introduced in 4.0.21 where a connection starting a transaction, doing updates, then `FLUSH TABLES WITH READ LOCK`, then `COMMIT`, would cause replication slaves to stop (complaining about error 1223). Bug surfaced when using the InnoDB `innobackup` script. (Bug#5949 [<http://bugs.mysql.com/5949>])
- `OPTIMIZE TABLE`, `REPAIR TABLE`, and `ANALYZE TABLE` are now replicated without any error code in the binary log. (Bug#5551 [<http://bugs.mysql.com/5551>])
- If a connection had an open transaction but had done no updates to transactional tables (for example if had just done a `SELECT FOR UPDATE` then executed a non-transactional update, that update automatically committed the transaction (thus releasing InnoDB's row-level locks etc). (Bug#5714 [<http://bugs.mysql.com/5714>])
- If a connection was interrupted by a network error and did a rollback, the network error code got stored into the `BEGIN` and `ROLLBACK` binary log events; that caused superfluous slave stops. (Bug#6522 [<http://bugs.mysql.com/6522>])
- Fixed a bug which prevented `mysqlbinlog` from being able to read from `stdin`, for example, when piping the output from `zcat` to `mysqlbinlog`. (Bug#7853 [<http://bugs.mysql.com/7853>])

## D.1.23. Changes in release 5.0.1 (27 July 2004)

**Note:** This build passes our test suite and fixes a lot of reported bugs found in the previous 5.0.0 release. However, please be aware that this is not a “standard MySQL build” in the sense that there are still some open critical bugs in our bugs database at <http://bugs.mysql.com/> that affect this release as well. We are actively fixing these and will make a new release where these are fixed as soon as pos-

sible. However, this binary should be a good candidate for testing new MySQL 5.0 features for future products.

Functionality added or changed:

- **Warning: Incompatible change!** C API change: `mysql_shutdown()` now requires a second argument. This is a source-level incompatibility that affects how you compile client programs; it does not affect the ability of compiled clients to communicate with older servers. See Section 22.2.3.64, “`mysql_shutdown()`”.
- When installing a MySQL server as a Windows service, the installation command can include a `--local-service` option following the service name to cause the server to run using the LocalService Windows account that has limited privileges. This is in addition to the `--defaults-file` option that also can be given following the service name.
- Added support for read-only and updatable views based on a single table or other updatable views. View use requires that you upgrade your grant tables to add the view-related privileges. See Section 5.6.1, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.
- Implemented a new “greedy search” optimizer that can significantly reduce the time spent on query optimization for some many-table joins. (You are affected if not only some particular `SELECT` is slow, but even using `EXPLAIN` for it takes a noticeable amount of time.) Two new system variables, `optimizer_search_depth` and `optimizer_prune_level`, can be used to fine-tune optimizer behavior.
- A stored procedure is no longer “global.” That is, it now belongs to a specific database:
  - When a database is dropped, all routines belonging to that database are also dropped.
  - Procedure names may be qualified, for example, `db.p()`
  - When executed from another database, an implicit `USE db_name` is in effect.
  - Explicit `USE db_name` statements no longer are allowed in a stored procedure.

See Chapter 17, *Stored Procedures and Functions*.

- Fixed `SHOW TABLES` output field name and values according to standard. Field name changed from `Type` to `table_type`, values are `BASE TABLE`, `VIEW` and `ERROR`. (Bug#4603 [<http://bugs.mysql.com/4603>])
- Added the `sql_updatable_view_key` system variable.
- Added the `--replicate-same-server-id` server option.
- Added `Last_query_cost` status variable that reports optimizer cost for last compiled query.
- Added the `--to-last-log` option to `mysqlbinlog`, for use in conjunction with `--read-from-remote-server`.
- Added the `--innodb-safe-binlog` server option, which adds consistency guarantees between the content of InnoDB tables and the binary log. See Section 5.12.3, “The Binary Log”.
- `OPTIMIZE TABLE` for InnoDB tables is now mapped to `ALTER TABLE` instead of `ANALYZE TABLE`. This rebuilds the table, which updates index statistics and frees space in the clustered index.
- `sync_frm` is now a settable global variable (not only a startup option).
- For replication of `MEMORY (HEAP)` tables: Made the master automatically write a `DELETE FROM` statement to its binary log when a `MEMORY` table is opened for the first time since master's startup. This is for the case where the slave has replicated a non-empty `MEMORY` table, then the master is shut down and restarted: the table is now empty on master; the `DELETE FROM` emp-

ties it on slave too. Note that even with this fix, between the master's restart and the first use of the table on master, the slave still has out-of-date data in the table. But if you use the `--init-file` option to populate the MEMORY table on the master at startup, it ensures that the failing time interval is zero. (Bug#2477 [<http://bugs.mysql.com/2477>])

- When a session having open temporary tables terminates, the statement automatically written to the binary log is now `DROP TEMPORARY TABLE IF EXISTS` instead of `DROP TEMPORARY TABLE`, for more robustness.
- The MySQL server now returns an error if `SET SQL_LOG_BIN` is issued by a user without the SUPER privilege (in previous versions it just silently ignored the statement in this case).
- Changed that when the MySQL server has binary logging disabled (that is, no `--log-bin` option was used), then no transaction binary log cache is allocated for connections. This should save `binlog_cache_size` bytes of memory (32KB by default) for every connection.
- Added the `sync_binlog=N` global variable and startup option, which makes the MySQL server synchronize its binary log to disk (`fdatasync()`) after every Nth write to the binary log.
- Changed the slave SQL thread to print less useless error messages (no more message duplication; no more messages when an error is skipped because of `slave-skip-errors`).
- `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, single-table `DELETE`, and single-table `UPDATE` now are written to the binary log even if they changed nothing on the master (for example, even if a `DELETE` matched no rows). The old behavior sometimes caused bad surprises in replication setups.
- Replication and `mysqlbinlog` now have better support for the case that the session character set and collation variables are changed within a given session. See Section 6.7, “Replication Features and Known Problems”.
- Killing a `CHECK TABLE` statement does not result in the table being marked as “corrupted” any more; the table remains as if `CHECK TABLE` had not even started. See Section 13.5.5.3, “KILL Syntax”.

Bugs fixed:

- Strange results with index `(x, y) ... WHERE x=val_1 AND y>=val_2 ORDER BY pk;` (Bug#3155 [<http://bugs.mysql.com/3155>])
- Adding `ORDER BY` to a query that uses a subquery can cause incorrect results. (Bug#3118 [<http://bugs.mysql.com/3118>])
- `ALTER DATABASE` caused the client to hang if the database did not exist. (Bug#2333 [<http://bugs.mysql.com/2333>])
- `SLAVE START` (which is a deprecated syntax, `START SLAVE` should be used instead) could crash the slave. (Bug#2516 [<http://bugs.mysql.com/2516>])
- Multiple-table `DELETE` statements were never replicated by the slave if there were any `--replicate-*-table` options. (Bug#2527 [<http://bugs.mysql.com/2527>])
- The MySQL server did not report any error if a statement (submitted through `mysql_real_query()` or `mysql_stmt_prepare()`) was terminated by garbage characters. This can happen if you pass a wrong `length` parameter to these functions. The result was that the garbage characters were written into the binary log. (Bug#2703 [<http://bugs.mysql.com/2703>])
- Replication: If a client connects to a slave server and issues an administrative statement for a table (for example, `OPTIMIZE TABLE` or `REPAIR TABLE`), this could sometimes stop the slave SQL thread. This does not lead to any corruption, but you must use `START SLAVE` to get

replication going again. (Bug#1858 [<http://bugs.mysql.com/1858>])

- Made clearer the error message that one gets when an update is refused because of the `--read-only` option. (Bug#2757 [<http://bugs.mysql.com/2757>])
- Fixed that `--replicate-wild-*-table` rules apply to `ALTER DATABASE` when the table pattern is `%`, as is the case for `CREATE DATABASE` and `DROP DATABASE`. (Bug#3000 [<http://bugs.mysql.com/3000>])
- Fixed that when a `Rotate` event is found by the slave `SQL` thread in the middle of a transaction, the value of `Relay_Log_Pos` in `SHOW SLAVE STATUS` remains correct. (Bug#3017 [<http://bugs.mysql.com/3017>])
- Corrected the master's binary log position that `InnoDB` reports when it is doing a crash recovery on a slave server. (Bug#3015 [<http://bugs.mysql.com/3015>])
- Changed the column `Seconds_Behind_Master` in `SHOW SLAVE STATUS` to never show a value of `-1`. (Bug#2826 [<http://bugs.mysql.com/2826>])
- Changed that when a `DROP TEMPORARY TABLE` statement is automatically written to the binary log when a session ends, the statement is recorded with an error code of value zero (this ensures that killing a `SELECT` on the master does not result in a superfluous error on the slave). (Bug#3063 [<http://bugs.mysql.com/3063>])
- Changed that when a thread handling `INSERT DELAYED` (also known as a `delayed_insert` thread) is killed, its statements are recorded with an error code of value zero (killing such a thread does not endanger replication, so we thus avoid a superfluous error on the slave). (Bug#3081 [<http://bugs.mysql.com/3081>])
- Fixed deadlock when two `START SLAVE` commands were run at the same time. (Bug#2921 [<http://bugs.mysql.com/2921>])
- Fixed that a statement never triggers a superfluous error on the slave, if it must be excluded given the `--replicate-*` options. The bug was that if the statement had been killed on the master, the slave would stop. (Bug#2983 [<http://bugs.mysql.com/2983>])
- The `--local-load` option of `mysqlbinlog` now requires an argument.
- Fixed a segmentation fault when running `LOAD DATA FROM MASTER` after `RESET SLAVE`. (Bug#2922 [<http://bugs.mysql.com/2922>])
- `mysqlbinlog --read-from-remote-server` read all binary logs following the one that was requested. It now stops at the end of the requested file, the same as it does when reading a local binary log. There is an option `--to-last-log` to get the old behavior. (Bug#3204 [<http://bugs.mysql.com/3204>])
- Fixed `mysqlbinlog --read-from-remote-server` to print the exact positions of events in the "at #" lines. (Bug#3214 [<http://bugs.mysql.com/3214>])
- Fixed a rare error condition that caused the slave `SQL` thread spuriously to print the message `Binlog has bad magic number` and stop when it was not necessary to do so. (Bug#3401 [<http://bugs.mysql.com/3401>])
- Fixed `mysqlbinlog` not to forget to print a `USE` statement under rare circumstances where the binary log contained a `LOAD DATA INFILE` statement. (Bug#3415 [<http://bugs.mysql.com/3415>])
- Fixed a memory corruption when replicating a `LOAD DATA INFILE` when the master had version 3.23. (Bug#3422 [<http://bugs.mysql.com/3422>])
- Multiple-table `DELETE` statements were always replicated by the slave if there were some `--replicate-*-ignore-table` options and no `--replicate-*-do-table` options. (Bug#3461 [<http://bugs.mysql.com/3461>])

- Fixed a crash of the MySQL slave server when it was built with `--with-debug` and replicating itself. (Bug#3568 [<http://bugs.mysql.com/3568>])
- Fixed that in some replication error messages, a very long query caused the rest of the message to be invisible (truncated), by putting the query last in the message. (Bug#3357 [<http://bugs.mysql.com/3357>])
- If `server-id` was not set using startup options but with `SET GLOBAL`, the replication slave still complained that it was not set. (Bug#3829 [<http://bugs.mysql.com/3829>])
- `mysql_fix_privilege_tables` didn't correctly handle the argument of its `--password=password_val` option. (Bug#4240 [<http://bugs.mysql.com/4240>])
- Fixed potential memory overrun in `mysql_real_connect()` (which required a compromised DNS server and certain operating systems). (Bug#4017 [<http://bugs.mysql.com/4017>], CVE-2004-0836 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2004-0836>])
- During the installation process of the server RPM on Linux, `mysqld` was run as the `root` system user, and if you had `--log-bin=somewhere_out_of_var_lib_mysql` it created binary log files owned by `root` in this directory, which remained owned by `root` after the installation. This is now fixed by starting `mysqld` as the `mysql` system user instead. (Bug#4038 [<http://bugs.mysql.com/4038>])
- Made `DROP DATABASE` honor the value of `lower_case_table_names`. (Bug#4066 [<http://bugs.mysql.com/4066>])
- The slave SQL thread refused to replicate `INSERT ... SELECT` if it examined more than 4 billion rows. (Bug#3871 [<http://bugs.mysql.com/3871>])
- `mysqlbinlog` didn't escape the string content of user variables, and did not deal well when these variables were in non-ASCII character sets; this is now fixed by always printing the string content of user variables in hexadecimal. The character set and collation of the string is now also printed. (Bug#3875 [<http://bugs.mysql.com/3875>])
- Fixed incorrect destruction of expression that led to a server crash on complex AND/OR expressions if query was ignored (either by a replication server because of `--replicate-*-table` rules, or by any MySQL server because of a syntax error). (Bug#3969 [<http://bugs.mysql.com/3969>], Bug#4494 [<http://bugs.mysql.com/4494>])
- If `CREATE TEMPORARY TABLE t SELECT` failed while loading the data, the temporary table was not dropped. (Bug#4551 [<http://bugs.mysql.com/4551>])
- Fixed that when a multiple-table `DROP TABLE` failed to drop a table on the master server, the error code was not written to the binary log. (Bug#4553 [<http://bugs.mysql.com/4553>])
- When the slave SQL thread was replicating a `LOAD DATA INFILE` statement, it didn't show the statement in the output of `SHOW PROCESSLIST`. (Bug#4326 [<http://bugs.mysql.com/4326>])

## D.1.24. Changes in release 5.0.0 (22 December 2003: Alpha)

Functionality added or changed:

- The output of the `SHOW BINLOG EVENTS` statement has been modified. The `Orig_log_pos` column has been renamed to `End_log_pos` and now represents the offset of the last byte of the event, plus one.
- **Important note:** If you upgrade to MySQL 4.1.1 or higher, it is difficult to downgrade back to 4.0 or 4.1.0! That is because, for earlier versions, InnoDB is not aware of multiple tablespaces.

- Added support for `SUM(DISTINCT)`, `MIN(DISTINCT)`, and `MAX(DISTINCT)`.
- The `KILL` statement now takes `CONNECTION` and `QUERY` modifiers. The first is the same as `KILL` with no modifier (it kills a given connection thread). The second kills only the statement currently being executed by the connection.
- Added `TIMESTAMPADD()` and `TIMESTAMPDIFF()` functions.
- Added `WEEK` and `QUARTER` values as `INTERVAL` arguments for the `DATE_ADD()` and `DATE_SUB()` functions.
- New binary log format that enables replication of these session variables: `sql_mode`, `SQL_AUTO_IS_NULL`, `FOREIGN_KEY_CHECKS` (which was replicated since 4.0.14, but here it's done more efficiently and takes less space in the binary logs), `UNIQUE_CHECKS`. Other variables (like character sets, `SQL_SELECT_LIMIT`, ...) will be replicated in upcoming 5.0.x releases.
- Implemented Index Merge optimization for `OR` clauses. See Section 7.2.6, “Index Merge Optimization”.
- Basic support for stored procedures (SQL:2003 style). See Chapter 17, *Stored Procedures and Functions*.
- Added `SELECT INTO list_of_vars`, which can be of mixed (that is, global and local) types. See Section 17.2.7.3, “SELECT ... INTO Statement”.
- Easier replication upgrade (5.0.0 masters can read older binary logs and 5.0.0 slaves can read older relay logs). See Section 6.5, “Replication Compatibility Between MySQL Versions”, for more details). The format of the binary log and relay log is changed compared to that of MySQL 4.1 and older.

Bugs fixed:

## D.2. Changes in MySQL Cluster

Starting from 4.1.13 and 5.0.7, all Cluster changes are included in the MySQL Change History, and this manual section is no longer separately maintained.

### D.2.1. Changes in MySQL Cluster-5.0.7 (Not yet released)

**Note:** Starting with version 5.0.8, changes for MySQL Cluster can be found in the combined MySQL Change History.

Functionality added or changed:

Bugs fixed:

- (Bug#11019 [<http://bugs.mysql.com/11019>]) `mgmapi start backup` in some cases returns wrong `backupid`
- (Bug#10190 [<http://bugs.mysql.com/10190>]) Backup from cluster with `NoOfReplica=1` is corrupt
- (Bug#9246 [<http://bugs.mysql.com/9246>]) Condition pushdown and left join, wrong result
- (Bug#10956 [<http://bugs.mysql.com/10956>]) More than 7 node restarts with `--initial` caused cluster to fail.

- (Bug#9945 [<http://bugs.mysql.com/9945>]) ALTER TABLE caused server crash. (Linux/390)
- (Bug#9826 [<http://bugs.mysql.com/9826>]) (Bug#10948 [<http://bugs.mysql.com/10948>]) Schema change (DROP TABLE, ALTER TABLE) crashed HPUX and PPC32.
- (Bug#10711 [<http://bugs.mysql.com/10711>]) (Bug#9363 [<http://bugs.mysql.com/9363>]) (Bug#8918 [<http://bugs.mysql.com/8918>]) (Bug#10058 [<http://bugs.mysql.com/10058>]) (Bug#9025 [<http://bugs.mysql.com/9025>]) Cluster would time out and crash after first query; setting DataMemory to more than 2GB prevented cluster from starting; calling `ndb_select_count()` crashed the cluster. (64-bit Unix OSes)

## D.2.2. Changes in MySQL Cluster-5.0.6 (26 May 2005)

Functionality added or changed:

- Limit on number of metadata objects (number of tables, indexes and BLOBs) now increased to 20,320

Bugs fixed:

- The server would hang on successive calls to an INSERT ... ON DUPLICATE KEY UPDATE query. (Bug#9725 [<http://bugs.mysql.com/9725>])
- (Bug#10193 [<http://bugs.mysql.com/10193>]) Invalid DataDir in config causes ndbd segmentation fault
- (Bug#10813 [<http://bugs.mysql.com/10813>]) Build with SCI Transporter fails
- (Bug#10831 [<http://bugs.mysql.com/10831>]) ndb mgmd LogDestination maxfiles does not rotate logs properly

## D.2.3. Changes in MySQL Cluster-5.0.5 (Not released)

Functionality added or changed:

- Decreased IndexMemory Usage
- Parallel key lookup (read-multi-range) for queries like `SELECT * FROM t1 WHERE primary_key IN (1,2,3,4,5,6,7,8,9,10);`

Bugs fixed:

Patches merged from versions 4.1.11 and 4.1.12

- (Bug#8315 [<http://bugs.mysql.com/8315>]) NdbScanFilter cmp method only works for strings of exact word boundary length
- (Bug#8103 [<http://bugs.mysql.com/8103>]) Configuration handling error
- (Bug#8035 [<http://bugs.mysql.com/8035>]) mysqld signal 10 when ndbd is shutdown
- (Bug#7631 [<http://bugs.mysql.com/7631>]) NDB\$EVENT contains unreadable event and table names
- (Bug#7628 [<http://bugs.mysql.com/7628>]) Filtered event types are ignored

- (Bug#7627 [<http://bugs.mysql.com/7627>]) Drop Event operation fails
- (Bug#7424 [<http://bugs.mysql.com/7424>]) create index on datetime fails

## D.2.4. Changes in MySQL Cluster-5.0.4 (16 April 2005)

Functionality added or changed:

- Condition pushdown to storage engine now works for update and delete as well

Bugs fixed:

- (Bug#9675 [<http://bugs.mysql.com/9675>]) Auto-increment not working with INSERT..SELECT and NDB storage
- (Bug#9517 [<http://bugs.mysql.com/9517>]) Condition pushdown to storage engine does not work for update/delete
- (Bug#9282 [<http://bugs.mysql.com/9282>]) API Node Crashes/Reloads on 'DELETE FROM'
- (Bug#9280 [<http://bugs.mysql.com/9280>]) Memory leak in cluster when dependent sub-queries are used
- (Bug#8585 [<http://bugs.mysql.com/8585>]) ndb\_cache2 fails on aix52

## D.2.5. Changes in MySQL Cluster-5.0.3 (23 March 2005: Beta)

Functionality added or changed:

- Condition pushdown to storage engine
- Query cache enabled for cluster

Bugs fixed:

- Patches merged from version 4.1.10

## D.2.6. Changes in MySQL Cluster-5.0.1 (27 July 2004)

Functionality added or changed:

- This was the first MySQL Cluster release in the 5.0 series. As nearly all attention was still focused on getting 4.1 stable, it is not recommended to use MySQL 5.0.1 for MySQL Cluster.

Bugs fixed:

- N/A

## D.2.7. Changes in MySQL Cluster-4.1.13 (15 July 2005)

Functionality added or changed:

Bugs fixed:

- (Bug#11132 [<http://bugs.mysql.com/11132>]) Connections between data nodes and management nodes were not being closed following shutdown of `ndb_mgmd`.
- (Bug#11050 [<http://bugs.mysql.com/11050>]) `ndb_mgm> show` printed incorrectly after master data node failure.
- (Bug#10956 [<http://bugs.mysql.com/10956>]) More than 7 node restarts with `--initial` caused cluster to fail.
- (Bug#9826 [<http://bugs.mysql.com/9826>]) (Bug#10948 [<http://bugs.mysql.com/10948>]) Schema change (`DROP TABLE`, `ALTER TABLE`) crashed HPUX and PPC32.
- (Bug#9025 [<http://bugs.mysql.com/9025>]) Data nodes failed to restart on 64-bit Solaris.
- (Bug#11166 [<http://bugs.mysql.com/11166>]) Insert records were incorrectly applied by `ndb_restore`, thus making restoration from backup inconsistent if the binlog contained inserts.
- (Bug#8918 [<http://bugs.mysql.com/8918>]) (Bug#9363 [<http://bugs.mysql.com/9363>]) (Bug#10711 [<http://bugs.mysql.com/10711>]) (Bug#10058 [<http://bugs.mysql.com/10058>]) (Bug#9025 [<http://bugs.mysql.com/9025>]) Cluster would time out and crash after first query; setting `DataMemory` to more than 2GB prevented cluster from starting; calling `ndb_select_count()` crashed the cluster. (64-bit Unix OSes)
- (Bug#10190 [<http://bugs.mysql.com/10190>]) When making a backup of a cluster where `NumberOfReplicas` was equal to 1, the backup's metadata was corrupted. (Linux)
- (Bug#9945 [<http://bugs.mysql.com/9945>]) `ALTER TABLE` caused server crash. (Linux/390)
- (Bug#11133 [<http://bugs.mysql.com/11133>]) A delete operation performed as part of a transaction caused an erroneous result.
- (Bug#10294 [<http://bugs.mysql.com/10294>]) Not allowing sufficient parallelism in cluster configuration (for example, `NoOfTransactions` too small) caused `ndb_restore` to fail without generating any error messages.
- (Bug#11290 [<http://bugs.mysql.com/11290>]) Setting `TransactionInactiveTimeout=0` did not result in an infinite timeout.

## D.2.8. Changes in MySQL Cluster-4.1.12 (13 May 2005)

Functionality added or changed:

Bugs fixed:

- (Bug#10471 [<http://bugs.mysql.com/10471>]) Backup can become inconsistent with certain combinations of multiple-row updates
- (Bug#10287 [<http://bugs.mysql.com/10287>]) `ndb_select_all` "delimiter" option non functional
- (Bug#10142 [<http://bugs.mysql.com/10142>]) Unhandled resource shortage in UNIQUE index code
- (Bug#10029 [<http://bugs.mysql.com/10029>]) crash in ordered index scan after db full

- (Bug#10001 [<http://bugs.mysql.com/10001>]) 2 NDB nodes get signal 6 (abort) in DBTC
- (Bug#9969 [<http://bugs.mysql.com/9969>]) 4012 - has misleading error message
- (Bug#9960 [<http://bugs.mysql.com/9960>]) START BACKUP reports failure albeit succeeding
- (Bug#9924 [<http://bugs.mysql.com/9924>]) ABORT BACKUP 1 crashes 4 node cluster
- (Bug#9892 [<http://bugs.mysql.com/9892>]) Index activation file during node recovery
- (Bug#9891 [<http://bugs.mysql.com/9891>]) Crash in DBACC (line 7004) during commit
- (Bug#9865 [<http://bugs.mysql.com/9865>]) SELECT does not function properly
- (Bug#9839 [<http://bugs.mysql.com/9839>]) Column with AUTOINC contains -1 Value on node stop
- (Bug#9757 [<http://bugs.mysql.com/9757>]) Uncompleted node failure after gracefully stopping node
- (Bug#9749 [<http://bugs.mysql.com/9749>]) Transactions causes deadlock in ACC
- (Bug#9724 [<http://bugs.mysql.com/9724>]) Node fails to start: Message: File has already been opened
- (Bug#9691 [<http://bugs.mysql.com/9691>]) UPDATE fails on attempt to update primary key
- (Bug#9675 [<http://bugs.mysql.com/9675>]) Auto-increment not working with INSERT..SELECT and NDB storage
- (Bug#9318 [<http://bugs.mysql.com/9318>]) drop database does not drop ndb tables
- (Bug#9280 [<http://bugs.mysql.com/9280>]) Memory leak in cluster when dependent sub-queries are used
- (Bug#8928 [<http://bugs.mysql.com/8928>]) create table with keys will shutdown the cluster
- Creating a table did not work for a cluster with 6 nodes. (Bug#8928 [<http://bugs.mysql.com/8928>]) Databases with 1, 2, 4, 8, ... ( $2^n$  nodes) did not have the problem. After a rolling upgrade, restart each node manually by restarting it with the `--initial` option. Otherwise, use dump and restore after an upgrade.

## D.2.9. Changes in MySQL Cluster-4.1.11 (01 April 2005)

Functionality added or changed:

Bugs fixed:

- (Bug#9916 [<http://bugs.mysql.com/9916>]) DbaccMain.cpp / DBACC (Line: 4876) / Pointer too large
- (Bug#9435 [<http://bugs.mysql.com/9435>]) TIMESTAMP columns don't update
- (Bug#9052 [<http://bugs.mysql.com/9052>]) Uninitialized data during unique index build, potential cluster crash
- (Bug#8876 [<http://bugs.mysql.com/8876>]) Timeout when committing aborted transaction after node failure
- (Bug#8786 [<http://bugs.mysql.com/8786>]) ndb\_autodiscover, drop index can fail, wait 2 minutes timeout

- (Bug#8853 [<http://bugs.mysql.com/8853>]) Transaction aborted after long time during node failure (4012)
- (Bug#8753 [<http://bugs.mysql.com/8753>]) Invalid schema object version after dropping index (crash fixed, currently retry required)
- (Bug#8645 [<http://bugs.mysql.com/8645>]) Assertion failure with multiple management servers
- (Bug#8557 [<http://bugs.mysql.com/8557>]) ndbd does not get same nodeid on restart
- (Bug#8556 [<http://bugs.mysql.com/8556>]) corrupt ndb\_mgm show printout for certain configurations
- (Bug#8167 [<http://bugs.mysql.com/8167>]) cluster shared memory and mysqld signal usage clash

## D.2.10. Changes in MySQL Cluster-4.1.10 (12 February 2005)

Bugs fixed:

- (Bug#8284 [<http://bugs.mysql.com/8284>]) Out of fragment memory in DBACC
- (Bug#8262 [<http://bugs.mysql.com/8262>]) Node crash due to bug in DBLQH
- (Bug#8208 [<http://bugs.mysql.com/8208>]) node restart fails on Aix 5.2
- (Bug#8167 [<http://bugs.mysql.com/8167>]) cluster shared memory and mysqld signal usage clash
- (Bug#8101 [<http://bugs.mysql.com/8101>]) unique index and error 4209 while selecting
- (Bug#8070 [<http://bugs.mysql.com/8070>]) (Bug#7937 [<http://bugs.mysql.com/7937>]) (Bug#6716 [<http://bugs.mysql.com/6716>]) various ndb\_restore core dumps on HP-UX
- (Bug#8010 [<http://bugs.mysql.com/8010>]) 4006 forces MySQL Node Restart
- (Bug#7928 [<http://bugs.mysql.com/7928>]) out of connection objects
- (Bug#7898 [<http://bugs.mysql.com/7898>]) mysqld crash with ndb (solaris)
- (Bug#7864 [<http://bugs.mysql.com/7864>]) Not possible to have more than 4.5G data memory

## D.2.11. Changes in MySQL Cluster-4.1.9 (13 January 2005)

Functionality added or changed:

- New implementation of shared memory transporter.
- Cluster automatically configures shared memory transporter if possible.
- Cluster prioritizes usage of transporters with shared memory and localhost TCP
- Added switches to control the above functions, `ndb-shm` and `ndb-optimized-node-selection`.

Bugs fixed:

- (Bug#7805 [<http://bugs.mysql.com/7805>]) config.ini parsing error
- (Bug#7798 [<http://bugs.mysql.com/7798>]) Running range scan after alter table in different thread causes node failure
- (Bug#7761 [<http://bugs.mysql.com/7761>]) Alter table does not autocommit
- (Bug#7725 [<http://bugs.mysql.com/7725>]) Indexed DATETIME Columns Return Random Results
- (Bug#7660 [<http://bugs.mysql.com/7660>]) START BACKUP does not increment BACKUP-ID (Big Endian machines)
- (Bug#7593 [<http://bugs.mysql.com/7593>]) Cannot Create A Large NDB Data Warehouse
- (Bug#7480 [<http://bugs.mysql.com/7480>]) Mysqld crash in ha\_ndbcluster using Query Browser
- (Bug#7470 [<http://bugs.mysql.com/7470>]) shared memory transporter does not connect
- (Bug#7396 [<http://bugs.mysql.com/7396>]) Primary Key not working in NDB Mysql Clustered table (solaris)
- (Bug#7379 [<http://bugs.mysql.com/7379>]) ndb restore fails to handle blobs and multiple databases
- (Bug#7346 [<http://bugs.mysql.com/7346>]) ndb\_restore enters infinite loop
- (Bug#7340 [<http://bugs.mysql.com/7340>]) Problem for inserting data into the Text field on utf8
- (Bug#7124 [<http://bugs.mysql.com/7124>]) ndb\_mgmd is aborted on startup when using SHM connection

## D.2.12. Changes in MySQL Cluster-4.1.8 (14 December 2004)

Functionality added or changed:

- Default port for ndb\_mgmd was changed to 1186 (from 2200) as this port number was officially assigned to MySQL Cluster by IANA.
- New command in ndb\_mgm, PURGE STALE SESSIONS, as a workaround for cases where nodes fail to allocate a node id even if it is free to use.
- New command in ndb\_mgm, CONNECT.
- The ndb executables have been changed to make use of the regular MySQL command line option parsing features. See Section 15.5.5, “Command Options for MySQL Cluster Processes”, for notes on changes.
- As bonus of the above you can now specify all command line options in my.cnf using the executable names as sections, that is, [ndbd], [ndb\_mgmd], [ndb\_mgm], [ndb\_restore], and so forth.

```
[ndbd]
ndb-connectstring=myhost.domain.com:1234
[ndb_mgm]
ndb-connectstring=myhost.domain.com:1234
```

- Added use of section [mysql\_cluster] in my.cnf. All cluster executables, including mysqld, parse this section. For example, this is a convenient place to put ndb-

`connectstring` so that it need be specified only once.

- Added cluster log info events on allocation and deallocation of nodeid's.
- Added cluster log info events on connection refuse as a result of version mismatch.
- Extended `connectstring` syntax to allow for leaving the port number out. For example, `ndb-connectstring|connect-string=myhost1,myhost2,myhost3` is a valid connectstring and connect occurs on default port 1186.
- Clear text ndb error messages provided also for error codes that are mapped to corresponding mysql error codes, by executing `SHOW WARNINGS` after an error has occurred which relates to the ndb storage engine.
- Significant performance improvements done for read performance, especially for blobs.
- Added some variables for performance tuning, `ndb_force_send` and `ndb_use_exact_count`. Do show variables like `'ndb%'` in mysql client for listing. Use `set` command to alter variables.
- Added variables to set some options, `ndb_use_transactions` and `ndb_autoincrement_prefetch_sz`.

Bugs fixed:

- (Bug#7303 [<http://bugs.mysql.com/7303>]) `ndb_mgm`: Trying to set `CLUSTERLOG` for a specific node id core dumps
- (Bug#7193 [<http://bugs.mysql.com/7193>]) `start backup` gives false error printout
- (Bug#7153 [<http://bugs.mysql.com/7153>]) Cluster nodes don't report error on endianness mismatch
- (Bug#7152 [<http://bugs.mysql.com/7152>]) `ndb_mgmd` segmentation fault on incorrect Host-Name in configuration
- (Bug#7104 [<http://bugs.mysql.com/7104>]) `clusterlog` filtering and level setting broken
- (Bug#6995 [<http://bugs.mysql.com/6995>]) `ndb_recover` on varchar fields results in changing case of data
- (Bug#6919 [<http://bugs.mysql.com/6919>]) `all status` only shows 2 nodes on a 8-node cluster
- (Bug#6871 [<http://bugs.mysql.com/6871>]) `DBD execute failed: Got error 897 'Unknown error code' from ndbcluster`
- (Bug#6794 [<http://bugs.mysql.com/6794>]) Wrong outcome of update operation of ndb table
- (Bug#6791 [<http://bugs.mysql.com/6791>]) Segmentation fault when `config.ini` is not correctly set
- (Bug#6775 [<http://bugs.mysql.com/6775>]) failure in `acc` when running many mysql clients
- (Bug#6696 [<http://bugs.mysql.com/6696>]) `ndb_mgm` command line options inconsistent with behavior
- (Bug#6684 [<http://bugs.mysql.com/6684>]) `ndb_restore` doesn't give error messages if improper command given
- (Bug#6677 [<http://bugs.mysql.com/6677>]) `ndb_mgm` can crash on `"ALL CLUSTERLOG"`
- (Bug#6538 [<http://bugs.mysql.com/6538>]) Error code returned when `select max()` on empty ta-

ble with index

- (Bug#6451 [<http://bugs.mysql.com/6451>]) failing create table gives "ghost" tables which are impossible to remove
- (Bug#6435 [<http://bugs.mysql.com/6435>]) strange behavior of left join
- (Bug#6426 [<http://bugs.mysql.com/6426>]) update with long pk fails
- (Bug#6398 [<http://bugs.mysql.com/6398>]) update of primary key fails
- (Bug#6354 [<http://bugs.mysql.com/6354>]) mysql does not complain about --ndbcluster option when NDB is not compiled in
- (Bug#6331 [<http://bugs.mysql.com/6331>]) INSERT IGNORE .. SELECT breaks subsequent inserts
- (Bug#6288 [<http://bugs.mysql.com/6288>]) cluster nodes crash on data import
- (Bug#6031 [<http://bugs.mysql.com/6031>]) To drop database you have to execute DROP DATABASE command twice
- (Bug#6020 [<http://bugs.mysql.com/6020>]) LOCK TABLE + delete returns error 208
- (Bug#6018 [<http://bugs.mysql.com/6018>]) REPLACE does not work for BLOBs + NDB
- (Bug#6016 [<http://bugs.mysql.com/6016>]) Strange crash with blobs + different DATABASES
- (Bug#5973 [<http://bugs.mysql.com/5973>]) ndb table belonging to different database shows up in show tables
- (Bug#5872 [<http://bugs.mysql.com/5872>]) ALTER TABLE with blob from ndb table to myisam fails
- (Bug#5844 [<http://bugs.mysql.com/5844>]) Failing mysql-test-run leaves stray NDB processes behind
- (Bug#5824 [<http://bugs.mysql.com/5824>]) HELP text messed up in ndb\_mgm
- (Bug#5786 [<http://bugs.mysql.com/5786>]) Duplicate key error after restore
- (Bug#5785 [<http://bugs.mysql.com/5785>]) lock timeout during concurrent update
- (Bug#5782 [<http://bugs.mysql.com/5782>]) Unknown error when using LIMIT with ndb table
- (Bug#5756 [<http://bugs.mysql.com/5756>]) RESTART node from ndb\_mgm fails
- A few more not reported bugs fixed

## D.2.13. Changes in MySQL Cluster-4.1.7 (23 October 2004)

Functionality added or changed:

- Optimization 1: Improved performance on index scans. Measured 30% performance increase on query which do large amounts of index scans.
- Optimization 2: Improved performance on primary key lookups. Around double performance for autocommitted primary key lookups.
- Optimization 3: Improved performance when using blobs by avoiding usage of exclusive locks

for blobs.

Bugs fixed:

- A few bugs fixed.

## D.2.14. Changes in MySQL Cluster-4.1.6 (10 October 2004)

Functionality added or changed:

- Limited character set support for storage engine NDBCLUSTER:

Char set	Collation
big5	big5_chinese_ci
	big5_bin
binary	binary
euckr	euckr_korean_ci
	euckr_bin
gb2312	gb2312_chinese_ci
	gb2312_bin
gbk	gbk_chinese_ci
	gbk_bin
latin1	latin1_swedish_ci
	latin1_bin
sjis	sjis_japanese_ci
	sjis_bin
tis620	tis620_bin
ucs2	ucs2_general_ci
	ucs2_bin
ujis	ujis_japanese_ci
	ujis_bin
utf8	utf8_general_ci
	utf8_bin

- The SCI Transporter has been brought up-to-date with all changes and now works and has been documented as well.
- Optimizations when several clients to a MySQL Server access ndb tables.
- Added more checks and warnings for erroneous and inappropriate cluster configurations.
- SHOW TABLES now directly shows ndb tables created on a different MySQL server, that is, without a prior table access.
- Enhanced support for starting MySQL Server independently of nbd and ndb\_mgmd.
- Clear text ndb error messages provided by executing SHOW WARNINGS after an error has occurred which relates to the ndb storage engine.

Bugs fixed:

- Quite a few bugs fixed.

## D.2.15. Changes in MySQL Cluster-4.1.5 (16 September 2004)

Functionality added or changed:

- Many queries in MySQL Cluster are executed as range scans or full table scans. All queries that don't use a unique hash index or the primary hash index use this access method. In a distributed system it is crucial that batching is properly performed.

In previous versions, the batch size was fixed to 16 per data node. In this version it is configurable per MySQL Server. So for queries using lots of large scans it is appropriate to set this parameter rather large and for queries using many small scans only fetching a small amount of records it is appropriate to set it low.

The performance of queries can easily change as much as 40% based on how this variable is set.

In future versions more logic will be implemented for assessing the batch size on a per-query basis. Thus, the semantics of the new configuration variable `ScanBatchSize` are likely to change.

- The fixed size overhead of the `ndbd` process has been greatly decreased. This is also true for the overhead per operation record as well as overhead per table and index.

A number of new configuration variables have been introduced to enable configuration of system buffers. Configuration variables for specifying the numbers of tables, unique hash indexes, and ordered indexes have also been introduced.

New configuration variables: `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`

Configuration variables no longer used: `MaxNoOfIndexes` (split into the two above).

- In previous versions `ALTER TABLE`, `TRUNCATE TABLE`, and `LOAD DATA` were performed as one big transaction. In this version, all of these statements are automatically separated into several distinct transactions.

This removes the limitation that one could not change very large tables due to the `MaxNoOfConcurrentOperations` parameter.

- MySQL Cluster's online backup feature now backs up indexes so that both data and indexes are restored.
- In previous versions it was not possible to use `NULL` in indexes. This is now possible for all supported index types.
- Much work has been put onto making `AUTO_INCREMENT` features work as for other table handlers. Autoincrements as a partial key is still only supported by `MyISAM`.
- In earlier versions, `mysqld` would crash if the cluster wasn't started with the `--ndbcluster` option. Now `mysqld` handles cluster crashes and starts without crashing.
- The `-i` option for initial startup of `ndbd` has been removed. Initial startup still can be specified by using the `--initial` option. The reason for this is to ensure that it is clear what takes place when using `--initial`: this option completely removes all data from the disk and should only be used at initial start, in certain software upgrade cases, and in some cases as a workaround

when nodes cannot be restarted successfully.

- The management client (`ndb_mgm`) now has additional commands and more information is printed for some commands such as `show`.
- In previous versions, the files were called `ndb_0..` when it wasn't possible to allocate a node ID when starting the node. To ensure that files are not so easily overwritten, these files are now named `ndb_pid..`, where `pid` is the process ID assigned by the OS.
- The default parameters have changed for `ndb_mgmd` and `ndbd`. In particular, they are now started as daemons by default. The `-n` option has been removed since it could cause confusion as to its meaning (`nostart` or `nodaemon`).
- In the configuration file, you can now use `[NDBD]` as an alias for `[DB]`, `[MYSQLD]` as an alias for `[API]`, and `[NDB_MGMD]` as an alias for `[MGM]`. **Note:** In fact, `[NDBD]`, `[MYSQLD]`, and `[NDB_MGMD]` are now the preferred designations, although the older ones will continue to be supported for some time to come in order to maintain backward compatibility.
- Many more checks for consistency in configuration have been introduced to in order to provide quicker feedback on configuration errors.
- In the connect string, it is now possible to use both `;` and `,` as the separator between entries. Thus, `"nodeid=2,host=localhost:2200"` is equivalent to `"nodeid=2;host=localhost:2200"`.

In the configuration file, it is also possible to use `:` or `=` for assignment values. For example, `MaxNoOfOrderedIndexes : 128` and `MaxNoOfOrderedIndexes = 128` are equivalent expressions.

- The configuration variable names are now case insensitive, so `MaxNoOfOrderedIndexes : 128` is equivalent to `MAXNOOFORDEREDINDEXES = 128`.
- It is possible now to set the backup directory separately from the `FileSystemPath` by using the `BackupDir` configuration variable.

Log files and trace files can now be placed in any directory by setting the `DataDir` configuration variable.

`FileSystemPath` is no longer mandatory and defaults to `DataDir`.

- Queries involving tables from different databases are now supported.
- It is now possible to update the primary key.
- The performance of ordered indexes has been greatly improved, particularly the maintenance of indexes on updates, inserts and deletes.

Bugs fixed:

- Quite a few bugs fixed.

## D.2.16. Changes in MySQL Cluster-4.1.4 (31 August 2004)

Functionality added or changed:

- The names of the log files and trace files created by the `ndbd` and `ndb_mgmd` processes have changed.
- Support for the many BLOB data types was introduced in this version.

Bugs fixed:

- Quite a few bugs were fixed in the 4.1.4 release.

## D.2.17. Changes in MySQL Cluster-4.1.3 (28 June 2004)

Functionality added or changed:

- This was the first MySQL Cluster release so all functionality was new.

Bugs fixed:

- Various bugs fixed in the development process leading up to 4.1.3.

## D.3. Changes in MyODBC

### D.3.1. Changes in MyODBC 3.51.13

Functionality added or changed:

- N/A

Bugs fixed:

- The `SQLDriverConnect()` ODBC method did not work with recent MyODBC releases. (Bug#12393 [<http://bugs.mysql.com/12393>])

### D.3.2. Changes in MyODBC 3.51.12

Functionality added or changed:

- N/A

Bugs fixed:

- File DSNs could not be saved. (Bug#12019 [<http://bugs.mysql.com/12019>])
- `SQLColumns()` returned no information for tables that had a column named using a reserved word. (Bug#9539 [<http://bugs.mysql.com/9539>])

### D.3.3. Changes in MyODBC 3.51.11

Functionality added or changed: No changes.

Bugs fixed:

- `mysql_list_dbcolumns()` and `insert_fields()` were retrieving all rows from a table. Fixed the queries generated by these functions to return no rows. (Bug#8198 [<http://bugs.mysql.com/8198>])
- `SQLGetTypeInfo()` returned `tinyblob` for `SQL_VARBINARY` and nothing for `SQL_BINARY`. Fixed to return `varbinary` for `SQL_VARBINARY`, `binary` for `SQL_BINARY`, and `longblob` for `SQL_LONGVARBINARY`. (Bug#8138 [<http://bugs.mysql.com/8138>])

---

# Appendix E. Porting to Other Systems

This appendix helps you port MySQL to other operating systems. Do check the list of currently supported operating systems first. See Section 2.1.1, “Operating Systems Supported by MySQL”. If you have created a new port of MySQL, please let us know so that we can list it here and on our Web site (<http://www.mysql.com/>), recommending it to other users.

Note: If you create a new port of MySQL, you are free to copy and distribute it under the GPL license, but it does not make you a copyright holder of MySQL.

A working POSIX thread library is needed for the server. On Solaris 2.5 we use Sun PThreads (the native thread support in 2.4 and earlier versions is not good enough), on Linux we use LinuxThreads by Xavier Leroy, <[Xavier.Leroy@inria.fr](mailto:Xavier.Leroy@inria.fr)>.

The hard part of porting to a new Unix variant without good native thread support is probably to port MIT-pthreads. See [mit-pthreads/README](http://mit-pthreads.org/README) and Programming POSIX Threads (<http://www.humanfactor.com/pthreads/>).

Up to MySQL 4.0.2, the MySQL distribution included a patched version of Chris Provenzano's Pthreads from MIT (see the MIT Pthreads Web page at <http://www.mit.edu/afs/sipb/project/pthreads/> and a programming introduction at [http://www.mit.edu:8001/people/proven/IAP\\_2000/](http://www.mit.edu:8001/people/proven/IAP_2000/)). These can be used for some operating systems that do not have POSIX threads. See Section 2.9.5, “MIT-pthreads Notes”.

It is also possible to use another user level thread package named FSU Pthreads (see <http://moss.csc.ncsu.edu/~mueller/pthreads/>). This implementation is being used for the SCO port.

See the `thr_lock.c` and `thr_alarm.c` programs in the `mysys` directory for some tests/examples of these problems.

Both the server and the client need a working C++ compiler. We use `gcc` on many platforms. Other compilers that are known to work are SPARCworks, Sun Forte, Irix `cc`, HP-UX `aCC`, IBM AIX `x1C_r`, Intel `ecc/icc` and Compaq `cxx`.

To compile only the client use `./configure --without-server`.

There is currently no support for only compiling the server, nor is it likely to be added unless someone has a good reason for it.

If you want/need to change any Makefile or the configure script you also need GNU Automake and Autoconf. See Section 2.9.3, “Installing from the Development Source Tree”.

All steps needed to remake everything from the most basic files.

```
/bin/rm */.deps/*.P
/bin/rm -f config.cache
aclocal
autoheader
aclocal
automake
autoconf
./configure --with-debug=full --prefix='your installation directory'

# The makefiles generated above need GNU make 3.75 or newer.
# (called gmake below)
gmake clean all install init-db
```

If you run into problems with a new port, you may have to do some debugging of MySQL! See Section E.1, “Debugging a MySQL Server”.

**Note:** Before you start debugging `mysqld`, first get the test programs `mysys/thr_alarm` and `mysys/thr_lock` to work. This ensures that your thread installation has even a remote chance to

work!

## E.1. Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` (which disables all new, potentially unsafe functionality) or with `--safe-mode` which disables a lot of optimization that may cause problems. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

If `mysqld` doesn't want to start, you should verify that you don't have any `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults ...`

If `mysqld` starts to eat up CPU or memory or if it “hangs,” you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients can't connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you haven't compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See Chapter 5, *Database Administration*. You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See Section 2.13, “Operating System-Specific Notes”.

### E.1.1. Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `--with-debug` or the `--with-debug=full` option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysql ... --debug` in this case.

If you are using `gcc` or `egcs`, the recommended configure line is:

```
CC=gcc CFLAGS="-O2" CXX=gcc CXXFLAGS="-O2 -felide-constructors \  
-fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql \  
--with-debug --with-extra-charsets=complex
```

This avoids problems with the `libstdc++` library and with C++ exceptions (many compilers have problems with C++ exceptions in threaded code) and compile a MySQL version with support for all character sets.

If you suspect a memory overrun error, you can configure MySQL with `--with-debug=full`, which installs a memory allocation (`SAFEMALLOC`) checker. However, running with `SAFEMALLOC` is quite slow, so if you get performance problems you should start `mysqld` with the `--skip-safemalloc` option. This disables the memory overrun checks for each call to `malloc()` and `free()`.

If `mysqld` stops crashing when you compile it with `--with-debug`, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` to the `CFLAGS` and `CXXFLAGS` variables above and not use `--with-debug`. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something “unexpected,” an entry is written to `stderr`, which `mysqld_safe` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you

should do is to configure MySQL for debugging! (The second thing is to send mail to a MySQL mailing list and ask for help. See Section 1.7.1, “MySQL Mailing Lists”. If you believe that you have found a bug, please use the instructions at Section 1.8, “How to Report Bugs or Problems”.

In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files.

## E.1.2. Creating Trace Files

If the `mysqld` server doesn't start or if you can cause it to crash quickly, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld -V`. If the version number ends with `-debug`, it's compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld` as of MySQL 4.1.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `C:\mysqld.trace` on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start `mysqld` as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`.

Note that the trace file become **very big!** If you want to generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:0,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you make a bug report about this, please only send the lines from the trace file to the appropriate mailing list where something seems to go wrong! If you can't locate the wrong place, you can ftp the trace file, together with a full bug report, to `ftp://ftp.mysql.com/pub/mysql/upload/` so that a MySQL developer can take a look at it.

The trace file is made with the `DEBUG` package by Fred Fish. See Section E.3, “The `DEBUG` Package”.

## E.1.3. Debugging `mysqld` under `gdb`

On most systems you can also start `mysqld` from `gdb` to get more information if `mysqld` crashes.

With some older `gdb` versions on Linux you must use `run --one-thread` if you want to be able to debug `mysqld` threads. In this case, you can only have one thread active at a time. We recommend you to upgrade to `gdb 5.1` ASAP as thread debugging works much better with this version!

NTPL threads (the new thread library on Linux) may cause problems while running `mysqld` under `gdb`. Some symptoms are:

- `mysqld` hangs during startup (before it writes `ready for connections`).
- `mysqld` crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case, you should set the following environment variable in the shell before starting `gdb`:

```
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running `mysqld` under `gdb`, you should disable the stack trace with `--skip-stack-trace` to be able to catch segfaults within `gdb`.

In MySQL 4.0.14 and above you should use the `--gdb` option to `mysqld`. This installs an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling.

It's very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` doesn't free the memory for old threads. You can avoid this problem by starting `mysqld` with `--thread-cache-size='max_connections+1'`. In most cases just using `--thread-cache-size=5` helps a lot!

If you want to get a core dump on Linux if `mysqld` dies with a `SIGSEGV` signal, you can start `mysqld` with the `--core-file` option. This core file can be used to make a backtrace that may help you find out why `mysqld` died:

```
shell> gdb mysqld core
gdb> backtrace full
gdb> exit
```

See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

If you are using `gdb 4.17.x` or above on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop noprint
handle SIGUSR2 nostop noprint
handle SIGWAITING nostop noprint
handle SIGLWP nostop noprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop noprint
```

If you have problems debugging threads with `gdb`, you should download `gdb 5.x` and try this instead. The new `gdb` version has very improved thread handling!

Here is an example how to debug `mysqld`:

```
shell> gdb /usr/local/libexec/mysqld
gdb> run
...
backtrace full # Do this when mysqld crashes
```

Include the above output in a bug report, which you can file using the instructions in Section 1.8, “How to Report Bugs or Problems”.

If `mysqld` hangs you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where `mysqld` has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl DBI interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

## E.1.4. Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See Section 5.12.1, “The Error Log”. To get a stack trace, you must not compile `mysqld` with the `-fomit-frame-pointer` option to `gcc`. See Section E.1.1, “Compiling MySQL for Debugging”.

If the error file contains something like the following:

```
mysqld got signal 11;
The manual section 'Debugging a MySQL server' tells you how to use a
stack trace and/or the core file to produce a readable backtrace that may
help in finding out why mysqld died
Attempting backtrace. You can use the following information to find out
where mysqld died.  If you see no messages after this, something went
terribly wrong...
stack range sanity check, ok, backtrace follows
0x40077552
0x81281a0
0x8128f47
0x8127be0
0x8127995
0x8104947
0x80ff28f
0x810131b
0x80ee4bc
0x80c3c91
0x80c6b43
0x80c1fd9
0x80c1686
```

you can find where `mysqld` died by doing the following:

1. Copy the preceding numbers to a file, for example `mysqld.stack`.
2. Make a symbol file for the `mysqld` server:

```
nm -n libexec/mysqld > /tmp/mysqld.sym
```

Note that most MySQL binary distributions (except for the “debug” packages, where this information is included inside of the binaries themselves) ship with the above file, named `mysqld.sym.gz`. In this case, you can simply unpack it by doing:

```
gunzip < bin/mysqld.sym.gz > /tmp/mysqld.sym
```

3. Execute `resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack`.

This prints out where `mysqld` died. If this doesn't help you find out why `mysqld` died, you should make a bug report and include the output from the above command with the bug report.

Note however that in most cases it does not help us to just have a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, we would in most cases need to know the query that killed `mysqld` and preferable a test case so that we can repeat the problem! See Section 1.8, “How to Report Bugs or Problems”.

## E.1.5. Using Server Logs to Find Causes of Errors in `mysqld`

Note that before starting `mysqld` with `--log` you should check all your tables with `myisamchk`. See Chapter 5, *Database Administration*.

If `mysqld` dies or hangs, you should start `mysqld` with `--log`. When `mysqld` dies again, you can examine the end of the log file for the query that killed `mysqld`.

If you are using `--log` without a file name, the log is stored in the database directory as `host_name.log`. In most cases it is the last query in the log file that killed `mysqld`, but if possible you should verify this by restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that didn't complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See Section 7.2.1, “Optimizing Queries with `EXPLAIN`”.

You can find the queries that take a long time to execute by starting `mysqld` with `--log-slow-queries`. See Section 5.12.4, “The Slow Query Log”.

If you find the text `mysqld restarted` in the error log file (normally named `hostname.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see Chapter 5, *Database Administration*), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this doesn't help and you can't find anything in the `mysql` mail archive, you should report the bug to a MySQL mailing list. The mailing lists are described at <http://lists.mysql.com/>, which also has links to online list archives.

If you have started `mysqld` with `myisam-recover`, MySQL automatically checks and tries to repair MyISAM tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning: Checking table ...' which is followed by 'Warning: Repairing table' if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See Section 5.2.1, “`mysqld` Command Options”.

It is not a good sign if `mysqld` did die unexpectedly, but in this case, you should not investigate the 'Checking table ...' messages, but instead try to find out why `mysqld` died.

## E.1.6. Making a Test Case If You Experience Table Corruption

If you get corrupted tables or if `mysqld` always fails after some update commands, you can test whether this bug is reproducible by doing the following:

- Take down the MySQL daemon (with `mysqladmin shutdown`).
- Make a backup of the tables (to guard against the very unlikely case that the repair does something bad).
- Check all tables with `myisamchk -s database/*.MYI`. Repair any wrong tables with `myisamchk -r database/table.MYI`.
- Make a second backup of the tables.
- Remove (or move away) any old log files from the MySQL data directory if you need more space.
- Start `mysqld` with `--log-bin`. See Section 5.12.3, “The Binary Log”. If you want to find a query that crashes `mysqld`, you should use `--log --log-bin`.
- When you have gotten a crashed table, stop the `mysqld` server.
- Restore the backup.
- Restart the `mysqld` server **without** `--log-bin`
- Re-execute the commands with `mysqlbinlog update-log-file | mysql`. The update

log is saved in the MySQL database directory with the name `hostname-bin.#`.

- If the tables are corrupted again or you can get `mysqld` to die with the above command, you have found a reproducible bug that should be easy to fix! FTP the tables and the binary log to `ftp://ftp.mysql.com/pub/mysql/upload/` and report it in our bugs database using the instructions given in Section 1.8, “How to Report Bugs or Problems”. (Please note that the `/pub/mysql/upload/` FTP directory is not listable, so you'll not see what you've uploaded in your FTP client.) If you are a support customer, you can use the MySQL Customer Support Center <https://support.mysql.com/> to alert the MySQL team about the problem and have it fixed as soon as possible.

You can also use the script `mysql_find_rows` to just execute some of the update statements if you want to narrow down the problem.

## E.2. Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `--with-debug` or `--with-debug=full`. See Section 2.9.2, “Typical configure Options”.

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```
shell> MYSQL_DEBUG=d:t:O,/tmp/client.trace  
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
shell> mysql --debug=d:t:O,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See Section 1.8, “How to Report Bugs or Problems”.

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

## E.3. The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is debugging. See Section E.1.2, “Creating Trace Files”.

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support. For more information about programming with the DBUG package, see the DBUG manual in the `dbug` directory of MySQL source distributions. It's best to use a recent distribution for MySQL 5.0 to get the most updated DBUG manual.

You use the debug package by invoking a program with the `--debug="..."` or the `-#... option`.

Most MySQL programs have a default debug string that is used if you don't specify an option to `--debug`. The default trace file is usually `/tmp/program_name.trace` on Unix and `\program_name.trace` on Windows.

The debug control string is a sequence of colon-separated fields as follows:

```
<field_1>:<field_2>:...:<field_N>
```

Each field consists of a mandatory flag character followed by an optional ‘,’ and comma-separated list of modifiers:

```
flag[,modifier,modifier,...,modifier]
```

The currently recognized flag characters are:

Flag	Description
d	Enable output from <code>DEBUG_&lt;N&gt;</code> macros for the current state. May be followed by a list of keywords which selects output only for the <code>DEBUG</code> macros with that keyword. An empty list of keywords implies output for all macros.
D	Delay after each debugger output line. The argument is the number of tenths of seconds to delay, subject to machine capabilities. For example, <code>-#D,20</code> specifies a delay of two seconds.
f	Limit debugging, tracing, and profiling to the list of named functions. Note that a null list disables all functions. The appropriate <code>d</code> or <code>t</code> flags must still be given; this flag only limits their actions if they are enabled.
F	Identify the source file name for each line of debug or trace output.
i	Identify the process with the PID or thread ID for each line of debug or trace output.
g	Enable profiling. Create a file called <code>debugmon.out</code> containing information that can be used to profile the program. May be followed by a list of keywords that select profiling only for the functions in that list. A null list implies that all functions are considered.
L	Identify the source file line number for each line of debug or trace output.
n	Print the current function nesting depth for each line of debug or trace output.
N	Number each line of debug output.
o	Redirect the debugger output stream to the specified file. The default output is <code>stderr</code> .
O	Like <code>o</code> , but the file is really flushed between each write. When needed, the file is closed and reopened between each write.
p	Limit debugger actions to specified processes. A process must be identified with the <code>DEBUG_PROCESS</code> macro and match one in the list for debugger actions to occur.
P	Print the current process name for each line of debug or trace output.
r	When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin.
S	Do function <code>_sanity(_file_,_line_)</code> at each debugged function until <code>_sanity()</code> returns something that differs from 0. (Mostly used with <code>safemalloc</code> to find memory leaks)
t	Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.

Some examples of debug control strings that might appear on a shell command line (the `-#` is typically used to introduce a control string to an application program) are:

```
-#d:t
-#d:f,main,subr1:F:L:t,20
-#d,input,output,files:n
-#d:t:i:0,\\mysqld.trace
```

In MySQL, common tags to print (with the `d` option) are `enter`, `exit`, `error`, `warning`, `info`,

and loop.

## E.4. Comments about RTS Threads

I have tried to use the RTS thread packages with MySQL but stumbled on the following problems:

They use old versions of many POSIX calls and it is very tedious to make wrappers for all functions. I am inclined to think that it would be easier to change the thread libraries to the newest POSIX specification.

Some wrappers are currently written. See `mysys/my_pthread.c` for more info.

At least the following should be changed:

`pthread_get_specific` should use one argument. `sigwait` should take two arguments. A lot of functions (at least `pthread_cond_wait`, `pthread_cond_timedwait()`) should return the error code on error. Now they return -1 and set `errno`.

Another problem is that user-level threads use the `ALRM` signal and this aborts a lot of functions (`read`, `write`, `open`...). MySQL should do a retry on interrupt on all of these but it is not that easy to verify it.

The biggest unsolved problem is the following:

To get thread-level alarms I changed `mysys/thr_alarm.c` to wait between alarms with `pthread_cond_timedwait()`, but this aborts with error `EINTR`. I tried to debug the thread library as to why this happens, but couldn't find any easy solution.

If someone wants to try MySQL with RTS threads I suggest the following:

- Change functions MySQL uses from the thread library to POSIX. This shouldn't take that long.
- Compile all libraries with the `-DHAVE_rts_threads`.
- Compile `thr_alarm`.
- If there are some small differences in the implementation, they may be fixed by changing `my_pthread.h` and `my_pthread.c`.
- Run `thr_alarm`. If it runs without any "warning," "error," or aborted messages, you are on the right track. Here is a successful run on Solaris:

```
Main thread: 1
Thread 0 (5) started
Thread: 5  Waiting
process_alarm
Thread 1 (6) started
Thread: 6  Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6  Slept for 1 (1) sec
Thread: 6  Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6  Slept for 2 (2) sec
Thread: 6  Simulation of no alarm needed
Thread: 6  Slept for 0 (3) sec
Thread: 6  Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6  Slept for 4 (4) sec
Thread: 6  Waiting
```

```
process_alarm
thread_alarm
Thread: 5 Slept for 10 (10) sec
Thread: 5 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 5 (5) sec
Thread: 6 Waiting
process_alarm
process_alarm

...
thread_alarm
Thread: 5 Slept for 0 (1) sec
end
```

## E.5. Differences Between Thread Packages

MySQL is very dependent on the thread package used. So when choosing a good platform for MySQL, the thread package is very important.

There are at least three types of thread packages:

- User threads in a single process. Thread switching is managed with alarms and the threads library manages all non-thread-safe functions with locks. Read, write and select operations are usually managed with a thread-specific select that switches to another thread if the running threads have to wait for data. If the user thread packages are integrated in the standard libs (FreeBSD and BSDI threads) the thread package requires less overhead than thread packages that have to map all unsafe calls (MIT-pthreads, FSU Pthreads and RTS threads). In some environments (for example, SCO), all system calls are thread-safe so the mapping can be done very easily (FSU Pthreads on SCO). Downside: All mapped calls take a little time and it's quite tricky to be able to handle all situations. There are usually also some system calls that are not handled by the thread package (like MIT-pthreads and sockets). Thread scheduling isn't always optimal.
- User threads in separate processes. Thread switching is done by the kernel and all data are shared between threads. The thread package manages the standard thread calls to allow sharing data between threads. LinuxThreads is using this method. Downside: Lots of processes. Thread creating is slow. If one thread dies the rest are usually left hanging and you must kill them all before restarting. Thread switching is somewhat expensive.
- Kernel threads. Thread switching is handled by the thread library or the kernel and is very fast. Everything is done in one process, but on some systems, `ps` may show the different threads. If one thread aborts, the whole process aborts. Most system calls are thread-safe and should require very little overhead. Solaris, HP-UX, AIX and OSF/1 have kernel threads.

In some systems kernel threads are managed by integrating user level threads in the system libraries. In such cases, the thread switching can only be done by the thread library and the kernel isn't really "thread aware."

---

# Appendix F. Environment Variables

This appendix lists all the environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Note that any options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables.

In many cases, it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See Section 4.3.2, “Using Option Files”.

Variable	Description
CXX	The name of your C++ compiler (for running <code>configure</code> ).
CC	The name of your C compiler (for running <code>configure</code> ).
CFLAGS	Flags for your C compiler (for running <code>configure</code> ).
CXXFLAGS	Flags for your C++ compiler (for running <code>configure</code> ).
DBI_USER	The default username for Perl DBI.
DBI_TRACE	Trace options for Perl DBI.
HOME	The default path for the <code>mysql</code> history file is <code>\$HOME/.mysql_history</code> .
LD_RUN_PATH	Used to specify the location of <code>libmysqlclient.so</code> .
MYSQL_DEBUG	Debug trace options when debugging.
MYSQL_GROUP_SUFFIX	Option group suffix value (like specifying <code>-defaults-group-suffix</code> ).
MYSQL_HISTFILE	The path to the <code>mysql</code> history file. If this variable is set, its value overrides the default for <code>\$HOME/.mysql_history</code> .
MYSQL_HOME	The path to the directory in which the server-specific <code>my.cnf</code> file resides (as of MySQL 5.0.3).
MYSQL_HOST	The default hostname used by the <code>mysql</code> command-line client.
MYSQL_PS1	The command prompt to use in the <code>mysql</code> command-line client.
MYSQL_PWD	The default password when connecting to <code>mysqld</code> . Note that using this is insecure. See Section 5.9.6, “Keeping Your Password Secure”.
MYSQL_TCP_PORT	The default TCP/IP port number.
MYSQL_UNIX_PORT	The default Unix socket filename; used for connections to <code>localhost</code> .
PATH	Used by the shell to find MySQL programs.
TMPDIR	The directory where temporary files are created.
TZ	This should be set to your local time zone. See Section A.4.6, “Time Zone Problems”.
UMASK_DIR	The user-directory creation mask when creating directories. Note that this is ANDed with <code>UMASK</code> .
UMASK	The user-file creation mask when creating files.
USER	The default username on Windows and NetWare used when connecting to <code>mysqld</code> .

---

# Appendix G. Regular Expressions

A regular expression is a powerful way of specifying a pattern for a complex search.

MySQL uses Henry Spencer's implementation of regular expressions, which is aimed at conformance with POSIX 1003.2. See Appendix C, *Credits*. MySQL uses the extended version to support pattern-matching operations performed with the `REGEXP` operator in SQL statements. See Section 3.3.4.7, “Pattern Matching”, and Section 12.3.1, “String Comparison Functions”.

This appendix is a summary, with examples, of the special characters and constructs that can be used in MySQL for `REGEXP` operations. It does not contain all the details that can be found in Henry Spencer's `regex(7)` manual page. That manual page is included in MySQL source distributions, in the `regex.7` file under the `regex` directory.

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Non-trivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|word` matches either the string `hello` or the string `word`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of a or `n` characters in between.

A regular expression for the `REGEXP` operator may use any of the following special characters and constructs:

- `^`

Match the beginning of a string.

```
mysql> SELECT 'fo\nfo' REGEXP '^fo$';           -> 0
mysql> SELECT 'fofo' REGEXP '^fo';             -> 1
```

- `$`

Match the end of a string.

```
mysql> SELECT 'fo\no' REGEXP '^fo\no$';        -> 1
mysql> SELECT 'fo\no' REGEXP '^fo$';           -> 0
```

- `.`

Match any character (including carriage return and newline).

```
mysql> SELECT 'fofo' REGEXP '^f.*$';           -> 1
mysql> SELECT 'fo\r\nfo' REGEXP '^f.*$';       -> 1
```

- `a*`

Match any sequence of zero or more `a` characters.

```
mysql> SELECT 'Ban' REGEXP '^Ba*n';            -> 1
mysql> SELECT 'Baaan' REGEXP '^Ba*n';         -> 1
mysql> SELECT 'Bn' REGEXP '^Ba*n';            -> 1
```

- `a+`

Match any sequence of one or more a characters.

```
mysql> SELECT 'Ban' REGEXP '^Ba+n';      -> 1
mysql> SELECT 'Bn' REGEXP '^Ba+n';      -> 0
```

- a?

Match either zero or one a character.

```
mysql> SELECT 'Bn' REGEXP '^Ba?n';      -> 1
mysql> SELECT 'Ban' REGEXP '^Ba?n';     -> 1
mysql> SELECT 'Baan' REGEXP '^Ba?n';    -> 0
```

- de|abc

Match either of the sequences de or abc.

```
mysql> SELECT 'pi' REGEXP 'pi|apa';     -> 1
mysql> SELECT 'axe' REGEXP 'pi|apa';    -> 0
mysql> SELECT 'apa' REGEXP 'pi|apa';    -> 1
mysql> SELECT 'apa' REGEXP '^ (pi|apa)$'; -> 1
mysql> SELECT 'pi' REGEXP '^ (pi|apa)$'; -> 1
mysql> SELECT 'pix' REGEXP '^ (pi|apa)$'; -> 0
```

- (abc)\*

Match zero or more instances of the sequence abc.

```
mysql> SELECT 'pi' REGEXP '^ (pi)*$';   -> 1
mysql> SELECT 'pip' REGEXP '^ (pi)*$';  -> 0
mysql> SELECT 'pypi' REGEXP '^ (pi)*$'; -> 1
```

- {1}, {2, 3}

{n} or {m, n} notation provides a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. m and n are integers.

- a\*

Can be written as a{0, }.

- a+

Can be written as a{1, }.

- a?

Can be written as a{0, 1}.

To be more precise, a{n} matches exactly n instances of a. a{n, } matches n or more instances of a. a{m, n} matches m through n instances of a, inclusive.

m and n must be in the range from 0 to RE\_DUP\_MAX (default 255), inclusive. If both m and n are given, m must be less than or equal to n.

```
mysql> SELECT 'abcde' REGEXP 'a[bcd]{2}e'; -> 0
mysql> SELECT 'abcde' REGEXP 'a[bcd]{3}e'; -> 1
mysql> SELECT 'abcde' REGEXP 'a[bcd]{1,10}e'; -> 1
```

- [a-dX], [^a-dX]

Matches any character that is (or is not, if ^ is used) either a, b, c, d or X. A - character between two other characters forms a range that matches all characters from the first character to the second. For example, [0-9] matches any decimal digit. To include a literal - character, it must immediately follow the opening bracket [. To include a literal - character, it must be written first or last. Any character that does not have a defined special meaning inside a [] pair matches only itself.

```
mysql> SELECT 'aXbc' REGEXP '[a-dXYZ]';           -> 1
mysql> SELECT 'aXbc' REGEXP '^[a-dXYZ]$';       -> 0
mysql> SELECT 'aXbc' REGEXP '[a-dXYZ]+$';       -> 1
mysql> SELECT 'aXbc' REGEXP '^[^a-dXYZ]+$';     -> 0
mysql> SELECT 'gheis' REGEXP '^[^a-dXYZ]+$';    -> 1
mysql> SELECT 'gheisa' REGEXP '^[^a-dXYZ]+$';   -> 0
```

- [.characters.]

Within a bracket expression (written using [ and ]), matches the sequence of characters of that collating element. characters is either a single character or a character name like newline. You can find the full list of character names in the regexp/cname.h file.

```
mysql> SELECT '~' REGEXP '[[.~.]]';             -> 1
mysql> SELECT '~' REGEXP '[[.tilde.]]';        -> 1
```

- [=character\_class=]

Within a bracket expression (written using [ and ]), [=character\_class=] represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if o and (+) are the members of an equivalence class, then [[=o=]], [[=(+)=]], and [o(+)] are all synonymous. An equivalence class may not be used as an endpoint of a range.

- [:character\_class:]

Within a bracket expression (written using [ and ]), [:character\_class:] represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the ctype(3) manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

alnum	Alphanumeric characters
alpha	Alphabetic characters
blank	Whitespace characters
cntrl	Control characters
digit	Digit characters
graph	Graphic characters
lower	Lowercase alphabetic characters
print	Graphic or space characters
punct	Punctuation characters
space	Space, tab, newline, and carriage return
upper	Uppercase alphabetic characters
xdigit	Hexadecimal digit characters

```
mysql> SELECT 'justalnums' REGEXP '[:alnum:]+'; -> 1
mysql> SELECT '!!!' REGEXP '[:alnum:]+';      -> 0
```

- `[[[:<:]], [[[:>:]]]`

These markers stand for word boundaries. They match the beginning and end of words, respectively. A word is a sequence of word characters that is not preceded by or followed by word characters. A word character is an alphanumeric character in the `alnum` class or an underscore (`_`).

```
mysql> SELECT 'a word a' REGEXP '[[[:<:]]word[[[:>:]]]'; -> 1
mysql> SELECT 'a xword a' REGEXP '[[[:<:]]word[[[:>:]]]'; -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (`\`) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT '1+2' REGEXP '1+2'; -> 0
mysql> SELECT '1+2' REGEXP '1\+2'; -> 0
mysql> SELECT '1+2' REGEXP '1\\+2'; -> 1
```

---

# Appendix H. Limits in MySQL

This Appendix lists current limits in MySQL 5.0.

## H.1. Limits of Joins

The maximum number of tables that can be referenced in a single join is 61. This also applies to the number of tables that can be referenced in the definition of a view.

---

# Appendix I. Feature Restrictions

The discussion here describes restrictions that apply to the use of MySQL features such as subqueries or views.

## I.1. Restrictions on Stored Routines and Triggers

Some of the restrictions noted here apply to all stored routines; that is, both to stored procedures and stored functions. Some of restrictions apply only to stored functions, and not to stored procedures.

All of the restrictions for stored functions also apply to triggers. In addition, triggers currently are not activated by foreign key actions.

Stored routines cannot contain arbitrary SQL statements. The following statements are disallowed:

- The table-maintenance statements `CHECK TABLES` and `OPTIMIZE TABLES`. **Note:** This restriction is lifted beginning with MySQL 5.0.17.
- The locking statements `LOCK TABLES`, `UNLOCK TABLES`.
- `LOAD DATA` and `LOAD TABLE`.
- SQL prepared statements (`PREPARE`, `EXECUTE`, `DEALLOCATE PREPARE`). Implication: You cannot use dynamic SQL within stored routines (where you construct dynamically statements as strings and then execute them). This restriction is lifted as of MySQL 5.0.13 for stored procedures; it still applies to stored functions and triggers.

For stored functions (but not stored procedures), the following additional statements or operations are disallowed:

- Statements that do explicit or implicit commit or rollback.
- Statements that return a result set. This includes `SELECT` statements that do not have an `INTO var_list` clause and `SHOW` statements. A function can process a result set either with `SELECT ... INTO var_list` or by using a cursor and `FETCH` statements. See Section 17.2.7.3, “`SELECT ... INTO` Statement”.
- `FLUSH` statements.
- **Note:** Before MySQL 5.0.10, stored functions created with `CREATE FUNCTION` must not contain references to tables, with limited exceptions. They may include some `SET` statements that contain table references, for example `SET a := (SELECT MAX(id) FROM t)`, and `SELECT` statements that fetch values directly into variables, for example `SELECT i INTO var1 FROM t`.
- Recursive statements. That is, stored functions cannot be used recursively.
- Within a stored function or trigger, it is not allowable to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

Note that although some restrictions normally apply to stored functions and triggers but not to stored procedures, those restrictions do apply to stored procedures if they are invoked from within a stored function or trigger. For example, although you can use `FLUSH` in a stored procedure, such a stored procedure cannot be called from a stored function or trigger.

It is possible for the same identifier to be used for a routine parameter, a local variable, and a table column. Also, the same local variable name can be used in nested blocks. For example:

```
CREATE PROCEDURE p (i INT)
BEGIN
  DECLARE i INT DEFAULT 0;
  SELECT i FROM t;
  BEGIN
    DECLARE i INT DEFAULT 1;
    SELECT i FROM t;
  END;
END;
```

In such cases the identifier is ambiguous and the following precedence rules apply:

- A local variable takes precedence over a routine parameter or table column
- A routine parameter takes precedence over a table column
- A local variable in an inner block takes precedence over a local variable in an outer block

The behavior that table columns do not take precedence over variables is non-standard.

Use of stored routines can cause replication problems. This issue is discussed further in Section 17.4, “Binary Logging of Stored Routines and Triggers”.

INFORMATION\_SCHEMA does not yet have a PARAMETERS table, so applications that need to acquire routine parameter information at runtime must use workarounds such as parsing the output of SHOW CREATE statements.

There are no stored routine debugging facilities.

CALL statements cannot be prepared. This true both for server-side prepared statements and for SQL prepared statements.

UNDO handlers are not supported.

FOR loops are not supported.

To prevent problems of interaction between server threads, when a client issues a statement, the server uses a snapshot of routines and triggers available for execution of the statement. That is, the server calculates a list of procedures, functions, and triggers that may be used during execution of the statement, loads them, and then proceeds to execute the statement. This means that while the statement executes, it will not see changes to routines performed by other threads.

The RETURN statement is disallowed in triggers, which cannot return a value. To exit a trigger immediately, use the LEAVE statement.

## I.2. Restrictions on Server-Side Cursors

Server-side cursors are implemented beginning with the C API in MySQL 5.0.2 via the `mysql_stmt_attr_set()` function. A server-side cursor allows a result set to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

In MySQL, a server-side cursor is materialized into a temporary table. Initially, this is a MEMORY table, but is converted to a MyISAM table if its size reaches the value of the `max_heap_table_size` system variable. (Beginning with MySQL 5.0.14, the same temporary-table implementation also is used for cursors in stored routines.) One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.

Cursors are read-only; you cannot use a cursor to update rows.

UPDATE WHERE CURRENT OF and DELETE WHERE CURRENT OF are not implemented, because updatable cursors are not supported.

Cursors are non-holdable (not held open after a commit).

Cursors are asensitive.

Cursors are non-scrollable.

Cursors are not named. The statement handler acts as the cursor ID.

You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as CHECK TABLES, HANDLER READ, and SHOW BINLOG EVENTS.

## I.3. Restrictions on Subqueries

- Known bug to be fixed later: If you compare a NULL value to a subquery using ALL, ANY, or SOME, and the subquery returns an empty result, the comparison might evaluate to the non-standard result of NULL rather than to TRUE or FALSE.
- A subquery's outer statement can be any one of: SELECT, INSERT, UPDATE, DELETE, SET, or DO.
- Subquery optimization for IN is not as effective as for the = operator or for IN(value\_list) constructs.

A typical case for poor IN subquery performance is when the subquery returns a small number of rows but the outer query returns a large number of rows to be compared to the subquery result.

The problem is that, for a statement that uses an IN subquery, the optimizer rewrites it as a correlated subquery. Consider the following statement that uses an uncorrelated subquery:

```
SELECT ... FROM t1 WHERE t1.a IN (SELECT b FROM t2);
```

The optimizer rewrites the statement to a correlated subquery:

```
SELECT ... FROM t1 WHERE EXISTS (SELECT 1 FROM t2 WHERE t2.b = t1.a);
```

If the inner and outer queries return  $M$  and  $N$  rows, respectively, the execution time becomes on the order of  $O(M \times N)$ , rather than  $O(M + N)$  as it would be for an uncorrelated subquery.

An implication is that an IN subquery can be much slower than a query written using an IN(value\_list) construct that lists the same values that the subquery would return.

- In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

```
DELETE FROM t WHERE ... (SELECT ... FROM t ...);
UPDATE t ... WHERE col = (SELECT ... FROM t ...);
{INSERT|REPLACE} INTO t (SELECT ... FROM t ...);
```

Exception: The preceding prohibition does not apply if you are using a subquery for the modified table in the FROM clause. Example:

```
UPDATE t ... WHERE col = (SELECT (SELECT ... FROM t...) AS _t ...);
```

Here the prohibition does not apply because a subquery in the FROM clause is materialized as a temporary table, so the relevant rows in `t` have already been selected by the time the update to `t` takes place.

- Row comparison operations are only partially supported:
  - For `expr IN (subquery)`, `expr` can be an  $n$ -tuple (specified via row constructor syntax) and the subquery can return rows of  $n$ -tuples.
  - For `expr op {ALL|ANY|SOME} (subquery)`, `expr` must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

In other words, for a subquery that returns rows of  $n$ -tuples, this is supported:

```
(val_1, ..., val_n) IN (subquery)
```

But this is not supported:

```
(val_1, ..., val_n) op {ALL|ANY|SOME} (subquery)
```

The reason for supporting row comparisons for `IN` but not for the others is that `IN` is implemented by rewriting it as a sequence of `=` comparisons and `AND` operations. This approach cannot be used for `ALL`, `ANY`, or `SOME`.

- Row constructors are not well optimized. The following two expressions are equivalent, but only the second can be optimized:

```
(col1, col2, ...) = (val1, val2, ...)
col1 = val1 AND col2 = val2 AND ...
```

- Subqueries in the FROM clause cannot be correlated subqueries. They are materialized (executed to produce a result set) before evaluating the outer query, so they cannot be evaluated per row of the outer query.
- The optimizer is more mature for joins than for subqueries, so in many cases a statement that uses a subquery can be executed more efficiently if you rewrite it as a join.

An exception occurs for the case where an `IN` subquery can be rewritten as a `SELECT DISTINCT` join. Example:

```
SELECT col FROM t1 WHERE id_col IN (SELECT id_col2 FROM t2 WHERE condition);
```

That statement can be rewritten as follows:

```
SELECT DISTINCT col FROM t1, t2 WHERE t1.id_col = t2.id_col AND condition;
```

But in this case, the join requires an extra `DISTINCT` operation and is not more efficient than the subquery.

- Possible future optimization: MySQL does not rewrite the join order for subquery evaluation. In some cases, a subquery could be executed more efficiently if MySQL rewrote it as a join. This would give the optimizer a chance to choose between more execution plans. For example, it could decide whether to read one table or the other first.

Example:

```
SELECT a FROM outer_table AS ot
WHERE a IN (SELECT a FROM inner_table AS it WHERE ot.b = it.b);
```

For that query, MySQL always scans `outer_table` first and then executes the subquery on `inner_table` for each row. If `outer_table` has a lot of rows and `inner_table` has few rows, the query probably will not be as fast as it could be.

The preceding query could be rewritten like this:

```
SELECT a FROM outer_table AS ot, inner_table AS it
WHERE ot.a = it.a AND ot.b = it.b;
```

In this case, we can scan the small table (`inner_table`) and look up rows in `outer_table`, which will be fast if there is an index on `(ot.a, ot.b)`.

- Possible future optimization: A correlated subquery is evaluated for each row of the outer query. A better approach is that if the outer row values do not change from the previous row, do not evaluate the subquery again. Instead, use its previous result.
- Possible future optimization: A subquery in the `FROM` clause is evaluated by materializing the result into a temporary table, and this table does not use indexes. This does not allow the use of indexes in comparison with other tables in the query, although that might be useful.
- Possible future optimization: If a subquery in the `FROM` clause resembles a view to which the merge algorithm can be applied, rewrite the query and apply the merge algorithm so that indexes can be used. The following statement contains such a subquery:

```
SELECT * FROM (SELECT * FROM t1 WHERE t1.t1_col) AS _t1, t2 WHERE t2.t2_col;
```

The statement can be rewritten as a join like this:

```
SELECT * FROM t1, t2 WHERE t1.t1_col AND t2.t2_col;
```

This type of rewriting would provide two benefits:

- It avoids the use of a temporary table for which no indexes can be used. In the rewritten query, the optimizer can use indexes on `t1`.
- It gives the optimizer more freedom to choose between different execution plans. For example, rewriting the query as a join allows the optimizer to use `t1` or `t2` first.
- Possible future optimization: For `IN`, `= ANY`, `<> ANY`, `= ALL`, and `<> ALL` with non-correlated subqueries, use an in-memory hash for a result result or a temporary table with an index for larger results. Example:

```
SELECT a FROM big_table AS bt
WHERE non_key_field IN (SELECT non_key_field FROM table WHERE condition)
```

In this case, we could create a temporary table:

```
CREATE TABLE t (key (non_key_field))
(SELECT non_key_field FROM table WHERE condition)
```

Then, for each row in `big_table`, do a key lookup in `t` based on `bt.non_key_field`.

## I.4. Restrictions on Views

---

View processing is not optimized:

- It is not possible to create an index on a view.
- Indexes can be used for views processed using the merge algorithm. However, a view that is processed with the temptable algorithm is unable to take advantage of indexes on its underlying tables (although indexes can be used during generation of the temporary tables).

Subqueries cannot be used in the `FROM` clause of a view. This limitation will be lifted in the future.

There is a general principle that you cannot modify a table and select from the same table in a subquery. See Section I.3, “Restrictions on Subqueries”.

The same principle also applies if you select from a view that selects from the table, if the view selects from the table in a subquery and the view is evaluated using the merge algorithm. Example:

```
CREATE VIEW v1 AS
SELECT * FROM t2 WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t2.a);
UPDATE t1, v2 SET t1.a = 1 WHERE t1.b = v2.b;
```

If the view is evaluated using a temporary table, you *can* select from the table in the view subquery and still modify that table in the outer query. In this case the view will be materialized and thus you are not really selecting from the table in a subquery and modifying it “at the same time.” (This is another reason you might wish to force MySQL to use the temptable algorithm by specifying `ALGORITHM = TEMPTABLE` in the view definition.)

You can use `DROP TABLE` or `ALTER TABLE` to drop or alter a table that is used in a view definition (which invalidates the view) and no warning results from the drop or alter operation. An error occurs later when the view is used.

A view definition is “frozen” by certain statements:

- If a statement prepared by `PREPARE` refers to a view, the view contents seen each time the statement is executed later will be the contents of the view at the time it was prepared. This is true even if the view definition is changed after the statement is prepared and before it is executed. Example:

```
CREATE VIEW v AS SELECT 1;
PREPARE s FROM 'SELECT * FROM v';
ALTER VIEW v AS SELECT 2;
EXECUTE s;
```

The result returned by the `EXECUTE` statement is 1, not 2.

- If a statement in a stored routine refers to a view, the view contents seen by the statement are its contents the first time that statement is executed. For example, this means that if the statement is executed in a loop, further iterations of the statement see the same view contents, even if the view definition is changed later in the loop. Example:

```
CREATE VIEW v AS SELECT 1;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE i INT DEFAULT 0;
    WHILE i < 5 DO
        SELECT * FROM v;
        SET i = i + 1;
        ALTER VIEW v AS SELECT 2;
    END WHILE;
END;
```

```
//  
delimiter ;  
CALL p();
```

When the procedure `p()` is called, the `SELECT` returns 1 each time through the loop, even though the view definition is changed within the loop.

With regard to view updatability, the overall goal for views is that if any view is theoretically updatable, it should be updatable in practice. This includes views that have `UNION` in their definition. Currently, not all views that are theoretically updatable can be updated. The initial view implementation was deliberately written this way to get usable, updatable views into MySQL as quickly as possible. Many theoretically updatable views can be updated now, but limitations still exist:

- Updatable views with subqueries anywhere other than in the `WHERE` clause. Some views that have subqueries in the `SELECT` list may be updatable.
- You cannot use `UPDATE` to update more than one underlying table of a view that is defined as a join.
- You cannot use `DELETE` to update a view that is defined as a join.

## I.5. Restrictions on XA Transactions

XA transaction support is limited to the InnoDB storage engine.

The MySQL XA implementation is for “external XA,” where a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. “Internal XA” is not implemented. This would allow individual storage engines within a MySQL server to act as RMs, and the server itself to act as a TM. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA is incomplete because it requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for InnoDB.

For `XA START`, the `JOIN` and `RESUME` clauses are not supported.

For `XA END`, the `SUSPEND [FOR MIGRATE]` clause is not supported.

The requirement that the *bqual* part of the *xid* value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

If an XA transaction has reached the `PREPARED` state and the MySQL server is killed (for example, with `kill -9` on Unix) or shuts down abnormally, the transaction can be continued after the server restarts. However, if the client reconnects and commits the transaction, the transaction will be absent from the binary log even though it has been committed. This means the data and the binary log have gone out of synchrony. An implication is that XA cannot be used safely together with replication.

It is possible that the server will roll back a pending XA transaction, even one that has reached the `PREPARED` state. This happens if a client connection terminates and the server continues to run, or if clients are connected and the server shuts down gracefully. (In the latter case, the server marks each connection to be terminated, and then rolls back the `PREPARED` XA transaction associated with it.) It should be possible to commit or roll back a `PREPARED` XA transaction, but this cannot be done without changes to the binary logging mechanism.

---

# Appendix J. GNU General Public License

Version 2, June 1991

Copyright © 1989, 1991 Free Software Foundation, Inc.  
59 Temple Place - Suite 330, Boston, MA 02111-1307, USA  
Everyone is permitted to copy and distribute verbatim copies  
of this license document, but changing it is not allowed.

## Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software---to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

## GNU GENERAL PUBLIC LICENSE TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

1. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The ``Program'', below, refers to any such program or work, and a ``work based on the Program'' means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or trans-

lated into another language. (Hereinafter, translation is included without limitation in the term ``modification".) Each licensee is addressed as ``you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

2. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

3. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:
  - a. You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.
  - b. You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.
  - c. If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

4. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:
  - a. Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,
  - b. Accompany it with a written offer, valid for at least three years, to give any third-party,

for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

- c. Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

5. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.
6. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.
7. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.
8. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and

a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

9. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.
10. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and ``any later version'', you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

11. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

#### NO WARRANTY

12. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM ``AS IS'' WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.
13. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

#### END OF TERMS AND CONDITIONS

#### **How to Apply These Terms to Your New Programs**

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each

source file to most effectively convey the exclusion of warranty; and each file should have at least the ``copyright" line and a pointer to where the full notice is found.

*one line to give the program's name and a brief idea of what it does.*  
Copyright (C) yyyy name of author

This program is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 2 of the License, or (at your option) any later version.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program; if not, write to the Free Software Foundation, Inc., 59 Temple Place - Suite 330, Boston, MA 02111-1307, USA.

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

```
Gnomovision version 69, Copyright (C) 19yy name of author
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type `show w'.
This is free software, and you are welcome to redistribute it
under certain conditions; type `show c' for details.
```

The hypothetical commands 'show w' and 'show c' should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than 'show w' and 'show c'; they could even be mouse-clicks or menu items---whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a ``copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

```
Yoyodyne, Inc., hereby disclaims all copyright interest in the program
`Gnomovision' (which makes passes at compilers) written by James Hacker.
```

```
signature of Ty Coon, 1 April 1989
Ty Coon, President of Vice
```

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Library General Public License instead of this License.

---

# Appendix K. MySQL FLOSS License Exception

The MySQL AB Exception for Free/Libre and Open Source Software-only Applications Using MySQL Client Libraries (the "FLOSS Exception").

*Version 0.4, 08 September 2005*

## Exception Intent

We want specified Free/Libre and Open Source Software ("FLOSS") applications to be able to use specified GPL-licensed MySQL client libraries (the "Program") despite the fact that not all FLOSS licenses are compatible with version 2 of the GNU General Public License (the "GPL").

## Legal Terms and Conditions

As a special exception to the terms and conditions of version 2.0 of the GPL:

1. You are free to distribute a Derivative Work that is formed entirely from the Program and one or more works (each, a "FLOSS Work") licensed under one or more of the licenses listed below in section 1, as long as:
  - a. You obey the GPL in all respects for the Program and the Derivative Work, except for identifiable sections of the Derivative Work which are not derived from the Program, and which can reasonably be considered independent and separate works in themselves,
  - b. all identifiable sections of the Derivative Work which are not derived from the Program, and which can reasonably be considered independent and separate works in themselves,
    - i. are distributed subject to one of the FLOSS licenses listed below, and
    - ii. the object code or executable form of those sections are accompanied by the complete corresponding machine-readable source code for those sections on the same medium and under the same FLOSS license as the corresponding object code or executable forms of those sections, and
  - c. any works which are aggregated with the Program or with a Derivative Work on a volume of a storage or distribution medium in accordance with the GPL, can reasonably be considered independent and separate works in themselves which are not derivatives of either the Program, a Derivative Work or a FLOSS Work.

If the above conditions are not met, then the Program may only be copied, modified, distributed or used under the terms and conditions of the GPL or another valid licensing option from MySQL AB.

## 2. FLOSS License List

License name	Version(s)/Copyright Date
Academic Free License	2.0
Apache Software License	1.0/1.1/2.0
Apple Public Source License	2.0
Artistic license	From Perl 5.8.0
BSD license	"July 22 1999"
Common Public License	1.0
GNU Library or "Lesser" General Public License (LGPL)	2.0/2.1
Jabber Open Source License	1.0

MIT license	-
Mozilla Public License (MPL)	1.0/1.1
Open Software License	2.0
OpenSSL license (with original SSLeay license)	"2003" ("1998")
PHP License	3.0
Python license (CNRI Python License)	—
Python Software Foundation License	2.1.1
Sleepycat License	"1999"
W3C License	"2001"
X11 License	"2001"
Zlib/libpng License	—
Zope Public License	2.0

Due to the many variants of some of the above licenses, we require that any version follow the 2003 version of the Free Software Foundation's Free Software Definition (<http://www.gnu.org/philosophy/free-sw.html>) or version 1.9 of the Open Source Definition by the Open Source Initiative (<http://www.opensource.org/docs/definition.php>).

3. Definitions

- a. Terms used, but not defined, herein shall have the meaning provided in the GPL.
- b. Derivative Work means a derivative work under copyright law.

4. **Applicability:** This FLOSS Exception applies to all Programs that contain a notice placed by MySQL AB saying that the Program may be distributed under the terms of this FLOSS Exception. If you create or distribute a work which is a Derivative Work of both the Program and any other work licensed under the GPL, then this FLOSS Exception is not available for that work; thus, you must remove the FLOSS Exception notice from that work and comply with the GPL in all respects, including by retaining all GPL notices. You may choose to redistribute a copy of the Program exclusively under the terms of the GPL by removing the FLOSS Exception notice from that copy of the Program, provided that the copy has never been modified by you or any third party.

**Appendix A. Qualified Libraries and Packages**

The following is a non-exhaustive list of libraries and packages which are covered by the FLOSS License Exception. Please note that this appendix is provided merely as an additional service to specific FLOSS projects wishing to simplify licensing information for their users. Compliance with one of the licenses noted under the "FLOSS license list" section remains a prerequisite.

Package Name	Qualifying License and Version
Apache Portable Runtime (APR)	Apache Software License 2.0
