

# MySQL 5.0 Reference Manual

---

# MySQL 5.0 Reference Manual

## Abstract

This is the MySQL Reference Manual. It documents MySQL 5.0 through 5.0.22.

Document generated on: 2006-05-11 (revision: 2078)

# Table of Contents

Preface .....	xx
1. General Information .....	1
1.1. About This Manual .....	1
1.2. Conventions Used in This Manual .....	2
1.3. Overview of MySQL AB .....	4
1.4. Overview of the MySQL Database Management System .....	4
1.4.1. History of MySQL .....	5
1.4.2. The Main Features of MySQL .....	6
1.4.3. MySQL Stability .....	8
1.4.4. How Large MySQL Tables Can Be .....	9
1.4.5. Year 2000 Compliance .....	10
1.5. Overview of the MaxDB Database Management System .....	12
1.5.1. What is MaxDB? .....	12
1.5.2. History of MaxDB .....	12
1.5.3. Features of MaxDB .....	13
1.5.4. Licensing and Support .....	13
1.5.5. Feature Differences Between MaxDB and MySQL .....	14
1.5.6. Interoperability Features Between MaxDB and MySQL .....	14
1.5.7. MaxDB-Related Links .....	15
1.6. MySQL Development Roadmap .....	15
1.6.1. What's New in MySQL 5.0 .....	16
1.7. MySQL Information Sources .....	18
1.7.1. MySQL Mailing Lists .....	18
1.7.2. MySQL Community Support at the MySQL Forums .....	20
1.7.3. MySQL Community Support on Internet Relay Chat (IRC) .....	21
1.8. How to Report Bugs or Problems .....	21
1.9. MySQL Standards Compliance .....	25
1.9.1. What Standards MySQL Follows .....	25
1.9.2. Selecting SQL Modes .....	26
1.9.3. Running MySQL in ANSI Mode .....	26
1.9.4. MySQL Extensions to Standard SQL .....	26
1.9.5. MySQL Differences from Standard SQL .....	29
1.9.6. How MySQL Deals with Constraints .....	35
2. Installing and Upgrading MySQL .....	39
2.1. General Installation Issues .....	39
2.1.1. Operating Systems Supported by MySQL .....	39
2.1.2. Choosing Which MySQL Distribution to Install .....	41
2.1.3. How to Get MySQL .....	52
2.1.4. Verifying Package Integrity Using MD5 Checksums or GnuPG .....	52
2.1.5. Installation Layouts .....	55
2.2. Standard MySQL Installation Using a Binary Distribution .....	56
2.3. Installing MySQL on Windows .....	57
2.3.1. Choosing An Installation Package .....	58
2.3.2. Installing MySQL with the Automated Installer .....	58
2.3.3. Using the MySQL Installation Wizard .....	58
2.3.4. Using the Configuration Wizard .....	61
2.3.5. Installing MySQL from a Noinstall Zip Archive .....	65
2.3.6. Extracting the Install Archive .....	66
2.3.7. Creating an Option File .....	66
2.3.8. Selecting a MySQL Server type .....	67
2.3.9. Starting the Server for the First Time .....	68
2.3.10. Starting MySQL from the Windows Command Line .....	69
2.3.11. Starting MySQL as a Windows Service .....	70
2.3.12. Testing The MySQL Installation .....	72
2.3.13. Troubleshooting a MySQL Installation Under Windows .....	73
2.3.14. Upgrading MySQL on Windows .....	74
2.3.15. MySQL on Windows Compared to MySQL on Unix .....	75

---

2.4. Installing MySQL on Linux .....	78
2.5. Installing MySQL on Mac OS X .....	80
2.6. Installing MySQL on Solaris .....	82
2.7. Installing MySQL on NetWare .....	83
2.8. Installing MySQL on Other Unix-Like Systems .....	85
2.9. MySQL Installation Using a Source Distribution .....	87
2.9.1. Source Installation Overview .....	88
2.9.2. Typical configure Options .....	91
2.9.3. Installing from the Development Source Tree .....	94
2.9.4. Dealing with Problems Compiling MySQL .....	96
2.9.5. MIT-pthreads Notes .....	99
2.9.6. Installing MySQL from Source on Windows .....	100
2.9.7. Compiling MySQL Clients on Windows .....	104
2.10. Post-Installation Setup and Testing .....	104
2.10.1. Windows Post-Installation Procedures .....	104
2.10.2. Unix Post-Installation Procedures .....	105
2.10.3. Securing the Initial MySQL Accounts .....	116
2.11. Upgrading MySQL .....	119
2.11.1. Upgrading from MySQL 5.0 to 5.1 .....	120
2.11.2. Upgrading from MySQL 4.1 to 5.0 .....	120
2.11.3. Copying MySQL Databases to Another Machine .....	126
2.12. Downgrading MySQL .....	127
2.12.1. Downgrading to MySQL 4.1 .....	128
2.13. Operating System-Specific Notes .....	128
2.13.1. Linux Notes .....	129
2.13.2. Mac OS X Notes .....	135
2.13.3. Solaris Notes .....	136
2.13.4. BSD Notes .....	140
2.13.5. Other Unix Notes .....	143
2.13.6. OS/2 Notes .....	159
2.14. Perl Installation Notes .....	160
2.14.1. Installing Perl on Unix .....	160
2.14.2. Installing ActiveState Perl on Windows .....	161
2.14.3. Problems Using the Perl DBI/DBD Interface .....	162
3. Tutorial .....	165
3.1. Connecting to and Disconnecting from the Server .....	165
3.2. Entering Queries .....	166
3.3. Creating and Using a Database .....	169
3.3.1. Creating and Selecting a Database .....	170
3.3.2. Creating a Table .....	171
3.3.3. Loading Data into a Table .....	172
3.3.4. Retrieving Information from a Table .....	173
3.4. Getting Information About Databases and Tables .....	186
3.5. Using <code>mysql</code> in Batch Mode .....	187
3.6. Examples of Common Queries .....	188
3.6.1. The Maximum Value for a Column .....	189
3.6.2. The Row Holding the Maximum of a Certain Column .....	189
3.6.3. Maximum of Column per Group .....	190
3.6.4. The Rows Holding the Group-wise Maximum of a Certain Field .....	190
3.6.5. Using User-Defined Variables .....	190
3.6.6. Using Foreign Keys .....	190
3.6.7. Searching on Two Keys .....	192
3.6.8. Calculating Visits Per Day .....	192
3.6.9. Using <code>AUTO_INCREMENT</code> .....	193
3.7. Queries from the Twin Project .....	195
3.7.1. Find All Non-distributed Twins .....	195
3.7.2. Show a Table of Twin Pair Status .....	197
3.8. Using MySQL with Apache .....	197
4. Using MySQL Programs .....	199
4.1. Overview of MySQL Programs .....	199
4.2. Invoking MySQL Programs .....	200
4.3. Specifying Program Options .....	201
4.3.1. Using Options on the Command Line .....	201

---

---

4.3.2. Using Option Files .....	203
4.3.3. Using Environment Variables to Specify Options .....	207
4.3.4. Using Options to Set Program Variables .....	208
5. Database Administration .....	210
5.1. Overview of Server-Side Programs .....	210
5.2. <code>mysqld</code> — The MySQL Server .....	211
5.2.1. <code>mysqld</code> Command Options .....	211
5.2.2. Server System Variables .....	222
5.2.3. Using System Variables .....	247
5.2.4. Server Status Variables .....	255
5.2.5. The Server SQL Mode .....	264
5.2.6. The MySQL Server Shutdown Process .....	269
5.3. The <code>mysqld-max</code> Extended MySQL Server .....	270
5.4. MySQL Server Startup Programs .....	273
5.4.1. <code>mysqld_safe</code> — MySQL Server Startup Script .....	273
5.4.2. <code>mysql.server</code> — MySQL Server Startup Script .....	276
5.4.3. <code>mysqld_multi</code> — Manage Multiple MySQL Servers .....	277
5.5. <code>mysqlmanager</code> — The MySQL Instance Manager .....	280
5.5.1. Starting the MySQL Server with MySQL Instance Manager .....	280
5.5.2. Connecting to the MySQL Instance Manager and Creating User Accounts .....	281
5.5.3. MySQL Instance Manager Command Options .....	282
5.5.4. MySQL Instance Manager Configuration Files .....	284
5.5.5. Commands Recognized by the MySQL Instance Manager .....	285
5.6. Installation-Related Programs .....	287
5.6.1. <code>mysql_fix_privilege_tables</code> — Upgrade MySQL System Tables .....	287
5.6.2. <code>mysql_upgrade</code> — Check Tables for MySQL Upgrade .....	288
5.7. General Security Issues .....	289
5.7.1. General Security Guidelines .....	289
5.7.2. Making MySQL Secure Against Attackers .....	292
5.7.3. Security-Related <code>mysqld</code> Options .....	293
5.7.4. Security Issues with <code>LOAD DATA LOCAL</code> .....	295
5.7.5. How to Run MySQL as a Normal User .....	295
5.8. The MySQL Access Privilege System .....	296
5.8.1. What the Privilege System Does .....	296
5.8.2. How the Privilege System Works .....	296
5.8.3. Privileges Provided by MySQL .....	301
5.8.4. Connecting to the MySQL Server .....	304
5.8.5. Access Control, Stage 1: Connection Verification .....	305
5.8.6. Access Control, Stage 2: Request Verification .....	308
5.8.7. When Privilege Changes Take Effect .....	311
5.8.8. Causes of <code>Access denied</code> Errors .....	311
5.8.9. Password Hashing as of MySQL 4.1 .....	316
5.9. MySQL User Account Management .....	320
5.9.1. MySQL Usernames and Passwords .....	320
5.9.2. Adding New User Accounts to MySQL .....	322
5.9.3. Removing User Accounts from MySQL .....	325
5.9.4. Limiting Account Resources .....	325
5.9.5. Assigning Account Passwords .....	326
5.9.6. Keeping Your Password Secure .....	328
5.9.7. Using Secure Connections .....	329
5.10. Backup and Recovery .....	335
5.10.1. Database Backups .....	335
5.10.2. Example Backup and Recovery Strategy .....	337
5.10.3. Point-in-Time Recovery .....	340
5.10.4. Table Maintenance and Crash Recovery .....	342
5.11. MySQL Localization and International Usage .....	353
5.11.1. The Character Set Used for Data and Sorting .....	353
5.11.2. Setting the Error Message Language .....	354
5.11.3. Adding a New Character Set .....	354
5.11.4. The Character Definition Arrays .....	356
5.11.5. String Collating Support .....	356

---

---

5.11.6. Multi-Byte Character Support .....	357
5.11.7. Problems With Character Sets .....	357
5.11.8. MySQL Server Time Zone Support .....	357
5.12. MySQL Server Logs .....	359
5.12.1. The Error Log .....	359
5.12.2. The General Query Log .....	359
5.12.3. The Binary Log .....	360
5.12.4. The Slow Query Log .....	363
5.12.5. Server Log Maintenance .....	364
5.13. Running Multiple MySQL Servers on the Same Machine .....	365
5.13.1. Running Multiple Servers on Windows .....	366
5.13.2. Running Multiple Servers on Unix .....	369
5.13.3. Using Client Programs in a Multiple-Server Environment .....	371
5.14. The MySQL Query Cache .....	371
5.14.1. How the Query Cache Operates .....	372
5.14.2. Query Cache <code>SELECT</code> Options .....	373
5.14.3. Query Cache Configuration .....	374
5.14.4. Query Cache Status and Maintenance .....	375
6. Replication .....	377
6.1. Introduction to Replication .....	377
6.2. Replication Implementation Overview .....	377
6.3. Replication Implementation Details .....	378
6.3.1. Replication Master Thread States .....	379
6.3.2. Replication Slave I/O Thread States .....	380
6.3.3. Replication Slave SQL Thread States .....	381
6.3.4. Replication Relay and Status Files .....	381
6.4. How to Set Up Replication .....	383
6.5. Replication Compatibility Between MySQL Versions .....	387
6.6. Upgrading a Replication Setup .....	387
6.6.1. Upgrading Replication to 5.0 .....	387
6.7. Replication Features and Known Problems .....	388
6.8. Replication Startup Options .....	393
6.9. How Servers Evaluate Replication Rules .....	400
6.10. Replication FAQ .....	402
6.11. Troubleshooting Replication .....	408
6.12. How to Report Replication Bugs or Problems .....	409
6.13. Auto-Increment in Multiple-Master Replication .....	409
7. Optimization .....	411
7.1. Optimization Overview .....	411
7.1.1. MySQL Design Limitations and Tradeoffs .....	411
7.1.2. Designing Applications for Portability .....	412
7.1.3. What We Have Used MySQL For .....	413
7.1.4. The MySQL Benchmark Suite .....	413
7.1.5. Using Your Own Benchmarks .....	414
7.2. Optimizing <code>SELECT</code> and Other Statements .....	414
7.2.1. Optimizing Queries with <code>EXPLAIN</code> .....	415
7.2.2. Estimating Query Performance .....	424
7.2.3. Speed of <code>SELECT</code> Queries .....	424
7.2.4. <code>WHERE</code> Clause Optimization .....	425
7.2.5. Range Optimization .....	426
7.2.6. Index Merge Optimization .....	430
7.2.7. <code>IS NULL</code> Optimization .....	432
7.2.8. <code>DISTINCT</code> Optimization .....	433
7.2.9. <code>LEFT JOIN</code> and <code>RIGHT JOIN</code> Optimization .....	434
7.2.10. Nested Join Optimization .....	435
7.2.11. Outer Join Simplification .....	441
7.2.12. <code>ORDER BY</code> Optimization .....	443
7.2.13. <code>GROUP BY</code> Optimization .....	445
7.2.14. <code>LIMIT</code> Optimization .....	447
7.2.15. How to Avoid Table Scans .....	447
7.2.16. Speed of <code>INSERT</code> Statements .....	448
7.2.17. Speed of <code>UPDATE</code> Statements .....	450
7.2.18. Speed of <code>DELETE</code> Statements .....	450

---

---

7.2.19. Other Optimization Tips .....	450
7.3. Locking Issues .....	453
7.3.1. Locking Methods .....	453
7.3.2. Table Locking Issues .....	455
7.3.3. Concurrent Inserts .....	456
7.4. Optimizing Database Structure .....	457
7.4.1. Design Choices .....	457
7.4.2. Make Your Data as Small as Possible .....	457
7.4.3. Column Indexes .....	458
7.4.4. Multiple-Column Indexes .....	459
7.4.5. How MySQL Uses Indexes .....	459
7.4.6. The MyISAM Key Cache .....	462
7.4.7. MyISAM Index Statistics Collection .....	466
7.4.8. How MySQL Opens and Closes Tables .....	468
7.4.9. Drawbacks to Creating Many Tables in the Same Database .....	469
7.5. Optimizing the MySQL Server .....	469
7.5.1. System Factors and Startup Parameter Tuning .....	470
7.5.2. Tuning Server Parameters .....	470
7.5.3. Controlling Query Optimizer Performance .....	473
7.5.4. How Compiling and Linking Affects the Speed of MySQL .....	474
7.5.5. How MySQL Uses Memory .....	475
7.5.6. How MySQL Uses DNS .....	476
7.6. Disk Issues .....	477
7.6.1. Using Symbolic Links .....	478
8. Client and Utility Programs .....	481
8.1. Overview of Client and Utility Programs .....	481
8.2. <code>myisam_ftdump</code> — Display Full-Text Index information .....	483
8.3. <code>myisamchk</code> — MyISAM Table-Maintenance Utility .....	484
8.3.1. <code>myisamchk</code> General Options .....	485
8.3.2. <code>myisamchk</code> Check Options .....	487
8.3.3. <code>myisamchk</code> Repair Options .....	488
8.3.4. Other <code>myisamchk</code> Options .....	489
8.3.5. <code>myisamchk</code> Memory Usage .....	490
8.4. <code>myisamlog</code> — Display MyISAM Log File Contents .....	491
8.5. <code>myisampack</code> — Generate Compressed, Read-Only MyISAM Tables .....	492
8.6. <code>mysql</code> — The MySQL Command-Line Tool .....	498
8.6.1. <code>mysql</code> Options .....	498
8.6.2. <code>mysql</code> Commands .....	503
8.6.3. Executing SQL Statements from a Text File .....	506
8.6.4. <code>mysql</code> Tips .....	507
8.7. <code>mysqlaccess</code> — Client for Checking Access Privileges .....	508
8.8. <code>mysqladmin</code> — Client for Administering a MySQL Server .....	510
8.9. <code>mysqlbinlog</code> — Utility for Processing Binary Log Files .....	515
8.10. <code>mysqlcheck</code> — A Table Maintenance and Repair Program .....	521
8.11. <code>mysqldump</code> — A Database Backup Program .....	524
8.12. <code>mysqlhotcopy</code> — A Database Backup Program .....	531
8.13. <code>mysqlimport</code> — A Data Import Program .....	534
8.14. <code>mysqlshow</code> — Display Database, Table, and Column Information .....	536
8.15. <code>mysqlzap</code> — Kill Processes That Match a Pattern .....	538
8.16. <code>perror</code> — Explain Error Codes .....	539
8.17. <code>replace</code> — A String-Replacement Utility .....	539
9. Language Structure .....	541
9.1. Literal Values .....	541
9.1.1. Strings .....	541
9.1.2. Numbers .....	543
9.1.3. Hexadecimal Values .....	543
9.1.4. Boolean Values .....	544
9.1.5. Bit-Field Values .....	544
9.1.6. NULL Values .....	544
9.2. Database, Table, Index, Column, and Alias Names .....	544
9.2.1. Identifier Qualifiers .....	546
9.2.2. Identifier Case Sensitivity .....	546
9.3. User-Defined Variables .....	548

---

---

9.4. Comment Syntax .....	549
9.5. Treatment of Reserved Words in MySQL .....	550
10. Character Set Support .....	553
10.1. Character Sets and Collations in General .....	553
10.2. Character Sets and Collations in MySQL .....	554
10.3. Specifying Character Sets and Collations .....	555
10.3.1. Server Character Set and Collation .....	555
10.3.2. Database Character Set and Collation .....	556
10.3.3. Table Character Set and Collation .....	557
10.3.4. Column Character Set and Collation .....	557
10.3.5. Character String Literal Character Set and Collation .....	558
10.3.6. National Character Set .....	559
10.3.7. Examples of Character Set and Collation Assignment .....	559
10.3.8. Compatibility with Other DBMSs .....	560
10.4. Connection Character Sets and Collations .....	560
10.5. Collation Issues .....	562
10.5.1. Using COLLATE in SQL Statements .....	562
10.5.2. COLLATE Clause Precedence .....	563
10.5.3. BINARY Operator .....	563
10.5.4. Some Special Cases Where the Collation Determination Is Tricky .....	564
10.5.5. Collations Must Be for the Right Character Set .....	565
10.5.6. An Example of the Effect of Collation .....	565
10.6. Operations Affected by Character Set Support .....	566
10.6.1. Result Strings .....	566
10.6.2. CONVERT ( ) and CAST ( ) .....	567
10.6.3. SHOW Statements and INFORMATION_SCHEMA .....	568
10.7. Unicode Support .....	569
10.8. UTF-8 for Metadata .....	570
10.9. Character Sets and Collations That MySQL Supports .....	571
10.9.1. Unicode Character Sets .....	572
10.9.2. West European Character Sets .....	574
10.9.3. Central European Character Sets .....	576
10.9.4. South European and Middle East Character Sets .....	576
10.9.5. Baltic Character Sets .....	577
10.9.6. Cyrillic Character Sets .....	577
10.9.7. Asian Character Sets .....	578
11. Data Types .....	582
11.1. Data Type Overview .....	582
11.1.1. Overview of Numeric Types .....	582
11.1.2. Overview of Date and Time Types .....	585
11.1.3. Overview of String Types .....	586
11.1.4. Data Type Default Values .....	589
11.2. Numeric Types .....	590
11.3. Date and Time Types .....	592
11.3.1. The DATETIME, DATE, and TIMESTAMP Types .....	593
11.3.2. The TIME Type .....	598
11.3.3. The YEAR Type .....	599
11.3.4. Y2K Issues and Date Types .....	599
11.4. String Types .....	600
11.4.1. The CHAR and VARCHAR Types .....	600
11.4.2. The BINARY and VARBINARY Types .....	601
11.4.3. The BLOB and TEXT Types .....	603
11.4.4. The ENUM Type .....	604
11.4.5. The SET Type .....	605
11.5. Data Type Storage Requirements .....	608
11.6. Choosing the Right Type for a Column .....	610
11.7. Using Data Types from Other Database Engines .....	611
12. Functions and Operators .....	612
12.1. Operators .....	612
12.1.1. Operator Precedence .....	612
12.1.2. Type Conversion in Expression Evaluation .....	613
12.1.3. Comparison Functions and Operators .....	614
12.1.4. Logical Operators .....	618

---

---

12.2. Control Flow Functions .....	620
12.3. String Functions .....	622
12.3.1. String Comparison Functions .....	631
12.4. Numeric Functions .....	633
12.4.1. Arithmetic Operators .....	633
12.4.2. Mathematical Functions .....	634
12.5. Date and Time Functions .....	641
12.6. What Calendar Is Used By MySQL? .....	657
12.7. Full-Text Search Functions .....	658
12.7.1. Boolean Full-Text Searches .....	661
12.7.2. Full-Text Searches with Query Expansion .....	663
12.7.3. Full-Text Stopwords .....	664
12.7.4. Full-Text Restrictions .....	666
12.7.5. Fine-Tuning MySQL Full-Text Search .....	666
12.8. Cast Functions and Operators .....	668
12.9. Other Functions .....	670
12.9.1. Bit Functions .....	670
12.9.2. Encryption and Compression Functions .....	672
12.9.3. Information Functions .....	675
12.9.4. Miscellaneous Functions .....	681
12.10. Functions and Modifiers for Use with GROUP BY Clauses .....	684
12.10.1. GROUP BY (Aggregate) Functions .....	684
12.10.2. GROUP BY Modifiers .....	688
12.10.3. GROUP BY and HAVING with Hidden Fields .....	690
13. SQL Statement Syntax .....	692
13.1. Data Definition Statements .....	692
13.1.1. ALTER DATABASE Syntax .....	692
13.1.2. ALTER TABLE Syntax .....	692
13.1.3. CREATE DATABASE Syntax .....	697
13.1.4. CREATE INDEX Syntax .....	698
13.1.5. CREATE TABLE Syntax .....	699
13.1.6. DROP DATABASE Syntax .....	710
13.1.7. DROP INDEX Syntax .....	710
13.1.8. DROP TABLE Syntax .....	710
13.1.9. RENAME TABLE Syntax .....	711
13.2. Data Manipulation Statements .....	712
13.2.1. DELETE Syntax .....	712
13.2.2. DO Syntax .....	714
13.2.3. HANDLER Syntax .....	714
13.2.4. INSERT Syntax .....	716
13.2.5. LOAD DATA INFILE Syntax .....	722
13.2.6. REPLACE Syntax .....	730
13.2.7. SELECT Syntax .....	732
13.2.8. Subquery Syntax .....	746
13.2.9. TRUNCATE Syntax .....	756
13.2.10. UPDATE Syntax .....	756
13.3. MySQL Utility Statements .....	758
13.3.1. DESCRIBE Syntax .....	758
13.3.2. USE Syntax .....	759
13.4. MySQL Transactional and Locking Statements .....	759
13.4.1. START TRANSACTION, COMMIT, and ROLLBACK Syntax .....	759
13.4.2. Statements That Cannot Be Rolled Back .....	761
13.4.3. Statements That Cause an Implicit Commit .....	761
13.4.4. SAVEPOINT and ROLLBACK TO SAVEPOINT Syntax .....	762
13.4.5. LOCK TABLES and UNLOCK TABLES Syntax .....	762
13.4.6. SET TRANSACTION Syntax .....	765
13.4.7. XA Transactions .....	765
13.5. Database Administration Statements .....	769
13.5.1. Account Management Statements .....	769
13.5.2. Table Maintenance Statements .....	778
13.5.3. SET Syntax .....	784
13.5.4. SHOW Syntax .....	789
13.5.5. Other Administrative Statements .....	810

---

---

13.6. Replication Statements .....	814
13.6.1. SQL Statements for Controlling Master Servers .....	814
13.6.2. SQL Statements for Controlling Slave Servers .....	816
13.7. SQL Syntax for Prepared Statements .....	824
14. Storage Engines and Table Types .....	827
14.1. The MyISAM Storage Engine .....	829
14.1.1. MyISAM Startup Options .....	831
14.1.2. Space Needed for Keys .....	832
14.1.3. MyISAM Table Storage Formats .....	832
14.1.4. MyISAM Table Problems .....	834
14.2. The InnoDB Storage Engine .....	836
14.2.1. InnoDB Overview .....	836
14.2.2. InnoDB Contact Information .....	837
14.2.3. InnoDB Configuration .....	837
14.2.4. InnoDB Startup Options and System Variables .....	843
14.2.5. Creating the InnoDB Tablespace .....	849
14.2.6. Creating and Using InnoDB Tables .....	851
14.2.7. Adding and Removing InnoDB Data and Log Files .....	858
14.2.8. Backing Up and Recovering an InnoDB Database .....	859
14.2.9. Moving an InnoDB Database to Another Machine .....	861
14.2.10. InnoDB Transaction Model and Locking .....	862
14.2.11. InnoDB Performance Tuning Tips .....	871
14.2.12. Implementation of Multi-Versioning .....	877
14.2.13. InnoDB Table and Index Structures .....	878
14.2.14. InnoDB File Space Management and Disk I/O .....	880
14.2.15. InnoDB Error Handling .....	882
14.2.16. Restrictions on InnoDB Tables .....	888
14.2.17. InnoDB Troubleshooting .....	890
14.3. The MERGE Storage Engine .....	891
14.3.1. MERGE Table Problems .....	893
14.4. The MEMORY (HEAP) Storage Engine .....	894
14.5. The BDB (BerkeleyDB) Storage Engine .....	896
14.5.1. Operating Systems Supported by BDB .....	897
14.5.2. Installing BDB .....	897
14.5.3. BDB Startup Options .....	898
14.5.4. Characteristics of BDB Tables .....	899
14.5.5. Things We Need to Fix for BDB .....	900
14.5.6. Restrictions on BDB Tables .....	901
14.5.7. Errors That May Occur When Using BDB Tables .....	901
14.6. The EXAMPLE Storage Engine .....	902
14.7. The FEDERATED Storage Engine .....	902
14.7.1. Description of the FEDERATED Storage Engine .....	902
14.7.2. How to use FEDERATED Tables .....	903
14.7.3. Limitations of the FEDERATED Storage Engine .....	904
14.8. The ARCHIVE Storage Engine .....	905
14.9. The CSV Storage Engine .....	906
14.10. The BLACKHOLE Storage Engine .....	906
15. MySQL Cluster .....	909
15.1. MySQL Cluster Overview .....	909
15.2. Basic MySQL Cluster Concepts .....	910
15.2.1. MySQL Cluster Nodes, Node Groups, Replicas, and Partitions .....	912
15.3. Simple Multi-Computer How-To .....	914
15.3.1. Hardware, Software, and Networking .....	916
15.3.2. Multi-Computer Installation .....	916
15.3.3. Multi-Computer Configuration .....	918
15.3.4. Initial Startup .....	920
15.3.5. Loading Sample Data and Performing Queries .....	921
15.3.6. Safe Shutdown and Restart .....	924
15.4. MySQL Cluster Configuration .....	925
15.4.1. Building MySQL Cluster from Source Code .....	925
15.4.2. Installing the Software .....	926
15.4.3. Quick Test Setup of MySQL Cluster .....	926
15.4.4. Configuration File .....	928

---

---

15.5. Process Management in MySQL Cluster .....	954
15.5.1. MySQL Server Process Usage for MySQL Cluster .....	954
15.5.2. ndbd, the Storage Engine Node Process .....	955
15.5.3. ndb_mgmd, the Management Server Process .....	956
15.5.4. ndb_mgm, the Management Client Process .....	957
15.5.5. Command Options for MySQL Cluster Processes .....	957
15.5.6. Using CLUSTERLOG STATISTICS .....	960
15.6. Upgrading and Downgrading MySQL Cluster .....	960
15.6.1. Performing a Rolling Upgrade or Downgrade .....	961
15.6.2. Cluster Upgrade and Downgrade Compatibility .....	961
15.7. Management of MySQL Cluster .....	962
15.7.1. MySQL Cluster Startup Phases .....	962
15.7.2. Commands in the Management Client .....	964
15.7.3. Event Reports Generated in MySQL Cluster .....	965
15.7.4. Single-User Mode .....	970
15.7.5. On-line Backup of MySQL Cluster .....	971
15.8. Using High-Speed Interconnects with MySQL Cluster .....	974
15.8.1. Configuring MySQL Cluster to use SCI Sockets .....	974
15.8.2. Understanding the Impact of Cluster Interconnects .....	978
15.9. Known Limitations of MySQL Cluster .....	979
15.10. MySQL Cluster Development Roadmap .....	984
15.10.1. MySQL Cluster Changes in MySQL 5.0 .....	984
15.10.2. MySQL 5.1 Development Roadmap for MySQL Cluster .....	985
15.11. MySQL Cluster FAQ .....	985
15.12. MySQL Cluster Glossary .....	992
16. Spatial Extensions .....	997
16.1. Introduction to MySQL Spatial Support .....	997
16.2. The OpenGIS Geometry Model .....	998
16.2.1. The Geometry Class Hierarchy .....	998
16.2.2. Class Geometry .....	999
16.2.3. Class Point .....	1000
16.2.4. Class Curve .....	1001
16.2.5. Class LineString .....	1001
16.2.6. Class Surface .....	1001
16.2.7. Class Polygon .....	1002
16.2.8. Class GeometryCollection .....	1002
16.2.9. Class MultiPoint .....	1002
16.2.10. Class MultiCurve .....	1003
16.2.11. Class MultiLineString .....	1003
16.2.12. Class MultiSurface .....	1003
16.2.13. Class MultiPolygon .....	1003
16.3. Supported Spatial Data Formats .....	1004
16.3.1. Well-Known Text (WKT) Format .....	1004
16.3.2. Well-Known Binary (WKB) Format .....	1005
16.4. Creating a Spatially Enabled MySQL Database .....	1006
16.4.1. MySQL Spatial Data Types .....	1006
16.4.2. Creating Spatial Values .....	1006
16.4.3. Creating Spatial Columns .....	1009
16.4.4. Populating Spatial Columns .....	1009
16.4.5. Fetching Spatial Data .....	1011
16.5. Analyzing Spatial Information .....	1011
16.5.1. Geometry Format Conversion Functions .....	1011
16.5.2. Geometry Functions .....	1012
16.5.3. Functions That Create New Geometries from Existing Ones .....	1018
16.5.4. Functions for Testing Spatial Relations Between Geometric Objects .....	1019
16.5.5. Relations on Geometry Minimal Bounding Rectangles (MBRs) .....	1019
16.5.6. Functions That Test Spatial Relationships Between Geometries .....	1020
16.6. Optimizing Spatial Analysis .....	1021
16.6.1. Creating Spatial Indexes .....	1021
16.6.2. Using a Spatial Index .....	1023
16.7. MySQL Conformance and Compatibility .....	1024
17. Stored Procedures and Functions .....	1025
17.1. Stored Routines and the Grant Tables .....	1025

---

---

17.2. Stored Routine Syntax .....	1026
17.2.1. CREATE PROCEDURE and CREATE FUNCTION Syntax .....	1026
17.2.2. ALTER PROCEDURE and ALTER FUNCTION Syntax .....	1030
17.2.3. DROP PROCEDURE and DROP FUNCTION Syntax .....	1030
17.2.4. CALL Statement Syntax .....	1030
17.2.5. BEGIN . . . END Compound Statement Syntax .....	1031
17.2.6. DECLARE Statement Syntax .....	1031
17.2.7. Variables in Stored Routines .....	1031
17.2.8. Conditions and Handlers .....	1032
17.2.9. Cursors .....	1034
17.2.10. Flow Control Constructs .....	1035
17.3. Stored Procedures, Functions, Triggers, and Replication: Frequently Asked Questions .....	1038
17.4. Binary Logging of Stored Routines and Triggers .....	1039
18. Triggers .....	1048
18.1. CREATE TRIGGER Syntax .....	1048
18.2. DROP TRIGGER Syntax .....	1051
18.3. Using Triggers .....	1052
19. Views .....	1055
19.1. ALTER VIEW Syntax .....	1055
19.2. CREATE VIEW Syntax .....	1055
19.3. DROP VIEW Syntax .....	1062
20. The INFORMATION_SCHEMA Database .....	1063
20.1. The INFORMATION_SCHEMA SCHEMATA Table .....	1065
20.2. The INFORMATION_SCHEMA TABLES Table .....	1065
20.3. The INFORMATION_SCHEMA COLUMNS Table .....	1066
20.4. The INFORMATION_SCHEMA STATISTICS Table .....	1067
20.5. The INFORMATION_SCHEMA USER_PRIVILEGES Table .....	1068
20.6. The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table .....	1068
20.7. The INFORMATION_SCHEMA TABLE_PRIVILEGES Table .....	1069
20.8. The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table .....	1069
20.9. The INFORMATION_SCHEMA CHARACTER_SETS Table .....	1070

21.1. Types of Numeric Values .....	1079
21.2. DECIMAL Data Type Changes .....	1080
21.3. Expression Handling .....	1081
21.4. Rounding Behavior .....	1083
21.5. Precision Math Examples .....	1084
22. APIs and Libraries .....	1089
22.1. libmysqld, the Embedded MySQL Server Library .....	1089
22.1.1. Overview of the Embedded MySQL Server Library .....	1089
22.1.2. Compiling Programs with libmysqld .....	1089
22.1.3. Restrictions when using the Embedded MySQL Server .....	1090
22.1.4. Options with the Embedded Server .....	1090
22.1.5. Things left to do in Embedded Server (TODO) .....	1091
22.1.6. Embedded Server Examples .....	1091
22.1.7. Licensing the Embedded Server .....	1094
22.2. MySQL C API .....	1094
22.2.1. C API Data types .....	1095
22.2.2. C API Function Overview .....	1099
22.2.3. C API Function Descriptions .....	1102
22.2.4. C API Prepared Statements .....	1146
22.2.5. C API Prepared Statement Data types .....	1147

---

---

22.2.6. C API Prepared Statement Function Overview .....	1150
22.2.7. C API Prepared Statement Function Descriptions .....	1153
22.2.8. C API Prepared statement problems .....	1174
22.2.9. C API Handling of Multiple Query Execution .....	1175
22.2.10. C API Handling of Date and Time Values .....	1175
22.2.11. C API Threaded Function Descriptions .....	1176
22.2.12. C API Embedded Server Function Descriptions .....	1177
22.2.13. Common questions and problems when using the C API .....	1179
22.2.14. Building Client Programs .....	1181
22.2.15. How to Make a Threaded Client .....	1181
22.3. MySQL PHP API .....	1182
22.3.1. Common Problems with MySQL and PHP .....	1183
22.3.2. Enabling Both <code>mysql</code> and <code>mysql_i</code> in PHP .....	1183
22.4. MySQL Perl API .....	1184
22.5. MySQL C++ API .....	1185
22.5.1. Borland C++ .....	1185
22.6. MySQL Python API .....	1185
22.7. MySQL Tcl API .....	1185
22.8. MySQL Eiffel Wrapper .....	1185
22.9. MySQL Program Development Utilities .....	1185
22.9.1. <code>msql2mysql</code> — Convert mSQL Programs for Use with MySQL ..	1185
22.9.2. <code>mysql_config</code> — Get Compile Options for Compiling Clients ...	1186
23. Connectors .....	1188
23.1. MySQL Connector/ODBC .....	1188
23.1.1. Introduction to MyODBC .....	1188
23.1.2. General Information About ODBC and MyODBC .....	1191
23.1.3. How to Install MyODBC .....	1193
23.1.4. Installing MyODBC from a Binary Distribution on Windows .....	1194
23.1.5. Installing MyODBC from a Binary Distribution on Unix .....	1194
23.1.6. Installing MyODBC from a Source Distribution on Windows .....	1195
23.1.7. Installing MyODBC from a Source Distribution on Unix .....	1196
23.1.8. Installing MyODBC from the Development Source Tree .....	1202
23.1.9. MyODBC Configuration .....	1202
23.1.10. MyODBC Connection-Related Issues .....	1220
23.1.11. MyODBC and Microsoft Access .....	1220
23.1.12. MyODBC and Microsoft VBA and ASP .....	1225
23.1.13. MyODBC and Third-Party ODBC Tools .....	1226
23.1.14. MyODBC General Functionality .....	1227
23.1.15. Basic MyODBC Application Steps .....	1231
23.1.16. MyODBC API Reference .....	1232
23.1.17. MyODBC Data Types .....	1236
23.1.18. MyODBC Error Codes .....	1237
23.1.19. MyODBC With VB: ADO, DAO and RDO .....	1239
23.1.20. MyODBC with Microsoft .NET .....	1243
23.1.21. Credits .....	1246
23.2. MySQL Connector/NET .....	1246
23.2.1. Introduction .....	1246
23.2.2. Downloading and Installing MySQL Connector/NET .....	1247
23.2.3. Connector/NET Architecture .....	1248
23.2.4. Using MySQL Connector/NET .....	1261
23.2.5. MySQL Connector/NET Change History .....	1279
23.3. MySQL Connector/J .....	1295
23.3.1. Basic JDBC concepts .....	1295
23.3.2. Installing Connector/J .....	1305
23.3.3. JDBC Reference .....	1309
23.3.4. Using Connector/J with J2EE and Other Java Frameworks .....	1332
23.3.5. Diagnosing Connector/J Problems .....	1338
23.3.6. MySQL Connector/J Change History .....	1343
23.4. MySQL Connector/MXJ .....	1385
23.4.1. Introduction .....	1385
23.4.2. Supported Platforms .....	1385
23.4.3. JUnit Test Requirements .....	1385
23.4.4. Running the JUnit Tests .....	1386

---

---

23.4.5. Running as part of the JDBC Driver .....	1387
23.4.6. Running within a Java Object .....	1388
23.4.7. The MysqldResource API .....	1389
23.4.8. Running within a JMX Agent (custom) .....	1390
23.4.9. Deployment in a standard JMX Agent environment (JBoss) .....	1391
23.4.10. Installation .....	1392
23.5. Connector/PHP .....	1393
24. Extending MySQL .....	1394
24.1. MySQL Internals .....	1394
24.1.1. MySQL Threads .....	1394

# Preface

This is the Reference Manual for the MySQL Database System, version 5.0, up to release 5.0.22. It is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.0 and previous versions. If you are using an earlier release of the MySQL software, please refer to the *MySQL 3.23, 4.0, 4.1 Reference Manual*, which provides coverage of the 3.22, 3.23, 4.0, and 4.1 series of MySQL software releases. Differences between minor versions of MySQL 5.0 are noted in the present text with reference to release numbers (5.0.x).

---

# Chapter 1. General Information

The MySQL® software delivers a very fast, multi-threaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. MySQL is a registered trademark of MySQL AB.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (<http://www.fsf.org/licenses/>) or can purchase a standard commercial license from MySQL AB. See <http://www.mysql.com/company/legal/licensing/> for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion about the capabilities of the MySQL Database Server, see Section 1.4.2, “The Main Features of MySQL”.
- For installation instructions, see Chapter 2, *Installing and Upgrading MySQL*. For information about upgrading MySQL, see Section 2.11, “Upgrading MySQL”.
- For information about configuring and administering MySQL Server, see Chapter 5, *Database Administration*.
- For information about setting up replication servers, see Chapter 6, *Replication*.
- For tips on porting the MySQL Database Software to new architectures or operating systems, see Appendix E, *Porting to Other Systems*.
- For a tutorial introduction to the MySQL Database Server, see Chapter 3, *Tutorial*.
- For benchmarking information, see the `sql-bench` benchmarking directory in your MySQL distribution.
- For a history of new features and bugfixes, see Appendix D, *MySQL Change History*.
- For a list of currently known bugs and misfeatures, see Section A.8, “Known Issues in MySQL”.
- For future plans, see Section 1.6, “MySQL Development Roadmap”.
- For a list of all the contributors to this project, see Appendix C, *Credits*.

## **Important:**

To report errors (often called “bugs”), please use the instructions at Section 1.8, “How to Report Bugs or Problems”.

If you have found a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to `<security@mysql.com>`.

## 1.1. About This Manual

This is the Reference Manual for the MySQL Database System, version 5.0, through release 5.0.22. It is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.0 and previous versions. If you are using a version 4.1 release of the MySQL software, please refer to the *MySQL 3.23, 4.0, 4.1 Reference Manual*, which covers the 3.23, 4.0, and 4.1 series of MySQL software releases. Differences between minor versions of MySQL 5.0 are noted in the present text with reference to release numbers (5.0.x).

Because this manual serves as a reference, it does not provide general instruction on SQL or rela-

tional database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at <http://dev.mysql.com/doc/>. Other formats also are available there, including HTML, PDF, and Windows CHM versions.

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see <http://docbook.org/>

The DocBook XML sources of this manual are available from <http://svn.mysql.com/svnpublic/mysql/doc/>.

If you have any suggestions concerning additions or corrections to this manual, please send them to the documentation team at [<docs@mysql.com>](mailto:docs@mysql.com).

This manual was originally written by David Axmark and Michael “Monty” Widenius. It is maintained by the MySQL Documentation Team, consisting of Paul DuBois, Stefan Hinz, Mike Hillyer, and Jon Stephens. For the many other contributors, see Appendix C, *Credits*.

The copyright to this manual is owned by the Swedish company MySQL AB. MySQL® and the MySQL logo are registered trademarks of MySQL AB. Other trademarks and registered trademarks referred to in this manual are the property of their respective owners, and are used for identification purposes only.

## 1.2. Conventions Used in This Manual

This manual uses certain typographical conventions:

- *Text in this style* is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”
- **Text in this style** indicates input that you type in examples.
- *Text in this style* indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command line client program) and `mysqld` (the MySQL server executable).
- *Text in this style* is used for variable input for which you should substitute a value of your own choosing.
- Filenames and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the ‘`%`’ character.”
- *Text in this style* is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell, and `mysql>` indicates a statement that you execute from the `mysql` client program:

```
shell> type a shell command here
mysql> type a mysql statement here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csch`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses *db\_name*, *tbl\_name*, and *col\_name*. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets (‘[’ and ‘]’) indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (‘|’). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets (‘[’ and ‘]’):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces (‘{’ and ‘}’):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (‘...’) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `INSERT ... SELECT` is shorthand for the form of `INSERT` statement that is followed by a `SELECT` statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple *reset\_option* values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csch` or `tcsh`, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

## 1.3. Overview of MySQL AB

MySQL AB is the company of the MySQL founders and main developers. MySQL AB was originally established in Sweden by David Axmark, Allan Larsson, and Michael “Monty” Widenius.

We are dedicated to developing the MySQL database software and promoting it to new users. MySQL AB owns the copyright to the MySQL source code, the MySQL logo and (registered) trademark, and this manual. See Section 1.4, “Overview of the MySQL Database Management System”.

The MySQL core values show our dedication to MySQL and Open Source.

These core values direct how MySQL AB works with the MySQL server software:

- To be the best and the most widely used database in the world
- To be available and affordable by all
- To be easy to use
- To be continuously improved while remaining fast and safe
- To be fun to use and improve
- To be free from bugs

These are the core values of the company MySQL AB and its employees:

- We subscribe to the Open Source philosophy and support the Open Source community
- We aim to be good citizens
- We prefer partners that share our values and mindset
- We answer email and provide support
- We are a virtual company, networking with others
- We work against software patents

The MySQL Web site (<http://www.mysql.com/>) provides the latest information about MySQL and MySQL AB.

By the way, the “AB” part of the company name is the acronym for the Swedish “aktiebolag,” or “stock company.” It translates to “MySQL, Inc.” In fact, MySQL, Inc. and MySQL GmbH are examples of MySQL AB subsidiaries. They are located in the United States and Germany, respectively.

## 1.4. Overview of the MySQL Database Management System

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by MySQL AB. MySQL AB is a commercial company, founded by the MySQL developers. It is a second generation Open Source company that unites Open Source values and methodology with a successful business model.

The MySQL Web site (<http://www.mysql.com/>) provides the latest information about MySQL software and MySQL AB.

- MySQL is a database management system.

A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- MySQL is a relational database management system.

A relational database stores data in separate tables rather than putting all the data in one big storeroom. This adds speed and flexibility. The SQL part of “MySQL” stands for “Structured Query Language.” SQL is the most common standardized language used to access databases and is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, and “SQL:2003” refers to the current version of the standard. We use the phrase “the SQL standard” to mean the current version of the SQL Standard at any time.

- MySQL software is Open Source.

Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), <http://www.fsf.org/licenses/>, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (<http://www.mysql.com/company/legal/licensing/>).

- The MySQL Database Server is very fast, reliable, and easy to use.

If that is what you are looking for, you should give it a try. MySQL Server also has a practical set of features developed in close cooperation with our users. You can find a performance comparison of MySQL Server with other database managers on our benchmark page. See Section 7.1.4, “The MySQL Benchmark Suite”.

MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- MySQL Server works in client/server or embedded systems.

The MySQL Database Software is a client/server system that consists of a multi-threaded SQL server that supports different backends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

We also provide MySQL Server as an embedded multi-threaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- A large amount of contributed MySQL software is available.

It is very likely that your favorite application or language supports the MySQL Database Server.

The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we don't mind if you pronounce it as “my sequel” or in some other localized way.

## 1.4.1. History of MySQL

We started out with the intention of using the `mSQL` database system to connect to our tables using our own fast low-level (`ISAM`) routines. However, after some testing, we came to the conclusion that `mSQL` was not fast enough or flexible enough for our needs. This resulted in a new `SQL` interface to our database but with almost the same `API` interface as `mSQL`. This `API` was designed to allow third-party code that was written for use with `mSQL` to be ported easily for use with `MySQL`.

The derivation of the name `MySQL` is not clear. Our base directory and a large number of our libraries and tools have had the prefix “my” for well over 10 years. However, co-founder Monty Widenius's daughter is also named My. Which of the two gave its name to `MySQL` is still a mystery, even for us.

The name of the `MySQL` Dolphin (our logo) is “Sakila,” which was chosen by the founders of `MySQL` AB from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Swaziland, Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Swaziland. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose's country of origin, Uganda.

## 1.4.2. The Main Features of `MySQL`

The following list describes some of the important characteristics of the `MySQL` Database Software. See also Section 1.6, “`MySQL` Development Roadmap”, for more information about current and upcoming features.

Internals and Portability:

- Written in C and C++.
- Tested with a broad range of different compilers.
- Works on many different platforms. See Section 2.1.1, “Operating Systems Supported by `MySQL`”.
- Uses GNU Automake, Autoconf, and Libtool for portability.
- `APIs` for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available. See Chapter 22, *APIs and Libraries*.
- Fully multi-threaded using kernel threads. It can easily use multiple CPUs if they are available.
- Provides transactional and non-transactional storage engines.
- Uses very fast B-tree disk tables (`MyISAM`) with index compression.
- Relatively easy to add other storage engines. This is useful if you want to add an `SQL` interface to an in-house database.
- A very fast thread-based memory allocation system.
- Very fast joins using an optimized one-sweep multi-join.
- In-memory hash tables, which are used as temporary tables.
- `SQL` functions are implemented using a highly optimized class library and should be as fast as possible. Usually there is no memory allocation at all after query initialization.
- The `MySQL` code is tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (<http://developer.kde.org/~sewardj/>).
- The server is available as a separate program for use in a client/server networked environment. It is also available as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

Data Types:

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, FLOAT, DOUBLE, CHAR, VARCHAR, TEXT, BLOB, DATE, TIME, DATETIME, TIMESTAMP, YEAR, SET, ENUM, and OpenGIS spatial types. See Chapter 11, *Data Types*.
- Fixed-length and variable-length records.

Statements and Functions:

- Full operator and function support in the SELECT and WHERE clauses of queries. For example:

```
mysql> SELECT CONCAT(first_name, ' ', last_name)
-> FROM citizen
-> WHERE income/dependents > 10000 AND age > 30;
```

- Full support for SQL GROUP BY and ORDER BY clauses. Support for group functions (COUNT(), COUNT(DISTINCT ...), AVG(), STD(), SUM(), MAX(), MIN(), and GROUP\_CONCAT()).
- Support for LEFT OUTER JOIN and RIGHT OUTER JOIN with both standard SQL and ODBC syntax.
- Support for aliases on tables and columns as required by standard SQL.
- DELETE, INSERT, REPLACE, and UPDATE return the number of rows that were changed (affected). It is possible to return the number of rows matched instead by setting a flag when connecting to the server.
- The MySQL-specific SHOW command can be used to retrieve information about databases, database engines, tables, and indexes.

The EXPLAIN command can be used to determine how the optimizer resolves a query.

- Function names do not clash with table or column names. For example, ABS is a valid column name. The only restriction is that for a function call, no spaces are allowed between the function name and the '(' that follows it. See Section 9.5, "Treatment of Reserved Words in MySQL".
- You can mix tables from different databases in the same query (as of MySQL 3.22).

Security:

- A privilege and password system that is very flexible and secure, and that allows host-based verification. Passwords are secure because all password traffic is encrypted when you connect to a server.

Scalability and Limits:

- Handles large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 60,000 tables and about 5,000,000,000 rows.
- Up to 64 indexes per table are allowed (32 before MySQL 4.1.2). Each index may consist of 1 to 16 columns or parts of columns. The maximum index width is 1000 bytes (767 for InnoDB); before MySQL 4.1.2, the limit is 500 bytes. An index may use a prefix of a column for CHAR, VARCHAR, BLOB, or TEXT column types.

Connectivity:

- Clients can connect to the MySQL server using TCP/IP sockets on any platform. On Windows systems in the NT family (NT, 2000, XP, or 2003), clients can connect using named pipes. On Unix systems, clients can connect using Unix domain socket files.
- In MySQL 4.1 and higher, Windows servers also support shared-memory connections if started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=memory` option.
- The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. MyODBC source is available. All ODBC 2.5 functions are supported, as are many others. See Chapter 23, *Connectors*.
- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See Chapter 23, *Connectors*.
- MySQL Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/NET is a fully managed ADO.NET driver written in 100% pure C#. See Chapter 23, *Connectors*.

Localization:

- The server can provide error messages to clients in many languages. See Section 5.11.2, “Setting the Error Message Language”.
- Full support for several different character sets, including `latin1 (cp1252)`, `german`, `big5`, `ujis`, and more. For example, the Scandinavian characters ‘å’, ‘ä’ and ‘ö’ are allowed in table and column names. Unicode support is available as of MySQL 4.1.
- All data is saved in the chosen character set. All comparisons for normal string columns are case-insensitive.
- Sorting is done according to the chosen character set (using Swedish collation by default). It is possible to change this when the MySQL server is started. To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.

Clients and Tools:

- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the `mysqlcheck` client. MySQL also includes `myisamchk`, a very fast command-line utility for performing these operations on MyISAM tables. See Chapter 5, *Database Administration*.
- All MySQL programs can be invoked with the `--help` or `-?` options to obtain online assistance.

### 1.4.3. MySQL Stability

This section addresses the questions, “*How stable is MySQL Server?*” and, “*Can I depend on MySQL Server in this project?*” We will try to clarify these issues and answer some important ques-

tions that concern many potential users. The information in this section is based on data gathered from the mailing lists, which are very active in identifying problems as well as reporting types of use.

The original code stems back to the early 1980s. It provides a stable code base, and the ISAM table format used by the original storage engine remains backward-compatible. At TcX, the predecessor of MySQL AB, MySQL code has worked in projects since mid-1996, without any problems. When the MySQL Database Software initially was released to a wider public, our new users quickly found some pieces of untested code. Each new release since then has had fewer portability problems, even though each new release has also had many new features.

Each release of the MySQL Server has been usable. Problems have occurred only when users try code from the “gray zones.” Naturally, new users don't know what the gray zones are; this section therefore attempts to document those areas that are currently known. The descriptions mostly deal with Versions 3.23 and later of MySQL Server. All known and reported bugs are fixed in the latest version, with the exception of those listed in the bugs section, which are design-related. See Section A.8, “Known Issues in MySQL”.

The MySQL Server design is multi-layered with independent modules. Some of the newer modules are listed here with an indication of how well-tested each of them is:

- Replication (Stable)

Large groups of servers using replication are in production use, with good results. Work on enhanced replication features is continuing.

- InnoDB tables (Stable)

The InnoDB transactional storage engine has been stable since version 3.23.49. InnoDB is being used in large, heavy-load production systems.

- BDB tables (Stable)

The Berkeley DB code is very stable, but we are still improving the BDB transactional storage engine interface in MySQL Server.

- Full-text searches (Stable)

Full-text searching is widely used. Important feature enhancements were added in MySQL 4.0 and 4.1.

- MyODBC 3.51 (Stable)

MyODBC 3.51 uses ODBC SDK 3.51 and is in wide production use. Some issues brought up appear to be application-related and independent of the ODBC driver or underlying database server.

## 1.4.4. How Large MySQL Tables Can Be

MySQL 3.22 had a 4GB (4 gigabyte) limit on table size. With the MyISAM storage engine in MySQL 3.23, the maximum table size was increased to 65536 terabytes ( $256^7 - 1$  bytes). With this larger allowed table size, the maximum effective table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits.

The InnoDB storage engine maintains InnoDB tables within a tablespace that can be created from several files. This allows a table to exceed the maximum individual file size. The tablespace can include raw disk partitions, which allows extremely large tables. The maximum tablespace size is 64TB.

The following table lists some examples of operating system file-size limits. This is only a rough guide and is not intended to be definitive. For the most up-to-date information, be sure to check the documentation specific to your operating system.

Operating System	File-size Limit
Linux 2.2-Intel 32-bit	2GB (LFS: 4GB)
Linux 2.4+	(using ext3 filesystem) 4TB
Solaris 9/10	16TB
NetWare w/NSS filesystem	8TB
Win32 w/ FAT/FAT32	2GB/4GB
Win32 w/ NTFS	2TB (possibly larger)
MacOS X w/ HFS+	2TB

On Linux 2.2, you can get MyISAM tables larger than 2GB in size by using the Large File Support (LFS) patch for the ext2 filesystem. On Linux 2.4, patches also exist for ReiserFS to get support for big files (up to 2TB). Most current Linux distributions are based on kernel 2.4 or higher and include all the required LFS patches. With JFS and XFS, petabyte and larger files are possible on Linux. However, the maximum available file size still depends on several factors, one of them being the filesystem used to store MySQL tables.

For a detailed overview about LFS in Linux, have a look at Andreas Jaeger's *Large File Support in Linux* page at [http://www.suse.de/~aj/linux\\_lfs.html](http://www.suse.de/~aj/linux_lfs.html).

Windows users please note: FAT and VFAT (FAT32) are *not* considered suitable for production use with MySQL. Use NTFS instead.

By default, MySQL creates MyISAM tables with an internal structure that allows a maximum size of about 4GB. You can check the maximum table size for a MyISAM table with the `SHOW TABLE STATUS` statement or with `myisamchk -dv tbl_name`. See Section 13.5.4, “SHOW Syntax”.

If you need a MyISAM table that is larger than 4GB and your operating system supports large files, the `CREATE TABLE` statement supports `AVG_ROW_LENGTH` and `MAX_ROWS` options. See Section 13.1.5, “CREATE TABLE Syntax”. You can also change these options with `ALTER TABLE` to increase a table's maximum allowable size after the table has been created. See Section 13.1.2, “ALTER TABLE Syntax”.

Other ways to work around file-size limits for MyISAM tables are as follows:

- If your large table is read-only, you can use `myisampack` to compress it. `myisampack` usually compresses a table by at least 50%, so you can have, in effect, much bigger tables. `myisampack` also can merge multiple tables into a single table. See Section 8.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”.
- MySQL includes a `MERGE` library that allows you to handle a collection of MyISAM tables that have identical structure as a single `MERGE` table. See Section 14.3, “The MERGE Storage Engine”.

## 1.4.5. Year 2000 Compliance

The MySQL Server itself has no problems with Year 2000 (Y2K) compliance:

- MySQL Server uses Unix time functions that handle dates into the year 2037 for `TIMESTAMP` values. For `DATE` and `DATETIME` values, dates through the year 9999 are accepted.
- All MySQL date functions are implemented in one source file, `sql/time.cc`, and are coded very carefully to be year 2000-safe.
- In MySQL, the `YEAR` data type can store the years 0 and 1901 to 2155 in one byte and display them using two or four digits. All two-digit years are considered to be in the range 1970 to 2069, which means that if you store 01 in a `YEAR` column, MySQL Server treats it as 2001.

The following simple demonstration illustrates that MySQL Server has no problems with DATE or DATETIME values through the year 9999, and no problems with TIMESTAMP values until after the year 2030:

```
mysql> DROP TABLE IF EXISTS y2k;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE y2k (date DATE,
->                          date_time DATETIME,
->                          time_stamp TIMESTAMP);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO y2k VALUES
-> ('1998-12-31','1998-12-31 23:59:59','1998-12-31 23:59:59'),
-> ('1999-01-01','1999-01-01 00:00:00','1999-01-01 00:00:00'),
-> ('1999-09-09','1999-09-09 23:59:59','1999-09-09 23:59:59'),
-> ('2000-01-01','2000-01-01 00:00:00','2000-01-01 00:00:00'),
-> ('2000-02-28','2000-02-28 00:00:00','2000-02-28 00:00:00'),
-> ('2000-02-29','2000-02-29 00:00:00','2000-02-29 00:00:00'),
-> ('2000-03-01','2000-03-01 00:00:00','2000-03-01 00:00:00'),
-> ('2000-12-31','2000-12-31 23:59:59','2000-12-31 23:59:59'),
-> ('2001-01-01','2001-01-01 00:00:00','2001-01-01 00:00:00'),
-> ('2004-12-31','2004-12-31 23:59:59','2004-12-31 23:59:59'),
-> ('2005-01-01','2005-01-01 00:00:00','2005-01-01 00:00:00'),
-> ('2030-01-01','2030-01-01 00:00:00','2030-01-01 00:00:00'),
-> ('2040-01-01','2040-01-01 00:00:00','2040-01-01 00:00:00'),
-> ('9999-12-31','9999-12-31 23:59:59','9999-12-31 23:59:59');
Query OK, 14 rows affected, 2 warnings (0.00 sec)
Records: 14 Duplicates: 0 Warnings: 2
```

```
mysql> SELECT * FROM y2k;
```

date	date_time	time_stamp
1998-12-31	1998-12-31 23:59:59	1998-12-31 23:59:59
1999-01-01	1999-01-01 00:00:00	1999-01-01 00:00:00
1999-09-09	1999-09-09 23:59:59	1999-09-09 23:59:59
2000-01-01	2000-01-01 00:00:00	2000-01-01 00:00:00
2000-02-28	2000-02-28 00:00:00	2000-02-28 00:00:00
2000-02-29	2000-02-29 00:00:00	2000-02-29 00:00:00
2000-03-01	2000-03-01 00:00:00	2000-03-01 00:00:00
2000-12-31	2000-12-31 23:59:59	2000-12-31 23:59:59
2001-01-01	2001-01-01 00:00:00	2001-01-01 00:00:00
2004-12-31	2004-12-31 23:59:59	2004-12-31 23:59:59
2005-01-01	2005-01-01 00:00:00	2005-01-01 00:00:00
2030-01-01	2030-01-01 00:00:00	2030-01-01 00:00:00
2040-01-01	2040-01-01 00:00:00	0000-00-00 00:00:00
9999-12-31	9999-12-31 23:59:59	0000-00-00 00:00:00

```
14 rows in set (0.00 sec)
```

The final two `TIMESTAMP` column values are zero because the year values (2040, 9999) exceed the `TIMESTAMP` maximum. The `TIMESTAMP` data type, which is used to store the current time, supports values that range from '1970-01-01 00:00:00' to '2030-01-01 00:00:00' on 32-bit machines (signed value). On 64-bit machines, `TIMESTAMP` handles values up to 2106 (unsigned value).

Although MySQL Server itself is Y2K-safe, you may run into problems if you use it with applications that are not Y2K-safe. For example, many old applications store or manipulate years using two-digit values (which are ambiguous) rather than four-digit values. This problem may be compounded by applications that use values such as 00 or 99 as “missing” value indicators. Unfortunately, these problems may be difficult to fix because different applications may be written by different programmers, each of whom may use a different set of conventions and date-handling functions.

Thus, even though MySQL Server has no Y2K problems, *it is the application's responsibility to*

*provide unambiguous input.* See Section 11.3.4, “Y2K Issues and Date Types”, for MySQL Server's rules for dealing with ambiguous date input data that contains two-digit year values.

## 1.5. Overview of the MaxDB Database Management System

MaxDB is a heavy-duty enterprise database. The database management system is SAP-certified.

MaxDB is the new name of a database management system formerly called SAP DB. In 2003 SAP AG and MySQL AB joined a partnership and re-branded the database system to MaxDB. The development of MaxDB has continued since then as it was done before—through the SAP developer team.

MySQL AB cooperates closely with the MaxDB team at SAP around delivering improvements to the MaxDB product. Joint efforts include development of new native drivers to enable more efficient usage of MaxDB in the Open Source community, and improvement of documentation to expand the MaxDB user base. Interoperability features between MySQL and MaxDB database also are seen as important. For example, the new MaxDB Synchronization Manager supports data synchronization from MaxDB to MySQL.

The MaxDB database management system does not share a common code-base with the MySQL database management system. The MaxDB and MySQL database management systems are independent products provided by MySQL AB.

MySQL AB offers a complete portfolio of Professional Services for MaxDB.

### 1.5.1. What is MaxDB?

MaxDB is an ANSI SQL-92 (entry level) compliant relational database management system (RDBMS) from SAP AG, that is delivered by MySQL AB as well. MaxDB fulfills the needs for enterprise usage: safety, scalability, high concurrency, and performance. It runs on all major operating systems. Over the years it has proven able to run SAP R/3 and terabytes of data in 24×7 operation.

The database development started in 1977 as a research project at the Technical University of Berlin. In the early 1980s it became a database product that subsequently was owned by Nixdorf, Siemens Nixdorf, Software AG, and today by SAP AG. Along the way, it has been named VDN, Reflex, Supra 2, DDB/4, Entire SQL-DB-Server, and ADABAS D. In 1997, SAP took over the software from Software AG and renamed it to SAP DB. Since October 2000, SAP DB sources additionally were released as Open Source under the GNU General Public License (see Appendix J, *GNU General Public License*).

In 2003, SAP AG and MySQL AB formed a partnership and re-branded the database system to MaxDB.

### 1.5.2. History of MaxDB

The history of MaxDB goes back to SAP DB, SAP AG's DBMS. That is, MaxDB is a re-branded and enhanced version of SAP DB. For many years, MaxDB has been used for small, medium, and large installations of the mySAP Business Suite and other demanding SQL applications requiring an enterprise-class DBMS with regard to the number of users, the transactional workload, and the size of the database.

SAP DB was meant to provide an alternative to third-party database systems such as Oracle, Microsoft SQL Server, and DB2 by IBM. In October 2000, SAP AG released SAP DB under the GNU GPL license (see Appendix J, *GNU General Public License*), thus making it Open Source software.

Today, MaxDB is used in about 3,500 SAP customer installations worldwide. Moreover, the majority of all DBMS installations on Unix and Linux within SAP's IT department rely on MaxDB. MaxDB is tuned toward heavy-duty online transaction processing (OLTP) with several thousand users and database sizes ranging from several hundred GB to multiple TB.

In 2003, SAP and MySQL concluded a partnership and development cooperation agreement. As a result, SAP's database system SAP DB has been delivered under the name of MaxDB by MySQL since the release of version 7.5 (November 2003).

Version 7.5 of MaxDB is a direct advancement of the SAP DB 7.4 code base. Therefore, the MaxDB software version 7.5 can be used as a direct upgrade of previous SAP DB versions starting 7.2.04 and higher.

The former SAP DB development team at SAP AG is responsible, now as before, for developing and supporting MaxDB. MySQL AB cooperates closely with the MaxDB team at SAP around delivering improvements to the MaxDB product, see Section 1.5, "Overview of the MaxDB Database Management System". Both SAP AG and MySQL AB handle the sale and distribution of MaxDB. The advancement of MaxDB and the MySQL Server leverages synergies that benefit both product lines.

MaxDB is subjected to SAP AG's complete quality assurance process before it is shipped with SAP solutions or provided as a download from the MySQL site.

### 1.5.3. Features of MaxDB

MaxDB is a heavy-duty, SAP-certified Open Source database for OLTP and OLAP usage which offers high reliability, availability, scalability, and a very comprehensive feature set. It is targeted for large mySAP Business Suite environments and other applications that require maximum enterprise-level database functionality and complements the MySQL database server.

MaxDB operates as a client/server product. It was developed to meet the needs of installations in OLTP and Data Warehouse/OLAP/Decision Support scenarios and offers these benefits:

- **Easy configuration and administration:** GUI-based Installation Manager and Database Manager as single administration tools for DBMS operations
- **Around-the-clock operation, no planned downtimes, no permanent attendance required:** Automatic space management, no need for reorganizations
- **Sophisticated backup and restore capabilities:** Online and incremental backups, recovery wizard to guide you through the recovery scenario
- **Supports large number of users, database sizes in the terabytes, and demanding workloads:** Proven reliability, performance, and scalability
- **High availability:** Cluster support, standby configuration, hot standby configuration

### 1.5.4. Licensing and Support

MaxDB can be used under the same licenses available for the other products distributed by MySQL AB. Thus, MaxDB is available under the GNU General Public License, and a commercial license. For more information on licensing, see <http://www.mysql.com/company/legal/licensing/>.

MySQL AB offers MaxDB technical support to non-SAP customers. MaxDB support is available on various levels (Basic, Silver, and Gold), which expand from unlimited email/web-support to 24x7 phone support for business critical systems.

MySQL AB also offers Licenses and Support for MaxDB when used with SAP Applications, like SAP NetWeaver and mySAP Business Suite. For more information on licenses and support for your needs, please contact MySQL AB. (See <http://www.mysql.com/company/contact/>.)

Consulting and training services are available. MySQL gives classes on MaxDB at regular intervals. See <http://www.mysql.com/training/> for a list of classes.

## 1.5.5. Feature Differences Between MaxDB and MySQL

MaxDB is MySQL AB's SAP-certified database. The MaxDB database server complements the MySQL AB product portfolio. Some MaxDB features are not available on the MySQL database management server and vice versa.

The following list summarizes the main differences between MaxDB and MySQL; it is not complete.

- MaxDB runs as a client/server system. MySQL can run as a client/server system or as an embedded system.
- MaxDB might not run on all platforms supported by MySQL.
- MaxDB uses a proprietary network protocol for client/server communication. MySQL uses either TCP/IP (with or without SSL encryption), sockets (under Unix-like systems), or named pipes or shared memory (under Windows NT-family systems).
- MaxDB supports stored procedures and functions. MySQL 5.0 and up also supports stored procedures and function and functions. MaxDB supports programming of triggers through an SQL extension. MySQL 5.0 supports triggers. MaxDB contains a debugger for stored procedure languages, can cascade nested triggers, and supports multiple triggers per action and row.
- MaxDB is distributed with user interfaces that are text-based, graphical, or Web-based. MySQL is distributed with text-based user interfaces only; graphical user interfaces (MySQL Query Browser, MySQL Administrator) are shipped separately from the main distributions. Web-based user interfaces for MySQL are offered by third parties.
- MaxDB supports a number of programming interfaces that also are supported by MySQL. For developing with MaxDB, the MaxDB ODBC Driver, SQL Database Connectivity (SQLDBC), JDBC Driver, Perl and Python modules and a MaxDB PHP extension, which provides access to MySQL MaxDB databases using PHP, are available. Third Party Programming Interfaces: Support for OLE DB, ADO, DAO, RDO and .NET through ODBC. MaxDB supports embedded SQL with C/C++.
- MaxDB includes administrative features that MySQL does not have: job scheduling by time, event, and alert, and sending messages to a database administrator on alert thresholds. (MySQL has scheduling support starting with version 5.1.6.)

## 1.5.6. Interoperability Features Between MaxDB and MySQL

MaxDB and MySQL are independent database management servers. The interoperation of the systems is possible in a way that the systems can exchange their data. To exchange data between MaxDB and MySQL, you can use the import and export tools of the systems or the MaxDB Synchronization Manager. The import and export tools can be used to transfer data in an infrequent, manual fashion. The MaxDB Synchronization Manager offers faster, automatic data transfer capabilities.

The MaxDB Loader can be used to export data and object definitions. The Loader can export data using MaxDB internal, binary formats and text formats (CSV). Data exported from MaxDB in text formats can be imported into MySQL using the `mysqlimport` client program. To export MySQL data, you can use either `mysqldump` to create `INSERT` statements or `SELECT ... INTO OUTFILE` to create a text file (CSV). Use the MaxDB Loader to import the data files generated by MySQL.

Object definitions can be exchanged between the systems using MaxDB Loader and the MySQL tool `mysqldump`. As the SQL dialects of both systems differ slightly and MaxDB has features currently not supported by MySQL like SQL constraints, we recommend to hand-tune the definition files. The `mysqldump` tool offers an option `--compatible=maxdb` to produce output that is

compatible with MaxDB to make porting easier.

The MaxDB Synchronization Manager is available as part of MaxDB 7.6. The Synchronization Manager supports creation of asynchronous replication scenarios between several MaxDB instances. However, interoperability features also are planned, so that the Synchronization Manager supports replication to and from a MySQL server.

In the first release, the Synchronization Manager supports inserting data into MySQL. This means that initially only replication from MaxDB to MySQL is supported. In the course of 2005, exporting of data from a MySQL server to the Synchronization Manager will be added, thus adding support for MySQL to MaxDB replication scenarios.

## 1.5.7. MaxDB-Related Links

The main page for MaxDB information is <http://www.mysql.com/products/maxdb>, which provides details about the features of the MaxDB database management systems and has pointers to available documentation.

The MySQL Reference Manual does not contain any MaxDB documentation other than the introduction given in this section. MaxDB has its own documentation, which is called the MaxDB library and is available at <http://dev.mysql.com/doc/maxdb/index.html>.

MySQL AB runs a community mailing list on MaxDB; see <http://lists.mysql.com/maxdb>. The list shows a vivid community discussion. Many of the core developers contribute to it. Product announcements are sent to the list.

A Web forum on MaxDB is available at <http://forums.mysql.com/>. The forum focuses on MaxDB questions not related to SAP applications.

## 1.6. MySQL Development Roadmap

This section provides a snapshot of the MySQL development roadmap, including major features implemented in or planned for various MySQL releases. The following sections provide information for each release series.

The current production release series is MySQL 5.0, which was declared stable for production use as of MySQL 5.0.15, released in October 2005. The previous production release series was MySQL 4.1, which was declared stable for production use as of MySQL 4.1.7, released in October 2004. “Production status” means that future 5.0 and 4.1 development is limited only to bugfixes. For the older MySQL 4.0 and 3.23 series, only critical bugfixes are made.

Active MySQL development is currently taking place in the MySQL 5.0 and 5.1 release series, and new features are being added only to the latter.

Before upgrading from one release series to the next, please see the notes in Section 2.11, “Upgrading MySQL”.

The most requested features and the versions in which they were implemented or are scheduled for implementation are summarized in the following table:

Feature	MySQL Series
Foreign keys	3.23 (for the InnoDB storage engine)
Unions	4.0
Subqueries	4.1
R-trees	4.1 (for the MyISAM storage engine)
Stored procedures	5.0
Views	5.0
Cursors	5.0
XA transactions	5.0

Foreign keys	5.2 (implemented in 3.23 for InnoDB)
Triggers	5.0 and 5.1
Partitioning	5.1
Pluggable Storage Engine API	5.1
Row-Based Replication	5.1

## 1.6.1. What's New in MySQL 5.0

The following features are implemented in MySQL 5.0.

- **BIT Data Type:** Can be used to store numbers in binary notation. See Section 11.1.1, “Overview of Numeric Types”.
- **Cursors:** Elementary support for server-side cursors. For information about using cursors within stored routines, see Section 17.2.9, “Cursors”. For information about using cursors from within the C API, see Section 22.2.7.3, “`mysql_stmt_attr_set()`”.
- **Information Schema:** The introduction of the `INFORMATION_SCHEMA` database in MySQL 5.0 provided a standards-compliant means for accessing the MySQL Server's metadata; that is, data about the databases (schemas) on the server and the objects which they contain. See Chapter 20, *The INFORMATION\_SCHEMA Database*.
- **Instance Manager:** Can be used to start and stop the MySQL Server, even from a remote host. See Section 5.5, “`mysqlmanager` — The MySQL Instance Manager”.
- **Precision Math:** MySQL 5.0 introduced stricter criteria for acceptance or rejection of data, and implemented a new library for fixed-point arithmetic. These contributed to a much higher degree of accuracy for mathematical operations and greater control over invalid values. See Chapter 21, *Precision Math*.
- **Storage Engines:** Storage engines added in MySQL 5.0 include `ARCHIVE` and `FEDERATED`. See Section 14.8, “The `ARCHIVE` Storage Engine”, and Section 14.7, “The `FEDERATED` Storage Engine”.
- **Stored Routines:** Support for named stored procedures and stored functions was implemented in MySQL 5.0. See Chapter 17, *Stored Procedures and Functions*.
- **Strict Mode and Standard Error Handling:** MySQL 5.0 added a strict mode where by it follows standard SQL in a number of ways in which it did not previously. Support for standard `SQLSTATE` error messages was also implemented. See Section 5.2.5, “The Server SQL Mode”.
- **Triggers:** MySQL 5.0 added limited support for triggers. See Chapter 18, *Triggers*, and Section 1.9.5.4, “Stored Routines and Triggers”.
- **VARCHAR Data Type:** The maximum effective length of a `VARCHAR` column was increased to 65,532 bytes, and stripping of trailing whitespace was eliminated. See Section 11.4, “String Types”.
- **Views:** MySQL 5.0 added support for named, updatable views. See Chapter 19, *Views*, and Section 1.9.5.6, “Views”.
- **XA Transactions:** See Section 13.4.7, “XA Transactions”.
- **Performance enhancements:** A number of improvements were made in MySQL 5.0 to improve the speed of certain types of queries and in the handling of certain types. These include:
  - MySQL 5.0 introduces a new “greedy” optimizer which can greatly reduce the time required to arrive at a query execution plan. This is particularly noticeable where several tables are to be joined and no good join keys can otherwise be found. Without the greedy optimizer, the

complexity of the search for an execution plan is calculated as  $N!$ , where  $N$  is the number of tables to be joined. The greedy optimizer reduces this to  $N! / (D-1)!$ , where  $D$  is the depth of the search. Although the greedy optimizer does not guarantee the best possible of all execution plans (this is currently being worked on), it can reduce the time spent arriving at an execution plan for a join involving a great many tables — 30, 40, or more — by a factor of as much as 1,000. This should eliminate most if not all situations where users thought that the optimizer had hung when trying to perform joins across many tables.

- Use of the *Index Merge* method to obtain better optimization of AND and OR relations over different keys. (Previously, these were optimized only where both relations in the WHERE clause involved the same key.) This also applies to other one-to-one comparison operators (>, <, and so on), including = and the IN operator. This means that MySQL can use multiple indexes in retrieving results for conditions such as WHERE key1 > 4 OR key2 < 7 and even combinations of conditions such as WHERE (key1 > 4 OR key2 < 7) AND (key3 >= 10 OR key4 = 1). See Section 7.2.6, “Index Merge Optimization”.
- A new equality detector finds and optimizes “hidden” equalities in joins. For example, a WHERE clause such as

```
t1.c1=t2.c2 AND t2.c2=t3.c3 AND t1.c1 < 5
```

can be reduced to

```
t1.c1=t3.c3 AND t2.c2 < 5 AND t3.c3 < 5
```

These optimizations can be applied with any combination of AND and OR operators. See Section 7.2.10, “Nested Join Optimization”, and Section 7.2.11, “Outer Join Simplification”.

- Optimization of NOT IN and NOT BETWEEN relations, reducing or eliminating table scans for queries making use of them by means of range analysis. The performance of MySQL with regard to these relations now matches its performance with regard to IN and BETWEEN.
- The VARCHAR data type as implemented in MySQL 5.0 is more efficient than in previous versions, due to the elimination of the old (and nonstandard) removal of trailing spaces during retrieval.
- The addition of a true BIT column type; this type is much more efficient for storage and retrieval of Boolean values than the workarounds required in MySQL in versions previous to 5.0.

- **Performance Improvements in the InnoDB Storage Engine:**

- New compact storage format which can save up to 20% of the disk space required in previous MySQL/InnoDB versions.
- Faster recovery from a failed or aborted ALTER TABLE.
- Faster implementation of TRUNCATE.

(See Section 14.2, “The InnoDB Storage Engine”.)

- **Performance Improvements in the NDBCluster Storage Engine:**

- Faster handling of queries that use IN and BETWEEN.
- **Condition pushdown:** In cases involving the comparison of an unindexed column with a constant, this condition is “pushed down” to the cluster where it is evaluated in all partitions simultaneously, eliminating the need to send non-matching records over the network. This can make such queries 10 to 100 times faster than in MySQL 4.1 Cluster.

See Section 7.2.1, “Optimizing Queries with EXPLAIN”, for more information.

(See Chapter 15, *MySQL Cluster*.)

For those wishing to take a look at the bleeding edge of MySQL development, we make our BitKeeper repository for MySQL publicly available. See Section 2.9.3, “Installing from the Development Source Tree”.

## 1.7. MySQL Information Sources

This section lists sources of additional information that you may find helpful, such as the MySQL mailing lists and user forums, and Internet Relay Chat.

### 1.7.1. MySQL Mailing Lists

This section introduces the MySQL mailing lists and provides guidelines as to how the lists should be used. When you subscribe to a mailing list, you receive all postings to the list as email messages. You can also send your own questions and answers to the list.

To subscribe to or unsubscribe from any of the mailing lists described in this section, visit <http://lists.mysql.com/>. For most of them, you can select the regular version of the list where you get individual messages, or a digest version where you get one large message per day.

Please *do not* send messages about subscribing or unsubscribing to any of the mailing lists, because such messages are distributed automatically to thousands of other users.

Your local site may have many subscribers to a MySQL mailing list. If so, the site may have a local mailing list, so that messages sent from `lists.mysql.com` to your site are propagated to the local list. In such cases, please contact your system administrator to be added to or dropped from the local MySQL list.

If you wish to have traffic for a mailing list go to a separate mailbox in your mail program, set up a filter based on the message headers. You can use either the `List-ID:` or `Delivered-To:` headers to identify list messages.

The MySQL mailing lists are as follows:

- `announce`

This list is for announcements of new versions of MySQL and related programs. This is a low-volume list to which all MySQL users should subscribe.

- `mysql`

This is the main list for general MySQL discussion. Please note that some topics are better discussed on the more-specialized lists. If you post to the wrong list, you may not get an answer.

- `bugs`

This list is for people who want to stay informed about issues reported since the last release of MySQL or who want to be actively involved in the process of bug hunting and fixing. See Section 1.8, “How to Report Bugs or Problems”.

- `internals`

This list is for people who work on the MySQL code. This is also the forum for discussions on MySQL development and for posting patches.

- `mysqldoc`

This list is for people who work on the MySQL documentation: people from MySQL AB, translators, and other community members.

- benchmarks

This list is for anyone interested in performance issues. Discussions concentrate on database performance (not limited to MySQL), but also include broader categories such as performance of the kernel, filesystem, disk system, and so on.

- packagers

This list is for discussions on packaging and distributing MySQL. This is the forum used by distribution maintainers to exchange ideas on packaging MySQL and on ensuring that MySQL looks and feels as similar as possible on all supported platforms and operating systems.

- java

This list is for discussions about the MySQL server and Java. It is mostly used to discuss JDBC drivers such as MySQL Connector/J.

- win32

This list is for all topics concerning the MySQL software on Microsoft operating systems, such as Windows 9x, Me, NT, 2000, XP, and 2003.

- myodbc

This list is for all topics concerning connecting to the MySQL server with ODBC.

- gui-tools

This list is for all topics concerning MySQL graphical user interface tools such as MySQL Administrator and MySQL Query Browser.

- cluster

This list is for discussion of MySQL Cluster.

- dotnet

This list is for discussion of the MySQL server and the .NET platform. It is mostly related to MySQL Connector/Net.

- plusplus

This list is for all topics concerning programming with the C++ API for MySQL.

- perl

This list is for all topics concerning Perl support for MySQL with DBD::mysql.

If you're unable to get an answer to your questions from a MySQL mailing list or forum, one option is to purchase support from MySQL AB. This puts you in direct contact with MySQL developers.

The following table shows some MySQL mailing lists in languages other than English. These lists are not operated by MySQL AB.

- <mysql-france-subscribe@yahoogroups.com>

A French mailing list.

- <list@tinc.net>

A Korean mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

### 1.7.1.1. Guidelines for Using the Mailing Lists

Please don't post mail messages from your browser with HTML mode turned on. Many users don't read mail with a browser.

When you answer a question sent to a mailing list, if you consider your answer to have broad interest, you may want to post it to the list instead of replying directly to the individual who asked. Try to make your answer general enough that people other than the original poster may benefit from it. When you post to the list, please make sure that your answer is not a duplication of a previous answer.

Try to summarize the essential part of the question in your reply. Don't feel obliged to quote the entire original message.

When answers are sent to you individually and not to the mailing list, it is considered good etiquette to summarize the answers and send the summary to the mailing list so that others may have the benefit of responses you received that helped you solve your problem.

### 1.7.2. MySQL Community Support at the MySQL Forums

The forums at <http://forums.mysql.com> are an important community resource. Many forums are available, grouped into these general categories:

- Migration
- MySQL Usage
- MySQL Connectors
- Programming Languages
- Tools
- 3rd-Party Applications
- Storage Engines
- MySQL Technology

- SQL Standards
- Business

### 1.7.3. MySQL Community Support on Internet Relay Chat (IRC)

In addition to the various MySQL mailing lists and forums, you can find experienced community people on Internet Relay Chat (IRC). These are the best networks/channels currently known to us:

**freenode** (see <http://www.freenode.net/> for servers)

- `#mysql` is primarily for MySQL questions, but other database and general SQL questions are welcome. Questions about PHP, Perl, or C in combination with MySQL are also common.

If you are looking for IRC client software to connect to an IRC network, take a look at `xChat` (<http://www.xchat.org/>). X-Chat (GPL licensed) is available for Unix as well as for Windows platforms (a free Windows build of X-Chat is available at <http://www.silverex.org/download/>).

## 1.8. How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

- Start by searching the MySQL online manual at <http://dev.mysql.com/doc/>. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. The change history (<http://dev.mysql.com/doc/mysql/en/news.html>) can be particularly useful since it is quite possible that a newer version contains a solution to your problem.
- If you get a parse error for a SQL statement, please check your syntax closely. If you can't find something wrong with it, it's extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement. In this case, your options are to implement the syntax yourself or email [licensing@mysql.com](mailto:licensing@mysql.com) and ask for an offer to implement it.

If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.

- For solutions to some common problems, see Appendix A, *Problems and Common Errors*.
- Search the bugs database at <http://bugs.mysql.com/> to see whether the bug has been reported and fixed.
- Search the MySQL mailing list archives at <http://lists.mysql.com/>. See Section 1.7.1, "MySQL Mailing Lists".
- You can also use <http://www.mysql.com/search/> to search all the Web pages (including the manual) that are located at the MySQL AB Web site.

If you can't find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still can't find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit <http://bugs.mysql.com/>, which is the address for our bugs

database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports. If you have no Web access, you can generate a bug report by using the `mysqlbug` script described at the end of this section.

Bugs posted in the bugs database at <http://bugs.mysql.com/> that are corrected for a given release are noted in the change history.

If you have found a sensitive security bug in MySQL, you can send email to `<security@mysql.com>`.

To discuss problems with other users, you can use one of the MySQL mailing lists. Section 1.7.1, “MySQL Mailing Lists”.

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you don't waste your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test < script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See Section E.1.6, “Making a Test Case If You Experience Table Corruption”.

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details don't matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See Section 23.1.1.9, “How to Report MyODBC Problems or Bugs”.

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the

use of \G.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.0.19). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.
- The manufacturer and model of the machine on which you experience the problem.
- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows” menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.
- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.
- If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.
- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.
- If `mysqld` died, you should also report the statement that crashed `mysqld`. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` crashes. See Section E.1.5, “Using Server Logs to Find Causes of Errors in `mysqld`”.
- If a database table is related to the problem, include the output from the `SHOW CREATE TABLE db_name.tbl_name` statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.
- For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the \G statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

```
mysql> SHOW VARIABLES;
mysql> SHOW COLUMNS FROM ... \G
<output from SHOW COLUMNS>
mysql> EXPLAIN SELECT ... \G
<output from EXPLAIN>
mysql> FLUSH STATUS;
mysql> SELECT ...;
<A short version of the output from SELECT,
including the time taken to run the query>
mysql> SHOW STATUS;
<output from SHOW STATUS>
```

- If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

If you can't provide a script, you should at least include the output from `mysqladmin vari-`

ables `extended-status` `processlist` in your report to provide some information on how your system is performing.

- If you can't produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`, and use `FTP` to transfer the archive to `ftp://ftp.mysql.com/pub/mysql/upload/`. Then enter the problem into our bugs database at `http://bugs.mysql.com/`.
- If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.
- When you provide an example of the problem, it's better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you don't want to be visible to others in the bug report, you can use `FTP` to transfer it to `ftp://ftp.mysql.com/pub/mysql/upload/`. If the information is really top secret and you don't want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.
- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD: :mysql` modules, include the version numbers for Perl, `DBI`, and `DBD: :mysql`.
- If your question is related to the privilege system, please include the output of `mysqlaccess`, the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should first run `mysqlaccess`. After this, execute `mysqladmin reload version` and try to connect with the program that gives you trouble. `mysqlaccess` can be found in the `bin` directory under your MySQL installation directory.
- If you have a patch for a bug, do include it. But don't assume that the patch is all we need, or that we can use it, if you don't provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we can't use it.

If we can't verify the exact purpose of the patch, we won't use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch won't work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team can't guess such things without first using a debugger to determine the real cause of a bug.
- Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.
- If the problem is that your data appears corrupt or you get errors when you access a particular table, you should first check your tables and then try to repair them with `CHECK TABLE` and `REPAIR TABLE` or with `myisamchk`. See Chapter 5, *Database Administration*.

If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` command. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in Section 9.2.2, "Identifier Case Sensitivity".

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See Section 5.12.1, “The Error Log”. Please include any relevant information from this file in your bug report. Normally `mysqld` should *never* crash a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it's much easier for us to provide you with a fix for the problem. See Section A.1, “How to Determine What Is Causing a Problem”.
- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software are thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See Section 2.1.2, “Choosing Which MySQL Distribution to Install”.

If you have no Web access and cannot report a bug by visiting <http://bugs.mysql.com/>, you can use the `mysqlbug` script to generate a bug report (or a report about any problem). `mysqlbug` helps you generate a report by determining much of the following information automatically, but if something important is missing, please include it with your message. `mysqlbug` can be found in the `scripts` directory (source distribution) and in the `bin` directory under your MySQL installation directory (binary distribution).

## 1.9. MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, and “SQL:2003” refers to the current version of the standard. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The `HANDLER` interface is an example of this strategy. See Section 13.2.3, “`HANDLER` Syntax”.

We continue to support transactional and non-transactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases, but the code can also be compiled in a reduced version suitable for hand-held and embedded devices. The compact design of the MySQL server makes development in both directions possible without any conflicts in the source tree.

Currently, we are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

MySQL supports high-availability database clustering using the `NDBCluster` storage engine. See Chapter 15, *MySQL Cluster*.

XML support is to be implemented in a future version of the database server.

### 1.9.1. What Standards MySQL Follows

Our aim is to support the full ANSI/ISO SQL standard, but without making concessions to speed and quality of the code.

ODBC levels 0-3.51.

## 1.9.2. Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differentially for different clients. This capability enables each application to tailor the server's operating mode to its own requirements.

SQL modes control aspects of server operation such as what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

You can set the default SQL mode by starting `mysqld` with the `--sql-mode="mode_value"` option. Beginning with MySQL 4.1, you can also change the mode at runtime by setting the `sql_mode` system variable with a `SET [SESSION|GLOBAL] sql_mode='mode_value'` statement.

For more information on setting the SQL mode, see Section 5.2.5, “The Server SQL Mode”.

## 1.9.3. Running MySQL in ANSI Mode

You can tell `mysqld` to run in ANSI mode with the `--ansi` startup option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

As of MySQL 4.1.1, you can achieve the same effect at runtime by executing these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;  
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the `sql_mode` system variable to 'ANSI' enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';  
mysql> SELECT @@global.sql_mode;  
-> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Note that running the server in ANSI mode with `--ansi` is not quite the same as setting the SQL mode to 'ANSI'. The `--ansi` option affects the SQL mode and also sets the transaction isolation level. Setting the SQL mode to 'ANSI' has no effect on the isolation level.

See Section 5.2.1, “`mysqld` Command Options”, and Section 1.9.2, “Selecting SQL Modes”.

## 1.9.4. MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you probably won't find in other SQL DBMSs. Be warned that if you use them, your code won't be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the ‘!’ character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```
CREATE /*!32302 TEMPORARY */ TABLE t (a INT);
```

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk

MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to filenames in the database directory. This has a few implications:

- Database and table names are case sensitive in MySQL Server on operating systems that have case-sensitive filenames (such as most Unix systems). See Section 9.2.2, “Identifier Case Sensitivity”.
- You can use standard system commands to back up, rename, move, delete, and copy tables that are managed by the MyISAM storage engine. For example, it is possible to rename a MyISAM table by renaming the `.MYD`, `.MYI`, and `.frm` files to which the table corresponds. (Nevertheless, it is preferable to use `RENAME TABLE` or `ALTER TABLE ... RENAME` and let the server rename the files.)

Database and table names cannot contain pathname separator characters (`/`, `\`).

- General language syntax

- By default, strings can be enclosed by either `"` or `'`, not just by `'`. (If the `ANSI_QUOTES` SQL mode is enabled, strings can be enclosed only by `'` and the server interprets strings enclosed by `"` as identifiers.)
- `\` is the escape character in strings.
- In SQL statements, you can access tables from different databases with the `db_name.tbl_name` syntax. Some SQL servers provide the same functionality but call this `User space`. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace`.

- SQL statement syntax

- The `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.
- The `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE` statements. See Section 13.1.3, “CREATE DATABASE Syntax”, Section 13.1.6, “DROP DATABASE Syntax”, and Section 13.1.1, “ALTER DATABASE Syntax”.
- The `DO` statement.
- `EXPLAIN SELECT` to obtain a description of how tables are processed by the query optimizer.
- The `FLUSH` and `RESET` statements.
- The `SET` statement. See Section 13.5.3, “SET Syntax”.
- The `SHOW` statement. See Section 13.5.4, “SHOW Syntax”. As of MySQL 5.0, the information produced by many of the MySQL-specific `SHOW` statements can be obtained in more standard fashion by using `SELECT` to query `INFORMATION_SCHEMA`. See Chapter 20, *The INFORMATION\_SCHEMA Database*.
- Use of `LOAD DATA INFILE`. In many cases, this syntax is compatible with Oracle's `LOAD`

DATA INFILE. See Section 13.2.5, “LOAD DATA INFILE Syntax”.

- Use of RENAME TABLE. See Section 13.1.9, “RENAME TABLE Syntax”.
- Use of REPLACE instead of DELETE plus INSERT. See Section 13.2.6, “REPLACE Syntax”.
- Use of CHANGE *col\_name*, DROP *col\_name*, or DROP INDEX, IGNORE or RENAME in ALTER TABLE statements. Use of multiple ADD, ALTER, DROP, or CHANGE clauses in an ALTER TABLE statement. See Section 13.1.2, “ALTER TABLE Syntax”.
- Use of index names, indexes on a prefix of a column, and use of INDEX or KEY in CREATE TABLE statements. See Section 13.1.5, “CREATE TABLE Syntax”.
- Use of TEMPORARY or IF NOT EXISTS with CREATE TABLE.
- Use of IF EXISTS with DROP TABLE and DROP DATABASE.
- The capability of dropping multiple tables with a single DROP TABLE statement.
- The ORDER BY and LIMIT clauses of the UPDATE and DELETE statements.
- INSERT INTO *tbl\_name* SET *col\_name* = ... syntax.
- The DELAYED clause of the INSERT and REPLACE statements.
- The LOW\_PRIORITY clause of the INSERT, REPLACE, DELETE, and UPDATE statements.
- Use of INTO OUTFILE or INTO DUMPFILE in SELECT statements. See Section 13.2.7, “SELECT Syntax”.
- Options such as STRAIGHT\_JOIN or SQL\_SMALL\_RESULT in SELECT statements.
- You don't need to name all selected columns in the GROUP BY clause. This gives better performance for some very specific, but quite normal queries. See Section 12.10, “Functions and Modifiers for Use with GROUP BY Clauses”.
- You can specify ASC and DESC with GROUP BY, not just with ORDER BY.
- The ability to set variables in a statement with the := assignment operator:

```
mysql> SELECT @a:=SUM(total),@b=COUNT(*),@a/@b AS avg
-> FROM test_table;
mysql> SELECT @t1:=(@t2:=1)+@t3:=4,@t1,@t2,@t3;
```

- Data types
  - The MEDIUMINT, SET, and ENUM data types, and the various BLOB and TEXT data types.
  - The AUTO\_INCREMENT, BINARY, NULL, UNSIGNED, and ZEROFILL data type attributes.
- Functions and operators
  - To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.
  - MySQL Server understands the || and && operators to mean logical OR and AND, as in the C programming language. In MySQL Server, || and OR are synonyms, as are && and AND. Because of this nice syntax, MySQL Server doesn't support the standard SQL || operator for string concatenation; use CONCAT() instead. Because CONCAT() takes any number of

arguments, it's easy to convert use of the `||` operator to MySQL Server.

- Use of `COUNT(DISTINCT value_list)` where `value_list` has more than one element.
- String comparisons are case-insensitive by default, with sort ordering determined by collation of the current character set, which is `latin1 (cp1252 West European)` by default. If you don't like this, you should declare your columns with the `BINARY` attribute or use the `BINARY` cast, which causes comparisons to be done using the underlying character code values rather than a lexical ordering.
- The `%` operator is a synonym for `MOD()`. That is, `N % M` is equivalent to `MOD(N,M)`. `%` is supported for C programmers and for compatibility with PostgreSQL.
- The `=`, `<>`, `<=<`, `>=>`, `<<`, `>>`, `<=>`, `AND`, `OR`, or `LIKE` operators may be used in expressions in the output column list (to the left of the `FROM`) in `SELECT` statements. For example:

```
mysql> SELECT col1=1 AND col2=2 FROM my_table;
```

- The `LAST_INSERT_ID()` function returns the most recent `AUTO_INCREMENT` value. See Section 12.9.3, “Information Functions”.
- `LIKE` is allowed on numeric values.
- The `REGEXP` and `NOT REGEXP` extended regular expression operators.
- `CONCAT()` or `CHAR()` with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)
- The `BIT_COUNT()`, `CASE`, `ELT()`, `FROM_DAYS()`, `FORMAT()`, `IF()`, `PASSWORD()`, `ENCRYPT()`, `MD5()`, `ENCODE()`, `DECODE()`, `PERIOD_ADD()`, `PERIOD_DIFF()`, `TO_DAYS()`, and `WEEKDAY()` functions.
- Use of `TRIM()` to trim substrings. Standard SQL supports removal of single characters only.
- The `GROUP BY` functions `STD()`, `BIT_OR()`, `BIT_AND()`, `BIT_XOR()`, and `GROUP_CONCAT()`. See Section 12.10, “Functions and Modifiers for Use with `GROUP BY` Clauses”.

For a prioritized list indicating when new extensions are added to MySQL Server, you should consult the online MySQL development roadmap at <http://dev.mysql.com/doc/mysql/en/roadmap.html>.

## 1.9.5. MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- For `VARCHAR` columns, trailing spaces are removed when the value is stored. (This is fixed in MySQL 5.0.3). See Section A.8, “Known Issues in MySQL”.
- In some cases, `CHAR` columns are silently converted to `VARCHAR` columns when you define a table or alter its structure. (This is fixed in MySQL 5.0.3). See Section 13.1.5.1, “Silent Column Specification Changes”.
- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see Section 13.5.1.5, “`REVOKE` Syntax”.

- The `CAST ( )` function does not support cast to `REAL` or `BIGINT`. See Section 12.8, “Cast Functions and Operators”.
- Standard SQL requires that a `HAVING` clause in a `SELECT` statement be able to refer to columns in the `GROUP BY` clause. This cannot be done before MySQL 5.0.2.

### 1.9.5.1. Subquery Support

MySQL 4.1 and up supports subqueries and derived tables. A “subquery” is a `SELECT` statement nested within another statement. A “derived table” (an unnamed view) is a subquery in the `FROM` clause of another statement. See Section 13.2.8, “Subquery Syntax”.

For MySQL versions older than 4.1, most subqueries can be rewritten using joins or other methods. See Section 13.2.8.11, “Rewriting Subqueries as Joins for Earlier MySQL Versions”, for examples that show how to do this.

### 1.9.5.2. SELECT INTO TABLE

MySQL Server doesn't support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See Section 13.2.4.1, “`INSERT ... SELECT` Syntax”. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

As of MySQL 5.0, you can use `SELECT ... INTO` with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See Section 17.2.7.3, “`SELECT ... INTO` Statement”.

### 1.9.5.3. Transactions and Atomic Operations

MySQL Server (version 3.23-max and all versions 4.0 and above) supports transactions with the `InnoDB` and `BDB` transactional storage engines. `InnoDB` provides *full* ACID compliance. See Chapter 14, *Storage Engines and Table Types*. For information about `InnoDB` differences from standard SQL with regard to treatment of transaction errors, see Section 14.2.15, “`InnoDB` Error Handling”.

The other non-transactional storage engines in MySQL Server (such as `MyISAM`) follow a different paradigm for data integrity called “atomic operations.” In transactional terms, `MyISAM` tables effectively always operate in `AUTO COMMIT=1` mode. Atomic operations often offer comparable integrity with higher performance.

Because MySQL Server supports both paradigms, you can decide whether your applications are best served by the speed of atomic operations or the use of transactional features. This choice can be made on a per-table basis.

As noted, the trade-off for transactional versus non-transactional storage engines lies mostly in performance. Transactional tables have significantly higher memory and disk space requirements, and more CPU overhead. On the other hand, transactional storage engines such as `InnoDB` also offer many significant features. MySQL Server's modular design allows the concurrent use of different storage engines to suit different requirements and deliver optimum performance in all situations.

But how do you use the features of MySQL Server to maintain rigorous integrity even with the non-transactional `MyISAM` tables, and how do these features compare with the transactional storage engines?

- If your applications are written in a way that is dependent on being able to call `ROLLBACK`

rather than `COMMIT` in critical situations, transactions are more convenient. Transactions also ensure that unfinished updates or corrupting activities are not committed to the database; the server is given the opportunity to do an automatic rollback and your database is saved.

If you use non-transactional tables, MySQL Server in almost all cases allows you to resolve potential problems by including simple checks before updates and by running simple scripts that check the databases for inconsistencies and automatically repair or warn if such an inconsistency occurs. Note that just by using the MySQL log or even adding one extra log, you can normally fix tables perfectly with no data integrity loss.

- More often than not, critical transactional updates can be rewritten to be atomic. Generally speaking, all integrity problems that transactions solve can be done with `LOCK TABLES` or atomic updates, ensuring that there are no automatic aborts from the server, which is a common problem with transactional database systems.
- To be safe with MySQL Server, regardless of whether you use transactional tables, you only need to have backups and have binary logging turned on. When that is true, you can recover from any situation that you could with any other transactional database system. It is always good to have backups, regardless of which database system you use.

The transactional paradigm has its benefits and its drawbacks. Many users and application developers depend on the ease with which they can code around problems where an abort appears to be necessary, or is necessary. However, even if you are new to the atomic operations paradigm, or more familiar with transactions, do consider the speed benefit that non-transactional tables can offer on the order of three to five times the speed of the fastest and most optimally tuned transactional tables.

In situations where integrity is of highest importance, MySQL Server offers transaction-level reliability and integrity even for non-transactional tables. If you lock tables with `LOCK TABLES`, all updates stall until integrity checks are made. If you obtain a `READ LOCAL` lock (as opposed to a write lock) for a table that allows concurrent inserts at the end of the table, reads are allowed, as are inserts by other clients. The newly inserted records are not be seen by the client that has the read lock until it releases the lock. With `INSERT DELAYED`, you can write inserts that go into a local queue until the locks are released, without having the client wait for the insert to complete. See Section 7.3.3, “Concurrent Inserts”, and Section 13.2.4.2, “`INSERT DELAYED` Syntax”.

“Atomic,” in the sense that we mean it, is nothing magical. It only means that you can be sure that while each specific update is running, no other user can interfere with it, and there can never be an automatic rollback (which can happen with transactional tables if you are not very careful). MySQL Server also guarantees that there are no dirty reads.

Following are some techniques for working with non-transactional tables:

- Loops that need transactions normally can be coded with the help of `LOCK TABLES`, and you don't need cursors to update records on the fly.
- To avoid using `ROLLBACK`, you can employ the following strategy:
  1. Use `LOCK TABLES` to lock all the tables you want to access.
  2. Test the conditions that must be true before performing the update.
  3. Update if the conditions are satisfied.
  4. Use `UNLOCK TABLES` to release your locks.

This is usually a much faster method than using transactions with possible rollbacks, although not always. The only situation this solution doesn't handle is when someone kills the threads in the middle of an update. In that case, all locks are released but some of the updates may not have been executed.

- You can also use functions to update records in a single operation. You can get a very efficient application by using the following techniques:
  - Modify columns relative to their current value.
  - Update only those columns that actually have changed.

For example, when we are updating customer information, we update only the customer data that has changed and test only that none of the changed data, or data that depends on the changed data, has changed compared to the original row. The test for changed data is done with the `WHERE` clause in the `UPDATE` statement. If the record wasn't updated, we give the client a message: "Some of the data you have changed has been changed by another user." Then we show the old row versus the new row in a window so that the user can decide which version of the customer record to use.

This gives us something that is similar to column locking but is actually even better because we only update some of the columns, using values that are relative to their current values. This means that typical `UPDATE` statements look something like these:

```
UPDATE tablename SET pay_back=pay_back+125;

UPDATE customer
SET
    customer_date='current_date',
    address='new address',
    phone='new phone',
    money_owed_to_us=money_owed_to_us-125
WHERE
    customer_id=id AND address='old address' AND phone='old phone';
```

This is very efficient and works even if another client has changed the values in the `pay_back` or `money_owed_to_us` columns.

- In many cases, users have wanted `LOCK TABLES` or `ROLLBACK` for the purpose of managing unique identifiers. This can be handled much more efficiently without locking or rolling back by using an `AUTO_INCREMENT` column and either the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 12.9.3, "Information Functions", and Section 22.2.3.36, "`mysql_insert_id()`".

You can generally code around the need for row-level locking. Some situations really do need it, and InnoDB tables support row-level locking. Otherwise, with MyISAM tables, you can use a flag column in the table and do something like the following:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID;
```

MySQL returns 1 for the number of affected rows if the row was found and `row_flag` wasn't 1 in the original row. You can think of this as though MySQL Server changed the preceding statement to:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID AND row_flag <> 1;
```

### 1.9.5.4. Stored Routines and Triggers

Stored procedures and functions are implemented beginning with MySQL 5.0. See Chapter 17, *Stored Procedures and Functions*.

Basic trigger functionality is implemented beginning with MySQL 5.0.2, with further development planned for MySQL 5.1. See Chapter 18, *Triggers*.

### 1.9.5.5. Foreign Keys

In MySQL Server 3.23.44 and up, the InnoDB storage engine supports checking of foreign key constraints, including CASCADE, ON DELETE, and ON UPDATE. See Section 14.2.6.4, “FOREIGN KEY Constraints”.

For storage engines other than InnoDB, MySQL Server parses the FOREIGN KEY syntax in CREATE TABLE statements, but does not use or store it. In the future, the implementation will be extended to store this information in the table specification file so that it may be retrieved by `mysql-dump` and ODBC. At a later stage, foreign key constraints will be implemented for MyISAM tables as well.

Foreign key enforcement offers several benefits to database developers:

- Assuming proper design of the relationships, foreign key constraints make it more difficult for a programmer to introduce an inconsistency into the database.
- Centralized checking of constraints by the database server makes it unnecessary to perform these checks on the application side. This eliminates the possibility that different applications may not all check the constraints in the same way.
- Using cascading updates and deletes can simplify the application code.
- Properly designed foreign key rules aid in documenting relationships between tables.

Do keep in mind that these benefits come at the cost of additional overhead for the database server to perform the necessary checks. Additional checking by the server affects performance, which for some applications may be sufficiently undesirable as to be avoided if possible. (Some major commercial applications have coded the foreign key logic at the application level for this reason.)

MySQL gives database developers the choice of which approach to use. If you don't need foreign keys and want to avoid the overhead associated with enforcing referential integrity, you can choose another storage engine instead, such as MyISAM. (For example, the MyISAM storage engine offers very fast performance for applications that perform only INSERT and SELECT operations. In this case, the table has no holes in the middle and the inserts can be performed concurrently with retrievals. See Section 7.3.3, “Concurrent Inserts”.)

If you choose not to take advantage of referential integrity checks, keep the following considerations in mind:

- In the absence of server-side foreign key relationship checking, the application itself must handle relationship issues. For example, it must take care to insert rows into tables in the proper order, and to avoid creating orphaned child records. It must also be able to recover from errors that occur in the middle of multiple-record insert operations.
- If ON DELETE is the only referential integrity capability an application needs, you can achieve a similar effect as of MySQL Server 4.0 by using multiple-table DELETE statements to delete rows from many tables with a single statement. See Section 13.2.1, “DELETE Syntax”.
- A workaround for the lack of ON DELETE is to add the appropriate DELETE statements to your application when you delete records from a table that has a foreign key. In practice, this is often as quick as using foreign keys and is more portable.

Be aware that the use of foreign keys can sometimes lead to problems:

- Foreign key support addresses many referential integrity issues, but it is still necessary to design key relationships carefully to avoid circular rules or incorrect combinations of cascading deletes.
- It is not uncommon for a DBA to create a topology of relationships that makes it difficult to restore individual tables from a backup. (MySQL alleviates this difficulty by allowing you to temporarily disable foreign key checks when reloading a table that depends on other tables. See Sec-

tion 14.2.6.4, “FOREIGN KEY Constraints”. As of MySQL 4.1.1, `mysqldump` generates dump files that take advantage of this capability automatically when they are reloaded.)

Note that foreign keys in SQL are used to check and enforce referential integrity, not to join tables. If you want to get results from multiple tables from a `SELECT` statement, you do this by performing a join between them:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.id;
```

See Section 13.2.7.1, “JOIN Syntax”, and Section 3.6.6, “Using Foreign Keys”.

The `FOREIGN KEY` syntax without `ON DELETE . . .` is often used by ODBC applications to produce automatic `WHERE` clauses.

### 1.9.5.6. Views

Views (including updatable views) are implemented beginning with MySQL Server 5.0.1. See Chapter 19, *Views*.

Views are useful for allowing users to access a set of relations (tables) as if it were a single table, and limiting their access to just that. Views can also be used to restrict access to rows (a subset of a particular table). For access control to columns, you can also use the sophisticated privilege system in MySQL Server. See Section 5.8, “The MySQL Access Privilege System”.

In designing an implementation of views, our ambitious goal, as much as is possible within the confines of SQL, has been full compliance with “Codd's Rule #6” for relational database systems: “All views that are theoretically updatable, should in practice also be updatable.”

### 1.9.5.7. '--' as the Start of a Comment

Standard SQL uses the C syntax `/* this is a comment */` for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that allow MySQL-specific SQL to be embedded in the comment, as described in Section 9.4, “Comment Syntax”.

Standard SQL uses `'--'` as a start-comment sequence. MySQL Server uses `'#'` as the start comment character. MySQL Server 3.23.3 and up also supports a variant of the `'--'` comment style. That is, the `'--'` start-comment sequence must be followed by a space (or by a control character such as a newline). The space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for payment:

```
UPDATE account SET credit=credit-payment
```

Consider about what happens if `payment` has a negative value such as `-1`:

```
UPDATE account SET credit=credit--1
```

`credit--1` is a legal expression in SQL, but `'--'` is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```
UPDATE account SET credit=credit
```

The statement produces no change in value at all. This illustrates that allowing comments to start with `'--'` can have serious consequences.

Using our implementation requires a space following the `'--'` in order for it to be recognized as a start-comment sequence in MySQL Server 3.23.3 and newer. Therefore, `credit--1` is safe to use.

Another safe feature is that the `mysql` command-line client ignores lines that start with `--`.

The following information is relevant only if you are running a MySQL version earlier than 3.23.3:

If you have an SQL script in a text file that contains `--` comments, you should use the `replace` utility as follows to convert the comments to use `#` characters before executing the script:

```
shell> replace " --" " #" < text-file-with-funny-comments.sql \  
| mysql db_name
```

That is safer than executing the script in the usual way:

```
shell> mysql db_name < text-file-with-funny-comments.sql
```

You can also edit the script file “in place” to change the `--` comments to `#` comments:

```
shell> replace " --" " #" -- text-file-with-funny-comments.sql
```

Change them back with this command:

```
shell> replace " #" " --" -- text-file-with-funny-comments.sql
```

See Section 8.17, “`replace` — A String-Replacement Utility”.

## 1.9.6. How MySQL Deals with Constraints

MySQL allows you to work both with transactional tables that allow rollback and with non-transactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a non-transactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce illegal values to the closest legal values.

Beginning with MySQL 5.0.2, several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See Section 5.2.5, “The Server SQL Mode”.

The following sections describe how MySQL Server handles different types of constraints.

### 1.9.6.1. PRIMARY KEY and UNIQUE Index Constraints

Normally, an error occurs when you try to `INSERT` or `UPDATE` a row that causes a primary key, unique key, or foreign key violation. If you are using a transactional storage engine such as `InnoDB`, MySQL automatically rolls back the statement. If you are using a non-transactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

If you want to ignore such key violations, MySQL supports an `IGNORE` keyword for `INSERT` and `UPDATE`. In this case, MySQL ignores any key violations and continues processing with the next

row. See Section 13.2.4, “INSERT Syntax”, and Section 13.2.10, “UPDATE Syntax”.

You can get information about the number of rows actually inserted or updated with the `mysql_info()` C API function. In MySQL 4.1 and up, you also can use the `SHOW WARNINGS` statement. See Section 22.2.3.34, “`mysql_info()`”, and Section 13.5.4.25, “SHOW WARNINGS Syntax”.

Currently, only InnoDB tables support foreign keys. See Section 14.2.6.4, “FOREIGN KEY Constraints”. Foreign key support in MyISAM tables is scheduled for implementation in MySQL 5.2. See Section 1.6, “MySQL Development Roadmap”.

## 1.9.6.2. Constraints on Invalid Data

Before MySQL 5.0.2, MySQL is forgiving of illegal or improper data values and coerces them to legal values for data entry. In MySQL 5.0.2 and up, that remains the default behavior, but you can change the server SQL mode to select more traditional treatment of bad values such that the server rejects them and aborts the statement in which they occur. Section 5.2.5, “The Server SQL Mode”.

This section describes the default (forgiving) behavior of MySQL, as well as the newer strict SQL mode and how it differs.

If you are not using strict mode, then whenever you insert an “incorrect” value into a column, such as a NULL into a NOT NULL column or a too-large numeric value into a numeric column, MySQL sets the column to the “best possible value” instead of producing an error: The following rules describe in more detail how this works:

- If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.
- For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.
- If you try to store a string that doesn't start with a number into a numeric column, MySQL Server stores 0.
- Invalid values for ENUM and SET columns are handled as described in Section 1.9.6.3, “ENUM and SET Constraints”.
- MySQL allows you to store certain incorrect date values into DATE and DATETIME columns (such as '2000-02-31' or '2000-02-00'). The idea is that it's not the job of the SQL server to validate dates. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special “zero” date value '0000-00-00' is stored in the column instead.
- If you try to store NULL into a column that doesn't take NULL values, an error occurs for single-row INSERT statements. For multiple-row INSERT statements or for INSERT INTO ... SELECT statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string ( ' ' ) for string types, and the “zero” value for date and time types. Implicit default values are discussed in Section 11.1.4, “Data Type Default Values”.
- If an INSERT statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit DEFAULT clause. If the definition has no such DEFAULT clause, MySQL inserts the implicit default value for the column data type.

The reason for using the preceding rules in non-strict mode is that we can't check these conditions until the statement has begun executing. We can't just roll back if we encounter a problem after updating a few rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be “half done,” which is probably the worst possible scenario. In this case, it's better to “do the best you can” and then continue as if nothing happened.

In MySQL 5.0.2 and up, you can select stricter treatment of input values by using the `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` SQL modes:

```
SET sql_mode = 'STRICT_TRANS_TABLES' ;
SET sql_mode = 'STRICT_ALL_TABLES' ;
```

`STRICT_TRANS_TABLES` enables strict mode for transactional storage engines, and also to some extent for non-transactional engines. It works like this:

- For transactional storage engines, bad data values occurring anywhere in a statement cause the statement to abort and roll back.
- For non-transactional storage engines, a statement aborts if the error occurs in the first row to be inserted or updated. (When the error occurs in the first row, the statement can be aborted to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement, because the table has already been changed by the first row. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with `STRICT_TRANS_TABLES`, a wrong value causes MySQL to roll back all updates done so far, if that can be done without changing the table. But once the table has been changed, further errors result in adjustments and warnings.

For even stricter checking, enable `STRICT_ALL_TABLES`. This is the same as `STRICT_TRANS_TABLES` except that for non-transactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a non-transactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for non-transactional tables, either use single-row statements or else use `STRICT_TRANS_TABLES` if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check column content. It is safest (and often faster) to let the application ensure that it passes only legal values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using `INSERT IGNORE` or `UPDATE IGNORE` rather than `INSERT` or `UPDATE` without `IGNORE`.

### 1.9.6.3. ENUM and SET Constraints

`ENUM` and `SET` columns provide an efficient way to define columns that can contain only a given set of values. See Section 11.4.4, “The `ENUM` Type”, and Section 11.4.5, “The `SET` Type”. However, before MySQL 5.0.2, `ENUM` and `SET` columns do not provide true constraints on entry of invalid data:

- `ENUM` columns always have a default value. If you specify no default value, then it is `NULL` for columns that can have `NULL`, otherwise it is the first enumeration value in the column definition.
- If you insert an incorrect value into an `ENUM` column or if you force a value into an `ENUM` column with `IGNORE`, it is set to the reserved enumeration value of 0, which is displayed as an empty string in string context.
- If you insert an incorrect value into a `SET` column, the incorrect value is ignored. For example, if the column can contain the values 'a', 'b', and 'c', an attempt to assign 'a,x,b,y' results in a value of 'a,b'.

As of MySQL 5.0.2, you can configure the server to use strict SQL mode. See Section 5.2.5, “The Server SQL Mode”. With strict mode enabled, the definition of a `ENUM` or `SET` column does act as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An `ENUM` value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as `ENUM('a', 'b', 'c')`, values such as `'`, `'d'`, or `'ax'` are illegal and are rejected.
- A `SET` value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as `SET('a', 'b', 'c')`, values such as `'d'` or `'a,b,c,d'` are illegal and are rejected.

Errors for invalid values can be suppressed in strict mode if you use `INSERT IGNORE` or `UPDATE IGNORE`. In this case, a warning is generated rather than an error. For `ENUM`, the value is inserted as the error member (0). For `SET`, the value is inserted as given except that any invalid substrings are deleted. For example, `'a,x,b,y'` results in a value of `'a,b'`.

---

# Chapter 2. Installing and Upgrading MySQL

This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see Section 2.11, “Upgrading MySQL”, for information about upgrade procedures and about issues that you should consider before upgrading.

1. **Determine whether your platform is supported.** Please note that not all supported systems are equally suitable for running MySQL. On some platforms it is much more robust and efficient than others. See Section 2.1.1, “Operating Systems Supported by MySQL”, for details.
2. **Choose which distribution to install.** Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. We also provide public access to our current source tree for those who want to see our most recent developments and help us test new code. To determine which version and type of distribution you should use, see Section 2.1.2, “Choosing Which MySQL Distribution to Install”.
3. **Download the distribution that you want to install.** For instructions, see Section 2.1.3, “How to Get MySQL”. To verify the integrity of the distribution, use the instructions in Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”.
4. **Install the distribution.** To install MySQL from a binary distribution, use the instructions in Section 2.2, “Standard MySQL Installation Using a Binary Distribution”. To install MySQL from a source distribution or from the current development source tree, use the instructions in Section 2.9, “MySQL Installation Using a Source Distribution”.

If you encounter installation difficulties, see Section 2.13, “Operating System-Specific Notes”, for information on solving problems for particular platforms.

5. **Perform any necessary post-installation setup.** After installing MySQL, read Section 2.10, “Post-Installation Setup and Testing”. This section contains important information about making sure the MySQL server is working properly. It also describes how to secure the initial MySQL user accounts, *which have no passwords* until you assign passwords. The section applies whether you install MySQL using a binary or source distribution.
6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See Section 2.14, “Perl Installation Notes”.

## 2.1. General Installation Issues

Before installing MySQL, you should do the following:

1. Determine whether MySQL runs on your platform.
2. Choose a distribution to install.
3. Download the distribution and verify its integrity.

This section contains the information necessary to carry out these steps. After doing so, you can use the instructions in later sections of the chapter to install the distribution that you choose.

### 2.1.1. Operating Systems Supported by MySQL

This section lists the operating systems on which you can expect to be able to run MySQL.

We use GNU Autoconf, so it is possible to port MySQL to all modern systems that have a C++ compiler and a working implementation of POSIX threads. (Thread support is needed for the server. To compile only the client code, the only requirement is a C++ compiler.) We use and develop the software ourselves primarily on Linux (SuSE and Red Hat), FreeBSD, and Sun Solaris (versions 8 and 9).

MySQL has been reported to compile successfully on the following combinations of operating system and thread package. Note that for many operating systems, native thread support works only in the latest versions.

- AIX 4.x, 5.x with native threads. See Section 2.13.5.3, “IBM-AIX notes”.
- Amiga.
- BSDI 2.x with the MIT-pthreads package. See Section 2.13.4.4, “BSD/OS Version 2.x Notes”.
- BSDI 3.0, 3.1 and 4.x with native threads. See Section 2.13.4.4, “BSD/OS Version 2.x Notes”.
- Digital Unix 4.x with native threads. See Section 2.13.5.5, “Alpha-DEC-UNIX Notes (Tru64)”.
- FreeBSD 2.x with the MIT-pthreads package. See Section 2.13.4.1, “FreeBSD Notes”.
- FreeBSD 3.x and 4.x with native threads. See Section 2.13.4.1, “FreeBSD Notes”.
- FreeBSD 4.x with LinuxThreads. See Section 2.13.4.1, “FreeBSD Notes”.
- HP-UX 10.20 with the DCE threads or the MIT-pthreads package. See Section 2.13.5.1, “HP-UX Version 10.20 Notes”.
- HP-UX 11.x with the native threads. See Section 2.13.5.2, “HP-UX Version 11.x Notes”.
- Linux 2.0+ with LinuxThreads 0.7.1+ or `glibc` 2.0.7+ for various CPU architectures. See Section 2.13.1, “Linux Notes”.
- Mac OS X. See Section 2.13.2, “Mac OS X Notes”.
- NetBSD 1.3/1.4 Intel and NetBSD 1.3 Alpha (requires GNU make). See Section 2.13.4.2, “NetBSD Notes”.
- Novell NetWare 6.0 and 6.5. See Section 2.7, “Installing MySQL on NetWare”.
- OpenBSD 2.5 and with native threads. OpenBSD earlier than 2.5 with the MIT-pthreads package. See Section 2.13.4.3, “OpenBSD 2.5 Notes”.
- OS/2 Warp 3, FixPack 29 and OS/2 Warp 4, FixPack 4. See Section 2.13.6, “OS/2 Notes”.
- SCO OpenServer 5.0.X with a recent port of the FSU Pthreads package. See Section 2.13.5.8, “SCO UNIX and OpenServer 5.0.x Notes”.
- SCO Openserver 6.0.x. See Section 2.13.5.9, “SCO OpenServer 6.0.x Notes”.
- SCO UnixWare 7.1.x. See Section 2.13.5.10, “SCO UnixWare 7.1.x and OpenUNIX 8.0.0 Notes”.
- SGI Irix 6.x with native threads. See Section 2.13.5.7, “SGI Irix Notes”.
- Solaris 2.5 and above with native threads on SPARC and x86. See Section 2.13.3, “Solaris Notes”.
- SunOS 4.x with the MIT-pthreads package. See Section 2.13.3, “Solaris Notes”.

- Tru64 Unix. See Section 2.13.5.5, “Alpha-DEC-UNIX Notes (Tru64)”.
- Windows 9x, Me, NT, 2000, XP, and Windows Server 2003. See Section 2.3, “Installing MySQL on Windows”.

Not all platforms are equally well-suited for running MySQL. How well a certain platform is suited for a high-load mission-critical MySQL server is determined by the following factors:

- General stability of the thread library. A platform may have an excellent reputation otherwise, but MySQL is only as stable as the thread library it calls, even if everything else is perfect.
- The capability of the kernel and the thread library to take advantage of symmetric multi-processor (SMP) systems. In other words, when a process creates a thread, it should be possible for that thread to run on a CPU different from the original process.
- The capability of the kernel and the thread library to run many threads that acquire and release a mutex over a short critical region frequently without excessive context switches. If the implementation of `pthread_mutex_lock()` is too anxious to yield CPU time, this hurts MySQL tremendously. If this issue is not taken care of, adding extra CPUs actually makes MySQL slower.
- General filesystem stability and performance.
- If your tables are large, performance is affected by the ability of the filesystem to deal with large files at all and to deal with them efficiently.
- Our level of expertise here at MySQL AB with the platform. If we know a platform well, we enable platform-specific optimizations and fixes at compile time. We can also provide advice on configuring your system optimally for MySQL.
- The amount of testing we have done internally for similar configurations.
- The number of users that have run MySQL successfully on the platform in similar configurations. If this number is high, the likelihood of encountering platform-specific surprises is much smaller.

Based on the preceding criteria, the best platforms for running MySQL at this point are x86 with SuSE Linux using a 2.4 or 2.6 kernel, and ReiserFS (or any similar Linux distribution) and SPARC with Solaris (2.7-9). FreeBSD comes third, but we really hope it joins the top club once the thread library is improved. We also hope that at some point we are able to include into the top category all other platforms on which MySQL currently compiles and runs, but not quite with the same level of stability and performance. This requires some effort on our part in cooperation with the developers of the operating systems and library components that MySQL depends on. If you are interested in improving one of those components, are in a position to influence its development, and need more detailed instructions on what MySQL needs to run better, send an email message to the MySQL `internals` mailing list. See Section 1.7.1, “MySQL Mailing Lists”.

Please note that the purpose of the preceding comparison is not to say that one operating system is better or worse than another in general. We are talking only about choosing an OS for the specific purpose of running MySQL. With this in mind, the result of this comparison might be different if other factors were considered. In some cases, the reason one OS is better for MySQL than another might simply be that we have been able to put more effort into testing and optimizing for a particular platform. We are just stating our observations to help you decide which platform to use for running MySQL.

## 2.1.2. Choosing Which MySQL Distribution to Install

When preparing to install MySQL, you should decide which version to use. MySQL development occurs in several release series, and you can pick the one that best fits your needs. After deciding which version to install, you can choose a distribution format. Releases are available in binary or

source format.

### 2.1.2.1. Choosing Which Version of MySQL to Install

The first decision to make is whether you want to use a production (stable) release or a development release. In the MySQL development process, multiple release series co-exist, each at a different stage of maturity:

- MySQL 5.1 is the current development release series.
- MySQL 5.0 is the current stable (production-quality) release series. New releases are issued for bugfixes only; no new features are being added that could effect stability.
- MySQL 4.1 is the previous stable (production-quality) release series. New releases are issued for critical bugfixes and security fixes. No significant new features are to be added to this series.
- MySQL 4.0 and 3.23 are the old stable (production-quality) release series. These versions are now retired, so new releases are issued only to fix extremely critical bugs (primarily security issues).

We do not believe in a complete code freeze because this prevents us from making bugfixes and other fixes that must be done. By “somewhat frozen” we mean that we may add small things that should not affect anything that currently works in a production release. Naturally, relevant bugfixes from an earlier series propagate to later series.

Normally, if you are beginning to use MySQL for the first time or trying to port it to some system for which there is no binary distribution, we recommend going with the production release series. Currently, this is MySQL 5.0. All MySQL releases, even those from development series, are checked with the MySQL benchmarks and an extensive test suite before being issued.

If you are running an older system and want to upgrade, but do not want to take the chance of having a non-seamless upgrade, you should upgrade to the latest version in the same release series you are using (where only the last part of the version number is newer than yours). We have tried to fix only fatal bugs and make only small, relatively “safe” changes to that version.

If you want to use new features not present in the production release series, you can use a version from a development series. Note that development releases are not as stable as production releases.

If you want to use the very latest sources containing all current patches and bugfixes, you can use one of our BitKeeper repositories. These are not “releases” as such, but are available as previews of the code on which future releases are to be based.

The MySQL naming scheme uses release names that consist of three numbers and a suffix; for example, **mysql-5.0.12-beta**. The numbers within the release name are interpreted as follows:

- The first number (**5**) is the major version and describes the file format. All MySQL 5 releases have the same file format.
- The second number (**0**) is the release level. Taken together, the major version and release level constitute the release series number.
- The third number (**12**) is the version number within the release series. This is incremented for each new release. Usually you want the latest version for the series you have chosen.

For each minor update, the last number in the version string is incremented. When there are major new features or minor incompatibilities with previous versions, the second number in the version string is incremented. When the file format changes, the first number is increased.

Release names also include a suffix to indicate the stability level of the release. Releases within a

series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- **alpha** indicates that the release contains new features that have not been thoroughly tested. Known bugs should be documented in the News section. See Appendix D, *MySQL Change History*. Most alpha releases implement new commands and extensions. Active development that may involve major code changes can occur in an alpha release. However, we do conduct testing before issuing a release.
- **beta** means that the release is intended to be feature-complete and that all new code has been tested. No major new features that are added. There should be no known critical bugs. A version changes from alpha to beta when there have been no reported fatal bugs within an alpha version for at least a month and we have no plans to add any new features that could make previously implemented features unreliable.

All APIs, externally visible structures, and columns for SQL statements will not change during future beta, release candidate, or production releases.

- **rc** is a release candidate; that is, a beta that has been around for a while and seems to work well. Only minor fixes are added. (A release candidate is what formerly was known as a gamma release.)
- If there is no suffix, it means that the version has been run for a while at many different sites with no reports of critical repeatable bugs other than platform-specific bugs. Only critical bugfixes are applied to the release. This is what we call a production (stable) or “General Availability” (GA) release.

MySQL uses a naming scheme that is slightly different from most other products. In general, it is usually safe to use any version that has been out for a couple of weeks without being replaced by a new version within the same release series.

All releases of MySQL are run through our standard tests and benchmarks to ensure that they are relatively safe to use. Because the standard tests are extended over time to check for all previously found bugs, the test suite keeps getting better.

All releases have been tested at least with these tools:

- An internal test suite

The `mysql-test` directory contains an extensive set of test cases. We run these tests for virtually every server binary. See Section 24.1.2, “MySQL Test Suite”, for more information about this test suite.

- The MySQL benchmark suite

This suite runs a range of common queries. It is also a test to determine whether the latest batch of optimizations actually made the code faster. See Section 7.1.4, “The MySQL Benchmark Suite”.

- The `crash-me` test

This test tries to determine what features the database supports and what its capabilities and limitations are. See Section 7.1.4, “The MySQL Benchmark Suite”.

We also test the newest MySQL version in our internal production environment, on at least one machine. We have more than 100GB of data to work with.

## 2.1.2.2. Choosing a Distribution Format

After choosing which version of MySQL to install, you should decide whether to use a binary distribution or a source distribution. In most cases, you should probably use a binary distribution, if one exists for your platform. Binary distributions are available in native format for many platforms, such as RPM files for Linux or PKG package installers for Mac OS X or Solaris. Distributions also are available as Zip archives or compressed tar files.

Reasons to choose a binary distribution include the following:

- Binary distributions generally are easier to install than source distributions.
- To satisfy different user requirements, we provide two different binary versions. One is compiled with the core feature set. The other (MySQL-Max) is compiled with an extended feature set. Both versions are compiled from the same source distribution. All native MySQL clients can connect to servers from either MySQL version.

The extended MySQL binary distribution is identified by the `-max` suffix and is configured with the same options as `mysqld-max`. See Section 5.3, “The `mysqld-max` Extended MySQL Server”.

For RPM distributions, if you want to use the MySQL-Max RPM, you must first install the standard MySQL-server RPM.

Under some circumstances, you may be better off installing MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.
- You want to configure `mysqld` to ensure that features are available that might not be included in the standard binary distributions. Here is a list of the most common extra options that you may want to use to ensure feature availability:
  - `--with-innodb`
  - `--with-berkeley-db` (not available on all platforms)
  - `--with-libwrap`
  - `--with-named-z-libs` (this is done for some of the binaries)
  - `--with-debug[=full]`
- You want to configure `mysqld` without some features that are included in the standard binary distributions. For example, distributions normally are compiled with support for all character sets. If you want a smaller MySQL server, you can recompile it with support for only the character sets you need.
- You have a special compiler (such as `pgcc`) or want to use compiler options that are better optimized for your processor. Binary distributions are compiled with options that should work on a variety of processors from the same processor family.
- You want to use the latest sources from one of the BitKeeper repositories to have access to all current bugfixes. For example, if you have found a bug and reported it to the MySQL development team, the bugfix is committed to the source repository and you can access it there. The bugfix does not appear in a release until a release actually is issued.
- You want to read (or modify) the C and C++ code that makes up MySQL. For this purpose, you should get a source distribution, because the source code is always the ultimate manual.
- Source distributions contain more tests and examples than binary distributions.

### 2.1.2.3. How and When Updates Are Released

MySQL is evolving quite rapidly and we want to share new developments with other MySQL users. We try to produce a new release whenever we have new and useful features that others also seem to have a need for.

We also try to help users who request features that are easy to implement. We take note of what our licensed users want, and we especially take note of what our support customers want and try to help them in this regard.

No one is *required* to download a new release. The News section helps you determine whether the new release has something you really want. See Appendix D, *MySQL Change History*.

We use the following policy when updating MySQL:

- Releases are issued within each series. For each release, the last number in the version is one more than the previous release within the same series.
- Production (stable) releases are meant to appear about 1-2 times a year. However, if small bugs are found, a release with only bugfixes is issued.
- Working releases/bugfixes to old releases are meant to appear about every 4-8 weeks.
- Binary distributions for some platforms are made by us for major releases. Other people may make binary distributions for other systems, but probably less frequently.
- We make fixes available as soon as we have identified and corrected small or non-critical but annoying bugs. The fixes are available immediately from our public BitKeeper repositories, and are included in the next release.
- If by any chance a fatal bug is found in a release, our policy is to fix it in a new release as soon as possible. (We would like other companies to do this, too!)

### 2.1.2.4. Release Philosophy—No Known Bugs in Releases

We put a lot of time and effort into making our releases bug-free. We haven't released a single MySQL version with any *known* fatal repeatable bugs. (A “fatal” bug is something that crashes MySQL under normal usage, produces incorrect answers for normal queries, or has a security problem.)

We have documented all open problems, bugs, and issues that are dependent on design decisions. See Section A.8, “Known Issues in MySQL”.

Our aim is to fix everything that is fixable without making a stable MySQL version less stable. In certain cases, this means we can fix an issue in the development versions, but not in the stable (production) version. Naturally, we document such issues so that users are aware of them.

Here is a description of our build process:

- We monitor bugs from our customer support list, the bugs database at <http://bugs.mysql.com/>, and the MySQL external mailing lists.
- All reported bugs for live versions are entered into the bugs database.
- When we fix a bug, we always try to make a test case for it and include it into our test system to ensure that the bug can never recur without being detected. (About 90% of all fixed bugs have test cases.)
- We create test cases for each new feature that we add to MySQL.

- Before we start to build a new MySQL release, we ensure that all reported repeatable bugs for that MySQL version (3.23.x, 4.0.x, 4.1.x, 5.0.x, 5.1.x, and so on) are fixed. If something is impossible to fix due to some internal design decision in MySQL, we document this in the manual. See Section A.8, “Known Issues in MySQL”.
- We do a build on all platforms for which we support binaries and run our test suite and benchmark suite on all of them.
- We do not publish a binary for a platform for which the test or benchmark suite fails. If the problem is due to a general error in the source, we fix it and do the build plus tests on all systems again from scratch.
- The build and test process takes a week. If we receive a report regarding a fatal bug during this process (for example, one that causes a core dump), we fix the problem and restart the build process.
- After publishing the binaries on <http://dev.mysql.com/>, we send out an announcement message to the `mysql` and `announce` mailing lists. See Section 1.7.1, “MySQL Mailing Lists”. The announcement message contains a list of all changes to the release and any known problems with the release. The **Known Problems** section in the release notes has been needed for only a handful of releases.
- To quickly give our users access to the latest MySQL features, we try to produce a new MySQL release every 4-8 weeks. Source code snapshots are built daily and are available at <http://downloads.mysql.com/snapshots.php>.
- If, despite our best efforts, we receive any bug reports after a release is issued that a critical problem exists for the build on a specific platform, we fix it at once and build a new 'a' release for that platform. Thanks to our large user base, problems are found and resolved very quickly.
- Our track record for making stable releases is quite good. In the last 150 releases, we had to do a new build for fewer than 10 of them. In three of these cases, the bug was a faulty `glibc` library on one of our build machines that took us a long time to track down.

### 2.1.2.5. MySQL Binaries Compiled by MySQL AB

As a service of MySQL AB, we provide a set of binary distributions of MySQL that are compiled on systems at our site or on systems where supporters of MySQL kindly have given us access to their machines.

In addition to the binaries provided in platform-specific package formats, we offer binary distributions for a number of platforms in the form of compressed `tar` files (`.tar.gz` files). See Section 2.2, “Standard MySQL Installation Using a Binary Distribution”.

The RPM distributions for MySQL 5.0 releases that we make available through our Web site are generated by MySQL AB.

For Windows distributions, see Section 2.3, “Installing MySQL on Windows”.

These distributions are generated using the script `Build-tools/Do-compile`, which compiles the source code and creates the binary `tar.gz` archive using `scripts/make_binary_distribution`.

These binaries are configured and built with the following compilers and options. This information can also be obtained by looking at the variables `COMP_ENV_INFO` and `CONFIGURE_LINE` inside the script `bin/mysqlbug` of every binary `tar` file distribution.

Anyone who has more optimal options for any of the following `configure` commands can mail them to the MySQL `internals` mailing list. See Section 1.7.1, “MySQL Mailing Lists”.

If you want to compile a debug version of MySQL, you should add `--with-debug` or `--with-debug=full` to the following `configure` commands and remove any -

fomit-frame-pointer options.

The following binaries are built on MySQL AB development systems:

- Linux 2.4.xx x86 with gcc 2.95.3:

```
CFLAGS="-O2 -mcpu=pentiumpro" CXX=gcc CXXFLAGS="-O2 -mcpu=pentiumpro
-felide-constructors" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --enable-assembler --disable-shared
--with-client-ldflags=-all-static --with-mysqld-ldflags=-all-static
```

- Linux 2.4.x x86 with icc (Intel C++ Compiler 8.1 or later releases):

```
CC=icc CXX=icpc CFLAGS="-O3 -unroll2 -ip -mp -no-gcc -restrict"
CXXFLAGS="-O3 -unroll2 -ip -mp -no-gcc -restrict" ./configure
--prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --enable-assembler
--disable-shared --with-client-ldflags=-all-static
--with-mysqld-ldflags=-all-static --with-embedded-server --with-innodb
```

Note that versions 8.1 and newer of the Intel compiler have separate drivers for 'pure' C (icc) and C++ (icpc); if you use icc version 8.0 or older for building MySQL, you will need to set CXX=icc.

- Linux 2.4.xx Intel Itanium 2 with ecc (Intel C++ Itanium Compiler 7.0):

```
CC=ecc CFLAGS="-O2 -tpp2 -ip -nolib_inline" CXX=ecc CXXFLAGS="-O2
-tpp2 -ip -nolib_inline" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile
```

- Linux 2.4.xx Intel Itanium with ecc (Intel C++ Itanium Compiler 7.0):

```
CC=ecc CFLAGS=-tpp1 CXX=ecc CXXFLAGS=-tpp1 ./configure
--prefix=/usr/local/mysql --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile
```

- Linux 2.4.xx alpha with ccc (Compaq C V6.2-505 / Compaq C++ V6.3-006):

```
CC=ccc CFLAGS="-fast -arch generic" CXX=cxx CXXFLAGS="-fast -arch
generic -noexceptions -nortti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --with-mysqld-ldflags=-non_shared
--with-client-ldflags=-non_shared --disable-shared
```

- Linux 2.x.xx ppc with gcc 2.95.4:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--localstatedir=/usr/local/mysql/data --libexecdir=/usr/local/mysql/bin
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared --with-embedded-server
--with-innodb
```

- Linux 2.4.xx s390 with gcc 2.95.3:

```
CFLAGS="-O2" CXX=gcc CXXFLAGS="-O2 -felide-constructors" ./configure
--prefix=/usr/local/mysql --with-extra-charsets=complex
```

```
--enable-thread-safe-client --enable-local-infile --disable-shared  
--with-client-ldflags=-all-static --with-mysqld-ldflags=-all-static
```

- Linux 2.4.xx x86\_64 (AMD64) with gcc 3.2.1:

```
CXX=gcc ./configure --prefix=/usr/local/mysql  
--with-extra-charsets=complex --enable-thread-safe-client  
--enable-local-infile --disable-shared
```

- Sun Solaris 8 x86 with gcc 3.2.3:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3  
-fno-omit-frame-pointer -felide-constructors -fno-exceptions  
-fno-rtti" ./configure --prefix=/usr/local/mysql  
--localstatedir=/usr/local/mysql/data --libexecdir=/usr/local/mysql/bin  
--with-extra-charsets=complex --enable-thread-safe-client  
--enable-local-infile --disable-shared --with-innodb
```

- Sun Solaris 8 SPARC with gcc 3.2:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3  
-fno-omit-frame-pointer -felide-constructors -fno-exceptions  
-fno-rtti" ./configure --prefix=/usr/local/mysql  
--with-extra-charsets=complex --enable-thread-safe-client  
--enable-local-infile --enable-assembler --with-named-z-libs=no  
--with-named-curses-libs=-lcurses --disable-shared
```

- Sun Solaris 8 SPARC 64-bit with gcc 3.2:

```
CC=gcc CFLAGS="-O3 -m64 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3  
-m64 -fno-omit-frame-pointer -felide-constructors -fno-exceptions  
-fno-rtti" ./configure --prefix=/usr/local/mysql  
--with-extra-charsets=complex --enable-thread-safe-client  
--enable-local-infile --with-named-z-libs=no  
--with-named-curses-libs=-lcurses --disable-shared
```

- Sun Solaris 9 SPARC with gcc 2.95.3:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3  
-fno-omit-frame-pointer -felide-constructors -fno-exceptions  
-fno-rtti" ./configure --prefix=/usr/local/mysql  
--with-extra-charsets=complex --enable-thread-safe-client  
--enable-local-infile --enable-assembler --with-named-curses-libs=-lcurses  
--disable-shared
```

- Sun Solaris 9 SPARC with cc-5.0 (Sun Forte 5.0):

```
CC=cc-5.0 CXX=CC ASFLAGS="-xarch=v9" CFLAGS="-Xa -xstrconst -mt  
-D_FORTEC_ -xarch=v9" CXXFLAGS="-noex -mt -D_FORTEC_ -xarch=v9"  
./configure --prefix=/usr/local/mysql --with-extra-charsets=complex  
--enable-thread-safe-client --enable-local-infile --enable-assembler  
--with-named-z-libs=no --enable-thread-safe-client --disable-shared
```

- IBM AIX 4.3.2 ppc with gcc 3.2.3:

```
CFLAGS="-O2 -mcpu=powerpc -Wa,-many " CXX=gcc CXXFLAGS="-O2  
-mcpu=powerpc -Wa,-many -felide-constructors -fno-exceptions  
-fno-rtti" ./configure --prefix=/usr/local/mysql  
--with-extra-charsets=complex --enable-thread-safe-client  
--enable-local-infile --with-named-z-libs=no --disable-shared
```

- IBM AIX 4.3.3 ppc with x1C\_r (IBM Visual Age C/C++ 6.0):

```
CC=x1c_r CFLAGS="-ma -O2 -qstrict -qoptimize=2 -qmaxmem=8192"
CXX=x1C_r CXXFLAGS="-ma -O2 -qstrict -qoptimize=2 -qmaxmem=8192"
./configure --prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --with-named-z-libs=no
--disable-shared --with-innodb
```

- IBM AIX 5.1.0 ppc with gcc 3.3:

```
CFLAGS="-O2 -mcpu=powerpc -Wa,-many" CXX=gcc CXXFLAGS="-O2 -mcpu=powerpc
-Wa,-many -felide-constructors -fno-exceptions -fno-rtti" ./configure
--prefix=/usr/local/mysql --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --with-named-z-libs=no
--disable-shared
```

- IBM AIX 5.2.0 ppc with x1C\_r (IBM Visual Age C/C++ 6.0):

```
CC=x1c_r CFLAGS="-ma -O2 -qstrict -qoptimize=2 -qmaxmem=8192"
CXX=x1C_r CXXFLAGS="-ma -O2 -qstrict -qoptimize=2 -qmaxmem=8192"
./configure --prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --with-named-z-libs=no
--disable-shared --with-embedded-server --with-innodb
```

- HP-UX 10.20 pa-risc1.1 with gcc 3.1:

```
CFLAGS="-DHPUX -I/opt/dce/include -O3 -fPIC" CXX=gcc CXXFLAGS="-DHPUX
-I/opt/dce /include -felide-constructors -fno-exceptions -fno-rtti
-O3 -fPIC" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --with-pthread --with-named-thread-libs=-ldce
--with-lib-ccflags=-fPIC --disable-shared
```

- HP-UX 11.00 pa-risc with aCC (HP ANSI C++ B3910B A.03.50):

```
CC=cc CXX=aCC CFLAGS="+DAportable" CXXFLAGS="+DAportable" ./configure
--prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --disable-shared
--with-embedded-server --with-innodb
```

- HP-UX 11.11 pa-risc2.0 64bit with aCC (HP ANSI C++ B3910B A.03.33):

```
CC=cc CXX=aCC CFLAGS="+DD64" CXXFLAGS="+DD64" ./configure
--prefix=/usr/local/mysql --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --disable-shared
```

- HP-UX 11.11 pa-risc2.0 32bit with aCC (HP ANSI C++ B3910B A.03.33):

```
CC=cc CXX=aCC CFLAGS="+DAportable" CXXFLAGS="+DAportable" ./configure
--prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --disable-shared
--with-innodb
```

- HP-UX 11.22 ia64 64bit with aCC (HP aC++/ANSI C B3910B A.05.50):

```
CC=cc CXX=aCC CFLAGS="+DD64 +DSitanium2" CXXFLAGS="+DD64 +DSitanium2"
./configure --prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --disable-shared
--with-embedded-server --with-innodb
```

- Apple Mac OS X 10.2 powerpc with gcc 3.1:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared
```

- FreeBSD 4.7 i386 with gcc 2.95.4:

```
CFLAGS=-DHAVE_BROKEN_REALPATH ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --enable-assembler --with-named-z-libs=not-used
--disable-shared
```

- FreeBSD 4.7 i386 using LinuxThreads with gcc 2.95.4:

```
CFLAGS="-DHAVE_BROKEN_REALPATH -D__USE_UNIX98 -D_REENTRANT
-D_THREAD_SAFE -I/usr/local/include/pthread/linuxthreads"
CXXFLAGS="-DHAVE_BROKEN_REALPATH -D__USE_UNIX98 -D_REENTRANT
-D_THREAD_SAFE -I/usr/local/include/pthread/linuxthreads" ./configure
--prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --enable-thread-safe-client
--enable-local-infile --enable-assembler
--with-named-thread-libs="-DHAVE_GLIBC2_STYLE_GETHOSTBYNAME_R
-D_THREAD_SAFE -I /usr/local/include/pthread/linuxthreads
-L/usr/local/lib -llthread -llgcc_r" --disable-shared
--with-embedded-server --with-innodb
```

- QNX Neutrino 6.2.1 i386 with gcc 2.95.3qnx-nto 20010315:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared
```

The following binaries are built on third-party systems kindly provided to MySQL AB by other users. These are provided only as a courtesy; MySQL AB does not have full control over these systems, so we can provide only limited support for the binaries built on them.

- SCO Unix 3.2v5.0.7 i386 with gcc 2.95.3:

```
CFLAGS="-O3 -mpentium" LDFLAGS=-static CXX=gcc CXXFLAGS="-O3 -mpentium
-felide-constructors" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --with-named-z-libs=no --enable-thread-safe-client
--disable-shared
```

- SCO UnixWare 7.1.4 i386 with CC 3.2:

```
CC=cc CFLAGS="-O" CXX=CC ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
```

```
--enable-local-infile --with-named-z-libs=no --enable-thread-safe-client
--disable-shared --with-readline
```

- SCO OpenServer 6.0.0 i386 with CC 3.2:

```
CC=cc CFLAGS="-O" CXX=CC ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --with-named-z-libs=no --enable-thread-safe-client
--disable-shared --with-readline
```

- Compaq Tru64 OSF/1 V5.1 732 alpha with cc/cxx (Compaq C V6.3-029i / DIGITAL C++ V6.1-027):

```
CC="cc -pthread" CFLAGS="-O4 -ansi_alias -ansi_args -fast -inline
speed -speculate all" CXX="cxx -pthread" CXXFLAGS="-O4 -ansi_alias
-fast -inline speed -speculate all -noexceptions -nortti" ./configure
--prefix=/usr/local/mysql --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile
--with-named-thread-libs="-lpthread -lmach -lexc -lc" --disable-shared
--with-mysqld-ldflags=-all-static
```

- SGI Irix 6.5 IP32 with gcc 3.0.1:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared
```

- FreeBSD/sparc64 5.0 with gcc 3.2.1:

```
CFLAGS=-DHAVE_BROKEN_REALPATH ./configure --prefix=/usr/local/mysql
--localstatedir=/usr/local/mysql/data --libexecdir=/usr/local/mysql/bin
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared --with-innodb
```

The following compile options have been used for binary packages that MySQL AB provided in the past. These binaries no longer are being updated, but the compile options are listed here for reference purposes.

- Linux 2.2.xx SPARC with egcs 1.1.2:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --enable-assembler --disable-shared
```

- Linux 2.2.x with x86 with gcc 2.95.2:

```
CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro
-felide-constructors -fno-exceptions -fno-rtti" ./configure
--prefix=/usr/local/mysql --enable-assembler
--with-mysqld-ldflags=-all-static --disable-shared
--with-extra-charsets=complex
```

- SunOS 4.1.4 2 sun4c with gcc 2.7.2.1:

```
CC=gcc CXX=gcc CXXFLAGS="-O3 -felide-constructors" ./configure
--prefix=/usr/local/mysql --disable-shared --with-extra-charsets=complex
--enable-asm
```

- SunOS 5.5.1 (and above) sun4u with egcs 1.0.3a or 2.90.27 or gcc 2.95.2 and newer:

```
CC=gcc CFLAGS="-O3" CXX=gcc CXXFLAGS="-O3 -felide-constructors
-fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql
--with-low-memory --with-extra-charsets=complex --enable-asm
```

- SunOS 5.6 i86pc with gcc 2.8.1:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 ./configure --prefix=/usr/local/mysql
--with-low-memory --with-extra-charsets=complex
```

- BSDI BSD/OS 3.1 i386 with gcc 2.7.2.1:

```
CC=gcc CXX=gcc CXXFLAGS=-O ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex
```

- BSDI BSD/OS 2.1 i386 with gcc 2.7.2:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex
```

- AIX 4.2 with gcc 2.7.2.2:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex
```

### 2.1.3. How to Get MySQL

Check our downloads page at <http://dev.mysql.com/downloads/> for information about the current version of MySQL and for downloading instructions. For a complete up-to-date list of MySQL download mirror sites, see <http://dev.mysql.com/downloads/mirrors.html>. You can also find information there about becoming a MySQL mirror site and how to report a bad or out-of-date mirror.

Our main mirror is located at <http://mirrors.sunsite.dk/mysql/>.

### 2.1.4. Verifying Package Integrity Using MD5 Checksums or GnuPG

After you have downloaded the MySQL package that suits your needs and before you attempt to install it, you should make sure that it is intact and has not been tampered with. MySQL AB offers three means of integrity checking:

- MD5 checksums
- Cryptographic signatures using GnuPG, the GNU Privacy Guard
- For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site. If you repeatedly cannot successfully verify the integrity of the package, please notify us about such incidents, including the full package name and the download site you have been using, at <webmaster@mysql.com> or <build@mysql.com>. Do not report downloading problems using the bug-reporting system.

### 2.1.4.1. Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify with the following command, where *package\_name* is the name of the package you downloaded:

```
shell> md5sum package_name
```

Example:

```
shell> md5sum mysql-standard-5.0.22-linux-i686.tar.gz
aaab65abbec64d5e907dcd41b8699945  mysql-standard-5.0.22-linux-i686.tar.gz
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

**Note:** Make sure to verify the checksum of the *archive file* (for example, the .zip or .tar.gz file) and not of the files that are contained inside of the archive.

Note that not all operating systems support the md5sum command. On some, it is simply called md5, and others do not ship it at all. On Linux, it is part of the **GNU Text Utilities** package, which is available for a wide range of platforms. You can download the source code from <http://www.gnu.org/software/textutils/> as well. If you have OpenSSL installed, you can use the command `openssl md5 package_name` instead. A Windows implementation of the md5 command line utility is available from <http://www.fourmilab.ch/md5/>. winMd5Sum is a graphical MD5 checking tool that can be obtained from <http://www.nullriver.com/index/products/winmd5sum>.

### 2.1.4.2. Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using MD5 checksums, but requires more work.

At MySQL AB, we sign MySQL downloadable packages with GnuPG (GNU Privacy Guard). GnuPG is an Open Source alternative to the well-known Pretty Good Privacy (PGP) by Phil Zimmermann. See <http://www.gnupg.org/> for more information about GnuPG and how to obtain and install it on your system. Most Linux distributions ship with GnuPG installed by default. For more information about GnuPG, see <http://www.openpgp.org/>.

To verify the signature for a specific package, you first need to obtain a copy of MySQL AB's public GPG build key, which you can download from <http://www.keyserver.net/>. The key that you want to obtain is named `build@mysql.com`. Alternatively, you can cut and paste the key directly from the following text:

```
Key ID:
pub 1024D/5072E1F5 2003-02-03
    MySQL Package signing key (www.mysql.com) <build@mysql.com>
Fingerprint: A4A9 4068 76FC BD3C 4567 70C8 8C71 8D3B 5072 E1F5
```

```
Public Key (ASCII-armored):
```

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v1.0.6 (GNU/Linux)
Comment: For info see http://www.gnupg.org
```

```
mQGIBD4+owwRBAC14GIufCyEDSIePvEW3SAFUdJBtoQHH/nJKZyQT7h9bPlUWC3
```

```

=YJkx
-----END PGP PUBLIC KEY BLOCK-----

```

To import the build key into your personal public GPG keyring, use `gpg --import`. For example, if you have saved the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
```

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension. For example:

Distribution file	<code>mysql-standard-5.0.22-linux-i686.tar.gz</code>
Signature file	<code>mysql-standard-5.0.22-linux-i686.tar.gz.asc</code>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
shell> gpg --verify package_name.asc
```

Example:

```

shell> gpg --verify mysql-standard-5.0.22-linux-i686.tar.gz.asc
gpg: Signature made Tue 12 Jul 2005 23:35:41 EST using DSA key ID 5072E1F5
gpg: Good signature from "MySQL Package signing key (www.mysql.com) <build@mysql.com>"

```

The Good signature message indicates that everything is all right. You can ignore any insecure memory warning you might obtain.

See the GPG documentation for more information on how to work with public keys.

### 2.1.4.3. Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-5.0.22-0.i386.rpm
MySQL-server-5.0.22-0.i386.rpm: md5 gpg OK
```

**Note:** If you are using RPM 4.1 and it complains about (GPG) NOT OK (MISSING KEYS: GPG#5072e1f5), even though you have imported the MySQL public build key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, it maintains its own keyring because it is a system-wide application and a user's GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key as described in Section 2.1.4.2, "Signature Checking Using GnuPG". Then use `rpm --import` to import the key. For example, if you have saved the public key in a file named `mysql_pubkey.asc`, import it using this command:

```
shell> rpm --import mysql_pubkey.asc
```

If you need to obtain the MySQL public key, see Section 2.1.4.2, "Signature Checking Using GnuPG".

## 2.1.5. Installation Layouts

This section describes the default layout of the directories created by installing binary or source distributions provided by MySQL AB. A distribution provided by another vendor might use a layout different from those shown here.

For MySQL 5.0 on Windows, the default installation directory is `C:\Program Files\MySQL\MySQL Server 5.0`. (Some Windows users prefer to install in `C:\mysql`, the directory that formerly was used as the default. However, the layout of the subdirectories remains the same.) The installation directory has the following subdirectories:

Directory	Contents of Directory
bin	Client programs and the <code>mysqld</code> server
data	Log files, databases
Docs	Documentation
examples	Example programs and scripts
include	Include (header) files
lib	Libraries
scripts	Utility scripts
share	Error message files

Installations created from MySQL AB's Linux RPM distributions result in files under the following system directories:

Directory	Contents of Directory
<code>/usr/bin</code>	Client programs and scripts
<code>/usr/sbin</code>	The <code>mysqld</code> server
<code>/var/lib/mysql</code>	Log files, databases
<code>/usr/share/doc/packages</code>	Documentation
<code>/usr/include/mysql</code>	Include (header) files

/usr/lib/mysql	Libraries
/usr/share/mysql	Error message and character set files
/usr/share/sql-bench	Benchmarks

On Unix, a tar file binary distribution is installed by unpacking it at the installation location you choose (typically /usr/local/mysql) and creates the following directories in that location:

Directory	Contents of Directory
bin	Client programs and the <code>mysqld</code> server
data	Log files, databases
docs	Documentation, <code>ChangeLog</code>
include	Include (header) files
lib	Libraries
scripts	<code>mysql_install_db</code>
share/mysql	Error message files
sql-bench	Benchmarks

A source distribution is installed after you configure and compile it. By default, the installation step installs files under /usr/local, in the following subdirectories:

Directory	Contents of Directory
bin	Client programs and scripts
include/mysql	Include (header) files
info	Documentation in Info format
lib/mysql	Libraries
libexec	The <code>mysqld</code> server
share/mysql	Error message files
sql-bench	Benchmarks and <code>crash-me</code> test
var	Databases and log files

Within its installation directory, the layout of a source installation differs from that of a binary installation in the following ways:

- The `mysqld` server is installed in the `libexec` directory rather than in the `bin` directory.
- The data directory is `var` rather than `data`.
- `mysql_install_db` is installed in the `bin` directory rather than in the `scripts` directory.
- The header file and library directories are `include/mysql` and `lib/mysql` rather than `include` and `lib`.

You can create your own binary installation from a compiled source distribution by executing the `scripts/make_binary_distribution` script from the top directory of the source distribution.

## 2.2. Standard MySQL Installation Using a Binary Distribution

The next several sections cover the installation of MySQL on platforms where we offer packages using the native packaging format of the respective platform. (This is also known as performing a “binary install.”) However, binary distributions of MySQL are available for many other platforms as well. See Section 2.8, “Installing MySQL on Other Unix-Like Systems”, for generic installation instructions for these packages that apply to all platforms.

See Section 2.1, “General Installation Issues”, for more information on what other binary distributions are available and how to obtain them.

## 2.3. Installing MySQL on Windows

A native Windows distribution of MySQL has been available from MySQL AB since version 3.21 and represents a sizable percentage of the daily downloads of MySQL. This section describes the process for installing MySQL on Windows.

**Note:** If you are upgrading MySQL from an existing installation older than MySQL 4.1.5, you must first perform the the procedure described in Section 2.3.14, “Upgrading MySQL on Windows”.

To run MySQL on Windows, you need the following:

- A 32-bit Windows operating system such as 9x, Me, NT, 2000, XP, or Windows Server 2003.  
A Windows NT-based operating system (NT, 2000, XP, 2003) permits you to run the MySQL server as a service. The use of a Windows NT-based operating system is strongly recommended. See Section 2.3.11, “Starting MySQL as a Windows Service”.
- Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the `Service Control Manager`.
- TCP/IP protocol support.
- Enough space on the hard drive to unpack, install, and create the databases in accordance with your requirements (generally a minimum of 200 megabytes is recommended.)

There may also be other requirements, depending on how you plan to use MySQL:

- If you plan to connect to the MySQL server via ODBC, you need a Connector/ODBC driver. See Section 23.1, “MySQL Connector/ODBC”.
- If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer filesystem. Don't forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See Section 13.1.5, “CREATE TABLE Syntax”.

MySQL for Windows is available in several distribution formats:

- Binary distributions are available that contain a setup program that installs everything you need so that you can start the server immediately. Another binary distribution format contains an archive that you simply unpack in the installation location and then configure yourself. For details, see Section 2.3.1, “Choosing An Installation Package”.
- The source distribution contains all the code and support files for building the executables using the Visual Studio 7.1 compiler system.

Generally speaking, you should use a binary distribution that includes an installer. It is simpler to use than the others, and you need no additional tools to get MySQL up and running. The installer for the Windows version of MySQL, combined with a GUI Configuration Wizard, automatically in-

stalls MySQL, creates an option file, starts the server, and secures the default user accounts.

The following section describes how to install MySQL on Windows using a binary distribution. To use an installation package that does not include an installer, follow the procedure described in Section 2.3.5, “Installing MySQL from a Noinstall Zip Archive”. To install using a source distribution, see Section 2.9.6, “Installing MySQL from Source on Windows”.

MySQL distributions for Windows can be downloaded from <http://dev.mysql.com/downloads/>. See Section 2.1.3, “How to Get MySQL”.

## 2.3.1. Choosing An Installation Package

For MySQL 5.0, there are three installation packages to choose from when installing MySQL on Windows:

- **The Essentials Package:** This package has a filename similar to `mysql-essential-5.0.22-win32.msi` and contains the minimum set of files needed to install MySQL on Windows, including the Configuration Wizard. This package does not include optional components such as the embedded server and benchmark suite.
- **The Complete Package:** This package has a filename similar to `mysql-5.0.22-win32.zip` and contains all files needed for a complete Windows installation, including the Configuration Wizard. This package includes optional components such as the embedded server and benchmark suite.
- **The Noinstall Archive:** This package has a filename similar to `mysql-noinstall-5.0.22-win32.zip` and contains all the files found in the Complete install package, with the exception of the Configuration Wizard. This package does not include an automated installer, and must be manually installed and configured.

The Essentials package is recommended for most users. It is provided as an `.msi` file for use with the Windows Installer. The Complete and Noinstall distributions are packaged as Zip archives. To use them, you must have a tool that can unpack `.zip` files.

Your choice of install package affects the installation process you must follow. If you choose to install either the Essentials or Complete install packages, see Section 2.3.2, “Installing MySQL with the Automated Installer”. If you choose to install MySQL from the Noinstall archive, see Section 2.3.5, “Installing MySQL from a Noinstall Zip Archive”.

## 2.3.2. Installing MySQL with the Automated Installer

New MySQL users can use the MySQL Installation Wizard and MySQL Configuration Wizard to install MySQL on Windows. These are designed to install and configure MySQL in such a way that new users can immediately get started using MySQL.

The MySQL Installation Wizard and MySQL Configuration Wizard are available in the Essentials and Complete install packages. They are recommended for most standard MySQL installations. Exceptions include users who need to install multiple instances of MySQL on a single server host and advanced users who want complete control of server configuration.

## 2.3.3. Using the MySQL Installation Wizard

### 2.3.3.1. Introduction to the Installation Wizard

MySQL Installation Wizard is an installer for the MySQL server that uses the latest installer technologies for Microsoft Windows. The MySQL Installation Wizard, in combination with the MySQL Configuration Wizard, allows a user to install and configure a MySQL server that is ready for use immediately after installation.

The MySQL Installation Wizard is the standard installer for all MySQL server distributions, version 4.1.5 and higher. Users of previous versions of MySQL need to shut down and remove their existing MySQL installations manually before installing MySQL with the MySQL Installation Wizard. See Section 2.3.3.7, “Upgrading MySQL with the Installation Wizard”, for more information on upgrading from a previous version.

Microsoft has included an improved version of their Microsoft Windows Installer (MSI) in the recent versions of Windows. MSI has become the de-facto standard for application installations on Windows 2000, Windows XP, and Windows Server 2003. The MySQL Installation Wizard makes use of this technology to provide a smoother and more flexible installation process.

The Microsoft Windows Installer Engine was updated with the release of Windows XP; those using a previous version of Windows can reference this Microsoft Knowledge Base article [<http://support.microsoft.com/default.aspx?scid=kb;EN-US;292539>] for information on upgrading to the latest version of the Windows Installer Engine.

In addition, Microsoft has introduced the WiX (Windows Installer XML) toolkit recently. This is the first highly acknowledged Open Source project from Microsoft. We have switched to WiX because it is an Open Source project and it allows us to handle the complete Windows installation process in a flexible manner using scripts.

Improving the MySQL Installation Wizard depends on the support and feedback of users like you. If you find that the MySQL Installation Wizard is lacking some feature important to you, or if you discover a bug, please report it in our bugs database using the instructions given in Section 1.8, “How to Report Bugs or Problems”.

### 2.3.3.2. Downloading and Starting the MySQL Installation Wizard

The MySQL installation packages can be downloaded from <http://dev.mysql.com/downloads/>. If the package you download is contained within a Zip archive, you need to extract the archive first.

The process for starting the wizard depends on the contents of the installation package you download. If there is a `setup.exe` file present, double-click it to start the installation process. If there is an `.msi` file present, double-click it to start the installation process.

### 2.3.3.3. Choosing an Install Type

There are three installation types available: **Typical**, **Complete**, and **Custom**.

The **Typical** installation type installs the MySQL server, the `mysql` command-line client, and the command-line utilities. The command-line clients and utilities include `mysqldump`, `myisamchk`, and several other tools to help you manage the MySQL server.

The **Complete** installation type installs all components included in the installation package. The full installation package includes components such as the embedded server library, the benchmark suite, support scripts, and documentation.

The **Custom** installation type gives you complete control over which packages you wish to install and the installation path that is used. See Section 2.3.3.4, “The Custom Install Dialog”, for more information on performing a custom install.

If you choose the **Typical** or **Complete** installation types and click the Next button, you advance to the confirmation screen to verify your choices and begin the installation. If you choose the **Custom** installation type and click the Next button, you advance to the custom installation dialog, described in Section 2.3.3.4, “The Custom Install Dialog”.

### 2.3.3.4. The Custom Install Dialog

If you wish to change the installation path or the specific components that are installed by the MySQL Installation Wizard, choose the **Custom** installation type.

A tree view on the left side of the custom install dialog lists all available components. Components

that are not installed have a red X icon; components that are installed have a gray icon. To change whether a component is installed, click on that component's icon and choose a new option from the drop-down list that appears.

You can change the default installation path by clicking the Change... button to the right of the displayed installation path.

After choosing your installation components and installation path, click the Next button to advance to the confirmation dialog.

### 2.3.3.5. The Confirmation Dialog

Once you choose an installation type and optionally choose your installation components, you advance to the confirmation dialog. Your installation type and installation path are displayed for you to review.

To install MySQL if you are satisfied with your settings, click the Install button. To change your settings, click the Back button. To exit the MySQL Installation Wizard without installing MySQL, click the Cancel button.

After installation is complete, you have the option of registering with the MySQL web site. Registration gives you access to post in the MySQL forums at [forums.mysql.com](http://forums.mysql.com) [<http://forums.mysql.com>], along with the ability to report bugs at [bugs.mysql.com](http://bugs.mysql.com) [<http://bugs.mysql.com>] and to subscribe to our newsletter. The final screen of the installer provides a summary of the installation and gives you the option to launch the MySQL Configuration Wizard, which you can use to create a configuration file, install the MySQL service, and configure security settings.

### 2.3.3.6. Changes Made by MySQL Installation Wizard

Once you click the Install button, the MySQL Installation Wizard begins the installation process and makes certain changes to your system which are described in the sections that follow.

#### Changes to the Registry

The MySQL Installation Wizard creates one Windows registry key in a typical install situation, located in `HKEY_LOCAL_MACHINE\SOFTWARE\MySQL AB`.

The MySQL Installation Wizard creates a key named after the major version of the server that is being installed, such as `MySQL Server 5.0`. It contains two string values, `Location` and `Version`. The `Location` string contains the path to the installation directory. In a default installation it contains `C:\Program Files\MySQL\MySQL Server 5.0\`. The `Version` string contains the release number. For example, for an installation of MySQL Server 5.0.22, the key contains a value of `5.0.22`.

These registry keys are used to help external tools identify the installed location of the MySQL server, preventing a complete scan of the hard-disk to determine the installation path of the MySQL server. The registry keys are not required to run the server, and if you install MySQL using the `noinstall` Zip archive, the registry keys are not created.

#### Changes to the Start Menu

The MySQL Installation Wizard creates a new entry in the Windows Start menu under a common MySQL menu heading named after the major version of MySQL that you have installed. For example, if you install MySQL 5.0, the MySQL Installation Wizard creates a MySQL Server 5.0 section in the Start menu.

The following entries are created within the new Start menu section:

- **MySQL Command Line Client:** This is a shortcut to the `mysql` command-line client and is configured to connect as the `root` user. The shortcut prompts for a `root` user password when you connect.

- **MySQL Server Instance Config Wizard:** This is a shortcut to the MySQL Configuration Wizard. Use this shortcut to configure a newly installed server, or to reconfigure an existing server.
- **MySQL Documentation:** This is a link to the MySQL server documentation that is stored locally in the MySQL server installation directory. This option is not available when the MySQL server is installed using the Essentials installation package.

### Changes to the File System

The MySQL Installation Wizard by default installs the MySQL 5.0 server to `C:\Program Files\MySQL\MySQL Server 5.0`, where *Program Files* is the default location for applications in your system, and `5.0` is the major version of your MySQL server. This is the recommended location for the MySQL server, replacing the former default location `C:\mysql`.

By default, all MySQL applications are stored in a common directory at `C:\Program Files\MySQL`, where *Program Files* is the default location for applications in your Windows installation. A typical MySQL installation on a developer machine might look like this:

```
C:\Program Files\MySQL\MySQL Server 5.0
C:\Program Files\MySQL\MySQL Administrator 1.0
C:\Program Files\MySQL\MySQL Query Browser 1.0
```

This approach makes it easier to manage and maintain all MySQL applications installed on a particular system.

## 2.3.3.7. Upgrading MySQL with the Installation Wizard

The MySQL Installation Wizard can perform server upgrades automatically using the upgrade capabilities of MSI. That means you do not need to remove a previous installation manually before installing a new release. The installer automatically shuts down and removes the previous MySQL service before installing the new version.

Automatic upgrades are available only when upgrading between installations that have the same major and minor version numbers. For example, you can upgrade automatically from MySQL 4.1.5 to MySQL 4.1.6, but not from MySQL 4.1 to MySQL 5.0.

See Section 2.3.14, “Upgrading MySQL on Windows”.

## 2.3.4. Using the Configuration Wizard

### 2.3.4.1. Introduction to the Configuration Wizard

The MySQL Configuration Wizard helps automate the process of configuring your server under Windows. The MySQL Configuration Wizard creates a custom `my.ini` file by asking you a series of questions and then applying your responses to a template to generate a `my.ini` file that is tuned to your installation.

The MySQL Configuration Wizard is included with the MySQL 5.0 server, and is currently available for Windows users only.

The MySQL Configuration Wizard is to a large extent the result of feedback that MySQL AB has received from many users over a period of several years. However, if you find that it lacks some feature important to you, please report it in our bugs database using the instructions given in Section 1.8, “How to Report Bugs or Problems”.

### 2.3.4.2. Starting the MySQL Configuration Wizard

The MySQL Configuration Wizard is typically launched from the MySQL Installation Wizard, as the MySQL Installation Wizard exits. You can also launch the MySQL Configuration Wizard by clicking the MySQL Server Instance Config Wizard entry in the MySQL section of the Windows

Start menu.

Alternatively, you can navigate to the `bin` directory of your MySQL installation and launch the `MySQLInstanceConfig.exe` file directly.

### 2.3.4.3. Choosing a Maintenance Option

If the MySQL Configuration Wizard detects an existing `my.ini` file, you have the option of either reconfiguring your existing server, or removing the server instance by deleting the `my.ini` file and stopping and removing the MySQL service.

To reconfigure an existing server, choose the Re-configure Instance option and click the Next button. Your existing `my.ini` file is renamed to `mytimestamp.ini.bak`, where `timestamp` is the date and time at which the existing `my.ini` file was created. To remove the existing server instance, choose the Remove Instance option and click the Next button.

If you choose the Remove Instance option, you advance to a confirmation window. Click the Execute button. The MySQL Configuration Wizard stops and removes the MySQL service, and then deletes the `my.ini` file. The server installation and its `data` folder are not removed.

If you choose the Re-configure Instance option, you advance to the Configuration Type dialog where you can choose the type of installation that you wish to configure.

### 2.3.4.4. Choosing a Configuration Type

When you start the MySQL Configuration Wizard for a new MySQL installation, or choose the Re-configure Instance option for an existing installation, you advance to the Configuration Type dialog.

There are two configuration types available: Detailed Configuration and Standard Configuration. The Standard Configuration option is intended for new users who want to get started with MySQL quickly without having to make many decisions about server configuration. The Detailed Configuration option is intended for advanced users who want more fine-grained control over server configuration.

If you are new to MySQL and need a server configured as a single-user developer machine, the Standard Configuration should suit your needs. Choosing the Standard Configuration option causes the MySQL Configuration Wizard to set all configuration options automatically with the exception of Service Options and Security Options.

The Standard Configuration sets options that may be incompatible with systems where there are existing MySQL installations. If you have an existing MySQL installation on your system in addition to the installation you wish to configure, the Detailed Configuration option is recommended.

To complete the Standard Configuration, please refer to the sections on Service Options and Security Options in Section 2.3.4.11, “The Service Options Dialog”, and Section 2.3.4.12, “The Security Options Dialog”, respectively.

### 2.3.4.5. The Server Type Dialog

There are three different server types available to choose from. The server type that you choose affects the decisions that the MySQL Configuration Wizard makes with regard to memory, disk, and processor usage.

- **Developer Machine:** Choose this option for a typical desktop workstation where MySQL is intended only for personal use. It is assumed that many other desktop applications are running. The MySQL server is configured to use minimal system resources.
- **Server Machine:** Choose this option for a server machine where the MySQL server is running alongside other server applications such as FTP, email, and Web servers. The MySQL server is configured to use a moderate portion of the system resources.

- **Dedicated MySQL Server Machine:** Choose this option for a server machine that is intended to run only the MySQL server. It is assumed that no other applications are running. The MySQL server is configured to use all available system resources.

### 2.3.4.6. The Database Usage Dialog

The Database Usage dialog allows you to indicate the storage engines that you expect to use when creating MySQL tables. The option you choose determines whether the InnoDB storage engine is available and what percentage of the server resources are available to InnoDB.

- **Multifunctional Database:** This option enables both the InnoDB and MyISAM storage engines and divides resources evenly between the two. This option is recommended for users who use both storage engines on a regular basis.
- **Transactional Database Only:** This option enables both the InnoDB and MyISAM storage engines, but dedicates most server resources to the InnoDB storage engine. This option is recommended for users who use InnoDB almost exclusively and make only minimal use of MyISAM.
- **Non-Transactional Database Only:** This option disables the InnoDB storage engine completely and dedicates all server resources to the MyISAM storage engine. This option is recommended for users who do not use InnoDB.

### 2.3.4.7. The InnoDB Tablespace Dialog

Some users may want to locate the InnoDB tablespace files in a different location than the MySQL server data directory. Placing the tablespace files in a separate location can be desirable if your system has a higher capacity or higher performance storage device available, such as a RAID storage system.

To change the default location for the InnoDB tablespace files, choose a new drive from the drop-down list of drive letters and choose a new path from the drop-down list of paths. To create a custom path, click the ... button.

If you are modifying the configuration of an existing server, you must click the Modify button before you change the path. In this situation you must move the existing tablespace files to the new location manually before starting the server.

### 2.3.4.8. The Concurrent Connections Dialog

To prevent the server from running out of resources, it is important to limit the number of concurrent connections to the MySQL server that can be established. The Concurrent Connections dialog allows you to choose the expected usage of your server, and sets the limit for concurrent connections accordingly. It is also possible to set the concurrent connection limit manually.

- **Decision Support (DSS)/OLAP:** Choose this option if your server does not require a large number of concurrent connections. The maximum number of connections is set at 100, with an average of 20 concurrent connections assumed.
- **Online Transaction Processing (OLTP):** Choose this option if your server requires a large number of concurrent connections. The maximum number of connections is set at 500.
- **Manual Setting:** Choose this option to set the maximum number of concurrent connections to the server manually. Choose the number of concurrent connections from the drop-down box provided, or enter the maximum number of connections into the drop-down box if the number you desire is not listed.

### 2.3.4.9. The Networking and Strict Mode Options Dialog

Use the Networking Options dialog to enable or disable TCP/IP networking and to configure the port number that is used to connect to the MySQL server.

TCP/IP networking is enabled by default. To disable TCP/IP networking, uncheck the box next to the Enable TCP/IP Networking option.

Port 3306 is used by default. To change the port used to access MySQL, choose a new port number from the drop-down box or type a new port number directly into the drop-down box. If the port number you choose is in use, you are prompted to confirm your choice of port number.

Set the Server SQL Mode to either enable or disable strict mode. Enabling strict mode (default) makes MySQL behave more like other database management systems. *If you run applications that rely on MySQL's old "forgiving" behavior, make sure to either adapt those applications or to disable strict mode.* For more information about strict mode, see Section 5.2.5, "The Server SQL Mode".

### 2.3.4.10. The Character Set Dialog

The MySQL server supports multiple character sets and it is possible to set a default server character set that is applied to all tables, columns, and databases unless overridden. Use the Character Set dialog to change the default character set of the MySQL server.

- **Standard Character Set:** Choose this option if you want to use `latin1` as the default server character set. `latin1` is used for English and many Western European languages.
- **Best Support For Multilingualism:** Choose this option if you want to use `utf8` as the default server character set. This is a Unicode character set that can store characters from many different languages.
- **Manual Selected Default Character Set / Collation:** Choose this option if you want to pick the server's default character set manually. Choose the desired character set from the provided drop-down list.

### 2.3.4.11. The Service Options Dialog

On Windows NT-based platforms, the MySQL server can be installed as a Windows service. When installed this way, the MySQL server can be started automatically during system startup, and even restarted automatically by Windows in the event of a service failure.

The MySQL Configuration Wizard installs the MySQL server as a service by default, using the service name `MySQL`. If you do not wish to install the service, uncheck the box next to the Install As Windows Service option. You can change the service name by picking a new service name from the drop-down box provided or by entering a new service name into the drop-down box.

To install the MySQL server as a service but not have it started automatically at startup, uncheck the box next to the Launch the MySQL Server Automatically option.

### 2.3.4.12. The Security Options Dialog

*It is strongly recommended that you set a root password for your MySQL server, and the MySQL Configuration Wizard requires by default that you do so.* If you do not wish to set a root password, uncheck the box next to the Modify Security Settings option.

To set the root password, enter the desired password into both the New root password and Confirm boxes. If you are reconfiguring an existing server, you need to enter the existing root password into the Current root password box.

To prevent root logins from across the network, check the box next to the Root may only connect from localhost option. This increases the security of your root account.

To create an anonymous user account, check the box next to the Create An Anonymous Account option. Creating an anonymous account can decrease server security and cause login and permission difficulties. For this reason, it is not recommended.

### 2.3.4.13. The Confirmation Dialog

The final dialog in the MySQL Configuration Wizard is the Confirmation Dialog. To start the configuration process, click the Execute button. To return to a previous dialog, click the Back button. To exit the MySQL Configuration Wizard without configuring the server, click the Cancel button.

After you click the Execute button, the MySQL Configuration Wizard performs a series of tasks and displays the progress onscreen as the tasks are performed.

The MySQL Configuration Wizard first determines configuration file options based on your choices using a template prepared by MySQL AB developers and engineers. This template is named `my-template.ini` and is located in your server installation directory.

The MySQL Configuration Wizard then writes these options to a `my.ini` file. The final location of the `my.ini` file is displayed next to the Write configuration file task.

If you chose to create a service for the MySQL server, the MySQL Configuration Wizard creates and starts the service. If you are reconfiguring an existing service, the MySQL Configuration Wizard restarts the service to apply your configuration changes.

If you chose to set a `root` password, the MySQL Configuration Wizard connects to the server, sets your new `root` password and applies any other security settings you may have selected.

After the MySQL Configuration Wizard has completed its tasks, it displays a summary. Click the Finish button to exit the MySQL Configuration Wizard.

### 2.3.4.14. The Location of the my.ini File

The MySQL Configuration Wizard places the `my.ini` file in the installation directory for the MySQL server. This helps associate configuration files with particular server instances.

To ensure that the MySQL server knows where to look for the `my.ini` file, an argument similar to this is passed to the MySQL server as part of the service installation:

```
--defaults-file="C:\Program Files\MySQL\MySQL Server 5.0\my.ini"
```

Here, `C:\Program Files\MySQL\MySQL Server 5.0` is replaced with the installation path to the MySQL Server. The `--defaults-file` option instructs the MySQL server to read the specified file for configuration options when it starts.

### 2.3.4.15. Editing the my.ini File

To modify the `my.ini` file, open it with a text editor and make any necessary changes. You can also modify the server configuration with the MySQL Administrator [<http://www.mysql.com/products/administrator/>] utility.

MySQL clients and utilities such as the `mysql` and `mysqldump` command-line clients are not able to locate the `my.ini` file located in the server installation directory. To configure the client and utility applications, create a new `my.ini` file in the `C:\WINDOWS` or `C:\WINNT` directory (whichever is applicable to your Windows version).

## 2.3.5. Installing MySQL from a Noinstall Zip Archive

Users who are installing from the Noinstall package can use the instructions in this section to manually install MySQL. The process for installing MySQL from a Zip archive is as follows:

1. Extract the archive to the desired install directory
2. Create an option file
3. Choose a MySQL server type
4. Start the MySQL server
5. Secure the default user accounts

This process is described in the sections that follow.

## 2.3.6. Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to Section 2.3.14, “Upgrading MySQL on Windows”, before beginning the upgrade process.
2. If you are using a Windows NT-based operating system such as Windows NT, Windows 2000, Windows XP, or Windows Server 2003, make sure that you are logged in as a user with administrator privileges.
3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. The MySQL Installation Wizard installs MySQL under `C:\Program Files\MySQL`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See Section 2.3.7, “Creating an Option File”.
4. Extract the install archive to the chosen installation location using your preferred Zip archive tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

## 2.3.7. Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (`C:\Program Files\MySQL\MySQL Server 5.0` and `C:\Program Files\MySQL\MySQL Server 5.0\data`).
- You need to tune the server settings.

When the MySQL server starts on Windows, it looks for options in two files: the `my.ini` file in the Windows directory, and the `C:\my.cnf` file. The Windows directory typically is named something like `C:\WINDOWS` or `C:\WINNT`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

MySQL looks for options first in the `my.ini` file, and then in the `my.cnf` file. However, to avoid confusion, it's best if you use only one file. If your PC uses a boot loader where `C:` is not the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

You can also make use of the example option files included with your MySQL distribution. Look in your install directory for files such as `my-small.cnf`, `my-medium.cnf`, `my-large.cnf`, and `my-huge.cnf`, which you can rename and copy to the appropriate location for use as a base configuration file.

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is in `E:\mydata\data`, you can create an option file containing a `[mysqld]` section to specify values for the `basedir` and `datadir` parameters:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=E:/mydata/data
```

Note that Windows pathnames are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, you must double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\\mysql
# set datadir to the location of your data directory
datadir=E:\\mydata\\data
```

On Windows, the MySQL installer places the data directory directly under the directory where you install MySQL. If you would like to use a data directory in a different location, you should copy the entire contents of the data directory to the new location. For example, if MySQL is installed in `C:\Program Files\MySQL\MySQL Server 5.0`, the data directory is by default in `C:\Program Files\MySQL\MySQL Server 5.0\data`. If you want to use `E:\mydata` as the data directory instead, you must do two things:

1. Move the entire data directory and all of its contents from `C:\Program Files\MySQL\MySQL Server 5.0\data` to `E:\mydata`.
2. Use a `--datadir` option to specify the new data directory location each time you start the server.

## 2.3.8. Selecting a MySQL Server type

The following table shows the available servers for Windows in MySQL 5.0:

Binary	Description
<code>mysqld-debug</code>	Compiled with full debugging and automatic memory allocation checking, as well as InnoDB and BDB support.
<code>mysqld</code>	Optimized binary with InnoDB support.
<code>mysqld-nt</code>	Optimized binary for Windows NT, 2000, and XP with support for named pipes.
<code>mysqld-max</code>	Optimized binary with InnoDB and BDB support.
<code>mysqld-max-nt</code>	Like <code>mysqld-max</code> , but compiled with support for named pipes.

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

All Windows MySQL 5.0 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. The `mysqld-nt` and `mysqld-max-nt` servers support named pipes on Windows NT, 2000, XP, and 2003. However, the default is to use TCP/IP regardless of platform. (Named pipes are slower than TCP/IP in many Windows configurations.)

Use of named pipes is subject to these conditions:

- Named pipes are enabled only if you start the server with the `--enable-named-pipe` option. It is necessary to use this option explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used.
- Named-pipe connections are allowed only by the `mysqld-nt` or `mysqld-max-nt` servers, and only if the server is run on a version of Windows that supports named pipes (NT, 2000, XP, 2003).
- These servers can be run on Windows 98 or Me, but only if TCP/IP is installed; named-pipe connections cannot be used.
- These servers cannot be run on Windows 95.

**Note:** Most of the examples in this manual use `mysqld` as the server name. If you choose to use a different server, such as `mysqld-nt`, make the appropriate substitutions in the commands that are shown in the examples.

## 2.3.9. Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the `Noinstall` version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

The examples in these sections assume that MySQL is installed under the default location of `C:\Program Files\MySQL\MySQL Server 5.0`. Adjust the pathnames shown in the examples if you have MySQL installed in a different location.

On NT-based systems such as Windows NT, 2000, XP, or 2003, clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections. For MySQL to work with TCP/IP on Windows NT 4, you must install service pack 3 (or newer).

On Windows 95, 98, or Me, MySQL clients always connect to the server using TCP/IP. (This allows any machine on your network to connect to your MySQL server.) Because of this, you must make sure that TCP/IP support is installed on your machine before starting MySQL. You can find TCP/IP on your Windows CD-ROM.

Note that if you are using an old Windows 95 release (for example, OSR2), it is likely that you have an old Winsock package; MySQL requires Winsock 2. You can get the newest Winsock from <http://www.microsoft.com/>. Windows 98 has the new Winsock 2 library, so it is unnecessary to update the library.

MySQL for Windows also supports shared-memory connections if the server is started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=memory` option.

For information about which server binary to run, see Section 2.3.8, “Selecting a MySQL Server type”.

Testing is best done from a command prompt in a console window (or “DOS window”). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqld" --console
```

For a server that includes InnoDB support, you should see the messages similar to those following as it starts (the pathnames and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25 InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '5.0.22' socket: '' port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` option, the server writes diagnostic output to the error log in the data directory (C:\Program Files\MySQL\MySQL Server 5.0\data by default). The error log is the file with the `.err` extension.

**Note:** The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Post-Installation Setup and Testing”.

## 2.3.10. Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

To start the `mysqld` server from the command line, you should start a console window (or “DOS window”) and enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

On non-NT versions of Windows, this command starts `mysqld` in the background. That is, after the server starts, you should see another command prompt. If you start the server this way on Windows NT, 2000, XP, or 2003, the server runs in the foreground and no command prompt appears until the server exits. Because of this, you should open another console window to run client programs while the server is running.

You can stop the MySQL server by executing this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqladmin" -u root shutdown
```

**Note:** If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the `C:\Program Files\MySQL\MySQL Server 5.0\data` directory. It is the file with a suffix of `.err`. You can also try to start the server as `mysqld --console`; in this case, you may get some useful information on the screen that may help solve the problem.

The last option is to start `mysqld` with the `--standalone` and `--debug` options. In this case, `mysqld` writes a log file `C:\mysqld.trace` that should contain the reason why `mysqld` doesn't start. See Section E.1.2, "Creating Trace Files".

Use `mysqld --verbose --help` to display all the options that `mysqld` understands.

## 2.3.11. Starting MySQL as a Windows Service

On the NT family (Windows NT, 2000, XP, 2003), the recommended way to run MySQL is to install it as a Windows service, whereby MySQL starts and stops automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using `NET` commands, or with the graphical `Services` utility.

The `Services` utility (the Windows Service Control Manager) can be found in the Windows Control Panel (under Administrative Tools on Windows 2000, XP, and Server 2003). To avoid conflicts, it is advisable to close the `Services` utility while performing server installation or removal operations from the command line.

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqladmin" -u root shutdown
```

**Note:** If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqld" --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

To make it easier to invoke MySQL programs, you can add the pathname of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click on the My Computer icon, and select Properties

- Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
- Under System Variables, select Path, and then click the Edit button. The Edit System Variable dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked Variable Value. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete pathname of your MySQL bin directory (for example, C:\Program Files\MySQL\MySQL Server 5.0\bin), Note that there should be a semicolon separating this path from any values present in this field. Dismiss this dialogue, and each dialogue in turn, by clicking OK until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL bin directory to your Windows PATH if you are running multiple MySQL servers on the same machine.

**Warning:** You must exercise great care when editing your system PATH by hand; accidental deletion or modification of any portion of the existing PATH value can leave you with a malfunctioning or even unusable system.

The following additional arguments can be used in MySQL 5.0 when installing the service:

- You can specify a service name immediately following the `--install` option. The default service name is MySQL.
- If a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=file_name` to specify the name of an option file from which the server should read options when it starts.

It is possible to use a single option other than `--defaults-file`, but this is discouraged. `--defaults-file` is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file. Also, in MySQL 5.0, use of an option different from `--defaults-file` is not supported until 5.0.3.

- As of MySQL 5.0.1, you can also specify a `--local-service` option following the service name. This causes the server to run using the LocalService Windows account that has limited system privileges. This account is available only for Windows XP or newer. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (MySQL) following the `--install` option, the server uses the a service name of MySQL and reads options from the `[mysqld]` group in the standard option files.
- If the service-installation command specifies a service name other than MySQL following the `--install` option, the server uses that service name. It reads options from the group that has the same name as the service, and reads options from the standard option files.

The server also reads options from the `[mysqld]` group from the standard option files. This allows you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the same name as a service for use by the server installed with that service name.

- If the service-installation command specifies a `--defaults-file` option after the service name, the server reads options only from the `[mysqld]` group of the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqld"
      --install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (MySQL) is given after the `--install` option. If no `--defaults-file` option had been given, this command would have the effect of causing the server to read the `[mysqld]` group from the standard option files. However, because the `--defaults-file` option is present, the server reads options from the `[mysqld]` option group, and only from the named file.

You can also specify options as Start parameters in the Windows *Services* utility before you start the MySQL service.

Once a MySQL server has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the *Services* utility, or by using a `NET START MySQL` command. The `NET` command is not case sensitive.

When run as a service, `mysqld` has no access to a console window, so no messages can be seen there. If `mysqld` does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, `C:\Program Files\MySQL\MySQL Server 5.0\data`). It is the file with a suffix of `.err`.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually by using the *Services* utility, the `NET STOP MySQL` command, or the `mysqladmin shutdown` command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the `--install-manual` option rather than the `--install` option:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqld" --install-manual
```

To remove a server that is installed as a service, first stop it if it is running by executing `NET STOP MySQL`. Then use the `--remove` option to remove it:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqld" --remove
```

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see Section 2.3.10, "Starting MySQL from the Windows Command Line".

Please see Section 2.3.13, "Troubleshooting a MySQL Installation Under Windows", if you encounter difficulties during installation.

## 2.3.12. Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqlshow"
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqlshow" -u root mysql
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqladmin" version status pr
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysql" test
```

If `mysqld` is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start `mysqld` with the `--skip-name-resolve` option and use only `localhost` and IP numbers in the `Host` column of the MySQL grant tables.

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Note that if you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then you must use the appropriate `-u` and `-p` options with the commands shown above in order to connect with the MySQL Server. See Section 5.8.4, “Connecting to the MySQL Server”.

For more information about `mysqlshow`, see Section 8.14, “`mysqlshow` — Display Database, Table, and Column Information”.

## 2.3.13. Troubleshooting a MySQL Installation Under Windows

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. The purpose of this section is to help you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the error log. The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the data directory specified in your `my.ini` file. The default data directory location is `C:\Program Files\MySQL\MySQL Server 5.0\data`. See Section 5.12.1, “The Error Log”.

Another source of information regarding possible errors is the console messages displayed when the MySQL service is starting. Use the `NET START MySQL` command from the command line after installing `mysqld` as a service to see any error messages regarding the starting of the MySQL server as a service. See Section 2.3.11, “Starting MySQL as a Windows Service”.

The following examples show other common error messages you may encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the `mysql` privileges database or other critical files, you may see these messages:

```
System error 1067 has occurred.  
Fatal error: Can't open privilege tables: Table 'mysql.host' doesn't exist
```

These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\Program Files\MySQL\MySQL Server 5.0` and `C:\Program Files\MySQL\MySQL Server 5.0\data`, respectively).

This situation may occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, there may be old and new configuration files that conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 5.0`, you need to ensure that the MySQL server is aware of this through the use of a configuration (`my.ini`) file. The `my.ini` file needs to be located in your Windows directory, typically `C:\WINDOWS` or `C:\WINNT`. You can determine its exact location from the value of the `WINDIR` environment variable by issuing the following command from the command prompt:

```
C:\> echo %WINDIR%
```

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` parameters:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Note that Windows pathnames are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, you must double them:

```
[mysqld]
# set basedir to your installation path
basedir=C:\\Program Files\\MySQL\\MySQL Server 5.0
# set datadir to the location of your data directory
datadir=D:\\MySQLdata
```

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See Section 2.3.7, “Creating an Option File”.

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Configuration Wizard, you may see this error:

```
Error: Cannot create Windows service for MySQL. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This allows the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command-line:

```
C:\> sc delete mysql
[SC] DeleteService SUCCESS
```

If the `sc` utility is not available for your version of Windows, download the `delsrv` utility from <http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp> and use the `delsrv mysql` syntax.

## 2.3.14. Upgrading MySQL on Windows

This section lists some of the steps you should take when upgrading MySQL on Windows.

1. Review Section 2.11, “Upgrading MySQL”, for additional information on upgrading MySQL that is not specific to Windows.
2. You should always back up your current MySQL installation before performing an upgrade. See Section 5.10.1, “Database Backups”.

3. Download the latest Windows distribution of MySQL from <http://dev.mysql.com/downloads/>.
4. Before upgrading MySQL, you must stop the server. If the server is installed as a service, stop the service with the following command from the command prompt:

```
C:\> NET STOP MySQL
```

If you are not running the MySQL server as a service, use the following command to stop it:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqladmin" -u root shutdown
```

**Note:** If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

5. When upgrading to MySQL 5.0 from a version previous to 4.1.5, or when upgrading from a version of MySQL installed from a Zip archive to a version of MySQL installed with the MySQL Installation Wizard, you must manually remove the previous installation and MySQL service (if the server is installed as a service).

To remove the MySQL service, use the following command:

```
C:\> C:\mysql\bin\mysqld --remove
```

**If you do not remove the existing service, the MySQL Installation Wizard may fail to properly install the new MySQL service.**

6. If you are using the MySQL Installation Wizard, start the wizard as described in Section 2.3.3, “Using the MySQL Installation Wizard”.
7. If you are installing MySQL from a Zip archive, extract the archive. You may either overwrite your existing MySQL installation (usually located at `C:\mysql`), or install it into a different directory, such as `C:\mysql5`. Overwriting the existing installation is recommended.
8. If you were running MySQL as a Windows service and you had to remove the service earlier in this procedure, reinstall the service. (See Section 2.3.11, “Starting MySQL as a Windows Service”.)
9. Restart the server. For example, use `NET START MySQL` if you run MySQL as a service, or invoke `mysqld` directly otherwise.
10. If you encounter errors, see Section 2.3.13, “Troubleshooting a MySQL Installation Under Windows”.

## 2.3.15. MySQL on Windows Compared to MySQL on Unix

MySQL for Windows has proven itself to be very stable. The Windows version of MySQL has the same features as the corresponding Unix version, with the following exceptions:

- **Windows 95 and threads**

Windows 95 leaks about 200 bytes of main memory for each thread creation. Each connection in MySQL creates a new thread, so you shouldn't run `mysqld` for an extended time on Windows 95 if your server handles many connections! Newer versions of Windows don't suffer from this bug.

- **Limited number of ports**

Windows systems have about 4,000 ports available for client connections, and after a connection on a port closes, it takes two to four minutes before the port can be reused. In situations where clients connect to and disconnect from the server at a high rate, it is possible for all available ports to be used up before closed ports become available again. If this happens, the MySQL server appears to be unresponsive even though it is running. Note that ports may be used by other applications running on the machine as well, in which case the number of ports available to MySQL is lower.

For more information about this problem, see <http://support.microsoft.com/default.aspx?scid=kb;en-us;196271>.

- **Concurrent reads**

MySQL depends on the `pread()` and `pwrite()` system calls to be able to mix `INSERT` and `SELECT`. Currently, we use mutexes to emulate `pread()` and `pwrite()`. We intend to replace the file level interface with a virtual interface in the future so that we can use the `readfile()/writefile()` interface on NT, 2000, and XP to get more speed. The current implementation limits the number of open files that MySQL 5.0 can use to 2,048, which means that you cannot run as many concurrent threads on Windows NT, 2000, XP, and 2003 as on Unix.

- **Blocking read**

MySQL uses a blocking read for each connection. That has the following implications if named-pipe connections are enabled:

- A connection is not disconnected automatically after eight hours, as happens with the Unix version of MySQL.
- If a connection hangs, it is not possible to break it without killing MySQL.
- `mysqladmin kill` does not work on a sleeping connection.
- `mysqladmin shutdown` cannot abort as long as there are sleeping connections.

We plan to fix this problem in the future.

- **ALTER TABLE**

While you are executing an `ALTER TABLE` statement, the table is locked from being used by other threads. This has to do with the fact that on Windows, you can't delete a file that is in use by another thread. In the future, we may find some way to work around this problem.

- **DROP TABLE**

`DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` handler does the table mapping hidden from the upper layer of MySQL. Because Windows does not allow dropping files that are open, you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.

- **DATA DIRECTORY and INDEX DIRECTORY**

The `DATA DIRECTORY` and `INDEX DIRECTORY` options for `CREATE TABLE` are ignored on Windows, because Windows doesn't support symbolic links. These options also are ignored on systems that have a non-functional `realpath()` call.

- **DROP DATABASE**

You cannot drop a database that is in use by some thread.

- **Killing MySQL from the Task Manager**

On Windows 95, you cannot kill MySQL from the Task Manager or with the shutdown utility. You must stop it with `mysqladmin shutdown`.

- **Case-insensitive names**

Filenames are not case sensitive on Windows, so MySQL database and table names are also not case sensitive on Windows. The only restriction is that database and table names must be specified using the same case throughout a given statement. See Section 9.2.2, “Identifier Case Sensitivity”.

- **The ‘\’ pathname separator character**

Pathname components in Windows are separated by the ‘\’ character, which is also the escape character in MySQL. If you are using `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, use Unix-style filenames with ‘/’ characters:

```
mysql> LOAD DATA INFILE 'C:/tmp/skr.txt' INTO TABLE skr;  
mysql> SELECT * INTO OUTFILE 'C:/tmp/skr.txt' FROM skr;
```

Alternatively, you must double the ‘\’ character:

```
mysql> LOAD DATA INFILE 'C:\\tmp\\skr.txt' INTO TABLE skr;  
mysql> SELECT * INTO OUTFILE 'C:\\tmp\\skr.txt' FROM skr;
```

- **Problems with pipes**

Pipes do not work reliably from the Windows command-line prompt. If the pipe includes the character `^Z / CHAR(24)`, Windows thinks that it has encountered end-of-file and aborts the program.

This is mainly a problem when you try to apply a binary log as follows:

```
C:\> mysqlbinlog binary_log_file | mysql --user=root
```

If you have a problem applying the log and suspect that it is because of a `^Z / CHAR(24)` character, you can use the following workaround:

```
C:\> mysqlbinlog binary_log_file --result-file=/tmp/bin.sql  
C:\> mysql --user=root --execute "source /tmp/bin.sql"
```

The latter command also can be used to reliably read in any SQL file that may contain binary data.

- **Access denied for user error**

If MySQL cannot resolve your hostname properly, you may get the following error when you attempt to run a MySQL client program to connect to a server running on the same machine:

```
Access denied for user 'some_user'@'unknown'  
to database 'mysql'
```

To fix this problem, you should create a file named `\windows\hosts` containing the following information:

```
127.0.0.1      localhost
```

Here are some open issues for anyone who might want to help us improve MySQL on Windows:

- Add macros to use the faster thread-safe increment/decrement methods provided by Windows.

## 2.4. Installing MySQL on Linux

The recommended way to install MySQL on Linux is by using the RPM packages. The MySQL RPMs are currently built on a SuSE Linux 7.3 system, but should work on most versions of Linux that support `rpm` and use `glibc`. To obtain RPM packages, see Section 2.1.3, “How to Get MySQL”.

MySQL AB does provide some platform-specific RPMs; the difference between a platform-specific RPM and a generic RPM is that a platform-specific RPM is built on the targeted platform and is linked dynamically whereas a generic RPM is linked statically with `LinuxThreads`.

**Note:** RPM distributions of MySQL often are provided by other vendors. Be aware that they may differ in features and capabilities from those built by MySQL AB, and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

If you have problems with an RPM file (for example, if you receive the error `Sorry, the host 'xxxx' could not be looked up`), see Section 2.13.1.2, “Linux Binary Distribution Notes”.

In most cases, you need to install only the `MySQL-server` and `MySQL-client` packages to get a functional MySQL installation. The other packages are not required for a standard installation. If you want to run a `MySQL-Max` server that has additional capabilities, you should also install the `MySQL-Max` RPM. However, you should do so only *after* installing the `MySQL-server` RPM. See Section 5.3, “The `mysqld-max` Extended MySQL Server”.

If you get a dependency failure when trying to install MySQL packages (for example, error: removing these packages would break dependencies: `libmysqlclient.so.10` is needed by ...), you should also install the `MySQL-shared-compat` package, which includes both the shared libraries for backward compatibility (`libmysqlclient.so.12` for MySQL 4.0 and `libmysqlclient.so.10` for MySQL 3.23).

Some Linux distributions still ship with MySQL 3.23 and they usually link applications dynamically to save disk space. If these shared libraries are in a separate package (for example, `MySQL-shared`), it is sufficient to simply leave this package installed and just upgrade the MySQL server and client packages (which are statically linked and do not depend on the shared libraries). For distributions that include the shared libraries in the same package as the MySQL server (for example, Red Hat Linux), you could either install our 3.23 `MySQL-shared` RPM, or use the `MySQL-shared-compat` package instead. (Do not install both.)

The following RPM packages are available:

- `MySQL-server-VERSION.i386.rpm`

The MySQL server. You need this unless you only want to connect to a MySQL server running on another machine.

Note: Server RPM files were called `MySQL-VERSION.i386.rpm` before MySQL 4.0.10. That is, they did not have `-server` in the name.

- `MySQL-Max-VERSION.i386.rpm`

The MySQL-Max server. This server has additional capabilities that the one provided in the `MySQL-server` RPM does not. You must install the `MySQL-server` RPM first, because the `MySQL-Max` RPM depends on it.

- `MySQL-client-VERSION.i386.rpm`

The standard MySQL client programs. You probably always want to install this package.

- `MySQL-bench-VERSION.i386.rpm`

Tests and benchmarks. Requires Perl and the DBI and DBD: :mysql modules.

- `MySQL-devel-VERSION.i386.rpm`

The libraries and include files that are needed if you want to compile other MySQL clients, such as the Perl modules.

- `MySQL-shared-VERSION.i386.rpm`

This package contains the shared libraries (`libmysqlclient.so*`) that certain languages and applications need to dynamically load and use MySQL. It contains single-threaded and thread-safe libraries. If you install this package, do not install the `MySQL-shared-compat` package.

- `MySQL-shared-compat-VERSION.i386.rpm`

This package includes the shared libraries for MySQL 3.23, 4.0, 4.1, and 5.0. It contains single-threaded and thread-safe libraries. Install this package instead of `MySQL-shared` if you have applications installed that are dynamically linked against older versions of MySQL but you want to upgrade to the current version without breaking the library dependencies.

- `MySQL-embedded-VERSION.i386.rpm`

The embedded MySQL server library (available as of MySQL 4.0).

- `MySQL-VERSION.src.rpm`

This contains the source code for all of the previous packages. It can also be used to rebuild the RPMs on other architectures (for example, Alpha or SPARC).

To see all files in an RPM package (for example, a `MySQL-server` RPM), run a command like this:

```
shell> rpm -qpl MySQL-server-VERSION.i386.rpm
```

To perform a standard minimal installation, install the server and client RPMs:

```
shell> rpm -i MySQL-server-VERSION.i386.rpm
shell> rpm -i MySQL-client-VERSION.i386.rpm
```

To install only the client programs, install just the client RPM:

```
shell> rpm -i MySQL-client-VERSION.i386.rpm
```

RPM provides a feature to verify the integrity and authenticity of packages before installing them. If you would like to learn more about this feature, see Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”.

The server RPM places data under the `/var/lib/mysql` directory. The RPM also creates a login account for a user named `mysql` (if one does not exist) to use for running the MySQL server, and creates the appropriate entries in `/etc/init.d/` to start the server automatically at boot time. (This means that if you have performed a previous installation and have made changes to its startup script, you may want to make a copy of the script so that you don't lose it when you install a newer RPM.) See Section 2.10.2.2, “Starting and Stopping MySQL Automatically”, for more information on how MySQL can be started automatically on system startup.

If you want to install the MySQL RPM on older Linux distributions that do not support initialization scripts in `/etc/init.d` (directly or via a symlink), you should create a symbolic link that points to the location where your initialization scripts actually are installed. For example, if that location is `/etc/rc.d/init.d`, use these commands before installing the RPM to create `/etc/init.d`

as a symbolic link that points there:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

However, all current major Linux distributions should support the new directory layout that uses `/etc/init.d`, because it is required for LSB (Linux Standard Base) compliance.

If the RPM files that you install include `MySQL-server`, the `mysqld` server should be up and running after installation. You should be able to start using MySQL.

If something goes wrong, you can find more information in the binary installation section. See Section 2.8, “Installing MySQL on Other Unix-Like Systems”.

**Note:** The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Post-Installation Setup and Testing”.

## 2.5. Installing MySQL on Mac OS X

You can install MySQL on Mac OS X 10.2.x (“Jaguar”) or newer using a Mac OS X binary package in PKG format instead of the binary tarball distribution. Please note that older versions of Mac OS X (for example, 10.1.x) are **not** supported by this package.

The package is located inside a disk image (`.dmg`) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

To obtain MySQL, see Section 2.1.3, “How to Get MySQL”.

**Note:** Before proceeding with the installation, be sure to shut down all running MySQL server instances by either using the MySQL Manager Application (on Mac OS X Server) or via `mysqladmin shutdown` on the command line.

To actually install the MySQL PKG file, double-click on the package icon. This launches the Mac OS X Package Installer, which guides you through the installation of MySQL.

Due to a bug in the Mac OS X package installer, you may see this error message in the destination disk selection dialog:

```
You cannot install this software on this disk. (null)
```

If this error occurs, simply click the `Go Back` button once to return to the previous screen. Then click `Continue` to advance to the destination disk selection again, and you should be able to choose the destination disk correctly. We have reported this bug to Apple and it is investigating this problem.

The Mac OS X PKG of MySQL installs itself into `/usr/local/mysql-VERSION` and also installs a symbolic link, `/usr/local/mysql`, that points to the new location. If a directory named `/usr/local/mysql` exists, it is renamed to `/usr/local/mysql.bak` first. Additionally, the installer creates the grant tables in the `mysql` database by executing `mysql_install_db`.

The installation layout is similar to that of a `tar` file binary distribution; all MySQL binaries are located in the directory `/usr/local/mysql/bin`. The MySQL socket file is created as `/tmp/mysql.sock` by default. See Section 2.1.5, “Installation Layouts”.

MySQL installation requires a Mac OS X user account named `mysql`. A user account with this name should exist by default on Mac OS X 10.2 and up.

If you are running Mac OS X Server, a version of MySQL should already be installed. The following table shows the versions of MySQL that ship with Mac OS X Server versions.

Mac OS X Server Version	MySQL Version
-------------------------	---------------

10.2-10.2.2	3.23.51
10.2.3-10.2.6	3.23.53
10.3	4.0.14
10.3.2	4.0.16
10.4.0	4.1.10a

This manual section covers the installation of the official MySQL Mac OS X PKG only. Make sure to read Apple's help information about installing MySQL: Run the "Help View" application, select "Mac OS X Server" help, do a search for "MySQL," and read the item entitled "Installing MySQL."

For pre-installed versions of MySQL on Mac OS X Server, note especially that you should start `mysqld` with `safe_mysqld` instead of `mysqld_safe` if MySQL is older than version 4.0.

If you previously used Marc Liyanage's MySQL packages for Mac OS X from <http://www.entropy.ch>, you can simply follow the update instructions for packages using the binary installation layout as given on his pages.

If you are upgrading from Marc's 3.23.x versions or from the Mac OS X Server version of MySQL to the official MySQL PKG, you also need to convert the existing MySQL privilege tables to the current format, because some new security privileges have been added. See Section 5.6.2, "mysql\_upgrade — Check Tables for MySQL Upgrade".

If you want MySQL to start automatically during system startup, you also need to install the MySQL Startup Item. It is part of the Mac OS X installation disk images as a separate installation package. Simply double-click the MySQLStartupItem.pkg icon and follow the instructions to install it. The Startup Item need be installed only once. There is no need to install it each time you upgrade the MySQL package later.

The Startup Item for MySQL is installed into `/Library/StartupItems/MySQLCOM`. (Before MySQL 4.1.2, the location was `/Library/StartupItems/MySQL`, but that collided with the MySQL Startup Item installed by Mac OS X Server.) Startup Item installation adds a variable `MYSQLCOM=-YES-` to the system configuration file `/etc/hostconfig`. If you want to disable the automatic startup of MySQL, simply change this variable to `MYSQLCOM=-NO-`.

On Mac OS X Server, the default MySQL installation uses the variable `MYSQL` in the `/etc/hostconfig` file. The MySQL AB Startup Item installer disables this variable by setting it to `MYSQL=-NO-`. This avoids boot time conflicts with the `MYSQLCOM` variable used by the MySQL AB Startup Item. However, it does not shut down a running MySQL server. You should do that yourself.

After the installation, you can start up MySQL by running the following commands in a terminal window. You must have administrator privileges to perform this task.

If you have installed the Startup Item, use this command:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM start  
(Enter your password, if necessary)  
(Press Control-D or enter "exit" to exit the shell)
```

If you don't use the Startup Item, enter the following command sequence:

```
shell> cd /usr/local/mysql  
shell> sudo ./bin/mysqld_safe  
(Enter your password, if necessary)  
(Press Control-Z)  
shell> bg  
(Press Control-D or enter "exit" to exit the shell)
```

You should be able to connect to the MySQL server, for example, by running /

`usr/local/mysql/bin/mysql`.

**Note:** The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Post-Installation Setup and Testing”.

You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `bash` is:

```
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For `tcsh`, use:

```
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. For example, add the following line to your `$HOME/.bashrc` file if your shell is `bash`:

```
PATH=${PATH}:/usr/local/mysql/bin
```

Add the following line to your `$HOME/.tcshrc` file if your shell is `tcsh`:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If no `.bashrc` or `.tcshrc` file exists in your home directory, create it with a text editor.

If you are upgrading an existing installation, note that installing a new MySQL PKG does not remove the directory of an older installation. Unfortunately, the Mac OS X Installer does not yet offer the functionality required to properly upgrade previously installed packages.

To use your existing databases with the new installation, you'll need to copy the contents of the old data directory to the new data directory. Make sure that neither the old server nor the new one is running when you do this. After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.

## 2.6. Installing MySQL on Solaris

If you install MySQL using a binary tarball distribution on Solaris, you may run into trouble even before you get the MySQL distribution unpacked, as the Solaris `tar` cannot handle long filenames. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution. You can find a precompiled copy for Solaris at <http://dev.mysql.com/downloads/os-solaris.html>.

You can install MySQL on Solaris using a binary package in PKG format instead of the binary tarball distribution. Some basic PKG-handling commands follow:

- To add a package:

```
pkgadd -d package_name.pkg
```

- To remove a package:

```
pkgrm package_name
```

- To get a full list of installed packages:  
`pkginfo`
- To get detailed information for a package:  
`pkginfo -l package_name`
- To list the files belonging to a package:  
`pkgchk -v package_name`
- To get packaging information for an arbitrary file:  
`pkgchk -l -p file_name`

For additional information about installing MySQL on Solaris, see Section 2.13.3, “Solaris Notes”.

## 2.7. Installing MySQL on NetWare

Porting MySQL to NetWare was an effort spearheaded by Novell. Novell customers should be pleased to note that NetWare 6.5 ships with bundled MySQL binaries, complete with an automatic commercial use license for all servers running that version of NetWare.

MySQL for NetWare is compiled using a combination of Metrowerks CodeWarrior for NetWare and special cross-compilation versions of the GNU autotools.

The latest binary packages for NetWare can be obtained at <http://dev.mysql.com/downloads/>. See Section 2.1.3, “How to Get MySQL”.

To host MySQL, the NetWare server must meet these requirements:

- The latest Support Pack of NetWare 6.5 [<http://support.novell.com/filefinder/18197/index.html>] must be installed.
- The system must meet Novell's minimum requirements to run the respective version of NetWare.
- MySQL data and the program binaries must be installed on an NSS volume; traditional volumes are not supported.

To install MySQL for NetWare, use the following procedure:

1. If you are upgrading from a prior installation, stop the MySQL server. This is done from the server console, using the following command:

```
SERVER: mysqladmin -u root shutdown
```

**Note:** If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

2. Log on to the target server from a client machine with access to the location where you are installing MySQL.
3. Extract the binary package Zip file onto the server. Be sure to allow the paths in the Zip file to

be used. It is safe to simply extract the file to `SYS:\`.

If you are upgrading from a prior installation, you may need to copy the data directory (for example, `SYS:MYSQL\DATA`), as well as `my.cnf`, if you have customized it. You can then delete the old copy of MySQL.

4. You might want to rename the directory to something more consistent and easy to use. The examples in this manual use `SYS:MYSQL` to refer to the installation directory.

Note that MySQL installation on NetWare does not detect if a version of MySQL is already installed outside the NetWare release. Therefore, if you have installed the latest MySQL version from the Web (for example, MySQL 4.1 or later) in `SYS:\MYSQL`, you must rename the folder before upgrading the NetWare server; otherwise, files in `SYS:\MYSQL` are overwritten by the MySQL version present in NetWare Support Pack.

5. At the server console, add a search path for the directory containing the MySQL NLMs. For example:

```
SERVER:  SEARCH ADD SYS:MYSQL\BIN
```

6. Initialize the data directory and the grant tables, if necessary, by executing `mysql_install_db` at the server console.
7. Start the MySQL server using `mysqld_safe` at the server console.
8. To finish the installation, you should also add the following commands to `autoexec.ncf`. For example, if your MySQL installation is in `SYS:MYSQL` and you want MySQL to start automatically, you could add these lines:

```
#Starts the MySQL 5.0.x database server
SEARCH ADD SYS:MYSQL\BIN
MYSQLD_SAFE
```

If you are running MySQL on NetWare 6.0, we strongly suggest that you use the `--skip-external-locking` option on the command line:

```
#Starts the MySQL 5.0.x database server
SEARCH ADD SYS:MYSQL\BIN
MYSQLD_SAFE --skip-external-locking
```

It is also necessary to use `CHECK TABLE` and `REPAIR TABLE` instead of `myisamchk`, because `myisamchk` makes use of external locking. External locking is known to have problems on NetWare 6.0; the problem has been eliminated in NetWare 6.5.

`mysqld_safe` on NetWare provides a screen presence. When you unload (shut down) the `mysqld_safe` NLM, the screen does not go away by default. Instead, it prompts for user input:

```
*<NLM has terminated; Press any key to close the screen>*
```

If you want NetWare to close the screen automatically instead, use the `--autoclose` option to `mysqld_safe`. For example:

```
#Starts the MySQL 5.0.x database server
SEARCH ADD SYS:MYSQL\BIN
MYSQLD_SAFE --autoclose
```

The behavior of `mysqld_safe` on NetWare is described further in Section 5.4.1, “`mysqld_safe` — MySQL Server Startup Script”.

9. When installing MySQL, either for the first time or upgrading from a previous version, download and install the latest and appropriate Perl module and PHP extensions for NetWare:
  - Perl: <http://forge.novell.com/modules/xfcontent/downloads.php/perl/Modules/>
  - PHP: <http://forge.novell.com/modules/xfcontent/downloads.php/php/Modules/>

If there was an existing installation of MySQL on the NetWare server, be sure to check for existing MySQL startup commands in `autoexec.ncf`, and edit or delete them as necessary.

**Note:** The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Post-Installation Setup and Testing”.

## 2.8. Installing MySQL on Other Unix-Like Systems

This section covers the installation of MySQL binary distributions that are provided for various platforms in the form of compressed `tar` files (files with a `.tar.gz` extension). See Section 2.1.2.5, “MySQL Binaries Compiled by MySQL AB”, for a detailed list.

To obtain MySQL, see Section 2.1.3, “How to Get MySQL”.

MySQL `tar` file binary distributions have names of the form `mysql-VERSION-OS.tar.gz`, where `VERSION` is a number (for example, `5.0.22`), and `OS` indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686`).

In addition to these generic packages, we also offer binaries in platform-specific package formats for selected platforms. See Section 2.2, “Standard MySQL Installation Using a Binary Distribution”, for more information on how to install these.

You need the following tools to install a MySQL `tar` file binary distribution:

- GNU `gunzip` to uncompress the distribution.
- A reasonable `tar` to unpack the distribution. GNU `tar` is known to work. Some operating systems come with a pre-installed version of `tar` that is known to have problems. For example, Mac OS X `tar` and Sun `tar` are known to have problems with long filenames. On Mac OS X, you can use the pre-installed `gnutar` program. On other systems with a deficient `tar`, you should install GNU `tar` first.

If you run into problems and need to file a bug report, please use the instructions in Section 1.8, “How to Report Bugs or Problems”.

The basic commands that you must execute to install and use a MySQL binary distribution are:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
shell> cd /usr/local
shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
shell> ln -s full-path-to-mysql-VERSION-OS mysql
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
shell> bin/mysqld_safe --user=mysql &
```

**Note:** This procedure does not set up any passwords for MySQL accounts. After following the pro-

cedure, proceed to Section 2.10, “Post-Installation Setup and Testing”.

A more detailed version of the preceding description for installing a binary distribution follows:

1. Add a login user and group for `mysqld` to run as:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
```

These commands add the `mysql` group and the `mysql` user. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following steps.

2. Pick the directory under which you want to unpack the distribution and change location into it. In the following example, we unpack the distribution under `/usr/local`. (The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.)

```
shell> cd /usr/local
```

3. Obtain a distribution file using the instructions in Section 2.1.3, “How to Get MySQL”. For a given release, binary distributions for all platforms are built from the same MySQL source distribution.
4. Unpack the distribution, which creates the installation directory. Then create a symbolic link to that directory:

```
shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
shell> ln -s full-path-to-mysql-VERSION-OS mysql
```

The `tar` command creates a directory named `mysql-VERSION-OS`. The `ln` command makes a symbolic link to that directory. This lets you refer more easily to the installation directory as `/usr/local/mysql`.

With GNU `tar`, no separate invocation of `gunzip` is necessary. You can replace the first line with the following alternative command to uncompress and extract the distribution:

```
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
```

5. Change location into the installation directory:

```
shell> cd mysql
```

You will find several files and subdirectories in the `mysql` directory. The most important for installation purposes are the `bin` and `scripts` subdirectories:

- The `bin` directory contains client programs and the server. You should add the full pathname of this directory to your `PATH` environment variable so that your shell finds the MySQL programs properly. See Appendix F, *Environment Variables*.
- The `scripts` directory contains the `mysql_install_db` script used to initialize the `mysql` database containing the grant tables that store the server access permissions.

6. If you have not installed MySQL before, you must create the MySQL grant tables:

```
shell> scripts/mysql_install_db --user=mysql
```

If you run the command as `root`, you must use the `--user` option as shown. The value of the option should be the name of the login account that you created in the first step to use for running the server. If you run the command while logged in as that user, you can omit the `-user` option.

After creating or updating the grant tables, you need to restart the server manually.

7. Change the ownership of program binaries to `root` and ownership of the data directory to the user that you run `mysqld` as. Assuming that you are located in the installation directory (`/usr/local/mysql`), the commands look like this:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

The first command changes the owner attribute of the files to the `root` user. The second changes the owner attribute of the data directory to the `mysql` user. The third changes the group attribute to the `mysql` group.

8. If you want MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the `support-files/mysql.server` script itself and in Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.
9. You can set up new accounts using the `bin/mysql_setpermission` script if you install the `DBI` and `DBD: :mysql` Perl modules. For instructions, see Section 2.14, “Perl Installation Notes”.
10. If you would like to use `mysqlaccess` and have the MySQL distribution in some non-standard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `bin/mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL = '/usr/local/bin/mysql'; # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error will occur when you run `mysqlaccess`.

After everything has been unpacked and installed, you should test your distribution. To start the MySQL server, use the following command:

```
shell> bin/mysqld_safe --user=mysql &
```

If that command fails immediately and prints `mysqld ended`, you can find some information in the `host_name.err` file in the data directory.

More information about `mysqld_safe` is given in Section 5.4.1, “`mysqld_safe` — MySQL Server Startup Script”.

**Note:** The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Post-Installation Setup and Testing”.

## 2.9. MySQL Installation Using a Source Distribution

Before you proceed with an installation from source, first check whether our binary is available for

your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options.

To obtain a source distribution for MySQL, Section 2.1.3, “How to Get MySQL”.

MySQL source distributions are provided as compressed `tar` archives and have names of the form `mysql-VERSION.tar.gz`, where `VERSION` is a number like `5.0.22`.

You need the following tools to build and install MySQL from source:

- GNU `gunzip` to uncompress the distribution.
- A reasonable `tar` to unpack the distribution. GNU `tar` is known to work. Some operating systems come with a pre-installed version of `tar` that is known to have problems. For example, Mac OS X `tar` and Sun `tar` are known to have problems with long filenames. On Mac OS X, you can use the pre-installed `gnutar` program. On other systems with a deficient `tar`, you should install GNU `tar` first.
- A working ANSI C++ compiler. `gcc` 2.95.2 or later, `egcs` 1.0.2 or later or `egcs` 2.91.66, SGI C++, and SunPro C++ are some of the compilers that are known to work. `libg++` is not needed when using `gcc`. `gcc` 2.7.x has a bug that makes it impossible to compile some perfectly legal C++ files, such as `sql/sql_base.cc`. If you have only `gcc` 2.7.x, you must upgrade your `gcc` to be able to compile MySQL. `gcc` 2.8.1 is also known to have problems on some platforms, so it should be avoided if a new compiler exists for the platform.

`gcc` 2.95.2 or later is recommended when compiling MySQL 3.23.x.

- A good `make` program. GNU `make` is always recommended and is sometimes required. If you have problems, we recommend GNU `make` 3.75 or newer.

If you are using a version of `gcc` recent enough to understand the `-fno-exceptions` option, it is *very important* that you use this option. Otherwise, you may compile a binary that crashes randomly. We also recommend that you use `-felide-constructors` and `-fno-rtti` along with `-fno-exceptions`. When in doubt, do the following:

```
CFLAGS="-O3" CXX=gcc CXXFLAGS="-O3 -felide-constructors \  
-fno-exceptions -fno-rtti" ./configure \  
--prefix=/usr/local/mysql --enable-assembly \  
--with-mysqld-ldflags=-all-static
```

On most systems, this gives you a fast and stable binary.

If you run into problems and need to file a bug report, please use the instructions in Section 1.8, “How to Report Bugs or Problems”.

## 2.9.1. Source Installation Overview

The basic commands that you must execute to install a MySQL source distribution are:

```
shell> groupadd mysql  
shell> useradd -g mysql mysql  
shell> gunzip < mysql-VERSION.tar.gz | tar -xvf -  
shell> cd mysql-VERSION  
shell> ./configure --prefix=/usr/local/mysql  
shell> make  
shell> make install  
shell> cp support-files/my-medium.cnf /etc/my.cnf  
shell> cd /usr/local/mysql  
shell> bin/mysql_install_db --user=mysql  
shell> chown -R root .  
shell> chown -R mysql var
```

```
shell> chgrp -R mysql .
shell> bin/mysqld_safe --user=mysql &
```

If you start from a source RPM, do the following:

```
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

This makes a binary RPM that you can install. For older versions of RPM, you may have to replace the command `rpmbuild` with `rpm` instead.

**Note:** This procedure does not set up any passwords for MySQL accounts. After following the procedure, proceed to Section 2.10, “Post-Installation Setup and Testing”, for post-installation setup and testing.

A more detailed version of the preceding description for installing MySQL from a source distribution follows:

1. Add a login user and group for `mysqld` to run as:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
```

These commands add the `mysql` group and the `mysql` user. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following steps.

2. Pick the directory under which you want to unpack the distribution and change location into it.
3. Obtain a distribution file using the instructions in Section 2.1.3, “How to Get MySQL”.
4. Unpack the distribution into the current directory:

```
shell> gunzip < /path/to/mysql-VERSION.tar.gz | tar xvf -
```

This command creates a directory named `mysql-VERSION`.

With GNU `tar`, no separate invocation of `gunzip` is necessary. You can use the following alternative command to uncompress and extract the distribution:

```
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
```

5. Change location into the top-level directory of the unpacked distribution:

```
shell> cd mysql-VERSION
```

Note that currently you must configure and build MySQL from this top-level directory. You cannot build it in a different directory.

6. Configure the release and compile everything:

```
shell> ./configure --prefix=/usr/local/mysql
shell> make
```

When you run `configure`, you might want to specify other options. Run `./configure -help` for a list of options. Section 2.9.2, “Typical configure Options”, discusses some of the more useful options.

If `configure` fails and you are going to send mail to a MySQL mailing list to ask for assistance, please include any lines from `config.log` that you think can help solve the problem. Also include the last couple of lines of output from `configure`. To file a bug report, please use the instructions in Section 1.8, “How to Report Bugs or Problems”.

If the compile fails, see Section 2.9.4, “Dealing with Problems Compiling MySQL”, for help.

7. Install the distribution:

```
shell> make install
```

If you want to set up an option file, use one of those present in the `support-files` directory as a template. For example:

```
shell> cp support-files/my-medium.cnf /etc/my.cnf
```

You might need to run these commands as `root`.

If you want to configure support for InnoDB tables, you should edit the `/etc/my.cnf` file, remove the `#` character before the option lines that start with `innodb_...`, and modify the option values to be what you want. See Section 4.3.2, “Using Option Files”, and Section 14.2.3, “InnoDB Configuration”.

8. Change location into the installation directory:

```
shell> cd /usr/local/mysql
```

9. If you haven't installed MySQL before, you must create the MySQL grant tables:

```
shell> bin/mysql_install_db --user=mysql
```

If you run the command as `root`, you should use the `--user` option as shown. The value of the option should be the name of the login account that you created in the first step to use for running the server. If you run the command while logged in as that user, you can omit the `--user` option.

After using `mysql_install_db` to create the grant tables for MySQL, you must restart the server manually. The `mysqld_safe` command to do this is shown in a later step.

10. Change the ownership of program binaries to `root` and ownership of the data directory to the user that you run `mysqld` as. Assuming that you are located in the installation directory (`/usr/local/mysql`), the commands look like this:

```
shell> chown -R root .
shell> chown -R mysql var
shell> chgrp -R mysql .
```

The first command changes the owner attribute of the files to the `root` user. The second changes the owner attribute of the data directory to the `mysql` user. The third changes the group attribute to the `mysql` group.

11. If you want MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the `support-files/mysql.server` script itself; see also Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.
12. You can set up new accounts using the `bin/mysql_setpermission` script if you install the DBI and DBD: `mysql` Perl modules. For instructions, see Section 2.14, “Perl Installation Notes”.

After everything has been installed, you should test your distribution. To start the MySQL server, use the following command:

```
shell> /usr/local/mysql/bin/mysqld_safe --user=mysql &
```

If that command fails immediately and prints `mysqld ended`, you can find some information in the `host_name.err` file in the data directory.

More information about `mysqld_safe` is given in Section 5.4.1, “`mysqld_safe` — MySQL Server Startup Script”.

**Note:** The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Post-Installation Setup and Testing”.

## 2.9.2. Typical configure Options

The `configure` script gives you a great deal of control over how you configure a MySQL source distribution. Typically you do this using options on the `configure` command line. You can also affect `configure` using certain environment variables. See Appendix F, *Environment Variables*. For a list of options supported by `configure`, run this command:

```
shell> ./configure --help
```

Some of the more commonly used `configure` options are described here:

- To compile just the MySQL client libraries and client programs and not the server, use the `--without-server` option:

```
shell> ./configure --without-server
```

If you have no C++ compiler, some client programs such as `mysql` cannot be compiled because they require C++. In this case, you can remove the code in `configure` that tests for the C++ compiler and then run `./configure` with the `--without-server` option. The compile step should still try to build all clients, but you can ignore any warnings about files such as `mysql.cc`. (If `make` stops, try `make -k` to tell it to continue with the rest of the build even if errors occur.)

- If you want to build the embedded MySQL library (`libmysqld.a`), use the `--with-embedded-server` option.
- If you don't want your log files and database directories located under `/usr/local/var`, use a `configure` command something like one of these:

```
shell> ./configure --prefix=/usr/local/mysql
shell> ./configure --prefix=/usr/local \
          --localstatedir=/usr/local/mysql/data
```

The first command changes the installation prefix so that everything is installed under `/usr/local/mysql` rather than the default of `/usr/local`. The second command preserves the default installation prefix, but overrides the default location for database directories (normally `/usr/local/var`) and changes it to `/usr/local/mysql/data`.

You can also specify the locations at server startup time by using a MySQL option file. See Section 4.3.2, “Using Option Files”.

- If you are using Unix and you want the MySQL socket file location to be somewhere other than the default location (normally in the directory `/tmp` or `/var/run`), use a `configure` command like this:

```
shell> ./configure \
        --with-unix-socket-path=/usr/local/mysql/tmp/mysql.sock
```

The socket filename must be an absolute pathname. You can also change the location of `mysql.sock` at server startup by using a MySQL option file. See Section A.4.5, "How to Protect or Change the MySQL Unix Socket File".

- If you want to compile statically linked programs (for example, to make a binary distribution, to get better performance, or to work around problems with some Red Hat Linux distributions), run `configure` like this:

```
shell> ./configure --with-client-ldflags=-all-static \
        --with-mysqld-ldflags=-all-static
```

- If you are using `gcc` and don't have `libg++` or `libstdc++` installed, you can tell `configure` to use `gcc` as your C++ compiler:

```
shell> CC=gcc CXX=gcc ./configure
```

When you use `gcc` as your C++ compiler, it does not attempt to link in `libg++` or `libstdc++`. This may be a good thing to do even if you have those libraries installed. Some versions of them have caused strange problems for MySQL users in the past.

The following list indicates some compilers and environment variable settings that are commonly used with each one.

- `gcc 2.7.2:`

```
CC=gcc CXX=gcc CXXFLAGS="-O3 -felide-constructors"
```

- `egcs 1.0.3a:`

```
CC=gcc CXX=gcc CXXFLAGS="-O3 -felide-constructors \
-fno-exceptions -fno-rtti"
```

- `gcc 2.95.2:`

```
CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro \
-felide-constructors -fno-exceptions -fno-rtti"
```

- `pgcc 2.90.29 or newer:`

```
CFLAGS="-O3 -mpentiumpro -mstack-align-double" CXX=gcc \
CXXFLAGS="-O3 -mpentiumpro -mstack-align-double \
-felide-constructors -fno-exceptions -fno-rtti"
```

In most cases, you can get a reasonably optimized MySQL binary by using the options from the preceding list and adding the following options to the `configure` line:

```
--prefix=/usr/local/mysql --enable- assembler \
--with-mysqld-ldflags=-all-static
```

The full `configure` line would, in other words, be something like the following for all recent `gcc` versions:

```
CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro \
-felide-constructors -fno-exceptions -fno-rtti" ./configure \
```

```
--prefix=/usr/local/mysql --enable-asm \
--with-mysqld-ldflags=-all-static
```

The binaries we provide on the MySQL Web site at <http://dev.mysql.com/downloads/> are all compiled with full optimization and should be perfect for most users. See Section 2.1.2.5, “MySQL Binaries Compiled by MySQL AB”. There are some configuration settings you can tweak to build an even faster binary, but these are only for advanced users. See Section 7.5.4, “How Compiling and Linking Affects the Speed of MySQL”.

If the build fails and produces errors about your compiler or linker not being able to create the shared library `libmysqlclient.so.N` (where *N* is a version number), you can work around this problem by giving the `--disable-shared` option to `configure`. In this case, `configure` does not build a shared `libmysqlclient.so.N` library.

- By default, MySQL uses the `latin1` (cp1252 West European) character set. To change the default set, use the `--with-charset` option:

```
shell> ./configure --with-charset=CHARSET
```

*CHARSET* may be one of `big5`, `cp1251`, `cp1257`, `czech`, `danish`, `dec8`, `dos`, `eur_kr`, `gb2312`, `gbk`, `german1`, `hebrew`, `hp8`, `hungarian`, `koi8_ru`, `koi8_ukr`, `latin1`, `latin2`, `sjis`, `swe7`, `tis620`, `ujis`, `usa7`, or `win1251ukr`. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

The default collation may also be specified. MySQL uses the `latin1_swedish_ci` collation by default. To change this, use the `--with-collation` option:

```
shell> ./configure --with-collation=COLLATION
```

To change both the character set and the collation, use both the `--with-charset` and `--with-collation` options. The collation must be a legal collation for the character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.)

If you want to convert characters between the server and the client, you should use the `SET NAMES` statement. See Section 13.5.3, “SET Syntax”, and Section 10.4, “Connection Character Sets and Collations”.

**Warning:** If you change character sets after having created any tables, you must run `mysql -u root -q --set-collation=collation_name on every MyISAM table`. Your indexes may be sorted incorrectly otherwise. This can happen if you install MySQL, create some tables, and then reconfigure MySQL to use a different character set and reinstall it.

With the `configure` option `--with-extra-charsets=LIST`, you can define which additional character sets should be compiled into the server. *LIST* is one of the following:

- A list of character set names separated by spaces
- `complex` to include all character sets that can't be dynamically loaded
- `all` to include all character sets into the binaries
- To configure MySQL with debugging code, use the `--with-debug` option:

```
shell> ./configure --with-debug
```

This causes a safe memory allocator to be included that can find some errors and that provides output about what is happening. See Section E.1, “Debugging a MySQL Server”.

- If your client programs are using threads, you must compile a thread-safe version of the MySQL

client library with the `--enable-thread-safe-client` configure option. This creates a `libmysqlclient_r` library with which you should link your threaded applications. See Section 22.2.15, “How to Make a Threaded Client”.

- It is possible to build MySQL 5.0 with large table support using the `--with-big-tables` option, beginning with MySQL 5.0.4.

This option causes the variables used to keep table row counts to be stored using `unsigned long long` rather than `unsigned long`. What this does is to allow tables to hold up to approximately  $1.844\text{E}+19$  ( $(2^{32})^2$ ) rows rather than  $2^{32}$  ( $\sim 4.295\text{E}+09$ ) rows. Previously it was necessary to pass `-DBIG_TABLES` to the compiler manually in order to enable this feature.

- Options that pertain to particular operating systems can be found in the system-specific section of this manual. See Section 2.13, “Operating System-Specific Notes”.

### 2.9.3. Installing from the Development Source Tree

**Caution:** You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL up and running on your system, you should use a standard release distribution (either a binary or source distribution).

To obtain our most recent development source tree, first download and install the BitKeeper free client if you do not have it. The client can be obtained from <http://www.bitmover.com/bk-client.shar>.

To install the BitKeeper client on Unix, use these commands:

```
shell> sh bk-client.shar
shell> cd bk_client-1.1
shell> make all
shell> PATH=$PWD:$PATH
```

To install the BitKeeper client on Windows, use these instructions:

1. Download and install Cygwin from <http://cygwin.com> [<http://cygwin.com/>].
2. Make sure `gcc` and `make` have been installed under Cygwin. You can test this by issuing `which gcc` and `which make` commands. If either one is not installed, run Cygwin's package manager, select `gcc`, `make`, or both, and install them.
3. Under Cygwin, execute these commands:

```
shell> sh bk-client.shar
shell> cd bk_client-1.1
```

Then edit the Makefile and change the line that reads `$(CC) $(CFLAGS) -o sfio -lz sfio.c` to this:

```
$(CC) $(CFLAGS) -o sfio sfio.c -lz
```

Now run the `make` command and set the path:

```
shell> make all
shell> PATH=$PWD:$PATH
```

The BitKeeper free client is shipped with its source code. The only documentation available for the free client is the source code itself.

After you have installed the BitKeeper client, you can access the MySQL development source tree:

1. Change location to the directory you want to work from, and then use the following command to make a local copy of the MySQL 5.0 branch:

```
shell> sfioball -r+ bk://mysql.bkbits.net/mysql-5.0 mysql-5.0
```

In the preceding example, the source tree is set up in the `mysql-5.0/` subdirectory of your current directory.

The initial download of the source tree may take a while, depending on the speed of your connection. Please be patient.

2. You need GNU `make`, `autoconf 2.58` (or newer), `automake 1.8`, `libtool 1.5`, and `m4` to run the next set of commands. Even though many operating systems come with their own implementation of `make`, chances are high that the compilation fails with strange error messages. Therefore, it is highly recommended that you use GNU `make` (sometimes named `gmake`) instead.

Fortunately, a large number of operating systems ship with the GNU toolchain preinstalled or supply installable packages of these. In any case, they can also be downloaded from the following locations:

- <http://www.gnu.org/software/autoconf/>
- <http://www.gnu.org/software/automake/>
- <http://www.gnu.org/software/libtool/>
- <http://www.gnu.org/software/m4/>
- <http://www.gnu.org/software/make/>

To configure MySQL 5.0, you also need GNU `bison 1.75` or later. Older versions of `bison` may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

Note: The maximum table size is not actually exceeded; the error is caused by bugs in older versions of `bison`.

The following example shows the typical commands required to configure a source tree. The first `cd` command changes location into the top-level directory of the tree; replace `mysql-5.0` with the appropriate directory name.

```
shell> cd mysql-5.0  
shell> aclocal; autoheader  
shell> libtoolize --automake --force  
shell> automake --force --add-missing; autoconf  
shell> (cd innobase; aclocal; autoheader; autoconf; automake)  
shell> (cd bdb/dist; sh s_all)  
shell> ./configure # Add your favorite options here  
shell> make
```

Or you can use `BUILD/autorun.sh` as a shortcut for the following sequence of commands:

```
shell> aclocal; autoheader  
shell> libtoolize --automake --force  
shell> automake --force --add-missing; autoconf  
shell> (cd innobase; aclocal; autoheader; autoconf; automake)  
shell> (cd bdb/dist; sh s_all)
```

The command lines that change directory into the `innobase` and `bdb/dist` directories are used to configure the InnoDB and Berkeley DB (BDB) storage engines. You can omit these command lines if you do not require InnoDB or BDB support.

If you get some strange errors during this stage, verify that you really have `libtool` installed.

A collection of our standard configuration scripts is located in the `BUILD/` subdirectory. You may find it more convenient to use the `BUILD/compile-pentium-debug` script than the preceding set of shell commands. To compile on a different architecture, modify the script by removing flags that are Pentium-specific.

3. When the build is done, run `make install`. Be careful with this on a production machine; the command may overwrite your live release installation. If you have another installation of MySQL, we recommend that you run `./configure` with different values for the `--prefix`, `--with-tcp-port`, and `--unix-socket-path` options than those used for your production server.
4. Play hard with your new installation and try to make the new features crash. Start by running `make test`. See Section 24.1.2, “MySQL Test Suite”.
5. If you have gotten to the `make` stage, but the distribution does not compile, please enter the problem into our bugs database using the instructions given in Section 1.8, “How to Report Bugs or Problems”. If you have installed the latest versions of the required GNU tools, and they crash trying to process our configuration files, please report that also. However, if you execute `aclocal` and get a `command not found` error or a similar problem, do not report it. Instead, make sure that all the necessary tools are installed and that your `PATH` variable is set correctly so that your shell can find them.
6. After initially copying the repository with `sfioball` to obtain the source tree, you should use `update` periodically to update your local copy. To do this any time after you have set up the repository, use this command:

```
shell> update bk://mysql.bkbits.net/mysql-5.0
```

7. You can examine the change history for the tree with all the diffs by viewing the `BK/ChangeLog` file in the source tree and looking at the `ChangeSet` descriptions listed there. To examine a particular changeset, you would have to use the `sfioball` command to extract two particular revisions of the source tree, and then use an external `diff` command to compare them. If you see some funny diffs or code that you have a question about, do not hesitate to send email to the MySQL `internals` mailing list. See Section 1.7.1, “MySQL Mailing Lists”. Also, if you think you have a better idea on how to do something, send an email message to the list with a patch.

You can also browse changesets, comments, and source code online. To browse this information for MySQL 5.0, go to <http://mysql.bkbits.net:8080/mysql-5.0>.

## 2.9.4. Dealing with Problems Compiling MySQL

All MySQL programs compile cleanly for us with no warnings on Solaris or Linux using `gcc`. On other systems, warnings may occur due to differences in system include files. See Section 2.9.5, “MIT-pthreads Notes”, for warnings that may occur when using MIT-pthreads. For other problems, check the following list.

The solution to many problems involves reconfiguring. If you do need to reconfigure, take note of the following:

- If `configure` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `config.cache`. When `config-`

ure starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.

- Each time you run `configure`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old configuration information or object files from being used, run these commands before re-running `configure`:

```
shell> rm config.cache
shell> make clean
```

Alternatively, you can run `make distclean`.

The following list describes some of the problems when compiling MySQL that have been found to occur most often:

- If you get errors such as the ones shown here when compiling `sql_yacc.cc`, you probably have run out of memory or swap space:

```
Internal compiler error: program cclplus got fatal signal 11
Out of virtual memory
Virtual memory exhausted
```

The problem is that `gcc` requires a huge amount of memory to compile `sql_yacc.cc` with inline functions. Try running `configure` with the `--with-low-memory` option:

```
shell> ./configure --with-low-memory
```

This option causes `-fno-inline` to be added to the compile line if you are using `gcc` and `-O0` if you are using something else. You should try the `--with-low-memory` option even if you have so much memory and swap space that you think you can't possibly have run out. This problem has been observed to occur even on systems with generous hardware configurations, and the `--with-low-memory` option usually fixes it.

- By default, `configure` picks `c++` as the compiler name and GNU `c++` links with `-lg++`. If you are using `gcc`, that behavior can cause problems during configuration such as this:

```
configure: error: installation or configuration problem:
C++ compiler cannot create executables.
```

You might also observe problems during compilation related to `g++`, `libg++`, or `libstdc++`.

One cause of these problems is that you may not have `g++`, or you may have `g++` but not `libg++`, or `libstdc++`. Take a look at the `config.log` file. It should contain the exact reason why your C++ compiler didn't work. To work around these problems, you can use `gcc` as your C++ compiler. Try setting the environment variable `CXX` to `"gcc -O3"`. For example:

```
shell> CXX="gcc -O3" ./configure
```

This works because `gcc` compiles C++ source files as well as `g++` does, but does not link in `libg++` or `libstdc++` by default.

Another way to fix these problems is to install `g++`, `libg++`, and `libstdc++`. However, we recommend that you not use `libg++` or `libstdc++` with MySQL because this only increases the binary size of `mysqld` without providing any benefits. Some versions of these libraries have also caused strange problems for MySQL users in the past.

- If your compile fails with errors such as any of the following, you must upgrade your version of make to GNU make:

```
making all in mit-pthreads
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome make programs.

GNU make 3.75 is known to work.

- If you want to define flags to be used by your C or C++ compilers, do so by adding the flags to the CFLAGS and CXXFLAGS environment variables. You can also specify the compiler names this way using CC and CXX. For example:

```
shell> CC=gcc
shell> CFLAGS=-O3
shell> CXX=gcc
shell> CXXFLAGS=-O3
shell> export CC CFLAGS CXX CXXFLAGS
```

See Section 2.1.2.5, “MySQL Binaries Compiled by MySQL AB”, for a list of flag definitions that have been found to be useful on various systems.

- If you get errors such as those shown here when compiling `mysqld`, `configure` did not correctly detect the type of the last argument to `accept()`, `getsockname()`, or `getpeername()`:

```
cxx: Error: mysqld.cc, line 645: In this statement, the referenced
      type of the pointer value 'length' is 'unsigned long',
      which is not compatible with 'int'.
new_sock = accept(sock, (struct sockaddr *)&cAddr, &length);
```

To fix this, edit the `config.h` file (which is generated by `configure`). Look for these lines:

```
/* Define as the base type of the last arg to accept */
#define SOCKET_SIZE_TYPE XXX
```

Change XXX to `size_t` or `int`, depending on your operating system. (You must do this each time you run `configure` because `configure` regenerates `config.h`.)

- The `sql_yacc.cc` file is generated from `sql_yacc.yy`. Normally, the build process does not need to create `sql_yacc.cc` because MySQL comes with a pre-generated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

This is a sign that your version of `yacc` is deficient. You probably need to install `bison` (the GNU version of `yacc`) and use that instead.

- On Debian Linux 3.0, you need to install `gawk` instead of the default `mawk` if you want to com-

pile MySQL with Berkeley DB support.

- If you need to debug `mysqld` or a MySQL client, run `configure` with the `--with-debug` option, and then recompile and link your clients with the new client library. See Section E.2, “Debugging a MySQL Client”.
- If you get a compilation error on Linux (for example, SuSE Linux 8.1 or Red Hat Linux 7.3) similar to the following one, you probably do not have `g++` installed:

```
libmysql.c:1329: warning: passing arg 5 of `gethostbyname_r' from
incompatible pointer type
libmysql.c:1329: too few arguments to function `gethostbyname_r'
libmysql.c:1329: warning: assignment makes pointer from integer
without a cast
make[2]: *** [libmysql.lo] Error 1
```

By default, the `configure` script attempts to determine the correct number of arguments by using `g++` (the GNU C++ compiler). This test yields incorrect results if `g++` is not installed. There are two ways to work around this problem:

- Make sure that the GNU C++ `g++` is installed. On some Linux distributions, the required package is called `gpp`; on others, it is named `gcc-c++`.
- Use `gcc` as your C++ compiler by setting the `CXX` environment variable to `gcc`:

```
export CXX="gcc"
```

You must run `configure` again after making either of those changes.

## 2.9.5. MIT-pthreads Notes

This section describes some of the issues involved in using MIT-pthreads.

On Linux, you should *not* use MIT-pthreads. Use the installed LinuxThreads implementation instead. See Section 2.13.1, “Linux Notes”.

If your system does not provide native thread support, you should build MySQL using the MIT-pthreads package. This includes older FreeBSD systems, SunOS 4.x, Solaris 2.4 and earlier, and some others. See Section 2.1.1, “Operating Systems Supported by MySQL”.

MIT-pthreads is not part of the MySQL 5.0 source distribution. If you require this package, you need to download it separately from [http://www.mysql.com/Downloads/Contrib/pthreads-1\\_60\\_beta6-mysql.tar.gz](http://www.mysql.com/Downloads/Contrib/pthreads-1_60_beta6-mysql.tar.gz)

After downloading, extract this source archive into the top level of the MySQL source directory. It creates a new subdirectory named `mit-pthreads`.

- On most systems, you can force MIT-pthreads to be used by running `configure` with the `--with-mit-threads` option:

```
shell> ./configure --with-mit-threads
```

Building in a non-source directory is not supported when using MIT-pthreads because we want to minimize our changes to this code.

- The checks that determine whether to use MIT-pthreads occur only during the part of the configuration process that deals with the server code. If you have configured the distribution using `--without-server` to build only the client code, clients do not know whether MIT-pthreads is being used and use Unix socket file connections by default. Because Unix socket files do not

work under MIT-pthreads on some platforms, this means you need to use `-h` or `--host` with a value other than `localhost` when you run client programs.

- When MySQL is compiled using MIT-pthreads, system locking is disabled by default for performance reasons. You can tell the server to use system locking with the `--external-locking` option. This is needed only if you want to be able to run two MySQL servers against the same data files, but that is not recommended, anyway.
- Sometimes the `pthread bind()` command fails to bind to a socket without any error message (at least on Solaris). The result is that all connections to the server fail. For example:

```
shell> mysqladmin version
mysqladmin: connect to server at '' failed;
error: 'Can't connect to mysql server on localhost (146)'
```

The solution to this problem is to kill the `mysqld` server and restart it. This has happened to us only when we have forcibly stopped the server and restarted it immediately.

- With MIT-pthreads, the `sleep()` system call isn't interruptible with `SIGINT` (break). This is noticeable only when you run `mysqladmin --sleep`. You must wait for the `sleep()` call to terminate before the interrupt is served and the process stops.
- When linking, you might receive warning messages like these (at least on Solaris); they can be ignored:

```
ld: warning: symbol `_iob' has differing sizes:
      (file /my/local/pthreads/lib/libpthread.a(findfp.o) value=0x4;
file /usr/lib/libc.so value=0x140);
      /my/local/pthreads/lib/libpthread.a(findfp.o) definition taken
ld: warning: symbol `__iob' has differing sizes:
      (file /my/local/pthreads/lib/libpthread.a(findfp.o) value=0x4;
file /usr/lib/libc.so value=0x140);
      /my/local/pthreads/lib/libpthread.a(findfp.o) definition taken
```

- Some other warnings also can be ignored:

```
implicit declaration of function `int strtoll(...)'
implicit declaration of function `int strtoul(...)'
```
- We have not been able to make `readline` work with MIT-pthreads. (This is not necessary, but may be of interest to some.)

## 2.9.6. Installing MySQL from Source on Windows

These instructions describe how to build binaries from source for MySQL 5.0 on Windows. Instructions are provided for building binaries from a standard source distribution or from the BitKeeper tree that contains the latest development source.

**Note:** The instructions here are strictly for users who want to test MySQL on Windows from the latest source distribution or from the BitKeeper tree. For production use, MySQL AB does not advise using a MySQL server built by yourself from source. Normally, it is best to use precompiled binary distributions of MySQL that are built specifically for optimal performance on Windows by MySQL AB. Instructions for installing a binary distributions are available in Section 2.3, "Installing MySQL on Windows".

To build MySQL on Windows from source, you need the following compiler and resources available on your Windows system:

- Visual Studio 7.1 compiler system

- Between 3GB and 5GB disk space.
- Windows 2000 or higher.

The exact system requirements can be found here: <http://msdn.microsoft.com/vstudio/productinfo/sysreqs/default.aspx>

You also need a MySQL source distribution for Windows. There are two ways to obtain a source distribution:

1. Obtain a source distribution packaged by MySQL AB. These are available from <http://dev.mysql.com/downloads/>.
2. You can package a source distribution yourself from the latest BitKeeper developer source tree. If you plan to do this, you must create the package on a Unix system and then transfer it to your Windows system. (Some of the configuration and build steps require tools that work only on Unix.) The BitKeeper approach thus requires:
  - A system running Unix, or a Unix-like system such as Linux.
  - BitKeeper 3.0 installed on that system. See Section 2.9.3, “Installing from the Development Source Tree”, for instructions how to download and install BitKeeper.

If you are using a Windows source distribution, you can go directly to Section 2.9.6.1, “Building MySQL Using VC++”. To build from the BitKeeper tree, proceed to Section 2.9.6.2, “Creating a Windows Source Package from the Latest Development Source”.

If you find something not working as expected, or you have suggestions about ways to improve the current build process on Windows, please send a message to the win32 mailing list. See Section 1.7.1, “MySQL Mailing Lists”.

### 2.9.6.1. Building MySQL Using VC++

**Note:** VC++ workspace files for MySQL 4.1 and above are compatible with Microsoft Visual Studio 7.1 and tested by MySQL AB staff before each release.

Follow this procedure to build MySQL:

1. Create a work directory (for example, `C:\workdir`).
2. Unpack the source distribution in the aforementioned directory using WinZip or another Windows tool that can read `.zip` files.
3. Start Visual Studio.
4. From the File menu, select Open Workspace.
5. Open the `mysql.dsw` workspace you find in the work directory.
6. From the Build menu, select the Set Active Configuration menu.
7. Click over the screen selecting `mysqld - Win32 Debug` and click OK.
8. Press **F7** to begin the build of the debug server, libraries, and some client applications.
9. Compile the release version in the same way.
10. Debug versions of the programs and libraries are placed in the `client_debug` and `lib_debug` directories. Release versions of the programs and libraries are placed in the `client_release` and `lib_release` directories. Note that if you want to build both de-

bug and release versions, you can select the Build All option from the Build menu.

11. Test the server. The server built using the preceding instructions expects that the MySQL base directory and data directory are `C:\mysql` and `C:\mysql\data` by default. If you want to test your server using the source tree root directory and its data directory as the base directory and data directory, you need to tell the server their pathnames. You can either do this on the command line with the `--basedir` and `--datadir` options, or by placing appropriate options in an option file. (See Section 4.3.2, “Using Option Files”.) If you have an existing data directory elsewhere that you want to use, you can specify its pathname instead.
12. Start your server from the `client_release` or `client_debug` directory, depending on which server you want to use. The general server startup instructions are in Section 2.3, “Installing MySQL on Windows”. You must adapt the instructions appropriately if you want to use a different base directory or data directory.
13. When the server is running in standalone fashion or as a service based on your configuration, try to connect to it from the `mysql` interactive command-line utility that exists in your `client_release` or `client_debug` directory.

When you are satisfied that the programs you have built are working correctly, stop the server. Then install MySQL as follows:

1. Create the directories where you want to install MySQL. For example, to install into `C:\mysql`, use these commands:

```
C:\> mkdir C:\mysql
C:\> mkdir C:\mysql\bin
C:\> mkdir C:\mysql\data
C:\> mkdir C:\mysql\share
C:\> mkdir C:\mysql\scripts
```

If you want to compile other clients and link them to MySQL, you should also create several additional directories:

```
C:\> mkdir C:\mysql\include
C:\> mkdir C:\mysql\lib
C:\> mkdir C:\mysql\lib\debug
C:\> mkdir C:\mysql\lib\opt
```

If you want to benchmark MySQL, create this directory:

```
C:\> mkdir C:\mysql\sql-bench
```

Benchmarking requires Perl support. See Section 2.14, “Perl Installation Notes”.

2. From the `workdir` directory, copy into the `C:\mysql` directory the following directories:

```
C:\> cd \workdir
C:\workdir> copy client_release\*.exe C:\mysql\bin
C:\workdir> copy client_debug\mysqld.exe C:\mysql\bin\mysqld-debug.exe
C:\workdir> xcopy scripts\*. * C:\mysql\scripts /E
C:\workdir> xcopy share\*. * C:\mysql\share /E
```

If you want to compile other clients and link them to MySQL, you should also copy several libraries and header files:

```
C:\workdir> copy lib_debug\mysqlclient.lib C:\mysql\lib\debug
C:\workdir> copy lib_debug\libmysql.* C:\mysql\lib\debug
C:\workdir> copy lib_debug\zlib.* C:\mysql\lib\debug
C:\workdir> copy lib_release\mysqlclient.lib C:\mysql\lib\opt
```

```
C:\workdir> copy lib_release\libmysql.* C:\mysql\lib\opt
C:\workdir> copy lib_release\zlib.* C:\mysql\lib\opt
C:\workdir> copy include\*.h C:\mysql\include
C:\workdir> copy libmysql\libmysql.def C:\mysql\include
```

If you want to benchmark MySQL, you should also do this:

```
C:\workdir> xcopy sql-bench\*.* C:\mysql\bench /E
```

Set up and start the server in the same way as for the binary Windows distribution. See Section 2.3, “Installing MySQL on Windows”.

## 2.9.6.2. Creating a Windows Source Package from the Latest Development Source

To create a Windows source package from the current BitKeeper source tree, use the instructions here. This procedure must be performed on a system running a Unix or Unix-like operating system because some of the configuration and build steps require tools that work only on Unix. For example, the following procedure is known to work well on Linux.

1. Copy the BitKeeper source tree for MySQL 5.0. For instructions on how to do this, see Section 2.9.3, “Installing from the Development Source Tree”.
2. Configure and build the distribution so that you have a server binary to work with. One way to do this is to run the following command in the top-level directory of your source tree:

```
shell> ./BUILD/compile-pentium-max
```

3. After making sure that the build process completed successfully, run the following utility script from top-level directory of your source tree:

```
shell> ./scripts/make_win_src_distribution
```

This script creates a Windows source package to be used on your Windows system. You can supply different options to the script based on your needs. It accepts the following options:

- `--help`  
Display a help message.
- `--debug`  
Print information about script operations, do not create package.
- `--tmp`  
Specify the temporary location.
- `--suffix`  
The suffix name for the package.
- `--dirname`  
Directory name to copy files (intermediate).
- `--silent`

Do not print verbose list of files processed.

- `--tar`

Create `tar.gz` package instead of `.zip` package.

By default, `make_win_src_distribution` creates a Zip-format archive with the name `mysql-VERSION-win-src.zip`, where `VERSION` represents the version of your MySQL source tree.

4. Copy or upload the Windows source package that you have just created to your Windows machine. To compile it, use the instructions in Section 2.9.6.1, “Building MySQL Using VC++”.

## 2.9.7. Compiling MySQL Clients on Windows

In your source files, you should include `my_global.h` before `mysql.h`:

```
#include <my_global.h>
#include <mysql.h>
```

`my_global.h` includes any other files needed for Windows compatibility (such as `windows.h`) if you compile your program on Windows.

You can either link your code with the dynamic `libmysql.lib` library, which is just a wrapper to load in `libmysql.dll` on demand, or link with the static `mysqlclient.lib` library.

The MySQL client libraries are compiled as threaded libraries, so you should also compile your code to be multi-threaded.

## 2.10. Post-Installation Setup and Testing

After installing MySQL, there are some issues that you should address. For example, on Unix, you should initialize the data directory and create the MySQL grant tables. On all platforms, an important security concern is that the initial accounts in the grant tables have no passwords. You should assign passwords to prevent unauthorized access to the MySQL server. Optionally, you can create time zone tables to enable recognition of named time zones.

The following sections include post-installation procedures that are specific to Windows systems and to Unix systems. Another section, Section 2.10.2.3, “Starting and Troubleshooting the MySQL Server”, applies to all platforms; it describes what to do if you have trouble getting the server to start. Section 2.10.3, “Securing the Initial MySQL Accounts”, also applies to all platforms. You should follow its instructions to make sure that you have properly protected your MySQL accounts by assigning passwords to them.

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in Section 5.8, “The MySQL Access Privilege System”, and Section 5.9, “MySQL User Account Management”.

### 2.10.1. Windows Post-Installation Procedures

On Windows, the data directory and the grant tables do not have to be created. MySQL Windows distributions include the grant tables with a set of preinitialized accounts in the `mysql` database under the data directory. It is unnecessary to run the `mysql_install_db` script that is used on Unix. Regarding passwords, if you installed MySQL using the Windows Installation Wizard, you may have already assigned passwords to the accounts. (See Section 2.3.3, “Using the MySQL Installation Wizard”.) Otherwise, use the password-assignment procedure given in Section 2.10.3, “Securing the Initial MySQL Accounts”.

Before setting up passwords, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see Section 2.3.9, “Starting the Server for the First Time”), and then issue the following commands to verify that you can retrieve information from the server. The output should be similar to what is shown here:

```
C:\> C:\mysql\bin\mysqlshow
```

```
+-----+
| Databases |
+-----+
|  mysql   |
|   test   |
+-----+
```

```
C:\> C:\mysql\bin\mysqlshow mysql
```

```
Database: mysql
```

```
+-----+
|          Tables          |
+-----+
| columns_priv |
| db           |
| func        |
| help_category |
| help_keyword |
| help_relation |
| help_topic   |
| host        |
| proc       |
| procs_priv  |
| tables_priv |
| time_zone  |
| time_zone_leap_second |
| time_zone_name |
| time_zone_transition |
| time_zone_transition_type |
| user       |
+-----+
```

```
C:\> C:\mysql\bin\mysql -e "SELECT Host,Db,User FROM db" mysql
```

```
+-----+-----+-----+
| host | db   | user |
+-----+-----+-----+
| %    | test% |    |
+-----+-----+-----+
```

If you are running a version of Windows that supports services and you want the MySQL server to run automatically when Windows starts, see Section 2.3.11, “Starting MySQL as a Windows Service”.

## 2.10.2. Unix Post-Installation Procedures

After installing MySQL on Unix, you need to initialize the grant tables, start the server, and make sure that the server works satisfactorily. You may also wish to arrange for the server to be started and stopped automatically when your system starts and stops. You should also assign passwords to the accounts in the grant tables.

On Unix, the grant tables are set up by the `mysql_install_db` program. For some installation methods, this program is run for you automatically:

- If you install MySQL on Linux using RPM distributions, the server RPM runs `mysql_install_db`.
- If you install MySQL on Mac OS X using a PKG distribution, the installer runs `mysql_install_db`.

Otherwise, you'll need to run `mysql_install_db` yourself.

The following procedure describes how to initialize the grant tables (if that has not previously been done) and then start the server. It also suggests some commands that you can use to test whether the server is accessible and working properly. For information about starting and stopping the server automatically, see Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

After you complete the procedure and have the server running, you should assign passwords to the accounts created by `mysql_install_db`. Instructions for doing so are given in Section 2.10.3, “Securing the Initial MySQL Accounts”.

In the examples shown here, the server runs under the user ID of the `mysql` login account. This assumes that such an account exists. Either create the account if it does not exist, or substitute the name of a different existing login account that you plan to use for running the server.

1. Change location into the top-level directory of your MySQL installation, represented here by *BASEDIR*:

```
shell> cd BASEDIR
```

*BASEDIR* is likely to be something like `/usr/local/mysql` or `/usr/local`. The following steps assume that you are located in this directory.

2. If necessary, run the `mysql_install_db` program to set up the initial MySQL grant tables containing the privileges that determine how users are allowed to connect to the server. You'll need to do this if you used a distribution type for which the installation procedure doesn't run the program for you.

Typically, `mysql_install_db` needs to be run only the first time you install MySQL, so you can skip this step if you are upgrading an existing installation. However, `mysql_install_db` does not overwrite any existing privilege tables, so it should be safe to run in any circumstances.

To initialize the grant tables, use one of the following commands, depending on whether `mysql_install_db` is located in the `bin` or `scripts` directory:

```
shell> bin/mysql_install_db --user=mysql
shell> scripts/mysql_install_db --user=mysql
```

The `mysql_install_db` script creates the server's data directory. Under the data directory, it creates directories for the `mysql` database that holds all database privileges and the `test` database that you can use to test MySQL. The script also creates privilege table entries for `root` and anonymous-user accounts. The accounts have no passwords initially. A description of their initial privileges is given in Section 2.10.3, “Securing the Initial MySQL Accounts”. Briefly, these privileges allow the MySQL `root` user to do anything, and allow anybody to create or use databases with a name of `test` or starting with `test_`.

It is important to make sure that the database directories and files are owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this, the `--user` option should be used as shown if you run `mysql_install_db` as `root`. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user` option from the command.

`mysql_install_db` creates several tables in the `mysql` database, including `user`, `db`, `host`, `tables_priv`, `columns_priv`, `func`, and others. See Section 5.8, “The MySQL Access Privilege System”, for a complete listing and description of these tables.

If you don't want to have the `test` database, you can remove it with `mysqladmin -u root drop test` after starting the server.

If you have trouble with `mysql_install_db` at this point, see Section 2.10.2.1, “Problems

Running `mysql_install_db`".

3. Start the MySQL server:

```
shell> bin/mysqld_safe --user=mysql &
```

It is important that the MySQL server be run using an unprivileged (non-`root`) login account. To ensure this, the `--user` option should be used as shown if you run `mysql_safe` as system `root`. Otherwise, you should execute the script while logged in to the system as `mysql`, in which case you can omit the `--user` option from the command.

Further instructions for running MySQL as an unprivileged user are given in Section 5.7.5, "How to Run MySQL as a Normal User".

If you neglected to create the grant tables before proceeding to this step, the following message appears in the error log file when you start the server:

```
mysqld: Can't find file: 'host.frm'
```

If you have other problems starting the server, see Section 2.10.2.3, "Starting and Troubleshooting the MySQL Server".

4. Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
shell> bin/mysqladmin version
mysqladmin Ver 14.12 Distrib 5.0.22, for pc-linux-gnu on i686
Copyright (C) 2000 MySQL AB & MySQL Finland AB & TCX DataKonsult AB
This software comes with ABSOLUTELY NO WARRANTY. This is free software,
and you are welcome to modify and redistribute it under the GPL license

Server version          5.0.22-Max
Protocol version        10
Connection              Localhost via UNIX socket
UNIX socket             /var/lib/mysql/mysql.sock
Uptime:                 14 days 5 hours 5 min 21 sec

Threads: 1  Questions: 366  Slow queries: 0
Opens: 0  Flush tables: 1  Open tables: 19
Queries per second avg: 0.000
```

To see what else you can do with `mysqladmin`, invoke it with the `--help` option.

5. Verify that you can shut down the server:

```
shell> bin/mysqladmin -u root shutdown
```

6. Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```
shell> bin/mysqld_safe --user=mysql --log &
```

If `mysqld_safe` fails, see Section 2.10.2.3, "Starting and Troubleshooting the MySQL Server".

7. Run some simple tests to verify that you can retrieve information from the server. The output should be similar to what is shown here:

```
shell> bin/mysqlshow
```

```
+-----+
| Databases |
+-----+
|  mysql  |
|  test   |
+-----+
```

```
shell> bin/mysqlshow mysql
```

```
Database: mysql
```

```

```

```
shell> bin/mysql -e "SELECT Host,Db,User FROM db" mysql
```

```
+-----+-----+-----+
| host | db   | user |
+-----+-----+-----+
| %    | test |      |
| %    | test_% |      |
+-----+-----+-----+
```

8. There is a benchmark suite in the `sql-bench` directory (under the MySQL installation directory) that you can use to compare how MySQL performs on different platforms. The benchmark suite is written in Perl. It requires the Perl DBI module that provides a database-independent interface to the various databases, and some other additional Perl modules:

```
DBI
DBD::mysql
Data::Dumper
Data::ShowTable
```

These modules can be obtained from CPAN (<http://www.cpan.org/>). See also Section 2.14.1, “Installing Perl on Unix”.

The `sql-bench/Results` directory contains the results from many runs against different databases and platforms. To run all tests, execute these commands:

```
shell> cd sql-bench
shell> perl run-all-tests
```

If you don't have the `sql-bench` directory, you probably installed MySQL using RPM files other than the source RPM. (The source RPM includes the `sql-bench` benchmark directory.) In this case, you must first install the benchmark suite before you can use it. There are separate

benchmark RPM files named `mysql-bench-VERSION-i386.rpm` that contain benchmark code and data.

If you have a source distribution, there are also tests in its `tests` subdirectory that you can run. For example, to run `auto_increment.tst`, execute this command from the top-level directory of your source distribution:

```
shell> mysql -vxf test < ./tests/auto_increment.tst
```

The expected result of the test can be found in the `./tests/auto_increment.res` file.

9. At this point, you should have the server running. However, none of the initial MySQL accounts have a password, so you should assign passwords using the instructions found in Section 2.10.3, “Securing the Initial MySQL Accounts”.

The MySQL 5.0 installation procedure creates time zone tables in the `mysql` database. However, you must populate the tables manually using the instructions in Section 5.11.8, “MySQL Server Time Zone Support”.

### 2.10.2.1. Problems Running `mysql_install_db`

The purpose of the `mysql_install_db` script is to generate new MySQL privilege tables. It does not overwrite existing MySQL privilege tables, and it does not affect any other data.

If you want to re-create your privilege tables, first stop the `mysqld` server if it's running. Then rename the `mysql` directory under the data directory to save it, and then run `mysql_install_db`. Suppose that your current directory is the MySQL installation directory and that `mysql_install_db` is located in the `bin` directory and the data directory is named `data`. To rename the `mysql` database and re-run `mysql_install_db`, use these commands.

```
shell> mv data/mysql data/mysql.old  
shell> bin/mysql_install_db --user=mysql
```

When you run `mysql_install_db`, you might encounter the following problems:

- **`mysql_install_db` fails to install the grant tables**

You may find that `mysql_install_db` fails to install the grant tables and terminates after displaying the following messages:

```
Starting mysqld daemon with databases from XXXXXXX  
mysqld ended
```

In this case, you should examine the error log file very carefully. The log should be located in the directory `XXXXXX` named by the error message and should indicate why `mysqld` didn't start. If you do not understand what happened, include the log when you post a bug report. See Section 1.8, “How to Report Bugs or Problems”.

- **There is a `mysqld` process running**

This indicates that the server is running, in which case the grant tables have probably been created already. If so, there is no need to run `mysql_install_db` at all because it needs to be run only once (when you install MySQL the first time).

- **Installing a second `mysqld` server does not work when one server is running**

This can happen when you have an existing MySQL installation, but want to put a new installation in a different location. For example, you might have a production installation, but you want to create a second installation for testing purposes. Generally the problem that occurs when you

try to run a second server is that it tries to use a network interface that is in use by the first server. In this case, you should see one of the following error messages:

```
Can't start server: Bind on TCP/IP port:
Address already in use
Can't start server: Bind on unix socket...
```

For instructions on setting up multiple servers, see Section 5.13, “Running Multiple MySQL Servers on the Same Machine”.

- **You do not have write access to the /tmp directory**

If you do not have write access to create temporary files or a Unix socket file in the default location (the /tmp directory), an error occurs when you run `mysql_install_db` or the `mysqld` server.

You can specify different locations for the temporary directory and Unix socket file by executing these commands prior to starting `mysql_install_db` or `mysqld`, where *some\_tmp\_dir* is the full pathname to some directory for which you have write permission:

```
shell> TMPDIR=/some_tmp_dir/
shell> MYSQL_UNIX_PORT=/some_tmp_dir/mysql.sock
shell> export TMPDIR MYSQL_UNIX_PORT
```

Then you should be able to run `mysql_install_db` and start the server with these commands:

```
shell> bin/mysql_install_db --user=mysql
shell> bin/mysqld_safe --user=mysql &
```

If `mysql_install_db` is located in the `scripts` directory, modify the first command to `scripts/mysql_install_db`.

See Section A.4.5, “How to Protect or Change the MySQL Unix Socket File”, and Appendix F, *Environment Variables*.

There are some alternatives to running the `mysql_install_db` script provided in the MySQL distribution:

- If you want the initial privileges to be different from the standard defaults, you can modify `mysql_install_db` before you run it. However, it is preferable to use `GRANT` and `REVOKE` to change the privileges *after* the grant tables have been set up. In other words, you can run `mysql_install_db`, and then use `mysql -u root mysql` to connect to the server as the MySQL `root` user so that you can issue the necessary `GRANT` and `REVOKE` statements.

If you want to install MySQL on several machines with the same privileges, you can put the `GRANT` and `REVOKE` statements in a file and execute the file as a script using `mysql` after running `mysql_install_db`. For example:

```
shell> bin/mysql_install_db --user=mysql
shell> bin/mysql -u root < your_script_file
```

By doing this, you can avoid having to issue the statements manually on each machine.

- It is possible to re-create the grant tables completely after they have previously been created. You might want to do this if you're just learning how to use `GRANT` and `REVOKE` and have made so many modifications after running `mysql_install_db` that you want to wipe out the tables and start over.

To re-create the grant tables, remove all the `.frm`, `.MYI`, and `.MYD` files in the `mysql` database directory. Then run the `mysql_install_db` script again.

- You can start `mysqld` manually using the `--skip-grant-tables` option and add the privilege information yourself using `mysql`:

```
shell> bin/mysqld_safe --user=mysql --skip-grant-tables &
shell> bin/mysql mysql
```

From `mysql`, manually execute the SQL commands contained in `mysql_install_db`. Make sure that you run `mysqladmin flush-privileges` or `mysqladmin reload` afterward to tell the server to reload the grant tables.

Note that by not using `mysql_install_db`, you not only have to populate the grant tables manually, you also have to create them first.

## 2.10.2.2. Starting and Stopping MySQL Automatically

Generally, you start the `mysqld` server in one of these ways:

- By invoking `mysqld` directly. This works on any platform.
- By running the MySQL server as a Windows service. This can be done on versions of Windows that support services (such as NT, 2000, XP, and 2003). The service can be set to start the server automatically when Windows starts, or as a manual service that you start on request. For instructions, see Section 2.3.11, “Starting MySQL as a Windows Service”.
- By invoking `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. This script is used on Unix and Unix-like systems. See Section 5.4.1, “`mysqld_safe` — MySQL Server Startup Script”.
- By invoking `mysql.server`. This script is used primarily at system startup and shutdown on systems that use System V-style run directories, where it usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See Section 5.4.2, “`mysql.server` — MySQL Server Startup Script”.
- On Mac OS X, you can install a separate MySQL Startup Item package to enable the automatic startup of MySQL on system startup. The Startup Item starts the server by invoking `mysql.server`. See Section 2.5, “Installing MySQL on Mac OS X”, for details.

The `mysqld_safe` and `mysql.server` scripts and the Mac OS X Startup Item can be used to start the server manually, or automatically at system startup time. `mysql.server` and the Startup Item also can be used to stop the server.

To start or stop the server manually using the `mysql.server` script, invoke it with `start` or `stop` arguments:

```
shell> mysql.server start
shell> mysql.server stop
```

Before `mysql.server` starts the server, it changes location to the MySQL installation directory, and then invokes `mysqld_safe`. If you want the server to run as some specific user, add an appropriate `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file, as shown later in this section. (It is possible that you will need to edit `mysql.server` if you've installed a binary distribution of MySQL in a non-standard location. Modify it to `cd` into the proper directory before it runs `mysqld_safe`. If you do this, your modified version of `mysql.server` may be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.)

`mysql.server stop` stops the server by sending a signal to it. You can also stop the server manually by executing `mysqladmin shutdown`.

To start and stop MySQL automatically on your server, you need to add start and stop commands to the appropriate places in your `/etc/rc*` files.

If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), the `mysql.server` script is installed in the `/etc/init.d` directory with the name `mysql`. You need not install it manually. See Section 2.4, “Installing MySQL on Linux”, for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. The script can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree.

To install `mysql.server` manually, copy it to the `/etc/init.d` directory with the name `mysql`, and then make it executable. Do this by changing location into the appropriate directory where `mysql.server` is located and executing these commands:

```
shell> cp mysql.server /etc/init.d/mysql
shell> chmod +x /etc/init.d/mysql
```

Older Red Hat systems use the `/etc/rc.d/init.d` directory rather than `/etc/init.d`. Adjust the preceding commands accordingly. Alternatively, first create `/etc/init.d` as a symbolic link that points to `/etc/rc.d/init.d`:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
shell> chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the `mysql` script:

```
shell> chkconfig --level 345 mysql on
```

On FreeBSD, startup scripts generally should go in `/usr/local/etc/rc.d/`. The `rc(8)` manual page states that scripts in this directory are executed only if their basename matches the `*.sh` shell filename pattern. Any other files or directories present within the directory are silently ignored. In other words, on FreeBSD, you should install the `mysql.server` script as `/usr/local/etc/rc.d/mysql.server.sh` to enable automatic startup.

As an alternative to the preceding setup, some operating systems also use `/etc/rc.local` or `/etc/init.d/boot.local` to start additional services on startup. To start up MySQL using this method, you could append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

For other systems, consult your operating system documentation to see how to install startup scripts.

You can add options for `mysql.server` in a global `/etc/my.cnf` file. A typical `/etc/my.cnf` file might look like this:

```
[mysqld]
```

```
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql
```

```
[mysql.server]
basedir=/usr/local/mysql
```

The `mysql.server` script understands the following options: `basedir`, `datadir`, and `pid-file`. If specified, they *must* be placed in an option file, not on the command line. `mysql.server` understands only `start` and `stop` as command-line arguments.

The following table shows which option groups the server and each startup script read from option files:

Script	Option Groups
<code>mysqld</code>	<code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld-major_version]</code>
<code>mysqld_safe</code>	<code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld_safe]</code>
<code>mysql.server</code>	<code>[mysqld]</code> , <code>[mysql.server]</code> , <code>[server]</code>

`[mysqld-major_version]` means that groups with names like `[mysqld-4.1]` and `[mysqld-5.0]` are read by servers having versions 4.1.x, 5.0.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysqld_safe` also reads the `[safe_mysqld]` group. However, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead when using MySQL 5.0.

See Section 4.3.2, “Using Option Files”.

### 2.10.2.3. Starting and Troubleshooting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server on Unix. If you are using Windows, see Section 2.3.13, “Troubleshooting a MySQL Installation Under Windows”.

If you have problems starting the server, here are some things to try:

- Check the error log to see why the server does not start.
- Specify any special options needed by the storage engines you are using.
- Make sure that the server knows where to find the data directory.
- Make sure that the server can access the data directory. The ownership and permissions of the data directory and its contents must be set such that the server can read and modify them.
- Verify that the network interfaces the server wants to use are available.

Some storage engines have options that control their behavior. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables (InnoDB, BDB, NDB), be sure that you have them configured the way you want before starting the server:

- If you are using InnoDB tables, see Section 14.2.3, “InnoDB Configuration”.
- If you are using BDB (Berkeley DB) tables, see Section 14.5.3, “BDB Startup Options”.

- If you are using MySQL Cluster, see Section 15.4, “MySQL Cluster Configuration”.

Storage engines will use default option values if you specify none, but it is recommended that you review the available options and specify explicit values for those for which the defaults are not appropriate for your installation.

When the `mysqld` server starts, it changes location to the data directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

The data directory location is hardwired in when the server is compiled. This is where the server looks for the data directory by default. If the data directory is located somewhere else on your system, the server will not work properly. You can determine what the default path settings are by invoking `mysqld` with the `--verbose` and `--help` options.

If the default locations don't match the MySQL installation layout on your system, you can override them by specifying options to `mysqld` or `mysqld_safe` on the command line or in an option file.

To specify the location of the data directory explicitly, use the `--datadir` option. However, normally you can tell `mysqld` the location of the base directory under which MySQL is installed and it looks for the data directory there. You can do this with the `--basedir` option.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location into the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options.

Once you determine the path settings you want, start the server without `--verbose` and `--help`.

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

`host_name` is the name of the MySQL server host.

If you get `Errcode 13` (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not allow the server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

On Unix, change location into the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use

these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

If the server fails to start up correctly, check the error log. Log files are located in the data directory (typically `C:\Program Files\MySQL\MySQL Server 5.0\data` on Windows, `/usr/local/mysql/data` for a Unix binary distribution, and `/usr/local/var` for a Unix source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. On Unix, you can use `tail` to display them:

```
shell> tail host_name.err
shell> tail host_name.log
```

The error log should contain information that indicates why the server couldn't start. For example, you might see something like this in the log:

```
000729 14:50:10 bdb: Recovery function for LSN 1 27595 failed
000729 14:50:10 bdb: warning: ./test/t1.db: No such file or directory
000729 14:50:10 Can't init databases
```

This means that you did not start `mysqld` with the `--bdb-no-recover` option and Berkeley DB found something wrong with its own log files when it tried to recover your databases. To be able to continue, you should move the old Berkeley DB log files from the database directory to some other place, where you can later examine them. The BDB log files are named in sequence beginning with `log.0000000001`, where the number increases over time.

If you are running `mysqld` with BDB table support and `mysqld` dumps core at startup, this could be due to problems with the BDB recovery log. In this case, you can try starting `mysqld` with `--bdb-no-recover`. If that helps, you should remove all BDB log files from the data directory and try starting `mysqld` again without the `--bdb-no-recover` option.

If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in Section 5.13, "Running Multiple MySQL Servers on the Same Machine".)

If no other server is running, try to execute the command `telnet your_host_name tcp_ip_port_number`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you don't get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. You'll need to track down what program this is and disable it, or else tell `mysqld` to listen to a different port with the `--port` option. In this case, you'll also need to specify the port number for client programs when connecting to the server via TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to allow access to the port.

If the server starts but you can't connect to it, you should make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1      localhost
```

This problem occurs only on systems that do not have a working thread library and for which

MySQL must be configured to use MIT-pthreads.

If you cannot get `mysqld` to start, you can try to make a trace file to find the problem by using the `--debug` option. See Section E.1.2, “Creating Trace Files”.

## 2.10.3. Securing the Initial MySQL Accounts

Part of the MySQL installation process is to set up the `mysql` database that contains the grant tables:

- Windows distributions contain preinitialized grant tables that are installed automatically.
- On Unix, the grant tables are populated by the `mysql_install_db` program. Some installation methods run this program for you. Others require that you execute it manually. For details, see Section 2.10.2, “Unix Post-Installation Procedures”.

The grant tables define the initial MySQL user accounts and their access privileges. These accounts are set up as follows:

- Accounts with the username `root` are created. These are superuser accounts that can do anything. The initial `root` account passwords are empty, so anyone can connect to the MySQL server as `root` — *without a password* — and be granted all privileges.
  - On Windows, one `root` account is created; this account allows connecting from the local host only. The Windows installer will optionally create an account allowing for connections from any host only if the user selects the Enable root access from remote machines option during installation.
  - On Unix, both `root` accounts are for connections from the local host. Connections must be made from the local host by specifying a hostname of `localhost` for one of the accounts, or the actual hostname or IP number for the other.
- Two anonymous-user accounts are created, each with an empty username. The anonymous accounts have no password, so anyone can use them to connect to the MySQL server.
  - On Windows, one anonymous account is for connections from the local host. It has all privileges, just like the `root` accounts. The other is for connections from any host and has all privileges for the `test` database and for other databases with names that start with `test`.
  - On Unix, both anonymous accounts are for connections from the local host. Connections must be made from the local host by specifying a hostname of `localhost` for one of the accounts, or the actual hostname or IP number for the other. These accounts have all privileges for the `test` database and for other databases with names that start with `test_`.

As noted, none of the initial accounts have passwords. This means that your MySQL installation is unprotected until you do something about it:

- If you want to prevent clients from connecting as anonymous users without a password, you should either assign a password to each anonymous account or else remove the accounts.
- You should assign a password to each MySQL `root` account.

The following instructions describe how to set up passwords for the initial MySQL accounts, first for the anonymous accounts and then for the `root` accounts. Replace “*newpwd*” in the examples with the actual password that you want to use. The instructions also cover how to remove the anonymous accounts, should you prefer not to allow anonymous access at all.

You might want to defer setting the passwords until later, so that you don't need to specify them while you perform additional setup or testing. However, be sure to set them before using your installation for production purposes.

### Anonymous Account Password Assignment

To assign passwords to the anonymous accounts, connect to the server as `root` and then use either `SET PASSWORD` or `UPDATE`. In either case, be sure to encrypt the password using the `PASSWORD()` function.

To use `SET PASSWORD` on Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR '@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR '@%' = PASSWORD('newpwd');
```

To use `SET PASSWORD` on Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR '@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR '@'host_name' = PASSWORD('newpwd');
```

In the second `SET PASSWORD` statement, replace `host_name` with the name of the server host. This is the name that is specified in the `Host` column of the non-`localhost` record for `root` in the `user` table. If you don't know what hostname this is, issue the following statement before using `SET PASSWORD`:

```
mysql> SELECT Host, User FROM mysql.user;
```

Look for the record that has `root` in the `User` column and something other than `localhost` in the `Host` column. Then use that `Host` value in the second `SET PASSWORD` statement.

The other way to assign passwords to the anonymous accounts is by using `UPDATE` to modify the `user` table directly. Connect to the server as `root` and issue an `UPDATE` statement that assigns a value to the `Password` column of the appropriate `user` table records. The procedure is the same for Windows and Unix. The following `UPDATE` statement assigns a password to both anonymous accounts at once:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
-> WHERE User = '';
mysql> FLUSH PRIVILEGES;
```

After you update the passwords in the `user` table directly using `UPDATE`, you must tell the server to re-read the grant tables with `FLUSH PRIVILEGES`. Otherwise, the change goes unnoticed until you restart the server.

### Anonymous Account Removal

If you prefer to remove the anonymous accounts instead, do so as follows:

```
shell> mysql -u root
mysql> DELETE FROM mysql.user WHERE User = '';
mysql> FLUSH PRIVILEGES;
```

The `DELETE` statement applies both to Windows and to Unix. On Windows, if you want to remove only the anonymous account that has the same privileges as `root`, do this instead:

```
shell> mysql -u root
mysql> DELETE FROM mysql.user WHERE Host='localhost' AND User='';
mysql> FLUSH PRIVILEGES;
```

That account allows anonymous access but has full privileges, so removing it improves security.

### **root Account Password Assignment**

You can assign passwords to the `root` accounts in several ways. The following discussion demonstrates three methods:

- Use the `SET PASSWORD` statement
- Use the `mysqladmin` command-line client program
- Use the `UPDATE` statement

To assign passwords using `SET PASSWORD`, connect to the server as `root` and issue two `SET PASSWORD` statements. Be sure to encrypt the password using the `PASSWORD()` function.

For Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'%' = PASSWORD('newpwd');
```

For Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('newpwd');
```

In the second `SET PASSWORD` statement, replace `host_name` with the name of the server host. This is the same hostname that you used when you assigned the anonymous account passwords.

To assign passwords to the `root` accounts using `mysqladmin`, execute the following commands:

```
shell> mysqladmin -u root password "newpwd"
shell> mysqladmin -u root -h host_name password "newpwd"
```

These commands apply both to Windows and to Unix. In the second command, replace `host_name` with the name of the server host. The double quotes around the password are not always necessary, but you should use them if the password contains spaces or other characters that are special to your command interpreter.

You can also use `UPDATE` to modify the `user` table directly. The following `UPDATE` statement assigns a password to both `root` accounts at once:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
->     WHERE User = 'root';
mysql> FLUSH PRIVILEGES;
```

The `UPDATE` statement applies both to Windows and to Unix.

After the passwords have been set, you must supply the appropriate password whenever you connect to the server. For example, if you want to use `mysqladmin` to shut down the server, you can do so using this command:

```
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

**Note:** If you forget your `root` password after setting it up, Section A.4.1, “How to Reset the Root Password”, covers the procedure for resetting it.

To set up additional accounts, you can use the `GRANT` statement. For instructions, see Section 5.9.2, “Adding New User Accounts to MySQL”.

## 2.11. Upgrading MySQL

As a general rule, we recommend that when upgrading from one release series to another, you should go to the next series rather than skipping a series. For example, if you currently are running MySQL 3.23 and wish to upgrade to a newer series, upgrade to MySQL 4.0 rather than to 4.1 or 5.0.

The following items form a checklist of things that you should do whenever you perform an upgrade:

- Before upgrading from MySQL 4.1 to 5.0, read Section 2.11.2, “Upgrading from MySQL 4.1 to 5.0”) as well as Appendix D, *MySQL Change History*. These provide information about features that are new in MySQL 5.0 or differ from those found in MySQL 4.1. If you wish to upgrade from a release series previous to MySQL 4.1, you should upgrade to each successive release series in turn until you have reached MySQL 4.1, and then proceed with the upgrade to MySQL 5.0. For information on upgrading from MySQL 4.1 or earlier releases, see the *MySQL 3.23, 4.0, 4.1 Reference Manual*.
- Before you perform an upgrade, back up your databases, including the `mysql` database that contains the grant tables.
- Some releases of MySQL introduce incompatible changes to tables. (Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.) Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.

To avoid problems due to such changes, after you upgrade to a new version of MySQL, you should run `mysql_upgrade` to check your tables (and repair them if necessary), and to update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

- If you are running MySQL Server on Windows, see Section 2.3.14, “Upgrading MySQL on Windows”.
- If you are using replication, see Section 6.6, “Upgrading a Replication Setup”, for information on upgrading your replication setup.
- If you previously installed a MySQL-Max distribution that includes a server named `mysqld-max`, and then upgrade later to a non-Max version of MySQL, `mysqld_safe` still attempts to run the old `mysqld-max` server. If you perform such an upgrade, you should remove the old `mysqld-max` server manually to ensure that `mysqld_safe` runs the new `mysqld` server.

You can always move the MySQL format files and data files between different versions on the same architecture as long as you stay within versions for the same release series of MySQL. If you change the character set when running MySQL, you must run `myisamchk -r -q -set-collation=collation_name` on all MyISAM tables. Otherwise, your indexes may not be ordered correctly, because changing the character set may also change the sort order.

If you are cautious about using new versions, you can always rename your old `mysqld` before installing a newer one. For example, if you are using MySQL 4.1.13 and want to upgrade to 5.0.10, rename your current server from `mysqld` to `mysqld-4.1.13`. If your new `mysqld` then does something unexpected, you can simply shut it down and restart with your old `mysqld`.

If, after an upgrade, you experience problems with recompiled client programs, such as Commands

out of sync or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, you should check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries.

If problems occur, such as that the new `mysqld` server does not start or that you cannot connect without a password, verify that you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.

It is a good idea to rebuild and reinstall the Perl `DBD::mysql` module whenever you install a new release of MySQL. The same applies to other MySQL interfaces as well, such as the PHP `mysql` extension and the Python `MySQLdb` module.

## 2.11.1. Upgrading from MySQL 5.0 to 5.1

When upgrading a 5.0 installation to 5.0.10 or above note that it is *necessary* to upgrade your grant tables. Otherwise, creating stored procedures and functions might not work. The procedure for doing this is described in Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

## 2.11.2. Upgrading from MySQL 4.1 to 5.0

**Note:** It is good practice to back up your data before installing any new version of software. Although MySQL works very hard to ensure a high level of quality, you should protect your data by making a backup. MySQL generally recommends that you dump and reload your tables from any previous version to upgrade to 5.0.

In general, you should do the following when upgrading from MySQL 4.1 from 5.0:

- Check the items in the change lists found later in this section to see whether any of them might affect your applications. Note particularly any that are marked **Incompatible change**. These result in incompatibilities with earlier versions of MySQL, and may require your attention *before you upgrade*.
- Some releases of MySQL introduce incompatible changes to tables. (Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.) Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.

To avoid problems due to such changes, after you upgrade to a new version of MySQL, you should check your tables (and repair them if necessary), and update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

- Read the MySQL 5.0 change history to see what significant new features you can use in 5.0. See Section D.1, “Changes in release 5.0.x (Production)”.
- If you are running MySQL Server on Windows, see Section 2.3.14, “Upgrading MySQL on Windows”.
- MySQL 5.0 adds support for stored procedures. This support requires the `mysql.proc` table. To create this table, you should run the `mysql_upgrade` program as described in Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.
- MySQL 5.0 adds support for views. This support requires extra privilege columns in the `mysql.user` and `mysql.db` tables. To create these columns, you should run the `mysql_upgrade` program as described in Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.
- If you are using replication, see Section 6.6, “Upgrading a Replication Setup”, for information

on upgrading your replication setup.

Several visible behaviors have changed between MySQL 4.1 and MySQL 5.0 to make MySQL more compatible with standard SQL. These changes may affect your applications.

The following lists describe changes that may affect applications and that you should watch out for when upgrading to MySQL 5.0.

#### Server Changes:

- **Incompatible change:** The indexing order for end-space in TEXT columns for InnoDB and MyISAM tables has changed. Starting from 5.0.3, TEXT indexes are compared as space-padded at the end (just as MySQL sorts CHAR, VARCHAR and TEXT fields). If you have an index on a TEXT column, you should run CHECK TABLE on it. If the check reports errors, rebuild the indexes: Dump and reload the table if it is an InnoDB table, or run OPTIMIZE TABLE or REPAIR TABLE if it is a MyISAM table.
- **Warning: Incompatible change.** For BINARY columns, the pad value and how it is handled has changed as of MySQL 5.0.15. The pad value for inserts now is 0x00 rather than space, and there is no stripping of the pad value for retrievals. For details, see Section 11.4.2, “The BINARY and VARBINARY Types”.
- **Incompatible change:** The implementation of DECIMAL has changed in MySQL 5.0.3. You should make your applications aware of that change, which is described in Section 21.2, “DECIMAL Data Type Changes”.

A consequence of the change in handling of the DECIMAL and NUMERIC fixed-point data types is that the server is more strict to follow standard SQL. For example, a data type of DECIMAL(3,1) stores a maximum value of 99.9. Before MySQL 5.0.3, the server allowed larger numbers to be stored. That is, it stored a value such as 100.0 as 100.0. As of MySQL 5.0.3, the server clips 100.0 to the maximum allowable value of 99.9. If you have tables that were created before MySQL 5.0.3 and that contain floating-point data not strictly legal for the data type, you should alter the data types of those columns. For example:

```
ALTER TABLE tbl_name MODIFY col_name DECIMAL(4,1);
```

The behavior used by the server for DECIMAL columns in a table depends on the version of MySQL used to create the table. If your server is from MySQL 5.0.3 or higher, but you have DECIMAL columns in tables that were created before 5.0.3, the old behavior still applies to those columns. To convert the tables to the newer DECIMAL format, dump them with mysqldump and reload them.

- **Incompatible change:** MyISAM and InnoDB tables created with DECIMAL columns in MySQL 5.0.3 to 5.0.5 will appear corrupt after an upgrade to MySQL 5.0.6. (The same incompatibility will occur for these tables created in MySQL 5.0.6 after a downgrade to MySQL 5.0.3 to 5.0.5.) If you have such tables, check and repair them with mysql\_upgrade after upgrading. See Section 5.6.2, “mysql\_upgrade — Check Tables for MySQL Upgrade”.
- **Incompatible change:** As of MySQL 5.0.3, the server by default no longer loads user-defined functions (UDFs) unless they have at least one auxiliary symbol (for example, an xxx\_init or xxx\_deinit symbol) defined in addition to the main function symbol. This behavior can be overridden with the --allow-suspicious-udfs option. See Section 24.2.4.6, “User-Defined Function Security Precautions”.
- **Incompatible change:** The update log has been removed in MySQL 5.0. If you had enabled it previously, you should enable the binary log instead.
- **Incompatible change:** Support for the ISAM storage engine has been removed in MySQL 5.0. If you have any ISAM tables, you should convert them *before* upgrading. For example, to convert an ISAM table to use the MyISAM storage engine, use this statement:

```
ALTER TABLE tbl_name ENGINE = MyISAM;
```

Use a similar statement for every ISAM table in each of your databases.

- **Incompatible change:** Support for RAID options in MyISAM tables has been removed in MySQL 5.0. If you have tables that use these options, you should convert them before upgrading. One way to do this is to dump them with `mysqldump`, edit the dump file to remove the RAID options in the `CREATE TABLE` statements, and reload the dump file. Another possibility is to use `CREATE TABLE new_tbl ... SELECT raid_tbl` to create a new table from the RAID table. However, the `CREATE TABLE` part of the statement must contain sufficient information to re-create column attributes as well as indexes, or column attributes may be lost and indexes will not appear in the new table. See Section 13.1.5, “`CREATE TABLE` Syntax”.

The `.MYD` files for RAID tables in a given database are stored under the database directory in subdirectories that have names consisting of two hex digits in the range from `00` to `ff`. After converting all tables that use RAID options, these RAID-related subdirectories still will exist but can be removed. Verify that they are empty, and then remove them manually. (If they are not empty, there is some RAID table that has not been converted.)

- In MySQL 5.0.6, binary logging of stored routines and triggers was changed. This change has implications for security, replication, and data recovery, as discussed in Section 17.4, “Binary Logging of Stored Routines and Triggers”.

### SQL Changes:

- **Incompatible change:** Beginning with MySQL 5.0.12, natural joins and joins with `USING`, including outer join variants, are processed according to the SQL:2003 standard. The changes include elimination of redundant output columns for `NATURAL` joins and joins specified with a `USING` clause and proper ordering of output columns. The precedence of the comma operator also now is lower compared to `JOIN`, `LEFT JOIN`, and so forth.

These changes make MySQL more compliant with standard SQL. However, they can result in different output columns for some joins. Also, some queries that appeared to work correctly prior to 5.0.12 must be rewritten to comply with the standard. For details about the scope of the changes and examples that show what query rewrites are necessary, see Section 13.2.7.1, “`JOIN` Syntax”.

- **Incompatible change:** Previously, a lock wait timeout caused InnoDB to roll back the entire current transaction. As of MySQL 5.0.13, it rolls back only the most recent SQL statement.
- **Incompatible change:** The namespace for triggers has changed in MySQL 5.0.10. Previously, trigger names had to be unique per table. Now they must be unique within the schema (database). An implication of this change is that `DROP TRIGGER` syntax now uses a schema name instead of a table name (schema name is optional and, if omitted, the current schema will be used).

When upgrading from a previous version of MySQL 5 to MySQL 5.0.10 or newer, you must drop all triggers and re-create them or `DROP TRIGGER` will not work after the upgrade. Here is a suggested procedure for doing this:

1. Upgrade to MySQL 5.0.10 or later to be able to access trigger information in the `INFORMATION_SCHEMA.TRIGGERS` table. (It should work even for pre-5.0.10 triggers.)
2. Dump all trigger definitions using the following `SELECT` statement:

```
SELECT CONCAT('CREATE TRIGGER ', t.TRIGGER_SCHEMA, '.', t.TRIGGER_NAME,
              ' ', t.ACTION_TIMING, ' ', t.EVENT_MANIPULATION, ' ON ',
              t.EVENT_OBJECT_SCHEMA, '.', t.EVENT_OBJECT_TABLE,
              ' FOR EACH ROW ', t.ACTION_STATEMENT, '///')
INTO OUTFILE '/tmp/triggers.sql'
```

```
FROM INFORMATION_SCHEMA.TRIGGERS AS t;
```

The statement uses `INTO OUTFILE`, so you must have the `FILE` privilege. The file will be created on the server host. Use a different filename if you like. To be 100% safe, inspect the trigger definitions in the `triggers.sql` file, and perhaps make a backup of the file.

3. Stop the server and drop all triggers by removing all `.TRG` files in your database directories. Change location to your data directory and issue this command:

```
shell> rm */*.TRG
```

4. Start the server and re-create all triggers using the `triggers.sql` file. For the file created earlier, use these commands in the `mysql` program:

```
mysql> delimiter // ;
mysql> source /tmp/triggers.sql //
```

5. Use the `SHOW TRIGGERS` statement to check that all triggers were created successfully.

- **Incompatible change:** As of MySQL 5.0.15, the `CHAR()` function returns a binary string rather than a string in the connection character set. An optional `USING charset_name` clause may be used to produce a result in a specific character set instead. Also, arguments larger than 256 produce multiple characters. They are no longer interpreted modulo 256 to produce a single character each. These changes may cause some incompatibilities:

- `CHAR(ORD('A')) = 'a'` is no longer true:

```
mysql> SELECT CHAR(ORD('A')) = 'a';
+-----+
| CHAR(ORD('A')) = 'a' |
+-----+
|                      0 |
+-----+
```

To perform a case-insensitive comparison, you can produce a result string in a non-binary character set by adding a `USING` clause or converting the result:

```
mysql> SELECT CHAR(ORD('A') USING latin1) = 'a';
+-----+
| CHAR(ORD('A') USING latin1) = 'a' |
+-----+
|                      1 |
+-----+
mysql> SELECT CONVERT(CHAR(ORD('A'))) USING latin1) = 'a';
+-----+
| CONVERT(CHAR(ORD('A'))) USING latin1) = 'a' |
+-----+
|                      1 |
+-----+
```

- `CREATE TABLE ... SELECT CHAR(...)` produces a `VARBINARY` column, not a `VARCHAR` column. To produce a `VARCHAR` column, use `USING` or `CONVERT()` as just described to convert the `CHAR()` result into a non-binary character set.
- Previously, the following statements inserted the value `0x00410041` ('AA' as a `ucs2` string) into the table:

```
CREATE TABLE t (ucs2_column CHAR(2) CHARACTER SET ucs2);
INSERT INTO t VALUES (CHAR(0x41,0x41));
```

As of MySQL 5.0.15, the statements insert a single UCS2 character with value 0x4141.

- **Incompatible change:** By default, integer subtraction involving an unsigned value should produce an unsigned result. Tracking of the “unsignedness” of an expression was improved in MySQL 5.0.13. This means that, in some cases where an unsigned subtraction would have resulted in a signed integer, it now results in an unsigned integer. One context in which this difference manifests itself is when a subtraction involving an unsigned operand would be negative.

Suppose that `i` is a `TINYINT UNSIGNED` column and has a value of 0. The server evaluates the following expression using 64-bit unsigned integer arithmetic with the following result:

```
mysql> SELECT i - 1 FROM t;
+-----+
| i - 1 |
+-----+
| 18446744073709551615 |
+-----+
```

If the expression is used in an `UPDATE t SET i = i - 1` statement, the expression is evaluated and the result assigned to `i` according to the usual rules for handling values outside the column range or 0 to 255. That is, the value is clipped to the nearest endpoint of the range. However, the result is version-specific:

- Before MySQL 5.0.13, the expression is evaluated but is treated as the equivalent 64-bit signed value (-1) for the assignment. The value of -1 is clipped to the nearest endpoint of the column range, resulting in a value of 0:

```
mysql> UPDATE t SET i = i - 1; SELECT i FROM t;
+-----+
| i |
+-----+
| 0 |
+-----+
```

- As of MySQL 5.0.13, the expression is evaluated and retains its unsigned attribute for the assignment. The value of 18446744073709551615 is clipped to the nearest endpoint of the column range, resulting in a value of 255:

```
mysql> UPDATE t SET i = i - 1; SELECT i FROM t;
+-----+
| i |
+-----+
| 255 |
+-----+
```

To get the older behavior, use `CAST()` to convert the expression result to a signed value:

```
UPDATE t SET i = CAST(i - 1 AS SIGNED);
```

Alternatively, set the `NO_UNSIGNED_SUBTRACTION` SQL mode. However, this will affect all integer subtractions involving unsigned values.

- **Incompatible change:** Before MySQL 5.0.13, `NOW()` and `SYSDATE()` return the same value (the time at which the statement in which the function occurs begins executing). As of MySQL 5.0.13, `SYSDATE()` returns the time at which it executes, which can differ from the value returned by `NOW()`. For information about the implications for binary logging and replication, see the description for `SYSDATE()` in Section 12.5, “Date and Time Functions” and for `SET TIMESTAMP` in Section 13.5.3, “SET Syntax”. To restore the former behavior for `SYSDATE()`

and cause it to be an alias for `NOW()`, start the server with the `--sysdate-is-now` option (available as of MySQL 5.0.20).

- **Incompatible change:** Before MySQL 5.0.13, `GREATEST(x, NULL)` and `LEAST(x, NULL)` return `x` when `x` is a non-NULL value. As of 5.0.3, both functions return NULL if any argument is NULL, the same as Oracle. This change can cause problems for applications that rely on the old behavior.
- **Incompatible change:** Before MySQL 4.1.13/5.0.8, conversion of DATETIME values to numeric form by adding zero produced a result in YYYYMMDDHHMMSS format. The result of `DATE-TIME+0` is now in YYYYMMDDHHMMSS.000000 format.
- **Incompatible change:** In MySQL 4.1.12/5.0.6, the behavior of `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` has changed when the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values both are empty. Formerly, a column was read or written the display width of the column. For example, `INT(4)` was read or written using a field with a width of 4. Now columns are read and written using a field width wide enough to hold all values in the field. However, data files written before this change was made might not be reloaded correctly with `LOAD DATA INFILE` for MySQL 4.1.12/5.0.6 and up. This change also affects data files read by `mysqlimport` and written by `mysqldump --tab`, which use `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`. For more information, see Section 13.2.5, “LOAD DATA INFILE Syntax”.
- Some keywords are reserved in MySQL 5.0 that were not reserved in MySQL 4.1. See Section 9.5, “Treatment of Reserved Words in MySQL”.
- As of MySQL 5.0.3, DECIMAL columns are stored in a more efficient format. To convert a table to use the new DECIMAL type, you should do an `ALTER TABLE` on it. The `ALTER TABLE` also will change the table's VARCHAR columns to use the new VARCHAR data type. For information about possible incompatibilities with old applications, see Chapter 21, *Precision Math*.
- MySQL 5.0.3 and up uses precision math when calculating with DECIMAL values (64 decimal digits) and for rounding exact-value numbers. See Chapter 21, *Precision Math*.
- Comparisons made between FLOAT or DOUBLE values that happened to work in MySQL 4.1 may not do so in 5.0. Values of these types are imprecise in all MySQL versions, and you are *strongly advised* to avoid such comparisons as `WHERE col_name=some_double`, regardless of the MySQL version you are using. See Section A.5.8, “Problems with Floating-Point Comparisons”.
- As of MySQL 5.0.3, trailing spaces no longer are removed from values stored in VARCHAR and VARBINARY columns. The maximum lengths for VARCHAR and VARBINARY columns in MySQL 5.0.3 and later are 65,535 characters and 65,535 bytes, respectively.  
**Note:** If you create a table with new VARCHAR or VARBINARY columns in MySQL 5.0.3 or later, the table will not be usable if you downgrade to a version older than 5.0.3. Dump the table with `mysqldump` before downgrading and reload it after downgrading.
- As of MySQL 5.0.3, BIT is a separate data type, not a synonym for `TINYINT(1)`. See Section 11.1.1, “Overview of Numeric Types”.
- MySQL 5.0.2 adds several SQL modes that allow stricter control over rejecting records that have invalid or missing values. See Section 5.2.5, “The Server SQL Mode”, and Section 1.9.6.2, “Constraints on Invalid Data”. If you want to enable this control but continue to use MySQL's capability for storing incorrect dates such as '2004-02-31', you should start the server with `--sql_mode="TRADITIONAL, ALLOW_INVALID_DATES"`.
- As of MySQL 5.0.2, the SCHEMA and SCHEMAS keywords are accepted as synonyms for DATABASE and DATABASES, respectively. (While “schemata” is grammatically correct and even appears in some MySQL 5.0 system database and table names, it cannot be used as a keyword.)
- User variables are not case sensitive in MySQL 5.0. In MySQL 4.1, `SET @x = 0; SET @X`

= 1; SELECT @x; created two variables and returned 0. In MySQL 5.0, it creates one variable and returns 1.

- A new startup option named `innodb_table_locks` was added that causes `LOCK TABLE` to also acquire InnoDB table locks. This option is enabled by default. This can cause deadlocks in applications that use `AUTOCOMMIT=1` and `LOCK TABLES`. If your application encounters deadlocks after upgrading, you may need to add `innodb_table_locks=0` to your `my.cnf` file.

### C API Changes:

- **Incompatible change:** Because the MySQL 5.0 server has a new implementation of the `DECIMAL` data type, a problem may occur if the server is used by older clients that still are linked against MySQL 4.1 client libraries. If a client uses the binary client/server protocol to execute prepared statements that generate result sets containing numeric values, an error will be raised: `'Using unsupported buffer type: 246'`

This error occurs because the 4.1 client libraries do not support the new `MYSQL_TYPE_NEWDECIMAL` type value added in 5.0. There is no way to disable the new `DECIMAL` data type on the server side. You can avoid the problem by relinking the application with the client libraries from MySQL 5.0.

- **Incompatible change:** The `ER_WARN_DATA_TRUNCATED` warning symbol was renamed to `WARN_DATA_TRUNCATED` in MySQL 5.0.3.
- The `reconnect` flag in the `MYSQL` structure is set to 0 by `mysql_real_connect()`. Only those client programs which did not explicitly set this flag to 0 or 1 after `mysql_real_connect()` experience a change. Having automatic reconnection enabled by default was considered too dangerous (due to the fact that table locks, temporary tables, user variables, and session variables are lost after reconnection).

## 2.11.3. Copying MySQL Databases to Another Machine

You can copy the `.frm`, `.MYI`, and `.MYD` files for MyISAM tables between different architectures that support the same floating-point format. (MySQL takes care of any byte-swapping issues.) See Section 14.1, “The MyISAM Storage Engine”.

In cases where you need to transfer databases between different architectures, you can use `mysqldump` to create a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the `mysql` client.

Use `mysqldump --help` to see what options are available. If you are moving the data to a newer version of MySQL, you should use `mysqldump --opt` to take advantage of any optimizations that result in a dump file that is smaller and can be processed more quickly.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
shell> mysqladmin -h 'other_hostname' create db_name
shell> mysqldump --opt db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
shell> mysqladmin create db_name
shell> mysqldump -h 'other_hostname' --opt --compress db_name | mysql db_name
```

You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source ma-

chine like this:

```
shell> mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
shell> mysqladmin create db_name
shell> gunzip < db_name.gz | mysql db_name
```

You can also use `mysqldump` and `mysqlimport` to transfer the database. For large tables, this is much faster than simply using `mysqldump`. In the following commands, `DUMPDIR` represents the full pathname of the directory you use to store the output from `mysqldump`.

First, create the directory for the output files and dump the database:

```
shell> mkdir DUMPDIR
shell> mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the `DUMPDIR` directory to some corresponding directory on the target machine and load the files into MySQL there:

```
shell> mysqladmin create db_name # create database
shell> cat DUMPDIR/*.sql | mysql db_name # create tables in database
shell> mysqlimport db_name DUMPDIR/*.txt # load data into tables
```

Do not forget to copy the `mysql` database because that is where the grant tables are stored. You might have to run commands as the MySQL `root` user on the new machine until you have the `mysql` database in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges` so that the server reloads the grant table information.

## 2.12. Downgrading MySQL

This section describes what you should do to downgrade to an older MySQL version in the unlikely case that the previous version worked better than the new one.

If you are downgrading within the same release series (for example, from 4.1.13 to 4.1.12) the general rule is that you just have to install the new binaries on top of the old ones. There is no need to do anything with the databases. As always, however, it is always a good idea to make a backup.

The following items form a checklist of things you should do whenever you perform a downgrade:

- Read the upgrading section for the release series from which you are downgrading to be sure that it does not have any features you really need. Section 2.11, “Upgrading MySQL”.
- If there is a downgrading section for that version, you should read that as well.

In most cases, you can move the MySQL format files and data files between different versions on the same architecture as long as you stay within versions for the same release series of MySQL.

If you downgrade from one release series to another, there may be incompatibilities in table storage formats. In this case, you can use `mysqldump` to dump your tables before downgrading. After downgrading, reload the dump file using `mysql` or `mysqlimport` to re-create your tables. For examples, see Section 2.11.3, “Copying MySQL Databases to Another Machine”.

The normal symptom of a downward-incompatible table format change when you downgrade is that

you can't open tables. In that case, use the following procedure:

1. Stop the older MySQL server that you are downgrading to.
2. Restart the newer MySQL server you are downgrading from.
3. Dump any tables that were inaccessible to the older server by using `mysqldump` to create a dump file.
4. Stop the newer MySQL server and restart the older one.
5. Reload the dump file into the older server. Your tables should be accessible.

## 2.12.1. Downgrading to MySQL 4.1

MySQL 4.1 does not support stored routines or triggers. If your databases contain stored routines or triggers, prevent them from being dumped when you use `mysqldump` by using the `--skip-routines` and `--skip-triggers` options. (See Section 8.11, “`mysqldump` — A Database Backup Program”.)

MySQL 4.1 does not support views. If your databases contain views, remove them with `DROP VIEW` before using `mysqldump`. (See Section 19.3, “`DROP VIEW` Syntax”.)

After downgrading from MySQL 5.0, you may see the following information in the `mysql.err` file:

```
Incorrect information in file: './mysql/user.frm'
```

In this case, you can do the following:

1. Start MySQL 5.0.4 (or newer).
2. Run `mysql_fix_privilege_tables`, which will change the `mysql.user` table to a format that both MySQL 4.1 and 5.0 can use.
3. Stop the MySQL server.
4. Start MySQL 4.1.

If the preceding procedure fails, you should be able to do the following instead:

1. Start MySQL 5.0.4 (or newer).
2. Run `mysqldump --opt --add-drop-table mysql > /tmp/mysql.dump`.
3. Stop the MySQL server.
4. Start MySQL 4.1 with the `--skip-grant` option.
5. Run `mysql mysql < /tmp/mysql.dump`.
6. Run `mysqladmin flush-privileges`.

## 2.13. Operating System-Specific Notes

## 2.13.1. Linux Notes

This section discusses issues that have been found to occur on Linux. The first few subsections describe general operating system-related issues, problems that can occur when using binary or source distributions, and post-installation issues. The remaining subsections discuss problems that occur with Linux on specific platforms.

Note that most of these problems occur on older versions of Linux. If you are running a recent version, you may see none of them.

### 2.13.1.1. Linux Operating System Notes

MySQL needs at least Linux version 2.0.

**Warning:** We have seen some strange problems with Linux 2.2.14 and MySQL on SMP systems. We also have reports from some MySQL users that they have encountered serious stability problems using MySQL with kernel 2.2.14. If you are using this kernel, you should upgrade to 2.2.19 (or newer) or to a 2.4 kernel. If you have a multiple-CPU box, you should seriously consider using 2.4 because it gives you a significant speed boost. Your system should be more stable.

When using LinuxThreads, you should see a minimum of three `mysqld` processes running. These are in fact threads. There is one thread for the LinuxThreads manager, one thread to handle connections, and one thread to handle alarms and signals.

### 2.13.1.2. Linux Binary Distribution Notes

The Linux-Intel binary and RPM releases of MySQL are configured for the highest possible speed. We are always trying to use the fastest stable compiler available.

The binary release is linked with `-static`, which means you do not normally need to worry about which version of the system libraries you have. You need not install LinuxThreads, either. A program linked with `-static` is slightly larger than a dynamically linked program, but also slightly faster (3-5%). However, one problem with a statically linked program is that you can't use user-defined functions (UDFs). If you are going to write or use UDFs (this is something for C or C++ programmers only), you must compile MySQL yourself using dynamic linking.

A known issue with binary distributions is that on older Linux systems that use `libc` (such as Red Hat 4.x or Slackware), you get some (non-fatal) issues with hostname resolution. If your system uses `libc` rather than `glibc2`, you probably will encounter some difficulties with hostname resolution and `getpwnam()`. This happens because `libc` (unfortunately) depends on some external libraries to implement hostname resolution and `getpwent()`, even when compiled with `-static`. These problems manifest themselves in two ways:

- You may see the following error message when you run `mysql_install_db`:

```
Sorry, the host 'xxxx' could not be looked up
```

You can deal with this by executing `mysql_install_db --force`, which does not execute the `resolveip` test in `mysql_install_db`. The downside is that you cannot use hostnames in the grant tables: except for `localhost`, you must use IP numbers instead. If you are using an old version of MySQL that does not support `--force`, you must manually remove the `resolveip` test in `mysql_install` using a text editor.

- You also may see the following error when you try to run `mysqld` with the `--user` option:

```
getpwnam: No such file or directory
```

To work around this problem, start `mysqld` by using the `su` command rather than by specifying the `--user` option. This causes the system itself to change the user ID of the `mysqld` process so that `mysqld` need not do so.

Another solution, which solves both problems, is not to use a binary distribution. Obtain a MySQL source distribution (in RPM or `tar.gz` format) and install that instead.

On some Linux 2.2 versions, you may get the error `Resource temporarily unavailable` when clients make a great many new connections to a `mysqld` server over TCP/IP. The problem is that Linux has a delay between the time that you close a TCP/IP socket and the time that the system actually frees it. There is room for only a finite number of TCP/IP slots, so you encounter the resource-unavailable error if clients attempt too many new TCP/IP connections over a short period of time. For example, you may see the error when you run the MySQL `test-connect` benchmark over TCP/IP.

We have inquired about this problem a few times on different Linux mailing lists but have never been able to find a suitable resolution. The only known “fix” is for clients to use persistent connections, or, if you are running the database server and clients on the same machine, to use Unix socket file connections rather than TCP/IP connections.

### 2.13.1.3. Linux Source Distribution Notes

The following notes regarding `glibc` apply only to the situation when you build MySQL yourself. If you are running Linux on an x86 machine, in most cases it is much better for you to use our binary. We link our binaries against the best patched version of `glibc` we can find and with the best compiler options, in an attempt to make it suitable for a high-load server. For a typical user, even for setups with a lot of concurrent connections or tables exceeding the 2GB limit, our binary is the best choice in most cases. After reading the following text, if you are in doubt about what to do, try our binary first to determine whether it meets your needs. If you discover that it is not good enough, you may want to try your own build. In that case, we would appreciate a note about it so that we can build a better binary next time.

MySQL uses LinuxThreads on Linux. If you are using an old Linux version that doesn't have `glibc2`, you must install LinuxThreads before trying to compile MySQL. You can obtain LinuxThreads from <http://dev.mysql.com/downloads/os-linux.html>.

Note that `glibc` versions before and including version 2.1.1 have a fatal bug in `pthread_mutex_timedwait()` handling, which is used when `INSERT DELAYED` statements are issued. We recommend that you not use `INSERT DELAYED` before upgrading `glibc`.

Note that Linux kernel and the LinuxThread library can by default handle a maximum of 1,024 threads. If you plan to have more than 1,000 concurrent connections, you need to make some changes to LinuxThreads, as follows:

- Increase `PTHREAD_THREADS_MAX` in `sysdeps/unix/sysv/linux/bits/local_lim.h` to 4096 and decrease `STACK_SIZE` in `linuxthreads/internals.h` to 256KB. The paths are relative to the root of `glibc`. (Note that MySQL is not stable with 600-1000 connections if `STACK_SIZE` is the default of 2MB.)
- Recompile LinuxThreads to produce a new `libpthread.a` library, and relink MySQL against it.

Additional information about circumventing thread limits in LinuxThreads can be found at <http://www.volano.com/linuxnotes.html>.

There is another issue that greatly hurts MySQL performance, especially on SMP systems. The mutex implementation in LinuxThreads in `glibc 2.1` is very poor for programs with many threads that hold the mutex only for a short time. This produces a paradoxical result: If you link MySQL against an unmodified LinuxThreads, removing processors from an SMP actually improves MySQL performance in many cases. We have made a patch available for `glibc 2.1.3` to correct this behavior (<http://www.mysql.com/Downloads/Linux/linuxthreads-2.1-patch>).

With `glibc 2.2.2`, MySQL uses the adaptive mutex, which is much better than even the patched one in `glibc 2.1.3`. Be warned, however, that under some conditions, the current mutex code in

glibc 2.2.2 overspins, which hurts MySQL performance. The likelihood that this condition occurs can be reduced by re-nicing the `mysqld` process to the highest priority. We have also been able to correct the overspin behavior with a patch, available at <http://www.mysql.com/Downloads/Linux/linuxthreads-2.2.2.patch>. It combines the correction of overspin, maximum number of threads, and stack spacing all in one. You need to apply it in the `linuxthreads` directory with `patch -p0 </tmp/linuxthreads-2.2.2.patch`. We hope it is included in some form in future releases of glibc 2.2. In any case, if you link against glibc 2.2.2, you still need to correct `STACK_SIZE` and `PTHREAD_THREADS_MAX`. We hope that the defaults is corrected to some more acceptable values for high-load MySQL setup in the future, so that the commands needed to produce your own build can be reduced to `./configure; make; make install`.

We recommend that you use these patches to build a special static version of `libpthread.a` and use it only for statically linking against MySQL. We know that these patches are safe for MySQL and significantly improve its performance, but we cannot say anything about their effects on other applications. If you link other applications that require LinuxThreads against the patched static version of the library, or build a patched shared version and install it on your system, you do so at your own risk.

If you experience any strange problems during the installation of MySQL, or with some common utilities hanging, it is very likely that they are either library or compiler related. If this is the case, using our binary resolves them.

If you link your own MySQL client programs, you may see the following error at runtime:

```
ld.so.1: fatal: libmysqlclient.so.#:
open failed: No such file or directory
```

This problem can be avoided by one of the following methods:

- Link clients with the `-Wl,r/full/path/to/libmysqlclient.so` flag rather than with `-Lpath`.
- Copy `libmysqlclient.so` to `/usr/lib`.
- Add the pathname of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable before running your client.

If you are using the Fujitsu compiler (`fcc/FCC`), you may have some problems compiling MySQL because the Linux header files are very `gcc` oriented. The following `configure` line should work with `fcc/FCC`:

```
CC=fcc CFLAGS="-O -K fast -K lib -K omitfp -Kpreex -D_GNU_SOURCE \
-DCONST=const -DNO_STRTOLL_PROTO" \
CXX=FCC CXXFLAGS="-O -K fast -K lib \
-K omitfp -K preex --no_exceptions --no_rtti -D_GNU_SOURCE \
-DCONST=const -Dalloca=__builtin_alloca -DNO_STRTOLL_PROTO \
'-D_EXTERN_INLINE=static __inline'" \
./configure \
--prefix=/usr/local/mysql --enable- assembler \
--with-mysqld-ldflags=-all-static --disable-shared \
--with-low-memory
```

### 2.13.1.4. Linux Post-Installation Notes

`mysql.server` can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

If MySQL cannot open enough files or connections, it may be that you have not configured Linux to

handle enough files.

In Linux 2.2 and onward, you can check the number of allocated file handles as follows:

```
shell> cat /proc/sys/fs/file-max
shell> cat /proc/sys/fs/dquot-max
shell> cat /proc/sys/fs/super-max
```

If you have more than 16MB of memory, you should add something like the following to your init scripts (for example, `/etc/init.d/boot.local` on SuSE Linux):

```
echo 65536 > /proc/sys/fs/file-max
echo 8192 > /proc/sys/fs/dquot-max
echo 1024 > /proc/sys/fs/super-max
```

You can also run the `echo` commands from the command line as `root`, but these settings are lost the next time your computer restarts.

Alternatively, you can set these parameters on startup by using the `sysctl` tool, which is used by many Linux distributions (including SuSE Linux 8.0 and later). Put the following values into a file named `/etc/sysctl.conf`:

```
# Increase some values for MySQL
fs.file-max = 65536
fs.dquot-max = 8192
fs.super-max = 1024
```

You should also add the following to `/etc/my.cnf`:

```
[mysqld_safe]
open-files-limit=8192
```

This should allow the server a limit of 8,192 for the combined number of connections and open files.

The `STACK_SIZE` constant in `LinuxThreads` controls the spacing of thread stacks in the address space. It needs to be large enough so that there is plenty of room for each individual thread stack, but small enough to keep the stack of some threads from running into the global `mysqld` data. Unfortunately, as we have experimentally discovered, the Linux implementation of `mmap()` successfully unmaps a mapped region if you ask it to map out an address currently in use, zeroing out the data on the entire page instead of returning an error. So, the safety of `mysqld` or any other threaded application depends on the “gentlemanly” behavior of the code that creates threads. The user must take measures to make sure that the number of running threads at any given time is sufficiently low for thread stacks to stay away from the global heap. With `mysqld`, you should enforce this behavior by setting a reasonable value for the `max_connections` variable.

If you build MySQL yourself, you can patch `LinuxThreads` for better stack use. See Section 2.13.1.3, “Linux Source Distribution Notes”. If you do not want to patch `LinuxThreads`, you should set `max_connections` to a value no higher than 500. It should be even less if you have a large key buffer, large heap tables, or some other things that make `mysqld` allocate a lot of memory, or if you are running a 2.2 kernel with a 2GB patch. If you are using our binary or RPM version, you can safely set `max_connections` at 1500, assuming no large key buffer or heap tables with lots of data. The more you reduce `STACK_SIZE` in `LinuxThreads` the more threads you can safely create. We recommend values between 128KB and 256KB.

If you use a lot of concurrent connections, you may suffer from a “feature” in the 2.2 kernel that attempts to prevent fork bomb attacks by penalizing a process for forking or cloning a child. This causes MySQL not to scale well as you increase the number of concurrent clients. On single-CPU systems, we have seen this manifest as very slow thread creation; it may take a long time to connect to MySQL (as long as one minute), and it may take just as long to shut it down. On multiple-CPU systems, we have observed a gradual drop in query speed as the number of clients increases. In the

process of trying to find a solution, we have received a kernel patch from one of our users who claimed it helped for his site. This patch is available at <http://www.mysql.com/Downloads/Patches/linux-fork.patch>. We have done rather extensive testing of this patch on both development and production systems. It has significantly improved MySQL performance without causing any problems and we recommend it to our users who still run high-load servers on 2.2 kernels.

This issue has been fixed in the 2.4 kernel, so if you are not satisfied with the current performance of your system, rather than patching your 2.2 kernel, it might be easier to upgrade to 2.4. On SMP systems, upgrading also gives you a nice SMP boost in addition to fixing the fairness bug.

We have tested MySQL on the 2.4 kernel on a two-CPU machine and found MySQL scales *much* better. There was virtually no slowdown on query throughput all the way up to 1,000 clients, and the MySQL scaling factor (computed as the ratio of maximum throughput to the throughput for one client) was 180%. We have observed similar results on a four-CPU system: Virtually no slowdown as the number of clients was increased up to 1,000, and a 300% scaling factor. Based on these results, for a high-load SMP server using a 2.2 kernel, we definitely recommend upgrading to the 2.4 kernel at this point.

We have discovered that it is essential to run the `mysqld` process with the highest possible priority on the 2.4 kernel to achieve maximum performance. This can be done by adding a `renice -20 $$` command to `mysqld_safe`. In our testing on a four-CPU machine, increasing the priority resulted in a 60% throughput increase with 400 clients.

We are currently also trying to collect more information on how well MySQL performs with a 2.4 kernel on four-way and eight-way systems. If you have access such a system and have done some benchmarks, please send an email message to [<benchmarks@mysql.com>](mailto:benchmarks@mysql.com) with the results. We will review them for inclusion in the manual.

If you see a dead `mysqld` server process with `ps`, this usually means that you have found a bug in MySQL or you have a corrupted table. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

To get a core dump on Linux if `mysqld` dies with a `SIGSEGV` signal, you can start `mysqld` with the `--core-file` option. Note that you also probably need to raise the core file size by adding `ulimit -c 1000000` to `mysqld_safe` or starting `mysqld_safe` with `--core-file-size=1000000`. See Section 5.4.1, “`mysqld_safe` — MySQL Server Startup Script”.

### 2.13.1.5. Linux x86 Notes

MySQL requires `libc` 5.4.12 or newer. It is known to work with `libc` 5.4.46. `glibc` 2.0.6 and later should also work. There have been some problems with the `glibc` RPMs from Red Hat, so if you have problems, check whether there are any updates. The `glibc` 2.0.7-19 and 2.0.7-29 RPMs are known to work.

If you are using Red Hat 8.0 or a new `glibc` 2.2.x library, you may see `mysqld` die in `gethostbyaddr()`. This happens because the new `glibc` library requires a stack size greater than 128KB for this call. To fix the problem, start `mysqld` with the `--thread-stack=192K` option. (Use `-O thread_stack=192K` before MySQL 4.) This stack size is the default on MySQL 4.0.10 and above, so you should not see the problem.

If you are using `gcc` 3.0 and above to compile MySQL, you must install the `libstdc++v3` library before compiling MySQL; if you don't do this, you get an error about a missing `__cxa_pure_virtual` symbol during linking.

On some older Linux distributions, `configure` may produce an error like this:

```
Syntax error in sched.h. Change _P to __P in the
/usr/include/sched.h file.
See the Installation chapter in the Reference Manual.
```

Just do what the error message says. Add an extra underscore to the `_P` macro name that has only

one underscore, and then try again.

You may get some warnings when compiling. Those shown here can be ignored:

```
mysqld.cc -o objs-thread/mysqld.o
mysqld.cc: In function `void init_signals()':
mysqld.cc:315: warning: assignment of negative value `-1' to
`long unsigned int'
mysqld.cc: In function `void * signal_hand(void *)':
mysqld.cc:346: warning: assignment of negative value `-1' to
`long unsigned int'
```

If `mysqld` always dumps core when it starts, the problem may be that you have an old `/lib/libc.a`. Try renaming it, and then remove `sql/mysqld` and do a new `make install` and try again. This problem has been reported on some Slackware installations.

If you get the following error when linking `mysqld`, it means that your `libg++.a` is not installed correctly:

```
/usr/lib/libc.a(putc.o): In function `_IO_putc':
putc.o(.text+0x0): multiple definition of `_IO_putc'
```

You can avoid using `libg++.a` by running `configure` like this:

```
shell> CXX=gcc ./configure
```

### 2.13.1.6. Linux SPARC Notes

In some implementations, `readdir_r()` is broken. The symptom is that the `SHOW DATABASES` statement always returns an empty set. This can be fixed by removing `HAVE_READDIR_R` from `config.h` after configuring and before compiling.

### 2.13.1.7. Linux Alpha Notes

We have tested MySQL 5.0 on Alpha with our benchmarks and test suite, and it appears to work well.

We currently build the MySQL binary packages on SuSE Linux 7.0 for AXP, kernel 2.4.4-SMP, Compaq C compiler (V6.2-505) and Compaq C++ compiler (V6.3-006) on a Compaq DS20 machine with an Alpha EV6 processor.

You can find the preceding compilers at <http://www.support.compaq.com/alpha-tools/>. By using these compilers rather than `gcc`, we get about 9-14% better MySQL performance.

For MySQL on Alpha, we use the `-arch generic` flag to our compile options, which ensures that the binary runs on all Alpha processors. We also compile statically to avoid library problems. The `configure` command looks like this:

```
CC=ccc CFLAGS="-fast -arch generic" CXX=cxx \  
CXXFLAGS="-fast -arch generic -noexceptions -nortti" \  
./configure --prefix=/usr/local/mysql --disable-shared \  
--with-extra-charsets=complex --enable-thread-safe-client \  
--with-mysqld-ldflags=-non_shared --with-client-ldflags=-non_shared
```

If you want to use `egcs`, the following `configure` line worked for us:

```
CFLAGS="-O3 -fomit-frame-pointer" CXX=gcc \  
CXXFLAGS="-O3 -fomit-frame-pointer -felide-constructors \  
-fno-exceptions -fno-rtti" \  
./configure --prefix=/usr/local/mysql --disable-shared
```

Some known problems when running MySQL on Linux-Alpha:

- Debugging threaded applications like MySQL does not work with `gdb 4.18`. You should use `gdb 5.1` instead.
- If you try linking `mysqld` statically when using `gcc`, the resulting image dumps core at startup time. In other words, *do not* use `--with-mysqld-ldflags=-all-static` with `gcc`.

### 2.13.1.8. Linux PowerPC Notes

MySQL should work on MkLinux with the newest `glibc` package (tested with `glibc 2.0.7`).

### 2.13.1.9. Linux MIPS Notes

To get MySQL to work on Qube2 (Linux Mips), you need the newest `glibc` libraries. `glibc-2.0.7-29C2` is known to work. You must also use the `egcs` C++ compiler (`egcs 1.0.2-9`, `gcc 2.95.2` or newer).

### 2.13.1.10. Linux IA-64 Notes

To get MySQL to compile on Linux IA-64, we use the following `configure` command for building with `gcc 2.96`:

```
CC=gcc \  
CFLAGS="-O3 -fno-omit-frame-pointer" \  
CXX=gcc \  
CXXFLAGS="-O3 -fno-omit-frame-pointer -felide-constructors \  
          -fno-exceptions -fno-rtti" \  
./configure --prefix=/usr/local/mysql \  
            "--with-comment=Official MySQL binary" \  
            "--with-extra-charsets=complex
```

On IA-64, the MySQL client binaries use shared libraries. This means that if you install our binary distribution at a location other than `/usr/local/mysql`, you need to add the path of the directory where you have `libmysqlclient.so` installed either to the `/etc/ld.so.conf` file or to the value of your `LD_LIBRARY_PATH` environment variable.

See Section A.3.1, "Problems Linking to the MySQL Client Library".

## 2.13.2. Mac OS X Notes

On Mac OS X, `tar` cannot handle long filenames. If you need to unpack a `.tar.gz` distribution, use `gnutar` instead.

### 2.13.2.1. Mac OS X 10.x (Darwin)

MySQL should work without major problems on Mac OS X 10.x (Darwin).

Known issues:

- If you have problems with performance under heavy load, try using the `-skip-thread-priority` option to `mysqld`. This runs all threads with the same priority. On Mac OS X, this gives better performance, at least until Apple fixes its thread scheduler.
- The connection times (`wait_timeout`, `interactive_timeout` and `net_read_timeout`) values are not honored.

This is probably a signal handling problem in the thread library where the signal doesn't break a

pending read and we hope that a future update to the thread libraries will fix this.

Our binary for Mac OS X is compiled on Darwin 6.3 with the following configure line:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc \  
CXXFLAGS="-O3 -fno-omit-frame-pointer -felide-constructors \  
-fno-exceptions -fno-rtti" \  
./configure --prefix=/usr/local/mysql \  
--with-extra-charsets=complex --enable-thread-safe-client \  
--enable-local-infile --disable-shared
```

See Section 2.5, “Installing MySQL on Mac OS X”.

### 2.13.2.2. Mac OS X Server 1.2 (Rhapsody)

For current versions of Mac OS X Server, no operating system changes are necessary before compiling MySQL. Compiling for the Server platform is the same as for the client version of Mac OS X.

For older versions (Mac OS X Server 1.2, a.k.a. Rhapsody), you must first install a pthread package before trying to configure MySQL.

See Section 2.5, “Installing MySQL on Mac OS X”.

### 2.13.3. Solaris Notes

For information about installing MySQL on Solaris using PKG distributions, see Section 2.6, “Installing MySQL on Solaris”.

On Solaris, you may run into trouble even before you get the MySQL distribution unpacked, as the Solaris `tar` cannot handle long filenames. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution. You can find a precompiled copy for Solaris at <http://dev.mysql.com/downloads/os-solaris.html>.

Sun native threads work only on Solaris 2.5 and higher. For Solaris 2.4 and earlier, MySQL automatically uses MIT-pthreads. See Section 2.9.5, “MIT-pthreads Notes”.

If you get the following error from `configure`, it means that you have something wrong with your compiler installation:

```
checking for restartable system calls... configure: error can not  
run test programs while cross compiling
```

In this case, you should upgrade your compiler to a newer version. You may also be able to solve this problem by inserting the following row into the `config.cache` file:

```
ac_cv_sys_restartable_syscalls=${ac_cv_sys_restartable_syscalls='no' }
```

If you are using Solaris on a SPARC, the recommended compiler is `gcc 2.95.2` or `3.2`. You can find this at <http://gcc.gnu.org/>. Note that `egcs 1.1.1` and `gcc 2.8.1` do not work reliably on SPARC.

The recommended `configure` line when using `gcc 2.95.2` is:

```
CC=gcc CFLAGS="-O3" \  
CXX=gcc CXXFLAGS="-O3 -felide-constructors -fno-exceptions -fno-rtti" \  
./configure --prefix=/usr/local/mysql --with-low-memory \  
--enable-asm
```

If you have an UltraSPARC system, you can get 4% better performance by adding `-mcpu=v8 -Wa, -xarch=v8plusa` to the `CFLAGS` and `CXXFLAGS` environment variables.

If you have Sun's Forte 5.0 (or newer) compiler, you can run `configure` like this:

```
CC=cc CFLAGS="-Xa -fast -native -xstrconst -mt" \  
CXX=CC CXXFLAGS="-noex -mt" \  
./configure --prefix=/usr/local/mysql --enable-asmbl
```

To create a 64-bit binary with Sun's Forte compiler, use the following configuration options:

```
CC=cc CFLAGS="-Xa -fast -native -xstrconst -mt -xarch=v9" \  
CXX=CC CXXFLAGS="-noex -mt -xarch=v9" ASFLAGS="-xarch=v9" \  
./configure --prefix=/usr/local/mysql --enable-asmbl
```

To create a 64-bit Solaris binary using `gcc`, add `-m64` to `CFLAGS` and `CXXFLAGS` and remove `--enable-asmbl` from the `configure` line.

In the MySQL benchmarks, we obtained a 4% speed increase on UltraSPARC when using Forte 5.0 in 32-bit mode, as compared to using `gcc` 3.2 with the `-mcpu` flag.

If you create a 64-bit `mysqld` binary, it is 4% slower than the 32-bit binary, but can handle more threads and memory.

When using Solaris 10 for `x86_64`, you should mount any filesystems on which you intend to store InnoDB files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so will cause a significant drop in performance when using the InnoDB storage engine on this platform.

If you get a problem with `fdatasync` or `sched_yield`, you can fix this by adding `LIBS=-lrt` to the `configure` line

For compilers older than WorkShop 5.3, you might have to edit the `configure` script. Change this line:

```
#if !defined(__STDC__) || __STDC__ != 1
```

To this:

```
#if !defined(__STDC__)
```

If you turn on `__STDC__` with the `-xc` option, the Sun compiler can't compile with the Solaris `pthread.h` header file. This is a Sun bug (broken compiler or broken include file).

If `mysqld` issues the following error message when you run it, you have tried to compile MySQL with the Sun compiler without enabling the `-mt` multi-thread option:

```
libc internal error: _rmutex_unlock: rmutex not held
```

Add `-mt` to `CFLAGS` and `CXXFLAGS` and recompile.

If you are using the SFW version of `gcc` (which comes with Solaris 8), you must add `/opt/sfw/lib` to the environment variable `LD_LIBRARY_PATH` before running `configure`.

If you are using the `gcc` available from `sunfreeware.com`, you may have many problems. To avoid this, you should recompile `gcc` and `GNU binutils` on the machine where you are running them.

If you get the following error when compiling MySQL with `gcc`, it means that your `gcc` is not configured for your version of Solaris:

```
shell> gcc -O3 -g -O2 -DDEBUG_OFF -o thr_alarm ...
./thr_alarm.c: In function `signal_hand':
./thr_alarm.c:556: too many arguments to function `sigwait'
```

The proper thing to do in this case is to get the newest version of `gcc` and compile it with your current `gcc` compiler. At least for Solaris 2.5, almost all binary versions of `gcc` have old, unusable include files that break all programs that use threads, and possibly other programs as well.

Solaris does not provide static versions of all system libraries (`libpthreads` and `libdl`), so you cannot compile MySQL with `--static`. If you try to do so, you get one of the following errors:

```
ld: fatal: library -ldl: not found
undefined reference to `dlopen'
cannot find -lrt
```

If you link your own MySQL client programs, you may see the following error at runtime:

```
ld.so.1: fatal: libmysqlclient.so.#:
open failed: No such file or directory
```

This problem can be avoided by one of the following methods:

- Link clients with the `-Wl,r/full/path/to/libmysqlclient.so` flag rather than with `-Lpath`.
- Copy `libmysqlclient.so` to `/usr/lib`.
- Add the pathname of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable before running your client.

If you have problems with `configure` trying to link with `-lz` when you don't have `zlib` installed, you have two options:

- If you want to be able to use the compressed communication protocol, you need to get and install `zlib` from [ftp.gnu.org](http://ftp.gnu.org).
- Run `configure` with the `--with-named-z-libs=no` option when building MySQL.

If you are using `gcc` and have problems with loading user-defined functions (UDFs) into MySQL, try adding `-lgcc` to the link line for the UDF.

If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.

If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

```
Error in accept: Protocol error
```

You might try starting the server with the `--back_log=50` option as a workaround for this. (Use `-O back_log=50` before MySQL 4.)

Solaris doesn't support core files for `setuid()` applications, so you can't get a core file from `mysqld` if you are using the `--user` option.

### 2.13.3.1. Solaris 2.7/2.8 Notes

Normally, you can use a Solaris 2.6 binary on Solaris 2.7 and 2.8. Most of the Solaris 2.6 issues also apply for Solaris 2.7 and 2.8.

MySQL should be able to detect new versions of Solaris automatically and enable workarounds for the following problems.

Solaris 2.7 / 2.8 has some bugs in the include files. You may see the following error when you use gcc:

```
/usr/include/widec.h:42: warning: `getwc' redefined
/usr/include/wchar.h:326: warning: this is the location of the previous
definition
```

If this occurs, you can fix the problem by copying `/usr/include/widec.h` to `.../lib/gcc-lib/os/gcc-version/include` and changing line 41 from this:

```
#if !defined(lint) && !defined(__lint)
```

To this:

```
#if !defined(lint) && !defined(__lint) && !defined(getwc)
```

Alternatively, you can edit `/usr/include/widec.h` directly. Either way, after you make the fix, you should remove `config.cache` and run `configure` again.

If you get the following errors when you run `make`, it's because `configure` didn't detect the `curses.h` file (probably because of the error in `/usr/include/widec.h`):

```
In file included from mysql.cc:50:
/usr/include/term.h:1060: syntax error before `,'
/usr/include/term.h:1081: syntax error before `;'
```

The solution to this problem is to do one of the following:

- Configure with `CFLAGS=-DHAVE_CURSES_H CXXFLAGS=-DHAVE_CURSES_H ./configure`.
- Edit `/usr/include/widec.h` as indicated in the preceding discussion and re-run `configure`.
- Remove the `#define HAVE_TERM` line from the `config.h` file and run `make` again.

If your linker cannot find `-lz` when linking client programs, the problem is probably that your `libz.so` file is installed in `/usr/local/lib`. You can fix this problem by one of the following methods:

- Add `/usr/local/lib` to `LD_LIBRARY_PATH`.
- Add a link to `libz.so` from `/lib`.
- If you are using Solaris 8, you can install the optional `zlib` from your Solaris 8 CD distribution.
- Run `configure` with the `--with-named-z-libs=no` option when building MySQL.

### 2.13.3.2. Solaris x86 Notes

On Solaris 8 on x86, `mysqld` dumps core if you remove the debug symbols using `strip`.

If you are using `gcc` or `egcs` on Solaris x86 and you experience problems with core dumps under load, you should use the following `configure` command:

```
CC=gcc CFLAGS="-O3 -fomit-frame-pointer -DHAVE_CURSES_H" \  
CXX=gcc \  
CXXFLAGS="-O3 -fomit-frame-pointer -felide-constructors \  
          -fno-exceptions -fno-rtti -DHAVE_CURSES_H" \  
./configure --prefix=/usr/local/mysql
```

This avoids problems with the `libstdc++` library and with C++ exceptions.

If this doesn't help, you should compile a debug version and run it with a trace file or under `gdb`. See Section E.1.3, "Debugging `mysqld` under `gdb`".

## 2.13.4. BSD Notes

This section provides information about using MySQL on variants of BSD Unix.

### 2.13.4.1. FreeBSD Notes

FreeBSD 4.x or newer is recommended for running MySQL, because the thread package is much more integrated. To get a secure and stable system, you should use only FreeBSD kernels that are marked `-RELEASE`.

The easiest (and preferred) way to install MySQL is to use the `mysql-server` and `mysql-client` ports available at <http://www.freebsd.org/>. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.
- Automatic configuration and build.
- Startup scripts installed in `/usr/local/etc/rc.d`.
- The ability to use `pkg_info -L` to see which files are installed.
- The ability to use `pkg_delete` to remove MySQL if you no longer want it on your machine.

It is recommended you use MIT-pthreads on FreeBSD 2.x, and native threads on FreeBSD 3 and up. It is possible to run with native threads on some late 2.2.x versions, but you may encounter problems shutting down `mysqld`.

Unfortunately, certain function calls on FreeBSD are not yet fully thread-safe. Most notably, this includes the `gethostbyname()` function, which is used by MySQL to convert hostnames into IP addresses. Under certain circumstances, the `mysqld` process suddenly causes 100% CPU load and is unresponsive. If you encounter this problem, try to start MySQL using the `-skip-name-resolve` option.

Alternatively, you can link MySQL on FreeBSD 4.x against the LinuxThreads library, which avoids a few of the problems that the native FreeBSD thread implementation has. For a very good comparison of LinuxThreads versus native threads, see Jeremy Zawodny's article *FreeBSD or Linux for your MySQL Server?* at <http://jeremy.zawodny.com/blog/archives/000697.html>.

Known problem when using LinuxThreads on FreeBSD is:

- The connection times (`wait_timeout`, `interactive_timeout` and

`net_read_timeout`) values are not honored. The symptom is that persistent connections can hang for a very long time without getting closed down and that a 'kill' for a thread will not take affect until the thread does it a new command

This is probably a signal handling problem in the thread library where the signal doesn't break a pending read. This is supposed to be fixed in FreeBSD 5.0

The MySQL build process requires GNU make (`gmake`) to work. If GNU make is not available, you must install it first before compiling MySQL.

The recommended way to compile and install MySQL on FreeBSD with `gcc` (2.95.2 and up) is:

```
CC=gcc CFLAGS="-O2 -fno-strength-reduce" \  
CXX=gcc CXXFLAGS="-O2 -fno-rtti -fno-exceptions \  
-felide-constructors -fno-strength-reduce" \  
./configure --prefix=/usr/local/mysql --enable-asm  
gmake  
gmake install  
cd /usr/local/mysql  
bin/mysql_install_db --user=mysql  
bin/mysqld_safe &
```

If you notice that `configure` uses MIT-pthreads, you should read the MIT-pthreads notes. See Section 2.9.5, "MIT-pthreads Notes".

If you get an error from `make install` that it can't find `/usr/include/pthreads`, `configure` didn't detect that you need MIT-pthreads. To fix this problem, remove `config.cache`, and then re-run `configure` with the `--with-mit-threads` option.

Be sure that your name resolver setup is correct. Otherwise, you may experience resolver delays or failures when connecting to `mysqld`. Also make sure that the `localhost` entry in the `/etc/hosts` file is correct. The file should start with a line similar to this:

```
127.0.0.1      localhost localhost.your.domain
```

FreeBSD is known to have a very low default file handle limit. See Section A.2.17, "File Not Found". Start the server by using the `--open-files-limit` option for `mysqld_safe`, or raise the limits for the `mysqld` user in `/etc/login.conf` and rebuild it with `cap_mkdb /etc/login.conf`. Also be sure that you set the appropriate class for this user in the password file if you are not using the default (use `chpass mysqld-user-name`). See Section 5.4.1, "mysqld\_safe — MySQL Server Startup Script".

FreeBSD limits the size of a process to 512MB, even if you have much more RAM available on the system. So you may get an error such as this:

```
Out of memory (Needed 16391 bytes)
```

In current versions of FreeBSD (at least 4.x and greater), you may increase this limit by adding the following entries to the `/boot/loader.conf` file and rebooting the machine (these are not settings that can be changed at run time with the `sysctl` command):

```
kern.maxdsiz="1073741824" # 1GB  
kern.dfldsiz="1073741824" # 1GB  
kern.maxssiz="134217728" # 128MB
```

For older versions of FreeBSD, you must recompile your kernel to change the maximum data segment size for a process. In this case, you should look at the `MAXDSIZ` option in the `LINT` config file for more information.

If you get problems with the current date in MySQL, setting the `TZ` variable should help. See Ap-

pendix F, *Environment Variables*.

### 2.13.4.2. NetBSD Notes

To compile on NetBSD, you need GNU make. Otherwise, the build process fails when make tries to run `lint` on C++ files.

### 2.13.4.3. OpenBSD 2.5 Notes

On OpenBSD 2.5, you can compile MySQL with native threads with the following options:

```
CFLAGS=-pthread CXXFLAGS=-pthread ./configure --with-mit-threads=no
```

### 2.13.4.4. BSD/OS Version 2.x Notes

If you get the following error when compiling MySQL, your `ulimit` value for virtual memory is too low:

```
item_func.h: In method
`Item_func_ge::Item_func_ge(const Item_func_ge &)`:
item_func.h:28: virtual memory exhausted
make[2]: *** [item_func.o] Error 1
```

Try using `ulimit -v 80000` and run make again. If this doesn't work and you are using `bash`, try switching to `cs`h or `sh`; some BSDI users have reported problems with `bash` and `ulimit`.

If you are using `gcc`, you may also use have to use the `--with-low-memory` flag for `configure` to be able to compile `sql_yacc.cc`.

If you get problems with the current date in MySQL, setting the `TZ` variable should help. See Appendix F, *Environment Variables*.

### 2.13.4.5. BSD/OS Version 3.x Notes

Upgrade to BSD/OS 3.1. If that is not possible, install BSDIpatch M300-038.

Use the following command when configuring MySQL:

```
env CXX=shlcc++ CC=shlcc2 \
./configure \
  --prefix=/usr/local/mysql \
  --localstatedir=/var/mysql \
  --without-perl \
  --with-unix-socket-path=/var/mysql/mysql.sock
```

The following is also known to work:

```
env CC=gcc CXX=gcc CXXFLAGS=-O3 \
./configure \
  --prefix=/usr/local/mysql \
  --with-unix-socket-path=/var/mysql/mysql.sock
```

You can change the directory locations if you wish, or just use the defaults by not specifying any locations.

If you have problems with performance under heavy load, try using the `--skip-thread-priority` option to `mysqld`. This runs all threads with the same priority. On BSDI 3.1, this gives better performance, at least until BSDI fixes its thread scheduler.

If you get the error `virtual memory exhausted` while compiling, you should try using `ulimit -v 80000` and running make again. If this doesn't work and you are using `bash`, try

switching to `cs`h or `sh`; some BSDI users have reported problems with `bash` and `ulimit`.

### 2.13.4.6. BSD/OS Version 4.x Notes

BSDI 4.x has some thread-related bugs. If you want to use MySQL on this, you should install all thread-related patches. At least M400-023 should be installed.

On some BSDI 4.x systems, you may get problems with shared libraries. The symptom is that you can't execute any client programs, for example, `mysqladmin`. In this case, you need to reconfigure not to use shared libraries with the `--disable-shared` option to configure.

Some customers have had problems on BSDI 4.0.1 that the `mysqld` binary after a while can't open tables. This occurs because some library/system-related bug causes `mysqld` to change current directory without having asked for that to happen.

The fix is to either upgrade MySQL to at least version 3.23.34 or, after running `configure`, remove the line `#define HAVE_REALPATH` from `config.h` before running `make`.

Note that this means that you can't symbolically link a database directories to another database directory or symbolic link a table to another database on BSDI. (Making a symbolic link to another disk is okay).

## 2.13.5. Other Unix Notes

### 2.13.5.1. HP-UX Version 10.20 Notes

There are a couple of small problems when compiling MySQL on HP-UX. We recommend that you use `gcc` instead of the HP-UX native compiler, because `gcc` produces better code.

We recommend using `gcc 2.95` on HP-UX. Don't use high optimization flags (such as `-O6`) because they may not be safe on HP-UX.

The following `configure` line should work with `gcc 2.95`:

```
CFLAGS="-I/opt/dce/include -fpic" \  
CXXFLAGS="-I/opt/dce/include -felide-constructors -fno-exceptions \  
-fno-rtti" \  
CXX=gcc \  
./configure --with-pthread \  
    --with-named-thread-libs='-ldce' \  
    --prefix=/usr/local/mysql --disable-shared
```

The following `configure` line should work with `gcc 3.1`:

```
CFLAGS="-DHPUX -I/opt/dce/include -O3 -fPIC" CXX=gcc \  
CXXFLAGS="-DHPUX -I/opt/dce/include -felide-constructors \  
-fno-exceptions -fno-rtti -O3 -fPIC" \  
./configure --prefix=/usr/local/mysql \  
    --with-extra-charsets=complex --enable-thread-safe-client \  
    --enable-local-infile --with-pthread \  
    --with-named-thread-libs=-ldce --with-lib-ccflags=-fPIC \  
    --disable-shared
```

### 2.13.5.2. HP-UX Version 11.x Notes

Because of some critical bugs in the standard HP-UX libraries, you should install the following patches before trying to run MySQL on HP-UX 11.0:

```
PHKL_22840 Streams cumulative  
PHNE_22397 ARPA cumulative
```

This solves the problem of getting EWOULDBLOCK from `recv()` and EBADF from `accept()` in threaded applications.

If you are using `gcc 2.95.1` on an unpatched HP-UX 11.x system, you may get the following error:

```
In file included from /usr/include/unistd.h:11,
                 from ../include/global.h:125,
                 from mysql_priv.h:15,
                 from item.cc:19:
/usr/include/sys/unistd.h:184: declaration of C function ...
/usr/include/sys/pthread.h:440: previous declaration ...
In file included from item.h:306,
                 from mysql_priv.h:158,
                 from item.cc:19:
```

The problem is that HP-UX does not define `pthread_atfork()` consistently. It has conflicting prototypes in `/usr/include/sys/unistd.h:184` and `/usr/include/sys/pthread.h:440`.

One solution is to copy `/usr/include/sys/unistd.h` into `mysql/include` and edit `unistd.h` and change it to match the definition in `pthread.h`. Look for this line:

```
extern int pthread_atfork(void (*prepare)(), void (*parent)(),
                          void (*child)());
```

Change it to look like this:

```
extern int pthread_atfork(void (*prepare)(void), void (*parent)(void),
                          void (*child)(void));
```

After making the change, the following configure line should work:

```
CFLAGS="-fomit-frame-pointer -O3 -fpic" CXX=gcc \
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti -O3" \
./configure --prefix=/usr/local/mysql --disable-shared
```

If you are using HP-UX compiler, you can use the following command (which has been tested with `cc B.11.11.04`):

```
CC=cc CXX=aCC CFLAGS=+DD64 CXXFLAGS=+DD64 ./configure \
--with-extra-character-set=complex
```

You can ignore any errors of the following type:

```
aCC: warning 901: unknown option: ` -3 ': use +help for online
documentation
```

If you get the following error from `configure`, verify that you don't have the path to the K&R compiler before the path to the HP-UX C and C++ compiler:

```
checking for cc option to accept ANSI C... no
configure: error: MySQL requires an ANSI C compiler (and a C++ compiler).
Try gcc. See the Installation chapter in the Reference Manual.
```

Another reason for not being able to compile is that you didn't define the `+DD64` flags as just described.

Another possibility for HP-UX 11 is to use the MySQL binaries provided at <http://dev.mysql.com/downloads/>, which we have built and tested ourselves. We have also received reports that the HP-UX 10.20 binaries supplied by MySQL can be run successfully on HP-UX 11. If

you encounter problems, you should be sure to check your HP-UX patch level.

### 2.13.5.3. IBM-AIX notes

Automatic detection of x1C is missing from Autoconf, so a number of variables need to be set before running configure. The following example uses the IBM compiler:

```
export CC="x1c_r -ma -O3 -qstrict -qoptimize=3 -qmaxmem=8192 "  
export CXX="x1c_r -ma -O3 -qstrict -qoptimize=3 -qmaxmem=8192 "  
export CFLAGS="-I /usr/local/include"  
export LDFLAGS="-L /usr/local/lib"  
export CPPFLAGS=$CFLAGS  
export CXXFLAGS=$CFLAGS  
  
./configure --prefix=/usr/local \  
            --localstatedir=/var/mysql \  
            --sbindir='/usr/local/bin' \  
            --libexecdir='/usr/local/bin' \  
            --enable-thread-safe-client \  
            --enable-large-files
```

The preceding options are used to compile the MySQL distribution that can be found at <http://www-frec.bull.com/>.

If you change the `-O3` to `-O2` in the preceding configure line, you must also remove the `-qstrict` option. This is a limitation in the IBM C compiler.

If you are using `gcc` or `egcs` to compile MySQL, you *must* use the `-fno-exceptions` flag, because the exception handling in `gcc/egcs` is not thread-safe! (This is tested with `egcs 1.1`.) There are also some known problems with IBM's assembler that may cause it to generate bad code when used with `gcc`.

We recommend the following configure line with `egcs` and `gcc 2.95` on AIX:

```
CC="gcc -pipe -mcpu=power -Wa,-many" \  
CXX="gcc -pipe -mcpu=power -Wa,-many" \  
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti" \  
./configure --prefix=/usr/local/mysql --with-low-memory
```

The `-Wa,-many` option is necessary for the compile to be successful. IBM is aware of this problem but is in no hurry to fix it because of the workaround that is available. We don't know if the `-fno-exceptions` is required with `gcc 2.95`, but because MySQL doesn't use exceptions and the option generates faster code, we recommend that you should always use it with `egcs/gcc`.

If you get a problem with assembler code, try changing the `-mcpu=xxx` option to match your CPU. Typically `power2`, `power`, or `powerpc` may need to be used. Alternatively, you might need to use `604` or `604e`. We are not positive but suspect that `power` would likely be safe most of the time, even on a `power2` machine.

If you don't know what your CPU is, execute a `uname -m` command. It produces a string that looks like `000514676700`, with a format of `xyyyyyyyymmss` where `xx` and `ss` are always `00`, `yyyyyy` is a unique system ID and `mm` is the ID of the CPU Planar. A chart of these values can be found at [http://www16.boulder.ibm.com/pseries/en\\_US/cmds/aixcmds5/uname.htm](http://www16.boulder.ibm.com/pseries/en_US/cmds/aixcmds5/uname.htm).

This gives you a machine type and a machine model you can use to determine what type of CPU you have.

If you have problems with signals (MySQL dies unexpectedly under high load), you may have found an OS bug with threads and signals. In this case, you can tell MySQL not to use signals by configuring as follows:

```
CFLAGS=-DDONT_USE_THR_ALARM CXX=gcc \  
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti \  
-DDONT_USE_THR_ALARM" \  

```

```
./configure --prefix=/usr/local/mysql --with-debug \
--with-low-memory
```

This doesn't affect the performance of MySQL, but has the side effect that you can't kill clients that are "sleeping" on a connection with `mysqladmin kill` or `mysqladmin shutdown`. Instead, the client dies when it issues its next command.

On some versions of AIX, linking with `libbind.a` makes `getservbyname()` dump core. This is an AIX bug and should be reported to IBM.

For AIX 4.2.1 and `gcc`, you have to make the following changes.

After configuring, edit `config.h` and `include/my_config.h` and change the line that says this:

```
#define HAVE_SNPRINTF 1
```

to this:

```
#undef HAVE_SNPRINTF
```

And finally, in `mysqld.cc`, you need to add a prototype for `initgroups()`.

```
#ifdef _AIX41
extern "C" int initgroups(const char *,int);
#endif
```

If you need to allocate a lot of memory to the `mysqld` process, it's not enough to just use `ulimit -d unlimited`. You may also have to modify `mysqld_safe` to add a line something like this:

```
export LDR_CNTRL='MAXDATA=0x80000000'
```

You can find more information about using a lot of memory at [http://publib16.boulder.ibm.com/pseries/en\\_US/aixprgpd/genprog/lrg\\_prg\\_support.htm](http://publib16.boulder.ibm.com/pseries/en_US/aixprgpd/genprog/lrg_prg_support.htm).

Users of AIX 4.3 should use `gmake` instead of the `make` utility included with AIX.

As of AIX 4.1, the C compiler has been unbundled from AIX as a separate product. We recommend using `gcc 3.3.2`, which can be obtained here: <ftp://ftp.software.ibm.com/aix/freeSoftware/aixtoolbox/RPMS/ppc/gcc/>

The steps for compiling MySQL on AIX with `gcc 3.3.2` are similar to those for using `gcc 2.95` (in particular, the need to edit `config.h` and `my_config.h` after running `configure`). However, before running `configure`, you should also patch the `curses.h` file as follows:

```
/opt/freeware/lib/gcc-lib/powerpc-ibm-aix5.2.0.0/3.3.2/include/curses.h.ORIG
Mon Dec 26 02:17:28 2005
--- /opt/freeware/lib/gcc-lib/powerpc-ibm-aix5.2.0.0/3.3.2/include/curses.h
Mon Dec 26 02:40:13 2005
*****
*** 2023,2029 ****

    #endif /* _AIX32_CURSES */
! #if defined(__USE_FIXED_PROTOTYPES__) || defined(__cplusplus) || defined
(__STRICT_ANSI__)
    extern int delwin (WINDOW *);
    extern int endwin (void);
    extern int getcurx (WINDOW *);
--- 2023,2029 ----
```

```
#endif /* _AIX32_CURSES */
! #if 0 && (defined(__USE_FIXED_PROTOTYPES__) || defined(__cplusplus)
|| defined
(__STRICT_ANSI__))
extern int delwin (WINDOW *);
extern int endwin (void);
extern int getcurx (WINDOW *);
```

#### 2.13.5.4. SunOS 4 Notes

On SunOS 4, MIT-pthreads is needed to compile MySQL. This in turn means you need GNU make.

Some SunOS 4 systems have problems with dynamic libraries and libtool. You can use the following configure line to avoid this problem:

```
./configure --disable-shared --with-mysqld-ldflags=-all-static
```

When compiling readline, you may get warnings about duplicate defines. These can be ignored.

When compiling mysqld, there are some implicit declaration of function warnings. These can be ignored.

#### 2.13.5.5. Alpha-DEC-UNIX Notes (Tru64)

If you are using egcs 1.1.2 on Digital Unix, you should upgrade to gcc 2.95.2, because egcs on DEC has some serious bugs!

When compiling threaded programs under Digital Unix, the documentation recommends using the -pthread option for cc and cxx and the -lmach -lexc libraries (in addition to -lpthread). You should run configure something like this:

```
CC="cc -pthread" CXX="cxx -pthread -O" \
./configure --with-named-thread-libs="-lpthread -lmach -lexc -lc"
```

When compiling mysqld, you may see a couple of warnings like this:

```
mysqld.cc: In function void handle_connections()':
mysqld.cc:626: passing long unsigned int '*' as argument 3 of
accept(int,sockaddr *, int *)'
```

You can safely ignore these warnings. They occur because configure can detect only errors, not warnings.

If you start the server directly from the command line, you may have problems with it dying when you log out. (When you log out, your outstanding processes receive a SIGHUP signal.) If so, try starting the server like this:

```
nohup mysqld [options] &
```

nohup causes the command following it to ignore any SIGHUP signal sent from the terminal. Alternatively, start the server by running mysqld\_safe, which invokes mysqld using nohup for you. See Section 5.4.1, "mysqld\_safe — MySQL Server Startup Script".

If you get a problem when compiling msys/get\_opt.c, just remove the #define \_NO\_PROTO line from the start of that file.

If you are using Compaq's CC compiler, the following configure line should work:

```
CC="cc -pthread"
```

```
CFLAGS="-O4 -ansi_alias -ansi_args -fast -inline speed all -arch host"
CXX="cxx -pthread"
CXXFLAGS="-O4 -ansi_alias -ansi_args -fast -inline speed all \
    -arch host -noexceptions -nortti"
export CC CFLAGS CXX CXXFLAGS
./configure \
    --prefix=/usr/local/mysql \
    --with-low-memory \
    --enable-large-files \
    --enable-shared=yes \
    --with-named-thread-libs="-lpthread -lmach -lexc -lc"
gnumake
```

If you get a problem with `libtool` when compiling with shared libraries as just shown, when linking `mysql`, you should be able to get around this by issuing these commands:

```
cd mysql
/bin/sh ../libtool --mode=link cxx -pthread -O3 -DDEBUG_OFF \
    -O4 -ansi_alias -ansi_args -fast -inline speed \
    -speculate all \ -arch host -DUNDEF_HAVE_GETHOSTBYNAME_R \
    -o mysql mysql.o readline.o sql_string.o completion_hash.o \
    ../readline/libreadline.a -lcurses \
    ../libmysql/.libs/libmysqlclient.so -lm
cd ..
gnumake
gnumake install
scripts/mysql_install_db
```

### 2.13.5.6. Alpha-DEC-OSF/1 Notes

If you have problems compiling and have DEC `CC` and `gcc` installed, try running `configure` like this:

```
CC=cc CFLAGS=-O CXX=gcc CXXFLAGS=-O3 \
./configure --prefix=/usr/local/mysql
```

If you get problems with the `c_asm.h` file, you can create and use a 'dummy' `c_asm.h` file with:

```
touch include/c_asm.h
CC=gcc CFLAGS=-I./include \
CXX=gcc CXXFLAGS=-O3 \
./configure --prefix=/usr/local/mysql
```

Note that the following problems with the `ld` program can be fixed by downloading the latest DEC (Compaq) patch kit from: <http://ftp.support.compaq.com/public/unix/>.

On OSF/1 V4.0D and compiler "DEC C V5.6-071 on Digital Unix V4.0 (Rev. 878)," the compiler had some strange behavior (undefined `asm` symbols). `/bin/ld` also appears to be broken (problems with `_exit` undefined errors occurring while linking `mysqld`). On this system, we have managed to compile MySQL with the following `configure` line, after replacing `/bin/ld` with the version from OSF 4.0C:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 ./configure --prefix=/usr/local/mysql
```

With the Digital compiler "C++ V6.1-029," the following should work:

```
CC=cc -pthread
CFLAGS=-O4 -ansi_alias -ansi_args -fast -inline speed \
    -speculate all -arch host
CXX=cxx -pthread
CXXFLAGS=-O4 -ansi_alias -ansi_args -fast -inline speed \
    -speculate all -arch host -noexceptions -nortti
```

```
export CC CFLAGS CXX CXXFLAGS
./configure --prefix=/usr/mysql/mysql \
--with-mysqld-ldflags=-all-static --disable-shared \
--with-named-thread-libs="-lmach -lexc -lc"
```

In some versions of OSF/1, the `alloca()` function is broken. Fix this by removing the line in `config.h` that defines `'HAVE_ALLOCA'`.

The `alloca()` function also may have an incorrect prototype in `/usr/include/alloca.h`. This warning resulting from this can be ignored.

```
configure uses the following thread libraries automatically: -
--with-named-thread-libs="-lpthread -lmach -lexc -lc".
```

When using `gcc`, you can also try running `configure` like this:

```
CFLAGS=-D_PTHREAD_USE_D4 CXX=gcc CXXFLAGS=-O3 ./configure ...
```

If you have problems with signals (MySQL dies unexpectedly under high load), you may have found an OS bug with threads and signals. In this case, you can tell MySQL not to use signals by configuring with:

```
CFLAGS=-DDONT_USE_THR_ALARM \
CXXFLAGS=-DDONT_USE_THR_ALARM \
./configure ...
```

This does not affect the performance of MySQL, but has the side effect that you can't kill clients that are "sleeping" on a connection with `mysqladmin kill` or `mysqladmin shutdown`. Instead, the client dies when it issues its next command.

With `gcc 2.95.2`, you may encounter the following compile error:

```
sql_acl.cc:1456: Internal compiler error in `scan_region',
at except.c:2566
Please submit a full bug report.
```

To fix this, you should change to the `sql` directory and do a cut-and-paste of the last `gcc` line, but change `-O3` to `-O0` (or add `-O0` immediately after `gcc` if you don't have any `-O` option on your compile line). After this is done, you can just change back to the top-level directory and run `make` again.

### 2.13.5.7. SGI Irix Notes

If you are using Irix 6.5.3 or newer, `mysqld` is able to create threads only if you run it as a user that has `CAP_SCHED_MGT` privileges (such as `root`) or give the `mysqld` server this privilege with the following shell command:

```
chcap "CAP_SCHED_MGT+epi" /opt/mysql/libexec/mysqld
```

You may have to undefine some symbols in `config.h` after running `configure` and before compiling.

In some Irix implementations, the `alloca()` function is broken. If the `mysqld` server dies on some `SELECT` statements, remove the lines from `config.h` that define `HAVE_ALLOC` and `HAVE_ALLOCA_H`. If `mysqladmin create` doesn't work, remove the line from `config.h` that defines `HAVE_READDIR_R`. You may have to remove the `HAVE_TERM_H` line as well.

SGI recommends that you install all the patches on this page as a set: [http://support.sgi.com/surfzone/patches/patchset/6.2\\_indigo.rps.html](http://support.sgi.com/surfzone/patches/patchset/6.2_indigo.rps.html)

At the very minimum, you should install the latest kernel rollup, the latest `rld` rollup, and the latest `libc` rollup.

You definitely need all the POSIX patches on this page, for pthreads support:

[http://support.sgi.com/surfzone/patches/patchset/6.2\\_posix.rps.html](http://support.sgi.com/surfzone/patches/patchset/6.2_posix.rps.html)

If you get the something like the following error when compiling `mysql.cc`:

```
"/usr/include/curses.h", line 82: error(1084):  
invalid combination of type
```

Type the following in the top-level directory of your MySQL source tree:

```
extra/replace bool curses_bool < /usr/include/curses.h > include/curses.h  
make
```

There have also been reports of scheduling problems. If only one thread is running, performance is slow. Avoid this by starting another client. This may lead to a two-to-tenfold increase in execution speed thereafter for the other thread. This is a poorly understood problem with Irix threads; you may have to improvise to find solutions until this can be fixed.

If you are compiling with `gcc`, you can use the following `configure` command:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 \  
./configure --prefix=/usr/local/mysql --enable-thread-safe-client \  
--with-named-thread-libs=-lpthread
```

On Irix 6.5.11 with native Irix C and C++ compilers ver. 7.3.1.2, the following is reported to work

```
CC=cc CXX=CC CFLAGS='-O3 -n32 -TARG:platform=IP22 -I/usr/local/include \  
-L/usr/local/lib' CXXFLAGS='-O3 -n32 -TARG:platform=IP22 \  
-I/usr/local/include -L/usr/local/lib' \  
./configure --prefix=/usr/local/mysql --with-innodb --with-berkeley-db \  
--with-libwrap=/usr/local \  
--with-named-curses-libs=/usr/local/lib/libncurses.a
```

## 2.13.5.8. SCO UNIX and OpenServer 5.0.x Notes

The current port is tested only on `sco3.2v5.0.5`, `sco3.2v5.0.6`, and `sco3.2v5.0.7` systems. There has also been progress on a port to `sco3.2v4.2`. Open Server 5.0.8 (Legend) has native threads and allows files greater than 2GB. The current maximum file size is 2GB.

We have been able to compile MySQL with the following `configure` command on OpenServer with `gcc 2.95.3`.

```
CC=gcc CFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \  
CXX=gcc CXXFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \  
./configure --prefix=/usr/local/mysql \  
--enable-thread-safe-client --with-innodb \  
--with-openssl --with-vio --with-extra-charsets=complex
```

`gcc` is available at <ftp://ftp.sco.com/pub/openserver5/opensrc/gnutools-5.0.7Kj>.

This development system requires the OpenServer Execution Environment Supplement `oss646B` on OpenServer 5.0.6 and `oss656B` and The OpenSource libraries found in `gwxlibs`. All OpenSource tools are in the `opensrc` directory. They are available at <ftp://ftp.sco.com/pub/openserver5/opensrc/>.

We recommend using the latest production release of MySQL.

---

SCO provides operating system patches at <ftp://ftp.sco.com/pub/openserver5> for OpenServer 5.0.[0-6] and <ftp://ftp.sco.com/pub/openserver5/507> for OpenServer 5.0.7.

SCO provides information about security fixes at <ftp://ftp.sco.com/pub/security/OpenServer> for OpenServer 5.0.x.

The maximum file size on an OpenServer 5.0.x system is 2GB.

The total memory which can be allocated for streams buffers, clists, and lock records cannot exceed 60MB on OpenServer 5.0.x.

Streams buffers are allocated in units of 4096 byte pages, clists are 70 bytes each, and lock records are 64 bytes each, so:

$$(NSTRPAGES \times 4096) + (NCLIST \times 70) + (MAX_FLCKREC \times 64) \leq 62914560$$

Follow this procedure to configure the Database Services option. If you are unsure whether an application requires this, see the documentation provided with the application.

1. Log in as root.
2. Enable the SUDS driver by editing the `/etc/conf/sdevice.d/suds` file. Change the N in the second field to a Y.
3. Use `mkdev aio` or the Hardware/Kernel Manager to enable support for asynchronous I/O and relink the kernel. To allow users to lock down memory for use with this type of I/O, update the `aiomemlock(F)` file. This file should be updated to include the names of users that can use AIO and the maximum amounts of memory they can lock down.
4. Many applications use `setuid` binaries so that you need to specify only a single user. See the documentation provided with the application to determine whether this is the case for your application.

After you complete this process, reboot the system to create a new kernel incorporating these changes.

By default, the entries in `/etc/conf/cf.d/mtune` are set as follows:

Value	Default	Min	Max
----	-----	---	---
NBUF	0	24	450000
NHBUF	0	32	524288
NMPBUF	0	12	512
MAX_INODE	0	100	64000

NREGION	0	500	160000

We recommend setting these values as follows:

- NOFILES should be 4096 or 2048.
- MAXUP should be 2048.

To make changes to the kernel, use the `idtune name parameter` command. `idtune` modifies the `/etc/conf/cf.d/stune` file for you. For example, to change `SEMMS` to 200, execute this command as root:

```
# /etc/conf/bin/idtune SEMMNS 200
```

Then rebuild and reboot the kernel by issuing this command:

```
# /etc/conf/bin/idbuild -B && init 6
```

We recommend tuning the system, but the proper parameter values to use depend on the number of users accessing the application or database and size of the database (that is, the used buffer pool). The following kernel parameters can be set with `idtune`:

- `SHMMAX` (recommended setting: 128MB) and `SHMSEG` (recommended setting: 15). These parameters have an influence on the MySQL database engine to create user buffer pools.
- `NOFILES` and `MAXUP` should be set to at least 2048.
- `MAXPROC` should be set to at least 3000/4000 (depends on number of users) or more.
- We also recommend using the following formulas to calculate values for `SEMMSL`, `SEMMNS`, and `SEMMNU`:

```
SEMMSL = 13
```

13 is what has been found to be the best for both Progress and MySQL.

$SEMMSL \times \text{number of db servers to be run on the system}$

Set `SEMMSL` to the value of `SEMMSL` multiplied by the number of database servers (maximum) that you are running on the system at one time.

$SEMMSL = SEMMSL$

Set the value of `SEMMSL` to equal the value of `SEMMSL`. You could probably set this to 75% of `SEMMSL`, but this is a conservative estimate.

You need to at least install the SCO OpenServer Linker and Application Development Libraries or the OpenServer Development System to use `gcc`. You cannot use the GCC Dev system without installing one of these.

You should get the FSU Pthreads package and install it first. This can be found at <http://moss.csc.ncsu.edu/~mueller/ftp/pub/PART/pthreads.tar.gz>. You can also get a precompiled package from <ftp://ftp.zenez.com/pub/zenez/prgms/FSU-threads-3.14.tar.gz>.

FSU Pthreads can be compiled with SCO Unix 4.2 with `tcip`, or using OpenServer 3.0 or Open Desktop 3.0 (OS 3.0 ODT 3.0) with the SCO Development System installed using a good port of GCC 2.5.x. For ODT or OS 3.0, you need a good port of GCC 2.5.x. There are a lot of problems without a good port. The port for this product requires the SCO Unix Development system. Without it, you are missing the libraries and the linker that is needed. You also need `SCO-3.2v4.2-includes.tar.gz`. This file contains the changes to the SCO Development include files that are needed to get MySQL to build. You need to replace the existing system include files with these modified header files. They can be obtained from <ftp://ftp.zenez.com/pub/zenez/prgms/SCO-3.2v4.2-includes.tar.gz>.

To build FSU Pthreads on your system, all you should need to do is run GNU `make`. The `Makefile` in `FSU-threads-3.14.tar.gz` is set up to make FSU-threads.

You can run `./configure` in the `threads/src` directory and select the SCO OpenServer option. This command copies `Makefile.SCO5` to `Makefile`. Then run `make`.

To install in the default `/usr/include` directory, log in as `root`, and then `cd` to the `thread/src` directory and run `make install`.

Remember that you must use GNU `make` to build MySQL.

**Note:** If you don't start `mysqld_safe` as `root`, you should get only the default 110 open files per process. `mysqld` writes a note about this in the log file.

With SCO 3.2V4.2, you should use FSU Pthreads version 3.14 or newer. The following `configure` command should work:

```
CFLAGS="-D_XOPEN_XPG4" CXX=gcc CXXFLAGS="-D_XOPEN_XPG4" \
./configure \
  --prefix=/usr/local/mysql \
  --with-named-thread-libs="-lgthreads -lsocket -lgen -lgthreads" \
  --with-named-curses-libs="-lcurses"
```

You may have problems with some include files. In this case, you can find new SCO-specific include files at <ftp://ftp.zenez.com/pub/zenez/prgms/SCO-3.2v4.2-includes.tar.gz>.

You should unpack this file in the `include` directory of your MySQL source tree.

SCO development notes:

- MySQL should automatically detect FSU Pthreads and link `mysqld` with `-lgthreads -lsocket -lgthreads`.
- The SCO development libraries are re-entrant in FSU Pthreads. SCO claims that its library functions are re-entrant, so they must be re-entrant with FSU Pthreads. FSU Pthreads on OpenServer tries to use the SCO scheme to make re-entrant libraries.
- FSU Pthreads (at least the version at <ftp://ftp.zenez.com>) comes linked with GNU `malloc`. If you encounter problems with memory usage, make sure that `gmalloc.o` is included in `libgthreads.a` and `libgthreads.so`.
- In FSU Pthreads, the following system calls are pthreads-aware: `read()`, `write()`, `getmsg()`, `connect()`, `accept()`, `select()`, and `wait()`.
- The CSSA-2001-SCO.35.2 (the patch is listed in custom as `erg711905-dscr_remap` security patch (version 2.0.0)) breaks FSU threads and makes `mysqld` unstable. You have to remove this one if you want to run `mysqld` on an OpenServer 5.0.6 machine.
- If you use SCO OpenServer 5, you may need to recompile FSU pthreads with `-DDRAFT7` in `CFLAGS`. Otherwise, InnoDB may hang at a `mysqld` startup.
- SCO provides operating system patches at <ftp://ftp.sco.com/pub/openserver5> for OpenServer 5.0.x.
- SCO provides security fixes and `libsocket.so.2` at <ftp://ftp.sco.com/pub/security/OpenServer> and <ftp://ftp.sco.com/pub/security/sse> for OpenServer 5.0.x.
- Pre-OSR506 security fixes. Also, the `telnetd` fix at <ftp://stage.caldera.com/pub/security/openserver/> or <ftp://stage.caldera.com/pub/security/openserver/CSSA-2001-SCO.10/> as both `libsocket.so.2` and `libresolv.so.1` with instructions for installing on pre-OSR506 systems.

It's probably a good idea to install these patches before trying to compile/use MySQL.

Beginning with Legend/OpenServer 6.0.0, there are native threads and no 2GB file size limit.

### 2.13.5.9. SCO OpenServer 6.0.x Notes

OpenServer 6 includes these key improvements:

- Larger file support up to 1 TB
- Multiprocessor support increased from 4 to 32 processors
- Increased memory support up to 64GB
- Extending the power of UnixWare into OpenServer 6
- Dramatic performance improvement

OpenServer 6.0.0 commands are organized as follows:

- `/bin` is for commands that behave exactly the same as on OpenServer 5.0.x.
- `/u95/bin` is for commands that have better standards conformance, for example Large File System (LFS) support.
- `/udk/bin` is for commands that behave the same as on UnixWare 7.1.4. The default is for the LFS support.

The following is a guide to setting `PATH` on OpenServer 6. If the user wants the traditional OpenServer 5.0.x then `PATH` should be `/bin` first. If the user wants LFS support, the path should be `/u95/bin:/bin`. If the user wants UnixWare 7 support first, the path would be `/udk/bin:/u95/bin:/bin`.

We recommend using the latest production release of MySQL. Should you choose to use an older release of MySQL on OpenServer 6.0.x, you must use a version of MySQL at least as recent as 3.22.13 to get fixes for some portability and OS problems.

MySQL distribution files with names of the following form are tar archives of media are tar archives of media images suitable for installation with the SCO Software Manager (`/etc/custom`) on SCO OpenServer 6:

```
mysql-PRODUCT-5.0.22-sco-osr6-i686.VOLS.tar
```

A distribution where `PRODUCT` is `pro-cert` is the Commercially licensed MySQL Pro Certified server. A distribution where `PRODUCT` is `pro-gpl-cert` is the MySQL Pro Certified server licensed under the terms of the General Public License (GPL).

Select whichever distribution you wish to install and, after download, extract the tar archive into an empty directory. For example:

```
shell> mkdir /tmp/mysql-pro
shell> cd /tmp/mysql-pro
shell> tar xf /tmp/mysql-pro-cert-5.0.22-sco-osr6-i686.VOLS.tar
```

Prior to installation, back up your data in accordance with the procedures outlined in Section 2.11, "Upgrading MySQL".

Remove any previously installed pkgadd version of MySQL:

```
shell> pkginfo mysql 2>&1 > /dev/null && pkgrm mysql
```

Install MySQL Pro from media images using the SCO Software Manager:

```
shell> /etc/custom -p SCO:MySQL -i -z /tmp/mysql-pro
```

Alternatively, the SCO Software Manager can be displayed graphically by clicking on the Software Manager icon on the desktop, selecting Software -> Install New, selecting the host, selecting Media Images for the Media Device, and entering `/tmp/mysql-pro` as the Image Directory.

After installation, run `mkdev mysql` as the root user to configure your newly installed MySQL Pro Certified server.

**Note:** The installation procedure for VOLS packages does not create the `mysql` user and group that the package uses by default. You should either create the `mysql` user and group, or else select a different user and group using an option in `mkdev mysql`.

If you wish to configure your MySQL Pro server to interface with the Apache Web server via PHP, download and install the PHP update from SCO at <ftp://ftp.sco.com/pub/updates/OpenServer/SCOSA-2006.17/>.

We have been able to compile MySQL with the following configure command on OpenServer 6.0.x:

```
CC=cc CFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \
CXX=CC CXXFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \
./configure --prefix=/usr/local/mysql \
--enable-thread-safe-client --with-berkeley-db \
--with-extra-charsets=complex \
```

```
--build=i686-unknown-sysv5SCO_SV6.0.0
```

If you use `gcc`, you must use `gcc 2.95.3` or newer.

```
CC=gcc CXX=g++ ... ./configure ...
```

The version of Berkeley DB that comes with either UnixWare 7.1.4 or OpenServer 6.0.0 is not used when building MySQL. MySQL instead uses its own version of Berkeley DB. The `configure` command needs to build both a static and a dynamic library in `src_directory/bdb/build_unix/`, but it does not with MySQL's own BDB version. The workaround is as follows.

1. Configure as normal for MySQL.
2. `cd bdb/build_unix/`
3. `cp -p Makefile Makefile.sav`
4. Use same options and run `../dist/configure`.
5. Run `gmake`.
6. `cp -p Makefile.sav Makefile`
7. Change location to the top source directory and run `gmake`.

This allows both the shared and dynamic libraries to be made and work.

SCO provides OpenServer 6 operating system patches at <ftp://ftp.sco.com/pub/openserver6>.

SCO provides information about security fixes at <ftp://ftp.sco.com/pub/security/OpenServer>.

By default, the maximum file size on a OpenServer 6.0.0 system is 1TB. Some operating system utilities have a limitation of 2GB. The maximum possible file size on UnixWare 7 is 1TB with VXFS or HTFS.

OpenServer 6 can be configured for large file support (file sizes greater than 2GB) by tuning the UNIX kernel.

By default, the entries in `/etc/conf/cf.d/mtune` are set as follows:

Value	Default	Min	Max
SVMLLIM	0x9000000	0x1000000	0x7FFFFFFF
HVMLLIM	0x9000000	0x1000000	0x7FFFFFFF

To make changes to the kernel, use the `idtune name parameter` command. `idtune` modifies the `/etc/conf/cf.d/stune` file for you. We recommend setting the kernel values by executing the following commands as root:

```
# /etc/conf/bin/idtune SDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SVMLLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HVMLLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SFNOLIM 2048
# /etc/conf/bin/idtune HFNOLIM 2048
```

Then rebuild and reboot the kernel by issuing this command:

```
# /etc/conf/bin/idbuild -B && init 6
```

We recommend tuning the system, but the proper parameter values to use depend on the number of users accessing the application or database and size of the database (that is, the used buffer pool). The following kernel parameters can be set with `idtune`:

- `SHMMAX` (recommended setting: 128MB) and `SHMSEG` (recommended setting: 15). These parameters have an influence on the MySQL database engine to create user buffer pools.
- `SFNOLIM` and `HFNOLIM` should be at maximum 2048.
- `NPROC` should be set to at least 3000/4000 (depends on number of users).
- We also recommend using the following formulas to calculate values for `SEMMSL`, `SEMMNS`, and `SEMMNU`:

```
SEMMSL = 13
```

13 is what has been found to be the best for both Progress and MySQL.

```
SEMMNS = SEMMSL × number of db servers to be run on the system
```

Set `SEMMNS` to the value of `SEMMSL` multiplied by the number of database servers (maximum) that you are running on the system at one time.

```
SEMMNU = SEMMNS
```

Set the value of `SEMMNU` to equal the value of `SEMMNS`. You could probably set this to 75% of `SEMMNS`, but this is a conservative estimate.

### 2.13.5.10. SCO UnixWare 7.1.x and OpenUNIX 8.0.0 Notes

We recommend using the latest production release of MySQL. Should you choose to use an older release of MySQL on UnixWare 7.1.x, you must use a version of MySQL at least as recent as 3.22.13 to get fixes for some portability and OS problems.

We have been able to compile MySQL with the following `configure` command on UnixWare 7.1.x:

```
CC="cc" CFLAGS="-I/usr/local/include" \  
CXX="CC" CXXFLAGS="-I/usr/local/include" \  
./configure --prefix=/usr/local/mysql \  
    --enable-thread-safe-client --with-berkeley-db=./bdb \  
    --with-innodb --with-openssl --with-extra-charsets=complex
```

If you want to use `gcc`, you must use `gcc 2.95.3` or newer.

```
CC=gcc CXX=g++ ... ./configure ...
```

The version of Berkeley DB that comes with either UnixWare 7.1.4 or OpenServer 6.0.0 is not used when building MySQL. MySQL instead uses its own version of Berkeley DB. The `configure` command needs to build both a static and a dynamic library in `src_directory/bdb/build_unix/`, but it does not with MySQL's own BDB version. The workaround is as follows.

1. Configure as normal for MySQL.
2. `cd bdb/build_unix/`

3. `cp -p Makefile Makefile.sav`
4. Use same options and run `../dist/configure`.
5. Run `gmake`.
6. `cp -p Makefile.sav Makefile`
7. Change to top source directory and run `gmake`.

This allows both the shared and dynamic libraries to be made and work.

SCO provides operating system patches at <ftp://ftp.sco.com/pub/unixware7> for UnixWare 7.1.1, <ftp://ftp.sco.com/pub/unixware7/713/> for UnixWare 7.1.3, <ftp://ftp.sco.com/pub/unixware7/714/> for UnixWare 7.1.4, and <ftp://ftp.sco.com/pub/openunix8> for OpenUNIX 8.0.0.

SCO provides information about security fixes at <ftp://ftp.sco.com/pub/security/OpenUNIX> for OpenUNIX and <ftp://ftp.sco.com/pub/security/UnixWare> for UnixWare.

The UnixWare 7 file size limit is 1 TB with VXFS. Some OS utilities have a limitation of 2GB.

On UnixWare 7.1.4 you do not need to do anything to get large file support, but to enable large file support on prior versions of UnixWare 7.1.x, run `fsadm`.

```
# fsadm -Fvxfs -o largefiles /
# fsadm / * Note
# ulimit unlimited
# /etc/conf/bin/idtune SFSZLIM 0x7FFFFFFF ** Note
# /etc/conf/bin/idtune HFSZLIM 0x7FFFFFFF ** Note
# /etc/conf/bin/idbuild -B
```

\* This should report "largefiles".  
 \*\* 0x7FFFFFFF represents infinity for these values.

Reboot the system using shutdown.

By default, the entries in `/etc/conf/cf.d/mtune` are set as follows:

Value	Default	Min	Max
SVMLLIM	0x9000000	0x1000000	0x7FFFFFFF
HVMLLIM	0x9000000	0x1000000	0x7FFFFFFF

To make changes to the kernel, use the `idtune name parameter` command. `idtune` modifies the `/etc/conf/cf.d/stune` file for you. We recommend setting the kernel values by executing the following commands as `root`:

```
# /etc/conf/bin/idtune SDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SVMLLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HVMLLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SFNOLIM 2048
# /etc/conf/bin/idtune HFNOLIM 2048
```

Then rebuild and reboot the kernel by issuing this command:

```
# /etc/conf/bin/idbuild -B && init 6
```

We recommend tuning the system, but the proper parameter values to use depend on the number of users accessing the application or database and size the of the database (that is, the used buffer pool). The following kernel parameters can be set with `idtune`:

- SHMMAX (recommended setting: 128MB) and SHMSEG (recommended setting: 15). These parameters have an influence on the MySQL database engine to create user buffer pools.
- SFNOLIM and HFNOLIM should be at maximum 2048.
- NPROC should be set to at least 3000/4000 (depends on number of users).
- We also recommend using the following formulas to calculate values for SEMMSL, SEMMNS, and SEMMNU:

```
SEMMSL = 13
```

13 is what has been found to be the best for both Progress and MySQL.

```
SEMMNS = SEMMSL × number of db servers to be run on the system
```

Set SEMMNS to the value of SEMMSL multiplied by the number of database servers (maximum) that you are running on the system at one time.

```
SEMMNU = SEMMNS
```

Set the value of SEMMNU to equal the value of SEMMNS. You could probably set this to 75% of SEMMNS, but this is a conservative estimate.

## 2.13.6. OS/2 Notes

MySQL uses quite a few open files. Because of this, you should add something like the following to your `CONFIG.SYS` file:

```
SET EMXOPT=-c -n -h1024
```

If you do not do this, you may encounter the following error:

```
File 'xxxx' not found (Errcode: 24)
```

When using MySQL with OS/2 Warp 3, FixPack 29 or above is required. With OS/2 Warp 4, FixPack 4 or above is required. This is a requirement of the Pthreads library. MySQL must be installed on a partition with a type that supports long filenames, such as HPFS, FAT32, and so on.

The `INSTALL.COMD` script must be run from OS/2's own `CMD.EXE` and may not work with replacement shells such as `4OS2.EXE`.

The `scripts/mysql-install-db` script has been renamed. It is called `install.cmd` and is a REXX script, which sets up the default MySQL security settings and creates the WorkPlace Shell icons for MySQL.

Dynamic module support is compiled in but not fully tested. Dynamic modules should be compiled using the Pthreads runtime library.

```
gcc -Zdll -Zmt -Zcrt.dll=pthrdrtl -I../include -I../regex -I.. \  
-o example udf_example.cc -L../lib -lmysqlclient udf_example.def  
mv example.dll example.udf
```

**Note:** Due to limitations in OS/2, UDF module name stems must not exceed eight characters. Modules are stored in the `/mysql2/udf` directory; the `safe-mysqld.cmd` script puts this directory in the `BEGINLIBPATH` environment variable. When using UDF modules, specified extensions are ignored--it is assumed to be `.udf`. For example, in Unix, the shared module might be named `ex-`

ample.so and you would load a function from it like this:

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'example.so';
```

In OS/2, the module would be named example.udf, but you would not specify the module extension:

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'example';
```

## 2.14. Perl Installation Notes

Perl support for MySQL is provided by means of the DBI/DBD client interface. The interface requires Perl 5.6.1 or later. It *does not work* if you have an older version of Perl.

If you want to use transactions with Perl DBI, you need to have DBD:mysql version 1.2216 or newer. DBD:mysql 2.9003 or newer is recommended.

If you are using the MySQL 4.1 or newer client library, you must use DBD:mysql 2.9003 or newer.

Perl support is not included with MySQL distributions. You can obtain the necessary modules from <http://search.cpan.org> for Unix, or by using the ActiveState ppm program on Windows. The following sections describe how to do this.

Perl support for MySQL must be installed if you want to run the MySQL benchmark scripts. See Section 7.1.4, “The MySQL Benchmark Suite”.

### 2.14.1. Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. However, if you installed MySQL from RPM files on Linux, be sure that you've installed the developer RPM. The client programs are in the client RPM, but client programming support is in the developer RPM.

If you want to install Perl support, the files you need can be obtained from the CPAN (Comprehensive Perl Archive Network) at <http://search.cpan.org>.

The easiest way to install Perl modules on Unix is to use the CPAN module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD:mysql
```

The DBD:mysql installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default username and password. (The default username is your login name on Unix, and ODBC on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD:mysql` to ignore the failed tests.

DBI requires the Data:Dumper module. It may be installed; if not, you should install it before installing DBI.

It is also possible to download the module distributions in the form of compressed tar archives and build the modules manually. For example, to unpack and build a DBI distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

```
shell> gunzip < DBI-VERSION.tar.gz | tar xvf -
```

This command creates a directory named `DBI-VERSION`.

2. Change location into the top-level directory of the unpacked distribution:

```
shell> cd DBI-VERSION
```

3. Build the distribution and compile everything:

```
shell> perl Makefile.PL
shell> make
shell> make test
shell> make install
```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD:mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the `DBD:mysql` distribution whenever you install a new release of MySQL, particularly if you notice symptoms such as that all your DBI scripts fail after you upgrade MySQL.

If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: <http://servers.digitaldaze.com/extensions/perl/modules.html#modules>

Look under the heading “Installing New Modules that Require Locally Installed Modules.”

## 2.14.2. Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL DBD module with ActiveState Perl:

1. Get ActiveState Perl from <http://www.activestate.com/Products/ActivePerl/> and install it.
2. Open a console window (a “DOS window”).
3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:

```
set HTTP_proxy=my.proxy.com:3128
```

4. Start the PPM program:

```
C:\> C:\perl\bin\ppm.pl
```

5. If you have not previously done so, install DBI:

```
ppm> install DBI
```

6. If this succeeds, run the following command:

```
ppm> install \  
ftp://ftp.de.uu.net/pub/CPAN/authors/id/JWIED/DBD-mysql-1.2212.x86.ppd
```

This procedure should work with ActiveState Perl 5.6 or newer.

If you cannot get the procedure to work, you should install the MyODBC driver instead and connect

to the MySQL server through ODBC:

```
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn", $user, $password) ||
    die "Got error $DBI::errstr when connecting to $dsn\n";
```

## 2.14.3. Problems Using the Perl DBI/DBD Interface

If Perl reports that it cannot find the `./mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Compile the `DBD::mysql` distribution with `perl Makefile.PL -static -config` rather than `perl Makefile.PL`.
- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).
- Modify the `-L` options used to compile `DBD::mysql` to reflect the actual location of `libmysqlclient.so`.
- On Linux, you can add the pathname of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.
- Add the pathname of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

Note that you may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD::mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the pathname of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

You may see the following error from `DBD::mysql` when you run the tests:

```
t/00base.....install_driver(mysql) failed:
Can't load './blib/arch/auto/DBD/mysql/mysql.so' for module DBD::mysql:
./blib/arch/auto/DBD/mysql/mysql.so: undefined symbol:
uncompress at /usr/lib/perl5/5.00503/i586-linux/DynaLoader.pm line 169.
```

This means that you need to include the `-lz` compression library on the link line. That can be done by changing the following line in the file `lib/DBD/mysql/Install.pm`:

```
$sysliblist .= " -lm";
```

Change that line to:

```
$sysliblist .= " -lm -lz";
```

After this, you *must* run `make realclean` and then proceed with the installation from the beginning.

If you want to install DBI on SCO, you have to edit the Makefile in DBI-xxx and each subdirectory. Note that the following assumes `gcc 2.95.2` or newer:

```

OLD:
CC = cc
CCCDLFLAGS = -KPIC -Wl,-Bexport
CCDLFLAGS = -wl,-Bexport

LD = ld
LDDLFLAGS = -G -L/usr/local/lib
LDFLAGS = -belf -L/usr/local/lib

LD = ld
OPTIMISE = -Od

OLD:
CCCFLAGS = -belf -dy -w0 -U M_XENIX -DPERL_SCO5 -I/usr/local/include

NEW:
CC = gcc
CCCDLFLAGS = -fpic
CCDLFLAGS =

LD = gcc -G -fpic
LDDLFLAGS = -L/usr/local/lib
LDFLAGS = -L/usr/local/lib

LD = gcc -G -fpic

NEW:
CCCFLAGS = -U M_XENIX -DPERL_SCO5 -I/usr/local/include

```

These changes are necessary because the Perl dynaloader does not load the DBI modules if they were compiled with `icc` or `cc`.

If you want to use the Perl module on a system that does not support dynamic linking (such as SCO), you can generate a static version of Perl that includes DBI and `DBD:mysql`. The way this works is that you generate a version of Perl with the DBI code linked in and install it on top of your current Perl. Then you use that to build a version of Perl that additionally has the `DBD` code linked in, and install that.

On SCO, you must have the following environment variables set:

```
LD_LIBRARY_PATH=/lib:/usr/lib:/usr/local/lib:/usr/progressive/lib
```

Or:

```

LD_LIBRARY_PATH=/usr/lib:/lib:/usr/local/lib:/usr/ccs/lib:\
/usr/progressive/lib:/usr/skunk/lib
LIBPATH=/usr/lib:/lib:/usr/local/lib:/usr/ccs/lib:\
/usr/progressive/lib:/usr/skunk/lib
MANPATH=scohelp:/usr/man:/usr/local/man:/usr/local/man:\
/usr/skunk/man:

```

First, create a Perl that includes a statically linked DBI module by running these commands in the directory where your DBI distribution is located:

```

shell> perl Makefile.PL -static -config
shell> make
shell> make install
shell> make perl

```

Then you must install the new Perl. The output of `make perl` indicates the exact make command you need to execute to perform the installation. On SCO, this is `make -f Makefile.aperl inst_perl MAP_TARGET=perl`.

Next, use the just-created Perl to create another Perl that also includes a statically linked `DBD:mysql` by running these commands in the directory where your `DBD:mysql` distribution

is located:

```
shell> perl Makefile.PL -static -config
shell> make
shell> make install
shell> make perl
```

Finally, you should install this new Perl. Again, the output of `make perl` indicates the command to use.

---

# Chapter 3. Tutorial

This chapter provides a tutorial introduction to MySQL by showing how to use the `mysql` client program to create and use a simple database. `mysql` (sometimes referred to as the “terminal monitor” or just “monitor”) is an interactive program that allows you to connect to a MySQL server, run queries, and view the results. `mysql` may also be used in batch mode: you place your queries in a file beforehand, then tell `mysql` to execute the contents of the file. Both ways of using `mysql` are covered here.

To see a list of options provided by `mysql`, invoke it with the `--help` option:

```
shell> mysql --help
```

This chapter assumes that `mysql` is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If *you* are the administrator, you need to consult the relevant portions of this manual, such as Chapter 5, *Database Administration*.)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip over the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

## 3.1. Connecting to and Disconnecting from the Server

To connect to the server, you will usually need to provide a MySQL user name when you invoke `mysql` and, most likely, a password. If the server runs on a machine other than the one where you log in, you will also need to specify a host name. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
shell> mysql -h host -u user -p
Enter password: *****
```

`host` and `user` represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The `*****` represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
shell> mysql -h host -u user -p
Enter password: *****
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 5.0.22-standard

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter commands.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
shell< mysql -u user -p
```

If, when you attempt to log in, you get an error message such as ERROR 2002 (HY000): Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2), it means that that MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of Chapter 2, *Installing and Upgrading MySQL* that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see Section A.2, "Common Errors When Using MySQL Programs".

Some MySQL installations allow users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
shell> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control-D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

## 3.2. Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that's okay. At this point, it's more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering commands, using several queries you can try out to familiarize yourself with how `mysql` works.

Here's a simple command that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+-----+-----+
| VERSION() | CURRENT_DATE |
+-----+-----+
| 5.0.7-beta-Max | 2005-07-11 |
+-----+-----+
1 row in set (0.01 sec)
mysql>
```

This query illustrates several things about `mysql`:

- A command normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We'll get to others later.)
- When you issue a command, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another command.
- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you're retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.

- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the “rows in set” line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here's another query. It demonstrates that you can use `mysql` as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+-----+-----+
| SIN(PI()/4) | (4+1)*5 |
+-----+-----+
| 0.70710678118655 | 25 |
+-----+-----+
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```
mysql> SELECT VERSION(); SELECT NOW();
+-----+
| VERSION() |
+-----+
| 5.0.7-beta-Max |
+-----+
1 row in set (0.00 sec)

+-----+
| NOW() |
+-----+
| 2005-07-11 17:59:36 |
+-----+
1 row in set (0.00 sec)
```

A command need not be given all on a single line, so lengthy commands that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here's a simple multiple-line statement:

```
mysql> SELECT
-> USER()
-> ,
-> CURRENT_DATE;
+-----+-----+
| USER() | CURRENT_DATE |
+-----+-----+
| jon@localhost | 2005-07-11 |
+-----+-----+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a command that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
      -> USER( )
      -> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new command.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in:

Prompt	Meaning
<code>mysql&gt;</code>	Ready for new command.
<code>-&gt;</code>	Waiting for next line of multiple-line command.
<code>'&gt;</code>	Waiting for next line, waiting for completion of a string that began with a single quote ('').
<code>"&gt;</code>	Waiting for next line, waiting for completion of a string that began with a double quote ("").
<code>`&gt;</code>	Waiting for next line, waiting for completion of an identifier that began with a backtick (`).
<code>/*&gt;</code>	Waiting for next line, waiting for completion of a comment that began with /*.

In the MySQL 5.0 series, the `/*>` prompt was implemented in MySQL 5.0.6.

Multiple-line statements commonly occur by accident when you intend to issue a command on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```
mysql> SELECT USER( )
      ->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely `mysql` is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER( )
      -> ;
+-----+
| USER( ) |
+-----+
| jon@localhost |
+-----+
```

The `'>` and `">` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either `'` or `"` characters (for example, `'hello'` or `"goodbye"`), and `mysql` lets you enter strings that span multiple lines. When you see a `'>` or `">` prompt, it means that you have entered a line containing a string that begins with a `'` or `"` quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
      '>
```

If you enter this `SELECT` statement, then press **Enter** and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `'>` prompt. It tells you that `mysql` expects to see the rest of an unterminated string. (Do you see the error in the statement? The string `'Smith` is missing the second single quote mark.)

At this point, what do you do? The simplest thing is to cancel the command. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
      '> '\c
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new command.

The ``>` prompt is similar to the `'>` and `">` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the `'>`, `">`, and ``>` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql` — including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current command.

## 3.3. Creating and Using a Database

Once you know how to enter commands, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to:

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL Web site. It is available in both compressed `tar` file and Zip formats at <http://dev.mysql.com/doc/>.

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| mysql   |
| test    |
| tmp     |
+-----+
```

The list of databases is probably different on your machine, but the `mysql` and `test` databases are likely to be among them. The `mysql` database is required because it describes user access privileges. The `test` database is often provided as a workspace for users to try things out.

Note that you may not see all databases if you do not have the `SHOW DATABASES` privilege. See Section 13.5.1.3, “GRANT Syntax”.

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

Note that `USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a command like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL user name assigned to you and `your_client_host` is the host from which you connect to the server.

### 3.3.1. Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, our recommended best practice is always to use the same lettercase that was used when the database was created.)

**Note:** If you get an error such as `ERROR 1044 (42000): Access denied for user 'monty'@'localhost' to database 'menagerie' when attempting to create a database`, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see Section 5.8, “The MySQL Access Privilege System”.

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this command:

```
mysql> USE menagerie;
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
shell> mysql -h host -u user -p menagerie
Enter password: *****
```

Note that `menagerie` in the command just shown is **not** your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-pmypassword`, *not* as `-p mypassword`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

## 3.3.2. Creating a Table

Creating the database is the easy part, but at this point it's empty, as `SHOW TABLES` tells you:

```
mysql> SHOW TABLES;  
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it's not a good thing to store in a database. Age changes as time passes, which means you'd have to update your records often. Instead, it's better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)
- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),  
-> species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be 20. You can normally pick any length from 1 to 65535, whatever seems most reasonable to you. (**Note:** Prior to MySQL 5.0.3, the upper limit was 255.) If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as `'m'` and `'f'`, or perhaps `'male'` and `'female'`. It is simplest to use the single characters `'m'` and `'f'`.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```
mysql> SHOW TABLES;  
+-----+  
| Tables in menagerie |
```

```
+-----+
| pet   |
+-----+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```
mysql> DESCRIBE pet;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| name  | varchar(20)   | YES  |     | NULL    |       |
| owner | varchar(20)   | YES  |     | NULL    |       |
| species | varchar(20)  | YES  |     | NULL    |       |
| sex   | char(1)       | YES  |     | NULL    |       |
| birth | date          | YES  |     | NULL    |       |
| death | date          | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

You can use `DESCRIBE` any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see Chapter 11, *Data Types*.

### 3.3.3. Loading Data into a Table

After creating your table, you need to populate it. The `LOAD DATA` and `INSERT` statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in 'YYYY-MM-DD' format; this may be different from what you are used to.)

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	
Claws	Gwen	cat	m	1994-03-17	
Buffy	Harold	dog	f	1989-05-13	
Fang	Benny	dog	m	1990-08-27	
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	
Whistler	Gwen	bird		1997-12-09	
Slim	Benny	snake	m	1996-04-29	

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the `CREATE TABLE` statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use `NULL` values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

```
Whistler      Gwen      bird      \N      1997-12-09      \N
```

To load the text file `pet.txt` into the `pet` table, use this command:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

Note that if you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
-> LINES TERMINATED BY '\r\n';
```

(On an Apple machine running OS X, you would likely want to use `LINES TERMINATED BY '\r'`.)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See Section 5.7.4, “Security Issues with `LOAD DATA LOCAL`”, for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an `INSERT` statement like this:

```
mysql> INSERT INTO pet
-> VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);
```

Note that string and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

### 3.3.4. Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

*what\_to\_select* indicates what you want to see. This can be a list of columns, or `*` to indicate “all columns.” *which\_table* indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it is present, *conditions\_to\_satisfy* specifies one or more conditions that rows must satisfy to qualify for retrieval.

#### 3.3.4.1. Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL
Fang	Benny	dog	m	1990-08-27	NULL
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
Slim	Benny	snake	m	1996-04-29	NULL

```
| Puffball | Diane | hamster | f | 1999-03-30 | NULL |
+-----+-----+-----+---+-----+-----+
```

This form of `SELECT` is useful if you want to review your entire table, for example, after you've just loaded it with your initial dataset. For example, you may happen to think that the birth date for Bowser doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file `pet.txt` to correct the error, then empty the table and reload it using `DELETE` and `LOAD DATA`:

```
mysql> DELETE FROM pet;
mysql> LOAD DATA LOCAL INFILE 'pet.txt' INTO TABLE pet;
```

However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an `UPDATE` statement:

```
mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
```

The `UPDATE` changes only the record in question and does not require you to reload the table.

### 3.3.4.2. Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don't want to see the entire table, particularly when it becomes large. Instead, you're usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let's look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser's birth date, select Bowser's record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+-----+-----+-----+---+-----+-----+
| name   | owner | species | sex | birth      | death   |
+-----+-----+-----+---+-----+-----+
| Bowser | Diane | dog      | m   | 1989-08-31 | 1995-07-29 |
+-----+-----+-----+---+-----+-----+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as `'bowser'`, `'BOWSER'`, and so forth. The query result is the same.

You can specify conditions on any column, not just name. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+-----+-----+-----+---+-----+-----+
| name      | owner | species | sex | birth      | death   |
+-----+-----+-----+---+-----+-----+
| Chirpy    | Gwen  | bird    | f   | 1998-09-11 | NULL    |
| Puffball  | Diane | hamster | f   | 1999-03-30 | NULL    |
+-----+-----+-----+---+-----+-----+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
```

name	owner	species	sex	birth	death
Buffy	Harold	dog	f	1989-05-13	NULL

The preceding query uses the AND logical operator. There is also an OR operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
```

name	owner	species	sex	birth	death
Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
Slim	Benny	snake	m	1996-04-29	NULL

AND and OR may be intermixed, although AND has higher precedence than OR. If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm')
-> OR (species = 'dog' AND sex = 'f');
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

### 3.3.4.3. Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the name and birth columns:

```
mysql> SELECT name, birth FROM pet;
```

name	birth
Fluffy	1993-02-04
Claws	1994-03-17
Buffy	1989-05-13
Fang	1990-08-27
Bowser	1989-08-31
Chirpy	1998-09-11
Whistler	1997-12-09
Slim	1996-04-29
Puffball	1999-03-30

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
```

owner
Harold
Gwen
Harold
Benny
Diane
Gwen

```

| Gwen |
| Benny |
| Diane |
+-----+

```

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword `DISTINCT`:

```

mysql> SELECT DISTINCT owner FROM pet;
+-----+
| owner |
+-----+
| Benny |
| Diane |
| Gwen  |
| Harold|
+-----+

```

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```

mysql> SELECT name, species, birth FROM pet
       -> WHERE species = 'dog' OR species = 'cat';
+-----+-----+-----+
| name  | species | birth  |
+-----+-----+-----+
| Fluffy| cat     | 1993-02-04 |
| Claws | cat     | 1994-03-17 |
| Buffy | dog     | 1989-05-13 |
| Fang  | dog     | 1990-08-27 |
| Bowser| dog     | 1989-08-31 |
+-----+-----+-----+

```

### 3.3.4.4. Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It's often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```

mysql> SELECT name, birth FROM pet ORDER BY birth;
+-----+-----+
| name  | birth  |
+-----+-----+
| Buffy | 1989-05-13 |
| Bowser| 1989-08-31 |
| Fang  | 1990-08-27 |
| Fluffy| 1993-02-04 |
| Claws | 1994-03-17 |
| Slim  | 1996-04-29 |
| Whistler| 1997-12-09 |
| Chirpy| 1998-09-11 |
| Puffball| 1999-03-30 |
+-----+-----+

```

On character type columns, sorting — like all other comparison operations — is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY` like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
```

name	birth
Puffball	1999-03-30
Chirpy	1998-09-11
Whistler	1997-12-09
Slim	1996-04-29
Claws	1994-03-17
Fluffy	1993-02-04
Fang	1990-08-27
Bowser	1989-08-31
Buffy	1989-05-13

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
-> ORDER BY species, birth DESC;
```

name	species	birth
Chirpy	bird	1998-09-11
Whistler	bird	1997-12-09
Claws	cat	1994-03-17
Fluffy	cat	1993-02-04
Fang	dog	1990-08-27
Bowser	dog	1989-08-31
Buffy	dog	1989-05-13
Puffball	hamster	1999-03-30
Slim	snake	1996-04-29

Note that the `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

### 3.3.4.5. Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, compute the difference in the year part of the current date and the birth date, then subtract one if the current date occurs earlier in the calendar year than the birth date. The following query shows, for each pet, the birth date, the current date, and the age in years.

```
mysql> SELECT name, birth, CURDATE(),
-> (YEAR(CURDATE())-YEAR(birth))
-> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
-> AS age
-> FROM pet;
```

name	birth	CURDATE()	age
Fluffy	1993-02-04	2003-08-19	10
Claws	1994-03-17	2003-08-19	9
Buffy	1989-05-13	2003-08-19	14
Fang	1990-08-27	2003-08-19	12
Bowser	1989-08-31	2003-08-19	13
Chirpy	1998-09-11	2003-08-19	4
Whistler	1997-12-09	2003-08-19	5
Slim	1996-04-29	2003-08-19	7
Puffball	1999-03-30	2003-08-19	4

+-----+-----+-----+-----+

Here, `YEAR()` pulls out the year part of a date and `RIGHT()` pulls off the rightmost five characters that represent the MM-DD (calendar year) part of the date. The part of the expression that compares the MM-DD values evaluates to 1 or 0, which adjusts the year difference down a year if `CURDATE()` occurs earlier in the year than `birth`. The full expression is somewhat ungainly, so an *alias* (`age`) is used to make the output column label more meaningful.

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

```
mysql> SELECT name, birth, CURDATE(),
-> (YEAR(CURDATE())-YEAR(birth))
-> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
-> AS age
-> FROM pet ORDER BY name;
```

name	birth	CURDATE()	age
Bowser	1989-08-31	2003-08-19	13
Buffy	1989-05-13	2003-08-19	14
Chirpy	1998-09-11	2003-08-19	4
Claws	1994-03-17	2003-08-19	9
Fang	1990-08-27	2003-08-19	12
Fluffy	1993-02-04	2003-08-19	10
Puffball	1999-03-30	2003-08-19	4
Slim	1996-04-29	2003-08-19	7
Whistler	1997-12-09	2003-08-19	5

To sort the output by age rather than name, just use a different `ORDER BY` clause:

```
mysql> SELECT name, birth, CURDATE(),
-> (YEAR(CURDATE())-YEAR(birth))
-> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
-> AS age
-> FROM pet ORDER BY age;
```

name	birth	CURDATE()	age
Chirpy	1998-09-11	2003-08-19	4
Puffball	1999-03-30	2003-08-19	4
Whistler	1997-12-09	2003-08-19	5
Slim	1996-04-29	2003-08-19	7
Claws	1994-03-17	2003-08-19	9
Fluffy	1993-02-04	2003-08-19	10
Fang	1990-08-27	2003-08-19	12
Bowser	1989-08-31	2003-08-19	13
Buffy	1989-05-13	2003-08-19	14

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the `death` value is `NULL`. Then, for those with non-`NULL` values, compute the difference between the `death` and `birth` values:

```
mysql> SELECT name, birth, death,
-> (YEAR(death)-YEAR(birth)) - (RIGHT(death,5)<RIGHT(birth,5))
-> AS age
-> FROM pet WHERE death IS NOT NULL ORDER BY age;
```

name	birth	death	age
Bowser	1989-08-31	1995-07-29	5

The query uses `death IS NOT NULL` rather than `death <> NULL` because `NULL` is a special value that cannot be compared using the usual comparison operators. This is discussed later. See Section 3.3.4.6, “Working with `NULL` Values”.

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the `birth` column. MySQL provides several functions for extracting parts of dates, such as `YEAR()`, `MONTH()`, and `DAYOFMONTH()`. `MONTH()` is the appropriate function here. To see how it works, run a simple query that displays the value of both `birth` and `MONTH(birth)`:

```
mysql> SELECT name, birth, MONTH(birth) FROM pet;
```

name	birth	MONTH(birth)
Fluffy	1993-02-04	2
Claws	1994-03-17	3
Buffy	1989-05-13	5
Fang	1990-08-27	8
Bowser	1989-08-31	8
Chirpy	1998-09-11	9
Whistler	1997-12-09	12
Slim	1996-04-29	4
Puffball	1999-03-30	3

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is 4 and you can look for animals born in May (month 5) like this:

```
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
```

name	birth
Buffy	1989-05-13

There is a small complication if the current month is December. You cannot merely add one to the month number (12) and look for animals born in month 13, because there is no such month. Instead, you look for animals born in January (month 1).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` allows you to add a time interval to a given date. If you add a month to the value of `CURDATE()`, then extract the month part with `MONTH()`, the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
-> WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(), INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add 1 to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to 0 if it is currently 12:

```
mysql> SELECT name, birth FROM pet
-> WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

Note that `MONTH` returns a number between 1 and 12. And `MOD(something, 12)` returns a number between 0 and 11. So the addition has to be after the `MOD()`, otherwise we would go from November (11) to January (1).

### 3.3.4.6. Working with `NULL` Values

The `NULL` value can be surprising until you get used to it. Conceptually, `NULL` means “a missing

unknown value” and it is treated somewhat differently from other values. To test for NULL, you cannot use the arithmetic comparison operators such as =, <, or <>. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+-----+-----+-----+-----+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+-----+-----+-----+-----+
|      NULL |      NULL |      NULL |      NULL |
+-----+-----+-----+-----+
```

Clearly you get no meaningful results from these comparisons. Use the IS NULL and IS NOT NULL operators instead:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----+-----+
| 1 IS NULL | 1 IS NOT NULL |
+-----+-----+
|          0 |          1 |
+-----+-----+
```

Note that in MySQL, 0 or NULL means false and anything else means true. The default truth value from a boolean operation is 1.

This special treatment of NULL is why, in the previous section, it was necessary to determine which animals are no longer alive using death IS NOT NULL instead of death <> NULL.

Two NULL values are regarded as equal in a GROUP BY.

When doing an ORDER BY, NULL values are presented first if you do ORDER BY ... ASC and last if you do ORDER BY ... DESC.

A common error when working with NULL is to assume that it is not possible to insert a zero or an empty string into a column defined as NOT NULL, but this is not the case. These are in fact values, whereas NULL means “not having a value.” You can test this easily enough by using IS [NOT] NULL as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----+-----+-----+-----+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----+-----+-----+-----+
|          0 |          1 |          0 |          1 |
+-----+-----+-----+-----+
```

Thus it is entirely possible to insert a zero or empty string into a NOT NULL column, as these are in fact NOT NULL. See Section A.5.3, “Problems with NULL Values”.

### 3.3.4.7. Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as vi, grep, and sed.

SQL pattern matching allows you to use ‘\_’ to match any single character and ‘%’ to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. Note that you do not use = or <> when you use SQL patterns; use the LIKE or NOT LIKE comparison operators instead.

To find names beginning with ‘b’:

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
+-----+-----+-----+-----+-----+-----+
| name | owner | species | sex | birth | death |
+-----+-----+-----+-----+-----+-----+
```

Buffy	Harold	dog	f	1989-05-13	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29

To find names ending with 'fy':

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

To find names containing a 'w':

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29
Whistler	Gwen	bird	NULL	1997-12-09	NULL

To find names containing exactly five characters, use five instances of the '\_' pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the REGEXP and NOT REGEXP operators (or RLIKE and NOT RLIKE, which are synonyms).

Some characteristics of extended regular expressions are:

- '.' matches any single character.
- A character class '[...]' matches any character within the brackets. For example, '[abc]' matches 'a', 'b', or 'c'. To name a range of characters, use a dash. '[a-z]' matches any letter, whereas '[0-9]' matches any digit.
- '\*' matches zero or more instances of the thing preceding it. For example, 'x\*' matches any number of 'x' characters, '[0-9]\*' matches any number of digits, and '.\*' matches any number of anything.
- A REGEXP pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a LIKE pattern match, which succeeds only if the pattern matches the entire value.)
- To anchor a pattern so that it must match the beginning or end of the value being tested, use '^' at the beginning or '\$' at the end of the pattern.

To demonstrate how extended regular expressions work, the LIKE queries shown previously are rewritten here to use REGEXP.

To find names beginning with 'b', use '^' to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^b';
```

name	owner	species	sex	birth	death
Buffy	Harold	dog	f	1989-05-13	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29

If you really want to force a REGEXP comparison to be case sensitive, use the BINARY keyword to make one of the strings a binary string. This query matches only lowercase 'b' at the beginning of a name:

```
mysql> SELECT * FROM pet WHERE name REGEXP BINARY '^b';
```

To find names ending with 'fy', use '\$' to match the end of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'fy$';
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

To find names containing a 'w', use this query:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'w';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29
Whistler	Gwen	bird	NULL	1997-12-09	NULL

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value like it would be if you used an SQL pattern.

To find names containing exactly five characters, use '^' and '\$' to match the beginning and end of the name, and five instances of '.' in between:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.....$';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

You could also write the previous query using the {n} ("repeat-n-times") operator:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

Appendix G, *Regular Expressions*, provides more information about the syntax for regular expressions.

### 3.3.4.8. Counting Rows

Databases are often used to answer the question, “How often does a certain type of data occur in a table?” For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as “How many rows are in the `pet` table?” because there is one record per pet. `COUNT(*)` counts the number of rows, so the query to count your animals looks like this:

```
mysql> SELECT COUNT(*) FROM pet;
+-----+
| COUNT(*) |
+-----+
|          9 |
+-----+
```

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` if you want to find out how many pets each owner has:

```
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
+-----+-----+
| owner | COUNT(*) |
+-----+-----+
| Benny |         2 |
| Diane |         2 |
| Gwen  |         3 |
| Harold|         2 |
+-----+-----+
```

Note the use of `GROUP BY` to group all records for each owner. Without it, all you get is an error message:

```
mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT(),...)
with no GROUP columns is illegal if there is no GROUP BY clause
```

`COUNT()` and `GROUP BY` are useful for characterizing your data in various ways. The following examples show different ways to perform animal census operations.

Number of animals per species:

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
+-----+-----+
| species | COUNT(*) |
+-----+-----+
| bird   |         2 |
| cat    |         2 |
| dog    |         3 |
| hamster|         1 |
| snake  |         1 |
+-----+-----+
```

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
+-----+-----+
| sex | COUNT(*) |
+-----+-----+
```

NULL	1
f	4
m	4

(In this output, NULL indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
```

species	sex	COUNT(*)
bird	NULL	1
bird	f	1
cat	f	1
cat	m	1
dog	f	1
dog	m	2
hamster	f	1
snake	m	1

You need not retrieve an entire table when you use COUNT(). For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
-> WHERE species = 'dog' OR species = 'cat'
-> GROUP BY species, sex;
```

species	sex	COUNT(*)
cat	f	1
cat	m	1
dog	f	1
dog	m	2

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
-> WHERE sex IS NOT NULL
-> GROUP BY species, sex;
```

species	sex	COUNT(*)
bird	f	1
cat	f	1
cat	m	1
dog	f	1
dog	m	2
hamster	f	1
snake	m	1

### 3.3.4.9. Using More Than one Table

The pet table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs:

- To contain the pet name so that you know which animal each event pertains to.

- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the CREATE TABLE statement for the event table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE,
-> type VARCHAR(15), remark VARCHAR(255));
```

As with the pet table, it's easiest to load the initial records by creating a tab-delimited text file containing the information:

name	date	type	remark
Fluffy	1995-05-15	litter	4 kittens, 3 female, 1 male
Buffy	1993-06-23	litter	5 puppies, 2 female, 3 male
Buffy	1994-06-19	litter	3 puppies, 3 female
Chirpy	1999-03-21	vet	needed beak straightened
Slim	1997-08-03	vet	broken rib
Bowser	1991-10-12	kennel	
Fang	1991-10-12	kennel	
Fang	1998-08-28	birthday	Gave him a new chew toy
Claws	1998-03-17	birthday	Gave him a new flea collar
Whistler	1998-12-09	birthday	First birthday

Load the records like this:

```
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you have learned from the queries that you have run on the pet table, you should be able to perform retrievals on the records in the event table; the principles are the same. But when is the event table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the event table, but to calculate her age on that date you need her birth date, which is stored in the pet table. This means the query requires both tables:

```
mysql> SELECT pet.name,
-> (YEAR(date)-YEAR(birth)) - (RIGHT(date,5)<RIGHT(birth,5)) AS age,
-> remark
-> FROM pet INNER JOIN event
-> ON pet.name = event.name
-> WHERE event.type = 'litter';
```

```
+-----+-----+-----+
| name | age | remark |
+-----+-----+-----+
| Fluffy | 2 | 4 kittens, 3 female, 1 male |
| Buffy | 4 | 5 puppies, 2 female, 3 male |
| Buffy | 5 | 3 puppies, 3 female |
+-----+-----+-----+
```

There are several things to note about this query:

- The `FROM` clause joins two tables because the query needs to pull information from both of them.
- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a name column. The query uses `WHERE` clause to match up records in the two tables based on the name values.

The query uses an `INNER JOIN` to combine the tables. An `INNER JOIN` allows for rows from either table to appear in the result if and only if both tables meet the conditions specified in the `ON` clause. In this example, the `ON` clause specifies that the name column in the `pet` table must match the name column in the `event` table. If a name appears in one table but not the other, the row will not appear in the result because the condition in the `ON` clause fails.

- Because the name column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the `pet` table with itself to produce candidate pairs of males and females of like species:

```
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
      -> FROM pet AS p1 INNER JOIN pet AS p2
      -> ON p1.species = p2.species AND p1.sex = 'f' AND p2.sex = 'm';
```

name	sex	name	sex	species
Fluffy	f	Claws	m	cat
Buffy	f	Fang	m	dog
Buffy	f	Bowser	m	dog

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

## 3.4. Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` function:

```
mysql> SELECT DATABASE();
```

DATABASE()
menagerie

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this command:

```
mysql> SHOW TABLES;
```

```
+-----+
| Tables in menagerie |
+-----+
| event
| pet
+-----+
```

If you want to find out about the structure of a table, the `DESCRIBE` command is useful; it displays information about each of a table's columns:

```
mysql> DESCRIBE pet;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| name  | varchar(20)   | YES  |     | NULL    |       |
| owner | varchar(20)   | YES  |     | NULL    |       |
| species | varchar(20)  | YES  |     | NULL    |       |
| sex   | char(1)       | YES  |     | NULL    |       |
| birth | date          | YES  |     | NULL    |       |
| death | date          | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

Field indicates the column name, Type is the data type for the column, NULL indicates whether the column can contain NULL values, Key indicates whether the column is indexed, and Default specifies the column's default value.

If you have indexes on a table, `SHOW INDEX FROM tbl_name` produces information about them.

## 3.5. Using `mysql` in Batch Mode

In the previous sections, you used `mysql` interactively to enter queries and view the results. You can also run `mysql` in batch mode. To do this, put the commands you want to run in a file, then tell `mysql` to read its input from the file:

```
shell> mysql < batch-file
```

If you are running `mysql` under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: *****
```

When you use `mysql` this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the `--force` command-line option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script allows you to avoid retyping it each time you execute it.
- You can generate new queries from existing ones that are similar by copying and editing script files.

- Batch mode can also be useful while you're developing a query, particularly for multiple-line commands or multiple-statement sequences of commands. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell `mysql` to execute it again.
- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

```
shell> mysql < batch-file | more
```

- You can catch the output in a file for further processing:

```
shell> mysql < batch-file > mysql.out
```

- You can distribute your script to other people so that they can also run the commands.
- Some situations do not allow for interactive use, for example, when you run a query from a cron job. In this case, you must use batch mode.

The default output format is different (more concise) when you run `mysql` in batch mode than when you use it interactively. For example, the output of `SELECT DISTINCT species FROM pet` looks like this when `mysql` is run interactively:

```
+-----+
| species |
+-----+
| bird    |
| cat     |
| dog     |
| hamster |
| snake   |
+-----+
```

In batch mode, the output looks like this instead:

```
species
bird
cat
dog
hamster
snake
```

If you want to get the interactive output format in batch mode, use `mysql -t`. To echo to the output the commands that are executed, use `mysql -vvv`.

You can also use scripts from the `mysql` prompt by using the `source` or `\.` command:

```
mysql> source filename;
mysql> \. filename
```

## 3.6. Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then `(article, dealer)` is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
shell> mysql your-database-name
```

(In most MySQL installations, you can use the database named `test`).

You can create and populate the example table with these statements:

```
mysql> CREATE TABLE shop (
-> article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
-> dealer CHAR(20) DEFAULT '' NOT NULL,
-> price DOUBLE(16,2) DEFAULT '0.00' NOT NULL,
-> PRIMARY KEY(article, dealer));
mysql> INSERT INTO shop VALUES
-> (1, 'A', 3.45), (1, 'B', 3.99), (2, 'A', 10.99), (3, 'B', 1.45),
-> (3, 'C', 1.69), (3, 'D', 1.25), (4, 'D', 19.95);
```

After issuing the statements, the table should have the following contents:

```
mysql> SELECT * FROM shop;
+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
| 0001    | A      | 3.45  |
| 0001    | B      | 3.99  |
| 0002    | A      | 10.99 |
| 0003    | B      | 1.45  |
| 0003    | C      | 1.69  |
| 0003    | D      | 1.25  |
| 0004    | D      | 19.95 |
+-----+-----+-----+
```

### 3.6.1. The Maximum Value for a Column

“What’s the highest item number?”

```
SELECT MAX(article) AS article FROM shop;
```

```
+-----+
| article |
+-----+
| 4       |
+-----+
```

### 3.6.2. The Row Holding the Maximum of a Certain Column

*Task: Find the number, dealer, and price of the most expensive article.*

This is easily done with a subquery:

```
SELECT article, dealer, price
FROM shop
WHERE price=(SELECT MAX(price) FROM shop);
```

Another solution is to sort all rows descending by price and get only the first row using the MySQL-specific `LIMIT` clause:

```
SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;
```

**Note:** If there were several most expensive articles, each with a price of 19.95, the `LIMIT` solution would show only one of them.

### 3.6.3. Maximum of Column per Group

*Task: Find the highest price per article.*

```
SELECT article, MAX(price) AS price
FROM   shop
GROUP BY article
```

article	price
0001	3.99
0002	10.99
0003	1.69
0004	19.95

### 3.6.4. The Rows Holding the Group-wise Maximum of a Certain Field

*Task: For each article, find the dealer or dealers with the most expensive price.*

This problem can be solved with a subquery like this one:

```
SELECT article, dealer, price
FROM   shop s1
WHERE  price=(SELECT MAX(s2.price)
              FROM shop s2
              WHERE s1.article = s2.article);
```

### 3.6.5. Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See Section 9.3, “User-Defined Variables”.)

For example, to find the articles with the highest and lowest price you can do this:

```
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
```

article	dealer	price
0003	D	1.25
0004	D	19.95

### 3.6.6. Using Foreign Keys

In MySQL, InnoDB tables support checking of foreign key constraints. See Section 14.2, “The InnoDB Storage Engine”, and Section 1.9.5.5, “Foreign Keys”.

A foreign key constraint is not required merely to join two tables. For storage engines other than InnoDB, it is possible when defining a column to use a `REFERENCES tbl_name(col_name)` clause, which has no actual effect, and *serves only as a memo or comment to you that the column*

which you are currently defining is intended to refer to a column in another table. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of CHECK to make sure that *col\_name* actually exists in *tbl\_name* (or even that *tbl\_name* itself exists).
- MySQL does not perform any sort of action on *tbl\_name* such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no ON DELETE or ON UPDATE behavior whatsoever. (Although you can write an ON DELETE or ON UPDATE clause as part of the REFERENCES clause, it is also ignored.)
- This syntax creates a *column*; it does **not** create any sort of index or key.
- This syntax will cause an error if used in trying to define an InnoDB table.

You can use a column so created as a join column, as shown here:

```
CREATE TABLE person (
  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
  name CHAR(60) NOT NULL,
  PRIMARY KEY (id)
);

CREATE TABLE shirt (
  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
  style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
  color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
  owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
  PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'polo', 'blue', @last),
(NULL, 'dress', 'white', @last),
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'dress', 'orange', @last),
(NULL, 'polo', 'red', @last),
(NULL, 'dress', 'blue', @last),
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
+-----+-----+
| id | name                |
+-----+-----+
|  1 | Antonio Paz        |
|  2 | Lilliana Angelovska |
+-----+-----+

SELECT * FROM shirt;
+-----+-----+-----+-----+
| id | style | color | owner |
+-----+-----+-----+-----+
|  1 | polo  | blue  | 1     |
|  2 | dress | white | 1     |
|  3 | t-shirt | blue  | 1     |
|  4 | dress | orange | 2     |
|  5 | polo  | red   | 2     |
+-----+-----+-----+-----+
```

6	dress	blue	2
7	t-shirt	white	2

```
SELECT s.* FROM person p INNER JOIN shirt s
  ON s.owner = p.id
 WHERE p.name LIKE 'Lilliana%'
    AND s.color <> 'white';
```

id	style	color	owner
4	dress	orange	2
5	polo	red	2
6	dress	blue	2

When used in this fashion, the REFERENCES clause is not displayed in the output of SHOW CREATE TABLE or DESCRIBE:

```
SHOW CREATE TABLE shirt\G
***** 1. row *****
Table: shirt
Create Table: CREATE TABLE `shirt` (
  `id` smallint(5) unsigned NOT NULL auto_increment,
  `style` enum('t-shirt','polo','dress') NOT NULL,
  `color` enum('red','blue','orange','white','black') NOT NULL,
  `owner` smallint(5) unsigned NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

The use of REFERENCES in this way as a comment or “reminder” in a column definition works with both MyISAM and BerkeleyDB tables.

### 3.6.7. Searching on Two Keys

An OR using a single key is well optimized, as is the handling of AND.

The one tricky case is that of searching on two different keys combined with OR:

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR field2_index = '1'
```

This case is optimized from MySQL 5.0.0. See Section 7.2.6, “Index Merge Optimization”.

You can also solve the problem efficiently by using a UNION that combines the output of two separate SELECT statements. See Section 13.2.7.2, “UNION Syntax”.

Each SELECT searches only one key and can be optimized:

```
SELECT field1_index, field2_index
  FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
  FROM test_table WHERE field2_index = '1';
```

### 3.6.8. Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR(4), month INT(2) UNSIGNED ZEROFILL,
                 day INT(2) UNSIGNED ZEROFILL);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
                    (2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
       GROUP BY year,month;
```

Which returns:

year	month	days
2000	01	3
2000	02	2

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

### 3.6.9. Using AUTO\_INCREMENT

The AUTO\_INCREMENT attribute can be used to generate a unique identity for new rows:

```
CREATE TABLE animals (
    id MEDIUMINT NOT NULL AUTO_INCREMENT,
    name CHAR(30) NOT NULL,
    PRIMARY KEY (id)
);

INSERT INTO animals (name) VALUES
    ('dog'),('cat'),('penguin'),
    ('lax'),('whale'),('ostrich');

SELECT * FROM animals;
```

Which returns:

id	name
1	dog
2	cat
3	penguin
4	lax
5	whale
6	ostrich

You can retrieve the most recent AUTO\_INCREMENT value with the LAST\_INSERT\_ID() SQL function or the mysql\_insert\_id() C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

**Note:** For a multiple-row insert, LAST\_INSERT\_ID() and mysql\_insert\_id() actually return the AUTO\_INCREMENT key from the *first* of the inserted rows. This allows multiple-row inserts to be reproduced correctly on other servers in a replication setup.

For MyISAM and BDB tables you can specify AUTO\_INCREMENT on a secondary column in a mul-

tuple-column index. In this case, the generated value for the `AUTO_INCREMENT` column is calculated as `MAX(auto_increment_column) + 1 WHERE prefix=given-prefix`. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (
  grp ENUM('fish','mammal','bird') NOT NULL,
  id MEDIUMINT NOT NULL AUTO_INCREMENT,
  name CHAR(30) NOT NULL,
  PRIMARY KEY (grp,id)
);

INSERT INTO animals (grp,name) VALUES
  ('mammal','dog'),('mammal','cat'),
  ('bird','penguin'),('fish','lax'),('mammal','whale'),
  ('bird','ostrich');

SELECT * FROM animals ORDER BY grp,id;
```

Which returns:

grp	id	name
fish	1	lax
mammal	1	dog
mammal	2	cat
mammal	3	whale
bird	1	penguin
bird	2	ostrich

Note that in this case (when the `AUTO_INCREMENT` column is part of a multiple-column index), `AUTO_INCREMENT` values are reused if you delete the row with the biggest `AUTO_INCREMENT` value in any group. This happens even for `MyISAM` tables, for which `AUTO_INCREMENT` values normally are not reused.

If the `AUTO_INCREMENT` column is part of multiple indexes, MySQL will generate sequence values using the index that begins with the `AUTO_INCREMENT` column, if there is one. For example, if the `animals` table contained indexes `PRIMARY KEY (grp, id)` and `INDEX (id)`, MySQL would ignore the `PRIMARY KEY` for generating sequence values. As a result, the table would contain a single sequence, not a sequence per `grp` value.

To start with an `AUTO_INCREMENT` value other than 1, you can set that value with `CREATE TABLE` or `ALTER TABLE`, like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

More information about `AUTO_INCREMENT` is available here:

- How to assign the `AUTO_INCREMENT` attribute to a column: Section 13.1.5, “`CREATE TABLE Syntax`”, and Section 13.1.2, “`ALTER TABLE Syntax`”.
- How `AUTO_INCREMENT` behaves depending on the SQL mode: Section 5.2.5, “`The Server SQL Mode`”.
- Find the row that contains the most recent `AUTO_INCREMENT` value: Section 12.1.3, “`Comparison Functions and Operators`”.
- Set the `AUTO_INCREMENT` value to be used: Section 13.5.3, “`SET Syntax`”.
- `AUTO_INCREMENT` and replication: Section 6.7, “`Replication Features and Known Problems`”.
- Server-system variables related to `AUTO_INCREMENT` (`auto_increment_increment`

and `auto_increment_offset`) that can be used for replication: Section 5.2.2, “Server System Variables”.

## 3.7. Queries from the Twin Project

At Analytikerna and Lentus, we have been doing the systems and field work for a big research project. This project is a collaboration between the Institute of Environmental Medicine at Karolinska Institutet Stockholm and the Section on Clinical Research in Aging and Psychology at the University of Southern California.

The project involves a screening part where all twins in Sweden older than 65 years are interviewed by telephone. Twins who meet certain criteria are passed on to the next stage. In this latter stage, twins who want to participate are visited by a doctor/nurse team. Some of the examinations include physical and neuropsychological examination, laboratory testing, neuroimaging, psychological status assessment, and family history collection. In addition, data are collected on medical and environmental risk factors.

More information about Twin studies can be found at: [http://www.mep.ki.se/twinreg/index\\_en.html](http://www.mep.ki.se/twinreg/index_en.html)

The latter part of the project is administered with a Web interface written using Perl and MySQL.

Each night all data from the interviews is moved into a MySQL database.

### 3.7.1. Find All Non-distributed Twins

The following query is used to determine who goes into the second part of the project:

```
SELECT
  CONCAT(p1.id, p1.tvab) + 0 AS tvid,
  CONCAT(p1.christian_name, ' ', p1.surname) AS Name,
  p1.postal_code AS Code,
  p1.city AS City,
  pg.abrev AS Area,
  IF(td.participation = 'Aborted', 'A', ' ') AS A,
  p1.dead AS dead1,
  l.event AS event1,
  td.suspect AS tsuspect1,
  id.suspect AS isuspect1,
  td.severe AS tsevere1,
  id.severe AS isevere1,
  p2.dead AS dead2,
  l2.event AS event2,
  h2.nurse AS nurse2,
  h2.doctor AS doctor2,
  td2.suspect AS tsuspect2,
  id2.suspect AS isuspect2,
  td2.severe AS tsevere2,
  id2.severe AS isevere2,
  l.finish_date
FROM
  twin_project AS tp
  /* For Twin 1 */
  LEFT JOIN twin_data AS td ON tp.id = td.id
    AND tp.tvab = td.tvab
  LEFT JOIN informant_data AS id ON tp.id = id.id
    AND tp.tvab = id.tvab
  LEFT JOIN harmony AS h ON tp.id = h.id
    AND tp.tvab = h.tvab
  LEFT JOIN lentus AS l ON tp.id = l.id
    AND tp.tvab = l.tvab
  /* For Twin 2 */
  LEFT JOIN twin_data AS td2 ON p2.id = td2.id
    AND p2.tvab = td2.tvab
  LEFT JOIN informant_data AS id2 ON p2.id = id2.id
```

```

        AND p2.tvab = id2.tvab
LEFT JOIN harmony AS h2 ON p2.id = h2.id
        AND p2.tvab = h2.tvab
LEFT JOIN lentus AS l2 ON p2.id = l2.id
        AND p2.tvab = l2.tvab,
person_data AS p1,
person_data AS p2,
postal_groups AS pg
WHERE
/* p1 gets main twin and p2 gets his/her twin. */
/* ptvab is a field inverted from tvab */
p1.id = tp.id AND p1.tvab = tp.tvab AND
p2.id = p1.id AND p2.ptvab = p1.tvab AND
/* Just the screening survey */
tp.survey_no = 5 AND
/* Skip if partner died before 65 but allow emigration (dead=9) */
(p2.dead = 0 OR p2.dead = 9 OR
 (p2.dead = 1 AND
  (p2.death_date = 0 OR
   (((TO_DAYS(p2.death_date) - TO_DAYS(p2.birthdate)) / 365)
    >= 65))))
AND
(
/* Twin is suspect */
(td.future_contact = 'Yes' AND td.suspect = 2) OR
/* Twin is suspect - Informant is Blessed */
(td.future_contact = 'Yes' AND td.suspect = 1
 AND id.suspect = 1) OR
/* No twin - Informant is Blessed */
(ISNULL(td.suspect) AND id.suspect = 1
 AND id.future_contact = 'Yes') OR
/* Twin broken off - Informant is Blessed */
(td.participation = 'Aborted'
 AND id.suspect = 1 AND id.future_contact = 'Yes') OR
/* Twin broken off - No inform - Have partner */
(td.participation = 'Aborted' AND ISNULL(id.suspect)
 AND p2.dead = 0))
AND
l.event = 'Finished'
/* Get at area code */
AND SUBSTRING(p1.postal_code, 1, 2) = pg.code
/* Not already distributed */
AND (h.nurse IS NULL OR h.nurse=00 OR h.doctor=00)
/* Has not refused or been aborted */
AND NOT (h.status = 'Refused' OR h.status = 'Aborted'
 OR h.status = 'Died' OR h.status = 'Other')
ORDER BY
tvid;

```

Some explanations:

- `CONCAT(p1.id, p1.tvab) + 0 AS tvid`

We want to sort on the concatenated id and tvab in numerical order. Adding 0 to the result causes MySQL to treat the result as a number.

- column `id`

This identifies a pair of twins. It is a key in all tables.

- column `tvab`

This identifies a twin in a pair. It has a value of 1 or 2.

- column `ptvab`

This is an inverse of `tvab`. When `tvab` is 1 this is 2, and vice versa. It exists to save typing and to make it easier for MySQL to optimize the query.

This query demonstrates, among other things, how to do lookups on a table from the same table with a join (`p1` and `p2`). In the example, this is used to check whether a twin's partner died before the age of 65. If so, the row is not returned.

All of the above exist in all tables with twin-related information. We have a key on both `id, tvab` (all tables), and `id, ptvab` (`person_data`) to make queries faster.

On our production machine (A 200MHz UltraSPARC), this query returns about 150-200 rows and takes less than one second.

The current number of records in the tables used in the query:

Table	Rows
<code>person_data</code>	71074
<code>lentus</code>	5291
<code>twin_project</code>	5286
<code>twin_data</code>	2012
<code>informant_data</code>	663
<code>harmony</code>	381
<code>postal_groups</code>	100

### 3.7.2. Show a Table of Twin Pair Status

Each interview ends with a status code called `event`. The query shown here is used to display a table over all twin pairs combined by event. This indicates in how many pairs both twins are finished, in how many pairs one twin is finished and the other refused, and so on.

```

SELECT
    t1.event,
    t2.event,
    COUNT(*)
FROM
    lentus AS t1,
    lentus AS t2,
    twin_project AS tp
WHERE
    /* We are looking at one pair at a time */
    t1.id = tp.id
    AND t1.tvab=tp.tvab
    AND t1.id = t2.id
    /* Just the screening survey */
    AND tp.survey_no = 5
    /* This makes each pair only appear once */
    AND t1.tvab='1' AND t2.tvab='2'
GROUP BY
    t1.event, t2.event;

```

## 3.8. Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```
LogFormat \
    "%h",%{Y%m%d%H%M%S}t,%>s,"%b",\%{Content-Type}o", \
    "%U",\%{Referer}i",\%{User-Agent}i"
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
```

The named table should be created to have columns that correspond to those that the LogFormat line writes to the log file.

---

# Chapter 4. Using MySQL Programs

This chapter provides a brief overview of the command-line programs provided by MySQL AB and discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for all of them. Later chapters provide more detailed descriptions of individual programs, including which options they recognize.

MySQL AB also provides three GUI client programs for use with MySQL Server:

- **MySQL Administrator:** This tool is used for administering MySQL servers, databases, tables, and user accounts.
- **MySQL Query Browser:** This graphical tool is provided by MySQL AB for creating, executing, and optimizing queries on MySQL databases.
- **MySQL Migration Toolkit:** This tool helps you migrate schemas and data from other relational database management systems for use with MySQL.

These GUI programs each have their own manuals that you can access at <http://dev.mysql.com/doc/>.

## 4.1. Overview of MySQL Programs

MySQL AB provides several types of programs:

- The MySQL server and server startup scripts:
  - `mysqld` is the MySQL server.
  - `mysqld_safe`, `mysql.server`, and `mysqld_multi` are server startup scripts.
  - `mysql_install_db` initializes the data directory and the initial databases.
  - MySQL Instance Manager monitors and manages MySQL Server instances.

Chapter 5, *Database Administration*, discusses these programs further

- Client programs that access the server:
  - `mysql` is a command-line client for executing SQL statements interactively or in batch mode.
  - `mysqladmin` is an administrative client.
  - `mysqlcheck` performs table maintenance operations.
  - `mysqldump` and `mysqlhotcopy` make database backups.
  - `mysqlimport` imports data files.
  - `mysqlshow` displays information about databases and tables.

Chapter 8, *Client and Utility Programs*, discusses these programs further

- Utility programs that operate independently of the server:
  - `myisamchk` performs table maintenance operations.
  - `myisampack` produces compressed, read-only tables.

- `mysqlbinlog` is a tool for processing binary log files.
- `perror` displays the meaning of error codes.

Chapter 8, *Client and Utility Programs*, discusses these programs further

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see Chapter 2, *Installing and Upgrading MySQL*, for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install something else.

## 4.2. Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. “shell>” represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are \$ for `sh` or `bash`, % for `csh` or `tcsh`, and C:\> for the Windows `command.com` or `cmd.exe` command interpreters.

```
shell> mysql -u root test
shell> mysqladmin extended-status variables
shell> mysqlshow --help
shell> mysqldump --user=root personnel
```

Arguments that begin with a single or double dash (‘-’, ‘--’) are option arguments. Options typically specify the type of connection a program should make to the server or affect its operational mode. Option syntax is described in Section 4.3, “Specifying Program Options”.

Non-option arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first non-option argument as a database name, so the command `mysql -u root test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program understands and describe the meaning of any additional non-option arguments.

Some options are common to a number of programs. The most common of these are the `--host` (or `-h`), `--user` (or `-u`), and `--password` (or `-p`) options that specify connection parameters. They indicate the host where the MySQL server is running, and the username and password of your MySQL account. All MySQL client programs understand these options; they allow you to specify which server to connect to and the account to use on that server.

Other connection options are `--port` (or `-P`) to specify a TCP/IP port number and `--socket` (or `-S`) to specify a Unix socket file on Unix (or named pipe name on Windows).

The default hostname is `localhost`. For client programs on Unix, the hostname `localhost` is special. It causes the client to connect to the MySQL server through a Unix socket file. This occurs even if a `--port` or `-P` option is given to specify a port number. To ensure that the client makes a TCP/IP connection to the local server, use `--host` or `-h` to specify a hostname value of `127.0.0.1`, or the IP address or name of the local server. You can also specify the connection protocol explicitly, even for `localhost`, by using the `--protocol=tcp` option.

You may find it necessary to invoke MySQL programs using the pathname to the `bin` directory in which they are installed. This is likely to be the case if you get a “program not found” error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the pathname of the `bin` directory to your `PATH`

environment variable setting. That enables you to run a program by typing only its name, not its entire pathname. For example, if `mysql` is installed in `/usr/local/mysql/bin`, you'll be able to run it by invoking it as `mysql`; it will not be necessary to invoke it as `/usr/local/mysql/bin/mysql`.

Consult the documentation for your command interpreter for instructions on setting your `PATH` variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in Section 4.3.3, "Using Environment Variables to Specify Options".)

## 4.3. Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is most common for options that apply to a specific invocation of the program.
- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.
- List the options in environment variables. This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose. However, Section 5.13.2, "Running Multiple Servers on Unix", discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for both the server and client programs.

MySQL programs determine which options are given first by examining environment variables, then by reading option files, and then by checking the command line. If an option is specified multiple times, the last occurrence takes precedence. This means that environment variables have the lowest precedence and command-line options the highest.

You can take advantage of the way that MySQL programs process options by specifying default values for a program's options in an option file. That enables you to avoid typing them each time you run the program, but also allows you to override the defaults if necessary by using command-line options.

### 4.3.1. Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.
- An option argument begins with one dash or two dashes, depending on whether it has a short name or a long name. Many options have both forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display its help message.
- Option names are case sensitive. `-v` and `-V` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)
- Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.
- For a long option that takes a value, separate the option name and the value by an '=' sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: `-hlocalhost` and `-h localhost` are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=pass_val` or as `--password`. In the latter case (with no password value given), the program prompts you for the password. The password option also may be given in short form as `-ppass_val` or as `-p`. However, for the short form, if the password

value is given, it must follow the option letter with *no intervening space*. The reason for this is that if a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```
shell> mysql -ptest
shell> mysql -p test
```

The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

Some options control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```
--disable-column-names
--skip-column-names
--column-names=0
```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

```
--column-names
--enable-column-names
--column-names=1
```

If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```
shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--no-such-option'
```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file. An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

Another option that may occasionally be useful with `mysql` is the `--execute` or `-e` option, which can be used to pass SQL statements to the server. The statements must be enclosed by single or double quotation marks. If you wish to use quoted values within a statement, you should use double quotes for the statement, and single quotes for any quoted values within the statement. When this option is used, `mysql` executes the statements and exits.

For example, you can use the following command to obtain a list of user accounts:

```
shell> mysql -u root -p --execute="SELECT User, Host FROM user" mysql
Enter password: *****
+-----+-----+
| User | Host |
+-----+-----+
| root | gigan |
| root | gigan |
+-----+-----+
```

```

| jon | localhost |
| root | localhost |
+-----+-----+
shell>

```

Note that the long form (`--execute`) is followed by an equals sign (=).

In the preceding example, the name of the `mysql` database was passed as a separate argument. However, the same statement could have been executed using this command, which specifies no default database:

```
mysql> mysql -u root -p --execute="SELECT User, Host FROM mysql.user"
```

Multiple SQL statements may be passed on the command line, separated by semicolons:

```

shell> mysql -u root -p -e "SELECT VERSION();SELECT NOW()"
Enter password: *****
+-----+
| VERSION() |
+-----+
| 5.0.19-log |
+-----+
+-----+-----+
| NOW() |
+-----+-----+
| 2006-01-05 21:19:04 |
+-----+-----+

```

The `--execute` or `-e` option may also be used to pass commands in an analogous fashion to the `ndb_mgm` management client for MySQL Cluster. See Section 15.3.6, “Safe Shutdown and Restart”, for an example.

## 4.3.2. Using Option Files

Most MySQL programs can read startup options from option files (also sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program.

To determine whether a program reads option files, invoke it with the `--help` option (`--verbose` and `--help` for `mysqld`). If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

**Note:** Option files used with MySQL Cluster programs are covered in Section 15.4, “MySQL Cluster Configuration”.

On Windows, MySQL programs read startup options from the following files:

Filename	Purpose
<code>WINDIR\my.ini</code>	Global options
<code>C:\my.cnf</code>	Global options
<code>INSTALLDIR\my.ini</code>	Global Options
<code>defaults-extra-file</code>	The file specified with <code>--defaults-extra-file=path</code> , if any

`WINDIR` represents the location of your Windows directory. This is commonly `C:\WINDOWS` or `C:\WINNT`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

*INSTALLDIR* represents the installation directory of MySQL. This is typically `C:\PROGRAMDIR\MySQL\MySQL 5.0 Server` where *PROGRAMDIR* represents the programs directory (usually Program Files on English-language versions of Windows), when MySQL 5.0 has been installed using the installation and configuration wizards. See Section 2.3.4.14, “The Location of the my.ini File”.

On Unix, MySQL programs read startup options from the following files:

Filename	Purpose
<code>/etc/my.cnf</code>	Global options
<code>\$MYSQL_HOME/my.cnf</code>	Server-specific options
<code>defaults-extra-file</code>	The file specified with <code>--defaults-extra-file=path</code> , if any
<code>~/my.cnf</code>	User-specific options

`MYSQL_HOME` is an environment variable containing the path to the directory in which the server-specific `my.cnf` file resides. (This was *DATADIR* prior to MySQL version 5.0.3.)

If `MYSQL_HOME` is not set and you start the server using the `mysqld_safe` program, `mysqld_safe` attempts to set `MYSQL_HOME` as follows:

- Let *BASEDIR* and *DATADIR* represent the pathnames of the MySQL base directory and data directory, respectively.
- If there is a `my.cnf` file in *DATADIR* but not in *BASEDIR*, `mysqld_safe` sets `MYSQL_HOME` to *DATADIR*.
- Otherwise, if `MYSQL_HOME` is not set and there is no `my.cnf` file in *DATADIR*, `mysqld_safe` sets `MYSQL_HOME` to *BASEDIR*.

Typically, *DATADIR* is `/usr/local/mysql/data` for a binary installation or `/usr/local/var` for a source installation. Note that this is the data directory location that was specified at configuration time, not the one specified with the `--datadir` option when `mysqld` starts. Use of `--datadir` at runtime has no effect on where the server looks for option files, because it looks for them before processing any options.

MySQL looks for option files in the order just described and reads any that exist. If an option file that you want to use does not exist, create it with a plain text editor.

If multiple instances of a given option are found, the last instance takes precedence. There is one exception: For `mysqld`, the *first* instance of the `--user` option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

**Note:** On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional, and acts as a security measure.

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the `-help` option.

The syntax for specifying options in an option file is similar to command-line syntax, except that you omit the leading two dashes. For example, `--quick` or `--host=localhost` on the command line should be specified as `quick` or `host=localhost` in an option file. To specify an option of the form `--loose-opt_name` in an option file, write it as `loose-opt_name`.

Empty lines in option files are ignored. Non-empty lines can take any of the following forms:

- `#comment, ;comment`

Comment lines start with '#' or ';'. A '#' comment can start in the middle of a line as well.

- *[group]*

*group* is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given.

- *opt\_name*

This is equivalent to `--opt_name` on the command line.

- *opt\_name=value*

This is equivalent to `--opt_name=value` on the command line. In an option file, you can have spaces around the '=' character, something that is not true on the command line. You can enclose the value within single quotes or double quotes, which is useful if the value contains a '#' comment character or whitespace.

For options that take a numeric value, the value can be given with a suffix of K, M, or G (either uppercase or lowercase) to indicate a multiplier of 1024, 1024<sup>2</sup> or 1024<sup>3</sup>. For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:

```
mysql> mysqladmin --count=1K --sleep=10 ping
```

Leading and trailing blanks are automatically deleted from option names and values. You may use the escape sequences '\b', '\t', '\n', '\r', '\\', and '\s' in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters.

Because the '\\' escape sequence represents a single backslash, you must write each '\' as '\\'. Alternatively, you can specify the value using '/' rather than '\' as the pathname separator.

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the `[mysqld]` and `[mysql]` groups apply to the `mysqld` server and the `mysql` client program, respectively.

The `[client]` option group is read by all client programs (but *not* by `mysqld`). This allows you to specify options that apply to all clients. For example, `[client]` is the perfect group to use to specify the password that you use to connect to the server. (But make sure that the option file is readable and writable only by yourself, so that other people cannot find out your password.) Be sure not to put an option in the `[client]` group unless it is recognized by *all* client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=8M

[mysqldump]
quick
```

The preceding option file uses `var_name=value` syntax for the lines that set the

key\_buffer\_size and max\_allowed\_packet variables.

Here is a typical user option file:

```
[client]
# The following password will be sent to all standard MySQL clients
password="my_password"

[mysql]
no-auto-rehash
connect_timeout=2

[mysqlhotcopy]
interactive-timeout
```

If you want to create option groups that should be read by mysqld servers from a specific MySQL release series only, you can do this by using groups with names of [mysqld-4.1], [mysqld-5.0], and so forth. The following group indicates that the --new option should be used only by MySQL servers with 5.0.x version numbers:

```
[mysqld-5.0]
new
```

Beginning with MySQL 5.0.4, it is possible to use !include directives in option files to include other option files and !includedir to search specific directories for option files. For example, to include the /home/mydir/myopt.cnf file, you can use the following directive:

```
!include /home/me/myopt.cnf
```

To search the /home/mydir directory and read option files found there, you would use this directive:

```
!includedir /home/mydir
```

**Note:** Currently, any files to be found and included using the !includedir directive on Unix operating systems *must* have filenames ending in .cnf. On Windows, this directive checks for files with the .ini or .cnf extension.

Note that options read from included files are applied in the context of the current option group. Suppose that you were to write the following lines in my.cnf:

```
[mysqld]
!include /home/mydir/myopt.cnf
```

In this case, the myopt.cnf file is processed only for the server, and the !include directive is ignored by any client applications. However, if you were to use the following lines, the directory /home/mydir/my-dump-options is checked for option files by mysqldump only, and not by the server or by any other client applications:

```
[mysqldump]
!includedir /home/mydir/my-dump-options
```

If you have a source distribution, you can find sample option files named my-xxxx.cnf in the support-files directory. If you have a binary distribution, look in the support-files directory under your MySQL installation directory. On Windows, the sample option files may be located in the MySQL installation directory (see earlier in this section or Chapter 2, *Installing and Upgrading MySQL*, if you do not know where this is). Currently, there are sample option files for small, medium, large, and very large systems. To experiment with one of these files, copy it to C:\my.cnf on Windows or to .my.cnf in your home directory on Unix.

**Note:** On Windows, the .cnf option file extension might not be displayed.

All MySQL programs that support option files handle the following options. They affect option-file handling, so they must be given on the command line and not in an option file. To work properly, each of these options must immediately follow the command name, with the exception that `-print-defaults` may be used immediately after `--defaults-file` or `-defaults-extra-file`.

- `--no-defaults`

Don't read any option files.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--defaults-file=filename`

Use only the given option file. *filename* is the full pathname to the file.

- `--defaults-extra-file=filename`

Read this option file after the global option file but (on Unix) before the user option file. *filename* is the full pathname to the file. As of MySQL 5.0.6, if the file does not exist or is otherwise inaccessible, the program will exit with an error.

- `--defaults-group-suffix=str`

If this option is given, the program reads not only its usual option groups, but also groups with the usual names and a suffix of *str*. For example, the `mysql` client normally reads the `[client]` and `[mysql]` groups. If the `--default-group-suffix=_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups. This option was added in MySQL 5.0.10.

In shell scripts, you can use the `my_print_defaults` program to parse option files and see what options would be used by a given program. The following example shows the output that `my_print_defaults` might produce when asked to show the options found in the `[client]` and `[mysql]` groups:

```
shell> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash
```

**Note for developers:** Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.

### 4.3.3. Using Environment Variables to Specify Options

To specify an option using an environment variable, set the variable using the syntax appropriate for your command processor. For example, on Windows or NetWare, you can set the `USER` variable to specify your MySQL account name. To do so, use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the `MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `bash`, `zsh`, and so on) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, place the appropriate command or commands in a startup file that your command interpreter reads each time it starts. Typical startup files are `AUTOEXEC.BAT` for Windows, `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`. Consult the documentation for your command interpreter for specific details.

Appendix F, *Environment Variables*, lists all environment variables that affect MySQL program operation.

## 4.3.4. Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime. Program variables are set the same way as any other long option that takes a value. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
shell> mysql --max_allowed_packet=16777216
shell> mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of K, M, or G (either uppercase or lowercase) to indicate a multiplier of  $1024$ ,  $1024^2$  or  $1024^3$ . (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.)

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in a variable name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M
```

```
[mysqld]
key-buffer-size=512M
```

**Note:** Before MySQL 4.0.2, the only syntax for setting program variables was `--set-variable=option=value` (or `set-variable=option=value` in option files). This syntax still is recognized, but is deprecated as of MySQL 4.0.2.

Many server system variables can also be set at runtime. For details, see Section 5.2.3.2, “Dynamic System Variables”.

---

# Chapter 5. Database Administration

This chapter covers topics that deal with administering a MySQL installation:

- Configuring the server
- Managing user accounts
- Performing backups
- The server log files
- The query cache

## 5.1. Overview of Server-Side Programs

The MySQL server, `mysqld`, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that perform setup operations when you install MySQL or that assist you in starting and stopping the server. This section provides an overview of the server and related programs. The following sections provide more detailed information about each of these programs.

Each MySQL program takes many different options. Most programs provide a `--help` option that you can use to get a description of the program's different options. For example, try `mysqld -help`.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. Section 4.3, “Specifying Program Options”.

The following list briefly describes the MySQL server and server-related programs:

- `mysqld`

The SQL daemon (that is, the MySQL server). To use client programs, `mysqld` must be running, because clients gain access to databases by connecting to the server. See Section 5.2, “`mysqld` — The MySQL Server”.
- `mysqld-max`

A version of the server that includes additional features. See Section 5.3, “The `mysqld-max` Extended MySQL Server”.
- `mysqld_safe`

A server startup script. `mysqld_safe` attempts to start `mysqld-max` if it exists, and `mysqld` otherwise. See Section 5.4.1, “`mysqld_safe` — MySQL Server Startup Script”.
- `mysql.server`

A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes `mysqld_safe` to start the MySQL server. See Section 5.4.2, “`mysql.server` — MySQL Server Startup Script”.
- `mysqld_multi`

A server startup script that can start or stop multiple servers installed on the system. See Section 5.4.3, “`mysqld_multi` — Manage Multiple MySQL Servers”. As of MySQL 5.0.3

(Unix-like systems) or 5.0.13 (Windows), an alternative to `mysqld_multi` is `mysqlmanager`, the MySQL Instance Manager. See Section 5.5, “`mysqlmanager` — The MySQL Instance Manager”.

- `mysql_install_db`

This script creates the MySQL database and initializes the grant tables with default privileges. It is usually executed only once, when first installing MySQL on a system. See Section 2.10.2, “Unix Post-Installation Procedures”.

- `mysql_fix_privilege_tables`

This program is used after a MySQL upgrade operation. It updates the grant tables with any changes that have been made in newer versions of MySQL. See Section 5.6.1, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.

Note: As of MySQL 5.0.19, this program has been superseded by `mysql_upgrade`.

- `mysql_upgrade`

This program is used after a MySQL upgrade operation. It checks tables for incompatibilities and repairs them if necessary, and updates the grant tables with any changes that have been made in newer versions of MySQL. See Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

- `mysqlmanager`

The MySQL Instance Manager, a program for monitoring and managing MySQL servers. See Section 5.5, “`mysqlmanager` — The MySQL Instance Manager”.

There are several other programs that are run on the server host:

- `make_binary_distribution`

This program makes a binary release of a compiled MySQL. This could be sent by FTP to `/pub/mysql/upload/` on `ftp.mysql.com` for the convenience of other MySQL users.

## 5.2. `mysqld` — The MySQL Server

`mysqld` is the MySQL server. The following discussion covers these MySQL server configuration topics:

- Startup options that the server supports
- Server system variables
- Server status variables
- How to set the server SQL mode
- The server shutdown process

### 5.2.1. `mysqld` Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in Section 4.3, “Specifying Program Options”. The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure

that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See Section 4.3.2, “Using Option Files”.

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld]`, `[server]`, `[mysqld_safe]`, and `[safe_mysqld]` groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups.

An embedded MySQL server usually reads options from the `[server]`, `[embedded]`, and `[xxxxxx_SERVER]` groups, where `xxxxxx` is the name of the application into which the server is embedded.

`mysqld` accepts many command options. For a brief summary, execute `mysqld --help`. To see the full list, use `mysqld --verbose --help`.

The following list shows some of the most common server options. Additional options are described in other sections:

- Options that affect security: See Section 5.7.3, “Security-Related `mysqld` Options”.
- SSL-related options: See Section 5.9.7.5, “SSL Command Options”.
- Binary log control options: See Section 5.12.3, “The Binary Log”.
- Replication-related options: See Section 6.8, “Replication Startup Options”.
- Options specific to particular storage engines: See Section 14.1.1, “MyISAM Startup Options”, Section 14.5.3, “BDB Startup Options”, Section 14.2.4, “InnoDB Startup Options and System Variables”, and Section 15.5.5.1, “MySQL Cluster-Related Command Options for `mysqld`”.

You can also set the values of server system variables by using variable names as options, as described later in this section.

- `--help, -?`

Display a short help message and exit. Use both the `--verbose` and `--help` options to see the full message.

- `--allow-suspicious-udfs`

This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. This option was added in version 5.0.3. See Section 24.2.4.6, “User-Defined Function Security Precautions”.

- `--ansi`

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the `--sql-mode` option instead. See Section 1.9.3, “Running MySQL in ANSI Mode”, and Section 5.2.5, “The Server SQL Mode”.

- `--basedir=path, -b path`

The path to the MySQL installation directory. All paths are usually resolved relative to this directory.

- `--bind-address=IP`

The IP address to bind to.

- `--bootstrap`

This option is used by the `mysql_install_db` script to create the MySQL privilege tables without having to start a full MySQL server.

- `--character-sets-dir=path`

The directory where character sets are installed. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

- `--character-set-client-handshake`

Don't ignore character set information sent by the client. To ignore client information and use the default server character set, use `--skip-character-set-client-handshake`; this makes MySQL behave like MySQL 4.0.

- `--character-set-filesystem=charset_name`

The filesystem character set. This option sets the `character_set_filesystem` system variable. It was added in MySQL 5.0.19.

- `--character-set-server=charset_name, -C charset_name`

Use `charset_name` as the default server character set. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

- `--chroot=path`

Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure. Note that use of this option somewhat limits `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`.

- `--collation-server=collation_name`

Use `collation_name` as the default server collation. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

- `--console`

(Windows only.) Write error log messages to `stderr` and `stdout` even if `--log-error` is specified. `mysqld` does not close the console window if this option is used.

- `--core-file`

Write a core file if `mysqld` dies. For some systems, you must also specify the `--core-file-size` option to `mysqld_safe`. See Section 5.4.1, “`mysqld_safe` — MySQL Server Startup Script”. Note that on some systems, such as Solaris, you do not get a core file if you are also using the `--user` option.

- `--datadir=path, -h path`

The path to the data directory.

- `--debug[=debug_options], -# [debug_options]`

If MySQL is configured with `--with-debug`, you can use this option to get a trace file of what `mysqld` is doing. The `debug_options` string often is `'d:t:o,file_name'`. The default is `'d:t:i:o,mysqld.trace'`. See Section E.1.2, “Creating Trace Files”.

- `--default-character-set=charset_name (DEPRECATED)`

Use `charset_name` as the default character set. This option is deprecated in favor of `--character-set-server`. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

- `--default-collation=collation_name`

Use *collation\_name* as the default collation. This option is deprecated in favor of `--collation-server`. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

- `--default-storage-engine=type`

Set the default storage engine (table type) for tables. See Chapter 14, *Storage Engines and Table Types*.

- `--default-table-type=type`

This option is a synonym for `--default-storage-engine`.

- `--default-time-zone=timezone`

Set the default server time zone. This option sets the global `time_zone` system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the `system_time_zone` system variable).

- `--delay-key-write[={OFF|ON|ALL}]`

Specify how to use delayed key writes. Delayed key writing causes key buffers not to be flushed between writes for MyISAM tables. OFF disables delayed key writes. ON enables delayed key writes for those tables that were created with the `DELAY_KEY_WRITE` option. ALL delays key writes for all MyISAM tables. See Section 7.5.2, “Tuning Server Parameters”, and Section 14.1.1, “MyISAM Startup Options”.

**Note:** If you set this variable to ALL, you should not use MyISAM tables from within another program (such as another MySQL server or `myisamchk`) when the tables are in use. Doing so leads to index corruption.

- `--des-key-file=file_name`

Read the default DES keys from this file. These keys are used by the `DES_ENCRYPT()` and `DES_DECRYPT()` functions.

- `--enable-named-pipe`

Enable support for named pipes. This option applies only on Windows NT, 2000, XP, and 2003 systems, and can be used only with the `mysqld-nt` and `mysqld-max-nt` servers that support named-pipe connections.

- `--exit-info[=flags], -T [flags]`

This is a bit mask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know *exactly* what it does!

- `--external-locking`

Enable external locking (system locking), which is disabled by default as of MySQL 4.0. Note that if you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysqld` to deadlock. This option previously was named `--enable-locking`.

**Note:** If you use this option to enable updates to MyISAM tables from many MySQL processes, you must ensure that the following conditions are satisfied:

- You should not use the query cache for queries that use tables that are updated by another process.
- You should not use `--delay-key-write=ALL` or `DELAY_KEY_WRITE=1` on any shared tables.

The easiest way to ensure this is to always use `--external-locking` together with -

`--delay-key-write=OFF` and `--query-cache-size=0`. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

- `--flush`

Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

- `--init-file=file_name`

Read SQL statements from this file at startup. Each statement must be on a single line and should not include comments.

- `--innodb-safe-binlog`

Adds consistency guarantees between the content of InnoDB tables and the binary log. See Section 5.12.3, “The Binary Log”. This option was removed in MySQL 5.0.3, having been made obsolete by the introduction of XA transaction support.

- `--innodb-xxx`

The InnoDB options are listed in Section 14.2.4, “InnoDB Startup Options and System Variables”.

- `--language=lang_name, -L lang_name`

Return client error messages in the given language. *lang\_name* can be given as the language name or as the full pathname to the directory where the language files are installed. See Section 5.11.2, “Setting the Error Message Language”.

- `--large-pages`

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and OS. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

Currently, MySQL supports only the Linux implementation of large pages support (which is called HugeTLB in Linux). We have plans to extend this support to FreeBSD, Solaris and possibly other platforms.

Before large pages can be used on Linux, it is necessary to configure the HugeTLB memory pool. For reference, consult the `hugetlbpage.txt` file in the Linux kernel source.

This option is disabled by default. It was added in MySQL 5.0.3.

- `--log[=file_name], -l [file_name]`

Log connections and SQL statements received from clients to this file. See Section 5.12.2, “The General Query Log”. If you omit the filename, MySQL uses `host_name.log` as the filename.

- `--log-bin[=base_name]`

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See Section 5.12.3, “The Binary Log”.

The option value, if given, is the basename for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the basename. It is recommended that you specify a basename (see Section A.8.1, “Open Issues in MySQL”, for the reason). Otherwise, MySQL uses `host_name-bin` as the basename.

- `--log-bin-index[=file_name]`

The index file for binary log filenames. See Section 5.12.3, “The Binary Log”. If you omit the filename, and if you didn't specify one with `--log-bin`, MySQL uses `host_name-bin.index` as the filename.

- `--log-bin-trust-function-creators[={0|1}]`

With no argument or an argument of 1, this option sets the `log_bin_trust_function_creators` system variable to 1. With an argument of 0, this option sets the system variable to 0. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function creation. See Section 17.4, “Binary Logging of Stored Routines and Triggers”.

This option was added in MySQL 5.0.16.

- `--log-bin-trust-routine-creators[={0|1}]`

This is the old name for `--log-bin-trust-function-creators`. Before MySQL 5.0.16, it also applies to stored procedures, not just stored functions and sets the `log_bin_trust_routine_creators` system variable. As of 5.0.16, this option is deprecated. It is recognized for backward compatibility but its use results in a warning.

This option was added in MySQL 5.0.6.

- `--log-error[=file_name]`

Log errors and startup messages to this file. See Section 5.12.1, “The Error Log”. If you omit the filename, MySQL uses `host_name.err`. If the filename has no extension, the server adds an extension of `.err`.

- `--log-isam[=file_name]`

Log all MyISAM changes to this file (used only when debugging MyISAM).

- `--log-long-format` (*DEPRECATED*)

Log extra information to the update log, binary update log, and slow query log, if they have been activated. For example, the username and timestamp are logged for all queries. This option is deprecated, as it now represents the default logging behavior. (See the description for `--log-short-format`.) The `--log-queries-not-using-indexes` option is available for the purpose of logging queries that do not use indexes to the slow query log.

- `--log-queries-not-using-indexes`

If you are using this option with `--log-slow-queries`, queries that do not use indexes are logged to the slow query log. See Section 5.12.4, “The Slow Query Log”.

- `--log-short-format`

Log less information to the update log, binary update log, and slow query log, if they have been activated. For example, the username and timestamp are not logged for queries.

- `--log-slow-admin-statements`

Log slow administrative statements such as `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `ALTER TABLE` to the slow query log.

- `--log-slow-queries[=file_name]`

Log all queries that have taken more than `long_query_time` seconds to execute to this file. See Section 5.12.4, “The Slow Query Log”. See the descriptions of the `--log-long-format` and `--log-short-format` options for details.

- `--log-warnings[=level], -W [level]`

Print out warnings such as `Aborted connection...` to the error log. Enabling this option is recommended, for example, if you use replication (you get more information about what is happening, such as messages about network failures and reconnections). This option is enabled (1) by default, and the default *level* value if omitted is 1. To disable this option, use `--log-warnings=0`. Aborted connections are not logged to the error log unless the value is greater than 1. See Section A.2.10, “Communication Errors and Aborted Connections”.

- `--low-priority-updates`

Give table-modifying operations (INSERT, REPLACE, DELETE, UPDATE) lower priority than selects. This can also be done via `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query, or by `SET LOW_PRIORITY_UPDATES=1` to change the priority in one thread. See Section 7.3.2, “Table Locking Issues”.

- `--memlock`

Lock the `mysqld` process in memory. This works on systems such as Solaris that support the `mlockall()` system call. This might help if you have a problem where the operating system is causing `mysqld` to swap on disk. Note that use of this option requires that you run the server as `root`, which is normally not a good idea for security reasons. See Section 5.7.5, “How to Run MySQL as a Normal User”.

- `--myisam-recover[=option[,option]...]`

Set the MyISAM storage engine recovery mode. The option value is any combination of the values of `DEFAULT`, `BACKUP`, `FORCE`, or `QUICK`. If you specify multiple values, separate them by commas. You can also use a value of `" "` to disable this option. If this option is used, each time `mysqld` opens a MyISAM table, it checks whether the table is marked as crashed or wasn't closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, `mysqld` runs a check on the table. If the table was corrupted, `mysqld` attempts to repair it.

The following options affect how the repair works:

Option	Description
DEFAULT	The same as not giving any option to <code>--myisam-recover</code> .
BACKUP	If the data file was changed during recovery, save a backup of the <code>tbl_name.MYD</code> file as <code>tbl_name-datetime.BAK</code> .
FORCE	Run recovery even if we would lose more than one row from the <code>.MYD</code> file.
QUICK	Don't check the rows in the table if there aren't any delete blocks.

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options `BACKUP`, `FORCE`. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See Section 14.1.1, “MyISAM Startup Options”.

- `--ndb-connectstring=connect_string`

When using the NDB storage engine, it is possible to point out the management server that distributes the cluster configuration by setting the connect string option. See Section 15.4.4.2, “The MySQL Cluster `connectstring`”, for syntax.

- `--ndbcluster`

If the binary includes support for the NDB `Cluster` storage engine, this option enables the engine, which is disabled by default. See Chapter 15, *MySQL Cluster*.

- `--old-passwords`

Force the server to generate short (pre-4.1) password hashes for new passwords. This is useful for compatibility when the server must support older client programs. See Section 5.8.9, “Password Hashing as of MySQL 4.1”.

- `--one-thread`

Only use one thread (for debugging under Linux). This option is available only if the server is built with debugging enabled. See Section E.1, “Debugging a MySQL Server”.

- `--open-files-limit=count`

Change the number of file descriptors available to `mysqld`. If this option is not set or is set to 0, `mysqld` uses the value to reserve file descriptors with `setrlimit()`. If the value is 0, `mysqld` reserves `max_connections×5` or `max_connections + table_open_cache×2` files (whichever is larger). You should try increasing this value if `mysqld` gives you the error `Too many open files`.

- `--pid-file=path`

The pathname of the process ID file. This file is used by other programs such as `mysqld_safe` to determine the server's process ID.

- `--port=port_num, -P port_num`

The port number to use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--port-open-timeout=num`

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait. This option was added in MySQL 5.0.19.

- `--safe-mode`

Skip some optimization stages.

- `--safe-show-database (DEPRECATED)`

See Section 5.8.3, “Privileges Provided by MySQL”.

- `--safe-user-create`

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement, if the user doesn't have the `INSERT` privilege for the `mysql.user` table or any column in the table.

- `--secure-auth`

Disallow authentication by clients that attempt to use accounts that have old (pre-4.1) passwords.

- `--shared-memory`

Enable shared-memory connections by local clients. This option is available only on Windows.

- `--shared-memory-base-name=name`

The name of shared memory to use for shared-memory connections. This option is available only on Windows. The default name is `MYSQL`. The name is case sensitive.

- `--skip-bdb`

Disable the BDB storage engine. This saves memory and might speed up some operations. Do not use this option if you require BDB tables.

- `--skip-concurrent-insert`

Turn off the ability to select and insert at the same time on MyISAM tables. (This is to be used only if you think you have found a bug in this feature.) See Section 7.3.3, “Concurrent Inserts”.

- `--skip-external-locking`

Do not use external locking (system locking). With external locking disabled, you must shut down the server to use `myisamchk`. (See Section 1.4.3, “MySQL Stability”.) To avoid this requirement, use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables.

External locking has been disabled by default since MySQL 4.0.

- `--skip-grant-tables`

This option causes the server not to use the privilege system at all, which gives anyone with access to the server *unrestricted access to all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement after connecting to the server. This option also suppresses loading of user-defined functions (UDFs).

- `--skip-host-cache`

Do not use the internal hostname cache for faster name-to-IP resolution. Instead, query the DNS server every time a client connects. See Section 7.5.6, “How MySQL Uses DNS”.

- `--skip-innodb`

Disable the InnoDB storage engine. This saves memory and disk space and might speed up some operations. Do not use this option if you require InnoDB tables.

- `--skip-name-resolve`

Do not resolve hostnames when checking client connections. Use only IP numbers. If you use this option, all `Host` column values in the grant tables must be IP numbers or `localhost`. See Section 7.5.6, “How MySQL Uses DNS”.

- `--skip-ndbcluster`

Disable the NDB Cluster storage engine. This is the default for binaries that were built with NDB Cluster storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See Section 15.4.3, “Quick Test Setup of MySQL Cluster”, for an example of usage.

- `--skip-networking`

Don't listen for TCP/IP connections at all. All interaction with `mysqld` must be made via named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are allowed. See Section 7.5.6, “How MySQL Uses DNS”.

- `--standalone`

Available on Windows NT-based systems only; instructs the MySQL server not to run as a service.

- `--symbolic-links`, `--skip-symbolic-links`

Enable or disable symbolic link support. This option has different effects on Windows and Unix:

- On Windows, enabling symbolic links allows you to establish a symbolic link to a database directory by creating a `db_name.sym` file that contains the path to the real directory. See Section 7.6.1.3, “Using Symbolic Links for Databases on Windows”.
- On Unix, enabling symbolic links means that you can link a MyISAM index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` options of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See Section 7.6.1.2, “Using Symbolic Links for Tables on Unix”.

- `--skip-safemalloc`

If MySQL is configured with `--with-debug=full`, all MySQL programs check for memory overruns during each memory allocation and memory freeing operation. This checking is very slow, so for the server you can avoid it when you don't need it by using the `--skip-safemalloc` option.

- `--skip-show-database`

With this option, the `SHOW DATABASES` statement is allowed only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. Without this option, `SHOW DATABASES` is allowed to all users, but displays each database name only if the user has the `SHOW DATABASES` privilege or some privilege for the database. Note that *any* global privilege is considered a privilege for the database.

- `--skip-stack-trace`

Don't write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See Section E.1, “Debugging a MySQL Server”.

- `--skip-thread-priority`

Disable using thread priorities for faster response time.

- `--socket=path`

On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is `/tmp/mysql.sock`. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is `MySQL` (not case sensitive).

- `--sql-mode=value[,value[,value...]]`

Set the SQL mode. See Section 5.2.5, “The Server SQL Mode”.

- `--sysdate-is-now`

As of MySQL 5.0.13, `SYSDATE()` by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of `NOW()`. This option causes `SYSDATE()` to be an alias for `NOW()`. For information about the implications for binary logging and replication, see the description for `SYSDATE()` in Section 12.5, “Date and Time Functions” and for `SET TIMESTAMP` in Section 13.5.3, “SET Syntax”.

This option was added in MySQL 5.0.20.

- `--temp-pool`

This option causes most temporary files created by the server to use a small set of names, rather than a unique name for each new file. This works around a problem in the Linux kernel dealing

with creating many new files with different names. With the old behavior, Linux seems to “leak” memory, because it is being allocated to the directory entry cache rather than to the disk cache.

- `--transaction-isolation=level`

Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. See Section 13.4.6, “SET TRANSACTION Syntax”.

- `--tmpdir=path, -t path`

The path of the directory to use for creating temporary files. It might be useful if your default /tmp directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (‘:’) on Unix and semicolon characters (‘;’) on Windows, NetWare, and OS/2. If the MySQL server is acting as a replication slave, you should not set `--tmpdir` to point to a directory on a memory-based filesystem or to a directory that is cleared when the server host restarts. For more information about the storage location of temporary files, see Section A.4.4, “Where MySQL Stores Temporary Files”. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

- `--user={user_name|user_id}, -u {user_name|user_id}`

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is *mandatory* when starting `mysqld` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See Section 5.7.1, “General Security Guidelines”.

To avoid a possible security hole where a user adds a `--user=root` option to a `my.cnf` file (thus causing the server to run as `root`), `mysqld` uses only the first `--user` option specified and produces a warning if there are multiple `--user` options. Options in `/etc/my.cnf` and `$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user` option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` option is found.

- `--version, -V`

Display version information and exit.

You can assign a value to a server system variable by using an option of the form `--var_name=value`. For example, `--key_buffer_size=32M` sets the `key_buffer_size` variable to a value of 32MB.

Note that when you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest allowable value if only certain values are allowed.

If you want to restrict the maximum value to which a variable can be set at runtime with `SET`, you can define this by using the `--maximum-var_name=value` command-line option.

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. *This syntax is deprecated.*

You can change the values of most system variables for a running server with the `SET` statement.

See Section 13.5.3, “SET Syntax”.

Section 5.2.2, “Server System Variables”, provides a full description for all variables, and additional information for setting them at server startup and runtime. Section 7.5.2, “Tuning Server Parameters”, includes information on optimizing the server by tuning system variables.

## 5.2.2. Server System Variables

The `mysql` server maintains many system variables that indicate how it is configured. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

There are several ways to see the names and values of system variables:

- To see the values that a server will use based on its compiled-in defaults and any option files that it reads, use this command:

```
mysqld --verbose --help
```

- To see the values that a server will use based on its compiled-in defaults, ignoring the settings in any option files, use this command:

```
mysqld --no-defaults --verbose --help
```

- To see the current values used by a running server, use the `SHOW VARIABLES` statement.

This section provides a description of each system variable. Variables with no version indicated are present in all MySQL 5.0 releases. For historical information concerning their implementation, please see *MySQL 3.23, 4.0, 4.1 Reference Manual*.

For additional system variable information, see these sections:

- Section 5.2.3, “Using System Variables”, discusses the syntax for setting and displaying system variable values.
- Section 5.2.3.2, “Dynamic System Variables”, lists the variables that can be set at runtime.
- Information on tuning system variables can be found in Section 7.5.2, “Tuning Server Parameters”.
- Section 14.2.4, “InnoDB Startup Options and System Variables”, lists InnoDB system variables.

*Note:* Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

- `auto_increment_increment`

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables can be set globally or locally, and each can as-

sume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a non-integer value gives rise to an error, and the actual value of the variable remains unchanged.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
```

Variable_name	Value
<code>auto_increment_increment</code>	1
<code>auto_increment_offset</code>	1

```
2 rows in set (0.00 sec)
```

```
mysql> CREATE TABLE autoincl
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)
```

```
mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
```

Variable_name	Value
<code>auto_increment_increment</code>	10
<code>auto_increment_offset</code>	1

```
2 rows in set (0.01 sec)
```

```
mysql> INSERT INTO autoincl VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT col FROM autoincl;
```

col
1
11
21
31

```
4 rows in set (0.00 sec)
```

(Note how `SHOW VARIABLES` is used here to obtain the current values for these variables.)

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
```

Variable_name	Value
---------------	-------

```

| auto_increment_increment | 10 |
| auto_increment_offset   | 5  |
+-----+-----+
2 rows in set (0.00 sec)

```

```

mysql> CREATE TABLE autoinc2
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

```

```

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

```

```

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5   |
| 15  |
| 25  |
| 35  |
+-----+
4 rows in set (0.02 sec)

```

If the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. In other words, the series is calculated like so:

$$\text{auto\_increment\_offset} + N \times \text{auto\_increment\_increment}$$

where  $N$  is a positive integer value in the series [1, 2, 3, ...]. For example:

```

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| auto_increment_increment | 10   |
| auto_increment_offset   | 5    |
+-----+-----+
2 rows in set (0.00 sec)

```

```

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1   |
| 11  |
| 21  |
| 31  |
+-----+
4 rows in set (0.00 sec)

```

```

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

```

```

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+

```

```

  1
 11
 21
 31
 35
 45
 55
 65
+-----+
8 rows in set (0.00 sec)

```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series  $5 + N \times 10$ , that is, [5, 15, 25, 35, 45, ...]. The greatest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is important to remember that it is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If one of these variables is set globally, its effects persist until the global value is changed or overridden by setting them locally, or until `mysqld` is restarted. If set locally, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The `auto_increment_increment` variable was added in MySQL 5.0.2. Its default value is 1. See Section 6.13, “Auto-Increment in Multiple-Master Replication”.

- `auto_increment_offset`

This variable was introduced in MySQL 5.0.2. Its default value is 1. For particulars, see the description for `auto_increment_increment`.

- `back_log`

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` cannot be set higher than your operating system limit.

- `basedir`

The MySQL installation base directory. This variable can be set with the `--basedir` option.

- `bdb_cache_size`

The size of the buffer that is allocated for caching indexes and rows for BDB tables. If you don't use BDB tables, you should start `mysqld` with `--skip-bdb` to not allocate memory for this cache.

- `bdb_home`

The base directory for BDB tables. This should be assigned the same value as the `datadir` variable.

- `bdb_log_buffer_size`

The size of the buffer that is allocated for caching indexes and rows for BDB tables. If you don't use BDB tables, you should set this to 0 or start `mysqld` with `--skip-bdb` to not allocate memory for this cache.

- `bdb_logdir`

The directory where the BDB storage engine writes its log files. This variable can be set with the `--bdb-logdir` option.

- `bdb_max_lock`

The maximum number of locks that can be active for a BDB table (10,000 by default). You should increase this value if errors such as the following occur when you perform long transactions or when `mysqld` has to examine many rows to calculate a query:

```
bdb: Lock table is out of available locks
Got error 12 from ...
```

- `bdb_shared_data`

This is ON if you are using `--bdb-shared-data` to start Berkeley DB in multi-process mode. (Do not use `DB_PRIVATE` when initializing Berkeley DB.)

- `bdb_tmpdir`

The BDB temporary file directory.

- `binlog_cache_size`

The size of the cache to hold the SQL statements for the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large, multiple-statement transactions, you can increase this cache size to get more performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.12.3, “The Binary Log”.

- `bulk_insert_buffer_size`

MyISAM uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...), (...), ...`, and `LOAD DATA INFILE` when adding data to non-empty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

- `character_set_client`

The character set for statements that arrive from the client.

- `character_set_connection`

The character set used for literals that do not have a character set introducer and for number-to-string conversion.

- `character_set_database`

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

- `character_set_filesystem`

The filesystem character set. This variable is used to interpret string literals that refer to file-

names, such as in the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such filenames are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multi-byte filenames are allowed, a different value may be more appropriate. For example, if the system represents filenames using UTF-8, set `character_set_filesystem` to `'utf8'`. This variable was added in MySQL 5.0.19.

- `character_set_results`

The character set used for returning query results to the client.

- `character_set_server`

The server's default character set.

- `character_set_system`

The character set used by the server for storing identifiers. The value is always `utf8`.

- `character_sets_dir`

The directory where character sets are installed.

- `collation_connection`

The collation of the connection character set.

- `collation_database`

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server`.

- `collation_server`

The server's default collation.

- `completion_type`

The transaction completion type:

- If the value is 0 (the default), `COMMIT` and `ROLLBACK` are unaffected.
- If the value is 1, `COMMIT` and `ROLLBACK` are equivalent to `COMMIT AND CHAIN` and `ROLLBACK AND CHAIN`, respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.)
- If the value is 2, `COMMIT` and `ROLLBACK` are equivalent to `COMMIT RELEASE` and `ROLLBACK RELEASE`, respectively. (The server disconnects after terminating the transaction.)

This variable was added in MySQL 5.0.3

- `concurrent_insert`

If `ON` (the default), MySQL allows `INSERT` and `SELECT` statements to run concurrently for MyISAM tables that have no free blocks in the middle. You can turn this option off by starting `mysqld` with `--safe` or `--skip-new`.

In MySQL 5.0.6, this variable was changed to take three integer values:

Value	Description
-------	-------------

0	Off
1	(Default) Enables concurrent insert for MyISAM tables that don't have holes
2	Enables concurrent inserts for all MyISAM tables. If table has a hole and is in use by another thread the new row will be inserted at end of table. If table is not in use, MySQL does a normal read lock and inserts the new row into the hole.

See also Section 7.3.3, “Concurrent Inserts”.

- `connect_timeout`

The number of seconds that the `mysqld` server waits for a connect packet before responding with `Bad handshake`.

- `datadir`

The MySQL data directory. This variable can be set with the `--datadir` option.

- `date_format`

This variable is not implemented.

- `datetime_format`

This variable is not implemented.

- `default_week_format`

The default mode value to use for the `WEEK()` function. See Section 12.5, “Date and Time Functions”.

- `delay_key_write`

This option applies only to MyISAM tables. It can have one of the following values to affect handling of the `DELAY_KEY_WRITE` table option that can be used in `CREATE TABLE` statements.

Option	Description
OFF	<code>DELAY_KEY_WRITE</code> is ignored.
ON	MySQL honors any <code>DELAY_KEY_WRITE</code> option specified in <code>CREATE TABLE</code> statements. This is the default value.
ALL	All new opened tables are treated as if they were created with the <code>DELAY_KEY_WRITE</code> option enabled.

If `DELAY_KEY_WRITE` is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all MyISAM tables by starting the server with the `--myisam-recover` option (for example, `--myisam-recover=BACKUP, FORCE`). See Section 5.2.1, “`mysqld` Command Options”, and Section 14.1.1, “MyISAM Startup Options”.

Note that enabling external locking with `--external-locking` offers no protection against index corruption for tables that use delayed key writes.

- `delayed_insert_limit`

After inserting `delayed_insert_limit` delayed rows, the `INSERT DELAYED` handler thread checks whether there are any `SELECT` statements pending. If so, it allows them to execute before continuing to insert delayed rows.

- `delayed_insert_timeout`

How many seconds an `INSERT DELAYED` handler thread should wait for `INSERT` statements before terminating.

- `delayed_queue_size`

This is a per-table limit on the number of rows to queue when handling `INSERT DELAYED` statements. If the queue becomes full, any client that issues an `INSERT DELAYED` statement waits until there is room in the queue again.

- `div_precision_increment`

This variable indicates the number of digits of precision by which to increase the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+-----+
| 1/7   |
+-----+
| 0.1429|
+-----+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+-----+
| 1/7   |
+-----+
| 0.142857142857|
+-----+
```

This variable was added in MySQL 5.0.6.

- `engine_condition_pushdown`

This variable applies to NDB. By default it is 0 (OFF): If you execute a query such as `SELECT * FROM t WHERE mycol = 42`, where `mycol` is a non-indexed column, the query is executed as a full table scan on every NDB node. Each node sends every row to the MySQL server, which applies the `WHERE` condition. If `engine_condition_pushdown` is set to 1 (ON), the condition is “pushed down” to the storage engine and sent to the NDB nodes. Each node uses the condition to perform the scan, and only sends back to the MySQL server the rows that match the condition.

This variable was added in MySQL 5.0.3. Before that, the default NDB behavior is the same as for a value of OFF.

- `expire_logs_days`

The number of days for automatic binary log removal. The default is 0, which means “no automatic removal.” Possible removals happen at startup and at binary log rotation.

- `flush`

If ON, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section A.4.2, “What to Do If MySQL Keeps Crashing”. This variable is set to ON if you start `mysqld` with the `--flush` option.

- `flush_time`

If this is set to a non-zero value, all tables are closed every `flush_time` seconds to free up resources and synchronize unflushed data to disk. We recommend that this option be used only on Windows 9x or Me, or on systems with minimal resources.

- `ft_boolean_syntax`

The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See Section 12.7.1, “Boolean Full-Text Searches”.

The default variable value is `' + -><()~*:""&| '`. The rules for changing the value are as follows:

- Operator function is determined by position within the string.
- The replacement value must be 14 characters.
- Each character must be an ASCII non-alphanumeric character.
- Either the first or second character must be a space.
- No duplicates are allowed except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
- Positions 10, 13, and 14 (which by default are set to `'`, `&`, and `|`) are reserved for future extensions.

- `ft_max_word_len`

The maximum length of the word to be included in a `FULLTEXT` index.

**Note:** `FULLTEXT` indexes must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_min_word_len`

The minimum length of the word to be included in a `FULLTEXT` index.

**Note:** `FULLTEXT` indexes must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_query_expansion_limit`

The number of top matches to use for full-text searches performed using `WITH QUERY EXPANSION`.

- `ft_stopword_file`

The file from which to read the list of stopwords for full-text searches. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the `mysam/ft_static.c` file). Setting this variable to the empty string (`' '`) disables stopword filtering.

**Note:** `FULLTEXT` indexes must be rebuilt after changing this variable or the contents of the stopword file. Use `REPAIR TABLE tbl_name QUICK`.

- `group_concat_max_len`

The maximum allowed result length for the `GROUP_CONCAT()` function. The default is 1024.

- `have_archive`

YES if `mysqld` supports ARCHIVE tables, NO if not.

- `have_bdb`

YES if `mysqld` supports BDB tables. DISABLED if `--skip-bdb` is used.

- `have_blackhole_engine`

YES if `mysqld` supports `BLACKHOLE` tables, NO if not.

- `have_compress`

YES if the `zlib` compression library is available to the server, NO if not. If not, the `COMPRESS()` and `UNCOMPRESS()` functions cannot be used.

- `have_crypt`

YES if the `crypt()` system call is available to the server, NO if not. If not, the `ENCRYPT()` function cannot be used.

- `have_csv`

YES if `mysqld` supports `ARCHIVE` tables, NO if not.

- `have_example_engine`

YES if `mysqld` supports `EXAMPLE` tables, NO if not.

`have_federated_engine`

YES if `mysqld` supports `FEDERATED` tables, NO if not. This variable was added in MySQL 5.0.3.

- `have_geometry`

YES if the server supports spatial data types, NO if not.

- `have_innodb`

YES if `mysqld` supports `InnoDB` tables. `DISABLED` if `--skip-innodb` is used.

- `have_isam`

In MySQL 5.0, this variable appears only for reasons of backward compatibility. It is always `NO` because `ISAM` tables are no longer supported.

- `have_ndbcluster`

YES if `mysqld` supports `NDB Cluster` tables. `DISABLED` if `--skip-ndbcluster` is used.

- `have_openssl`

YES if `mysqld` supports `SSL` connections, NO if not.

- `have_query_cache`

YES if `mysqld` supports the query cache, NO if not.

- `have_raid`

In MySQL 5.0, this variable appears only for reasons of backward compatibility. It is always `NO` because `RAID` tables are no longer supported.

- `have_rtree_keys`

YES if `RTREE` indexes are available, NO if not. (These are used for spatial indexes in `MyISAM` tables.)

- `have_symlink`

YES if symbolic link support is enabled, NO if not. This is required on `Unix` for support of the

DATA DIRECTORY and INDEX DIRECTORY table options, and on Windows for support of data directory symlinks.

- `init_connect`

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements. To specify multiple statements, separate them by semicolon characters. For example, each client begins by default with autocommit mode enabled. There is no global system variable to specify that autocommit should be disabled by default, but `init_connect` can be used to achieve the same effect:

```
SET GLOBAL init_connect='SET AUTOCOMMIT=0';
```

This variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

```
[mysqld]
init_connect='SET AUTOCOMMIT=0'
```

Note that the content of `init_connect` is not executed for users that have the SUPER privilege. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the SUPER privilege enables them to open a connection and fix the `init_connect` value.

- `init_file`

The name of the file specified with the `--init-file` option when you start the server. This should be a file containing SQL statements that you want the server to execute when it starts. Each statement must be on a single line and should not include comments.

- `init_slave`

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable.

- `innodb_xxx`

InnoDB system variables are listed in Section 14.2.4, “InnoDB Startup Options and System Variables”.

- `interactive_timeout`

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout`.

- `join_buffer_size`

The size of the buffer that is used for joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

- `key_buffer_size`

Index blocks for MyISAM tables are buffered and are shared by all threads. `key_buffer_size` is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum allowable setting for `key_buffer_size` is 4GB. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform.

Increase the value to get better index handling (for all reads and multiple writes) to as much as you can afford. Using a value that is 25% of total memory on a machine that mainly runs MySQL is quite common. However, if you make the value too large (for example, more than 50% of your total memory) your system might start to page and become extremely slow. MySQL relies on the operating system to perform filesystem caching for data reads, so you must leave some room for the filesystem cache. Consider also the memory requirements of other storage engines.

For even more speed when writing many rows at the same time, use `LOCK TABLES`. See Section 7.2.16, “Speed of `INSERT` Statements”.

You can check the performance of the key buffer by issuing a `SHOW STATUS` statement and examining the `Key_read_requests`, `Key_reads`, `Key_write_requests`, and `Key_writes` status variables. (See Section 13.5.4, “`SHOW` Syntax”.) The `Key_reads/Key_read_requests` ratio should normally be less than 0.01. The `Key_writes/Key_write_requests` ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the `DELAY_KEY_WRITE` table option.

The fraction of the key buffer in use can be determined using `key_buffer_size` in conjunction with the `Key_blocks_unused` status variable and the buffer block size, which is available from the `key_cache_block_size` system variable:

$$1 - ((\text{Key\_blocks\_unused} \times \text{key\_cache\_block\_size}) / \text{key\_buffer\_size})$$

This value is an approximation because some space in the key buffer may be allocated internally for administrative structures.

It is possible to create multiple MyISAM key caches. The size limit of 4GB applies to each cache individually, not as a group. See Section 7.4.6, “The MyISAM Key Cache”.

- `key_cache_age_threshold`

This value controls the demotion of buffers from the hot sub-chain of a key cache to the warm sub-chain. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See Section 7.4.6, “The MyISAM Key Cache”.

- `key_cache_block_size`

The size in bytes of blocks in the key cache. The default value is 1024. See Section 7.4.6, “The MyISAM Key Cache”.

- `key_cache_division_limit`

The division point between the hot and warm sub-chains of the key cache buffer chain. The value is the percentage of the buffer chain to use for the warm sub-chain. Allowable values range from 1 to 100. The default value is 100. See Section 7.4.6, “The MyISAM Key Cache”.

- `language`

The language used for error messages.

- `large_file_support`

Whether `mysqld` was compiled with options for large file support.

- `large_pages`

Whether large page support is enabled. This variable was added in MySQL 5.0.3.

- `license`

The type of license the server has.

- `local_infile`

Whether LOCAL is supported for LOAD DATA INFILE statements. See Section 5.7.4, “Security Issues with LOAD DATA LOCAL”.

- `locked_in_memory`

Whether mysqld was locked in memory with `--memlock`.

- `log`

Whether logging of all statements to the general query log is enabled. See Section 5.12.2, “The General Query Log”.

- `log_bin`

Whether the binary log is enabled. See Section 5.12.3, “The Binary Log”.

- `log_bin_trust_function_creators`

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that will cause unsafe events to be written to the binary log. If set to 0 (the default), users are not allowed to create or alter stored functions unless they have the SUPER privilege in addition to the CREATE ROUTINE or ALTER ROUTINE privilege. A setting of 0 also enforces the restriction that a function must be declared with the DETERMINISTIC characteristic, or with the READS SQL DATA or NO SQL characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. See Section 17.4, “Binary Logging of Stored Routines and Triggers”.

This variable was added in MySQL 5.0.16.

- `log_bin_trust_routine_creators`

This is the old name for `log_bin_trust_function_creators`. Before MySQL 5.0.16, it also applies to stored procedures, not just stored functions. As of 5.0.16, this variable is deprecated. It is recognized for backward compatibility but its use results in a warning.

This variable was added in MySQL 5.0.6.

- `log_error`

The location of the error log.

- `log_slave_updates`

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See Section 6.8, “Replication Startup Options”.

- `log_slow_queries`

Whether slow queries should be logged. “Slow” is determined by the value of the `long_query_time` variable. See Section 5.12.4, “The Slow Query Log”.

- `log_warnings`

Whether to produce additional warning messages. It is enabled (1) by default. Aborted connec-

tions are not logged to the error log unless the value is greater than 1.

- `long_query_time`

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If you are using the `--log-slow-queries` option, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum value is 1. The default is 10. See Section 5.12.4, “The Slow Query Log”.

- `low_priority_updates`

If set to 1, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. This variable previously was named `sql_low_priority_updates`.

- `lower_case_file_system`

This variable describes the case sensitivity of filenames on the filesystem where the data directory is located. `OFF` means filenames are case sensitive, `ON` means they are not case sensitive.

- `lower_case_table_names`

If set to 1, table names are stored in lowercase on disk and table name comparisons are not case sensitive. If set to 2 table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. See Section 9.2.2, “Identifier Case Sensitivity”.

If you are using InnoDB tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

You should *not* set this variable to 0 if you are running MySQL on a system that does not have case-sensitive filenames (such as Windows or Mac OS X). If this variable is not set at startup and the filesystem on which the data directory is located does not have case-sensitive filenames, MySQL automatically sets `lower_case_table_names` to 2.

- `max_allowed_packet`

The maximum size of one packet or any generated/intermediate string.

The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large BLOB columns or long strings. It should be as big as the largest BLOB you want to use. The protocol limit for `max_allowed_packet` is 1GB.

- `max_binlog_cache_size`

If a multiple-statement transaction requires more than this amount of memory, the server generates a Multi-statement transaction required more than 'max\_binlog\_cache\_size' bytes of storage error.

- `max_binlog_size`

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). You cannot set this variable to more than 1GB or to less than 4096 bytes. The default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary logs larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `max_connect_errors`

If there are more than this number of interrupted connections from a host, that host is blocked from further connections. You can unblock blocked hosts with the `FLUSH HOSTS` statement.

- `max_connections`

The number of simultaneous client connections allowed. Increasing this value increases the number of file descriptors that `mysqld` requires. See Section 7.4.8, “How MySQL Opens and Closes Tables”, for comments on file descriptor limits. See also Section A.2.6, “Too many connections”.

- `max_delayed_threads`

Do not start more than this number of threads to handle `INSERT DELAYED` statements. If you try to insert data into a new table after all `INSERT DELAYED` threads are in use, the row is inserted as if the `DELAYED` attribute wasn't specified. If you set this to 0, MySQL never creates a thread to handle `DELAYED` rows; in effect, this disables `DELAYED` entirely.

- `max_error_count`

The maximum number of error, warning, and note messages to be stored for display by the `SHOW ERRORS` and `SHOW WARNINGS` statements.

- `max_heap_table_size`

This variable sets the maximum size to which `MEMORY` tables are allowed to grow. The value of the variable is used to calculate `MEMORY` table `MAX_ROWS` values. Setting this variable has no effect on any existing `MEMORY` table, unless the table is re-created with a statement such as `CREATE TABLE` or altered with `ALTER TABLE` or `TRUNCATE TABLE`.

- `max_insert_delayed_threads`

This variable is a synonym for `max_delayed_threads`.

- `max_join_size`

Do not allow `SELECT` statements that probably need to examine more than `max_join_size` rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` disk seeks. By setting this value, you can catch `SELECT` statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows.

Setting this variable to a value other than `DEFAULT` resets the value of `SQL_BIG_SELECTS` to 0. If you set the `SQL_BIG_SELECTS` value again, the `max_join_size` variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

This variable previously was named `sql_max_join_size`.

- `max_length_for_sort_data`

The cutoff on the size of index values that determines which `filesort` algorithm to use. See Section 7.2.12, “`ORDER BY` Optimization”.

- `max_prepared_stmt_count`

This variable limits the total number of prepared statements in the server. It can be used in envir-

onments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. The default value is 16,382. The allowable range of values is from 0 to 1 million. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. This variable was added in MySQL 5.0.21.

- `max_relay_log_size`

If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If `max_relay_log_size` is 0, the server uses `max_binlog_size` for both the binary log and the relay log. If `max_relay_log_size` is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set `max_relay_log_size` to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See Section 6.3, “Replication Implementation Details”.

- `max_seeks_for_key`

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see Section 13.5.4.13, “SHOW INDEX Syntax”). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- `max_sort_length`

The number of bytes to use when sorting BLOB or TEXT values. Only the first `max_sort_length` bytes of each value are used; the rest are ignored.

- `max_tmp_tables`

The maximum number of temporary tables a client can keep open at the same time. (This option does not yet do anything.)

- `max_user_connections`

The maximum number of simultaneous connections allowed to any given MySQL account. A value of 0 means “no limit.”

Before MySQL 5.0.3, this variable has only global scope. Beginning with MySQL 5.0.3, it also has a read-only session scope. The session variable has the same value as the global variable unless the current account has a non-zero `MAX_USER_CONNECTIONS` resource limit. In that case, the session value reflects the account limit.

- `max_write_lock_count`

After this many write locks, allow some pending read lock requests to be processed in between.

- `myisam_data_pointer_size`

The default pointer size in bytes, to be used by `CREATE TABLE` for MyISAM tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6 (4 before MySQL 5.0.6). This variable was added in MySQL 4.1.2. See Section A.2.11, “The table is full”.

- `myisam_max_extra_sort_file_size` (*DEPRECATED*)

If the temporary file used for fast MyISAM index creation would be larger than using the key cache by the amount specified here, prefer the key cache method. This is mainly used to force long character keys in large tables to use the slower key cache method to create the index. The value is given in bytes.

**Note:** This variable was removed in MySQL 5.0.6.

- `myisam_max_sort_file_size`

The maximum size of the temporary file that MySQL is allowed to use while re-creating a MyISAM index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- `myisam_recover_options`

The value of the `--myisam-recover` option. See Section 5.2.1, “`mysqld` Command Options”.

- `myisam_repair_threads`

If this value is greater than 1, MyISAM table indexes are created in parallel (each index in its own thread) during the `Repair by sorting` process. The default value is 1.

**Note:** Multi-threaded repair is still *beta-quality* code.

- `myisam_sort_buffer_size`

The size of the buffer that is allocated when sorting MyISAM indexes during a `REPAIR TABLE` or when creating indexes with `CREATE INDEX` or `ALTER TABLE`.

- `myisam_stats_method`

How the server treats NULL values when collecting statistics about the distribution of index values for MyISAM tables. This variable has two possible values, `nulls_equal` and `nulls_unequal`. For `nulls_equal`, all NULL index values are considered equal and form a single value group that has a size equal to the number of NULL values. For `nulls_unequal`, NULL values are considered unequal, and each NULL forms a distinct value group of size 1.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in Section 7.4.7, “MyISAM Index Statistics Collection”.

This variable was added in MySQL 5.0.14. For older versions, the statistics collection method is equivalent to `nulls_equal`.

- `multi_read_range`

Specifies the maximum number of ranges to send to a storage engine during range selects. The default value is 256. Sending multiple ranges to an engine is a feature that can improve the performance of certain selects dramatically, particularly for NDBCLUSTER. This engine needs to send the range requests to all nodes, and sending many of those requests at once reduces the communication costs significantly. This variable was added in MySQL 5.0.3.

- `named_pipe`

(Windows only.) Indicates whether the server supports connections over named pipes.

- `ndb_autoincrement_prefetch_sz`

Determines the probability of gaps in an autoincremented column. Set to 1 to minimize this. Set to a high value for optimization — makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. Default value: 32. Minimum value: 1.

- `ndb_cache_check_time`

The number of seconds to wait before checking the NDB query cache. Setting this to 0 (the de-

fault and minimum value) means that the NDB query cache will be checked for validation upon each query. A large value means the NDB query cache will seldom be checked and invalidated because of updates on another `mysqld`. It is generally not desirable to set this to a value greater than 2.

- `ndb_force_send`

Forces sending of buffers to NDB immediately, without waiting for other threads. Defaults to ON.

- `ndb_index_stat_cache_entries`

Sets the granularity of the statistics by determining the number of starting and ending keys to store in the statistics memory cache. Zero means no caching takes place; in this case, the data nodes are always queries directly. Default value: 32.

- `ndb_index_stat_enable`

Use NDB index statistics in query optimization. Defaults to ON.

- `ndb_index_stat_update_freq`

How often to query data nodes instead of the statistics cache. For example, a value of 20 (the default) means to direct every 20<sup>th</sup> query to the data nodes.

- `ndb_report_thresh_binlog_epoch_slip`

This is a threshold on the number of epochs to be behind before reporting binlog status. For example, a value of 3 (the default) means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binlog is 3 or more, a status message will be sent to the cluster log.

- `ndb_report_thresh_binlog_mem_usage`

This is a threshold on the percentage of free memory remaining before reporting binlog status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binlog data from the data nodes falls below 10%, a status message will be sent to the cluster log.

- `ndb_use_exact_count`

Forces NDB to use an count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is ON. For faster queries overall, disable this feature by setting the value of `ndb_use_exact_count` to OFF.

- `ndb_use_transactions`

You can disable NDB transaction support by setting this variable's values to OFF (not recommended). The default is ON.

- `net_buffer_length`

The communication buffer is reset to this size between SQL statements. This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the buffer is automatically enlarged, up to `max_allowed_packet` bytes.

- `net_read_timeout`

The number of seconds to wait for more data from a connection before aborting the read. This timeout applies only to TCP/IP connections, not to connections made via Unix socket files, named pipes, or shared memory. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `slave_net_timeout`.

- `net_retry_count`

If a read on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- `net_write_timeout`

The number of seconds to wait for a block to be written to a connection before aborting the write. This timeout applies only to TCP/IP connections, not to connections made via Unix socket files, named pipes, or shared memory. See also `net_read_timeout`.

- `new`

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. In MySQL 5.0, its value is always `OFF`.

- `old_passwords`

Whether the server should use pre-4.1-style passwords for MySQL user accounts. See Section A.2.3, “Client does not support authentication protocol”.

- `one_shot`

This is not a variable, but it can be used when setting some variables. It is described in Section 13.5.3, “SET Syntax”.

- `open_files_limit`

The number of files that the operating system allows `mysqld` to open. This is the real value allowed by the system and might be different from the value you gave using the `--open-files-limit` option to `mysqld` or `mysqld_safe`. The value is 0 on systems where MySQL can't change the number of open files.

- `optimizer_prune_level`

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans. This variable was added in MySQL 5.0.1.

- `optimizer_search_depth`

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value. If set to the maximum number of tables used in a query plus 2, the optimizer switches to the algorithm used in MySQL 5.0.0 (and previous versions) for performing searches. This variable was added in MySQL 5.0.1.

- `pid_file`

The pathname of the process ID (PID) file. This variable can be set with the `--pid-file` option.

- `port`

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- `preload_buffer_size`

The size of the buffer that is allocated when preloading indexes.

- `prepared_stmt_count`

The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.) This variable was added in MySQL 5.0.21.

- `protocol_version`

The version of the client/server protocol used by the MySQL server.

- `query_alloc_block_size`

The allocation size of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this a bit.

- `query_cache_limit`

Don't cache results that are larger than this number of bytes. The default value is 1MB.

- `query_cache_min_res_unit`

The minimum size (in bytes) for blocks allocated by the query cache. The default value is 4096 (4KB). Tuning information for this variable is given in Section 5.14.3, "Query Cache Configuration".

- `query_cache_size`

The amount of memory allocated for caching query results. The default value is 0, which disables the query cache. The allowable values are multiples of 1024; other values are rounded down to the nearest multiple. Note that `query_cache_size` bytes of memory are allocated even if `query_cache_type` is set to 0. See Section 5.14.3, "Query Cache Configuration", for more information.

- `query_cache_type`

Set the query cache type. Setting the GLOBAL value sets the type for all clients that connect thereafter. Individual clients can set the SESSION value to affect their own use of the query cache. Possible values are shown in the following table:

Option	Description
0 or OFF	Don't cache results in or retrieve results from the query cache. Note that this does not deallocate the query cache buffer. To do that, you should set <code>query_cache_size</code> to 0.
1 or ON	Cache all query results except for those that begin with <code>SELECT SQL_NO_CACHE</code> .
2 or DEMAND	Cache results only for queries that begin with <code>SELECT SQL_CACHE</code> .

This variable defaults to ON.

- `query_cache_wlock_invalidate`

Normally, when one client acquires a WRITE lock on a MyISAM table, other clients are not blocked from issuing statements that read from the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a WRITE lock for a table to invalidate any queries in the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect.

- `query_prealloc_size`

The size of the persistent buffer used for statement parsing and execution. This buffer is not

freed between statements. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

- `range_alloc_block_size`

The size of blocks that are allocated when doing range optimization.

- `read_buffer_size`

Each thread that does a sequential scan allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072.

- `read_only`

When the variable is set to `ON` for a replication slave server, it causes the slave to allow no updates except from slave threads or from users that have the `SUPER` privilege. This can be useful to ensure that a slave server accepts updates only from its master server and not from clients. As of MySQL 5.0.16, this variable does not apply to `TEMPORARY` tables.

- `relay_log_purge`

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is `1` (`ON`).

- `read_rnd_buffer_size`

When reading rows in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. Setting the variable to a large value can improve `ORDER BY` performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

- `secure_auth`

If the MySQL server has been started with the `--secure-auth` option, it blocks connections from all accounts that have passwords stored in the old (pre-4.1) format. In that case, the value of this variable is `ON`, otherwise it is `OFF`.

You should enable this option if you want to prevent all use of passwords employing the old format (and hence insecure communication over the network).

Server startup fails with an error if this option is enabled and the privilege tables are in pre-4.1 format. See Section A.2.3, “Client does not support authentication protocol”.

- `server_id`

The server ID. This value is set by the `--server-id` option. It is used for replication to enable master and slave servers to identify themselves uniquely.

- `shared_memory`

(Windows only.) Whether the server allows shared-memory connections.

- `shared_memory_base_name`

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is `MYSQL`. The name is case sensitive.

- `skip_external_locking`

This is OFF if `mysqld` uses external locking, ON if external locking is disabled.

- `skip_networking`

This is ON if the server allows only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. On NetWare, only TCP/IP connections are supported, so do not set this variable to ON. This variable can be set to ON with the `--skip-networking` option.

- `skip_show_database`

This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES` privilege: If the variable value is ON, the `SHOW DATABASES` statement is allowed only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. If the value is OFF, `SHOW DATABASES` is allowed to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` or other privilege.

- `slave_compressed_protocol`

Whether to use compression of the slave/master protocol if both the slave and the master support it.

- `slave_load_tmpdir`

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements.

- `slave_net_timeout`

The number of seconds to wait for more data from a master/slave connection before aborting the read. This timeout applies only to TCP/IP connections, not to connections made via Unix socket files, named pipes, or shared memory.

- `slave_skip_errors`

The replication errors that the slave should skip (ignore).

- `slave_transaction_retries`

If a replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or exceeded InnoDB's `innodb_lock_wait_timeout` or NDBCluster's `Transaction-DeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default prior to MySQL 4.0.3 is 0. You must explicitly set the value greater than 0 to enable the “retry” behavior, which is probably a good idea. In MySQL 5.0.3 or newer, the default is 10.

- `slow_launch_time`

If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` status variable.

- `socket`

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case sensitive).

- `sort_buffer_size`

Each thread that needs to do a sort allocates a buffer of this size. Increase this value for faster `ORDER BY` or `GROUP BY` operations. See Section A.4.4, “Where MySQL Stores Temporary Files”.

- `sql_mode`

The current server SQL mode, which can be set dynamically. See Section 5.2.5, “The Server SQL Mode”.

- `sql_slave_skip_counter`

The number of events from the master that a slave server should skip. See Section 13.6.2.6, “`SET GLOBAL SQL_SLAVE_SKIP_COUNTER` Syntax”.

- `storage_engine`

The default storage engine (table type). To set the storage engine at server startup, use the `--default-storage-engine` option. See Section 5.2.1, “`mysqld` Command Options”.

- `sync_binlog`

If the value of this variable is positive, the MySQL server synchronizes its binary log to disk (using `fdatasync()`) after every `sync_binlog` writes to the binary log. Note that there is one write to the binary log per statement if `autocommit` is enabled, and one write per transaction otherwise. The default value is 0, which does no synchronizing to disk. A value of 1 is the safest choice, because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

If the value of `sync_binlog` is 0 (the default), no extra flushing is done. The server relies on the operating system to flush the file contents occasionally as for any other file.

- `sync_frm`

If this variable is set to 1, when any non-temporary table is created its `.frm` file is synchronized to disk (using `fdatasync()`). This is slower but safer in case of a crash. The default is 1.

- `system_time_zone`

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. Typically the time zone is specified by the `TZ` environment variable. It also can be specified using the `--timezone` option of the `mysqld_safe` script.

The `system_time_zone` variable differs from `time_zone`. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See Section 5.11.8, “MySQL Server Time Zone Support”.

- `table_cache`

The number of open tables for all threads. Increasing this value increases the number of file descriptors that `mysqld` requires. You can check whether you need to increase the table cache by checking the `Opened_tables` status variable. See Section 5.2.4, “Server Status Variables”. If the value of `Opened_tables` is large and you don't do `FLUSH TABLES` often (which just forces all tables to be closed and reopened), then you should increase the value of the `table_cache` variable. For more information about the table cache, see Section 7.4.8, “How MySQL Opens and Closes Tables”.

- `table_lock_wait_timeout`

Specifies a wait timeout for table-level locks, in seconds. The default timeout is 50 seconds. The timeout is active only if the connection has open cursors. This variable can also be set globally

at runtime (you need the `SUPER` privilege to do this). It's available as of MySQL 5.0.10.

- `table_type`

This variable is a synonym for `storage_engine`. In MySQL 5.0, `storage_engine` is the preferred name.

- `thread_cache_size`

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. (Normally, this doesn't provide a notable performance improvement if you have a good thread implementation.) By examining the difference between the `Connections` and `Threads_created` status variables, you can see how efficient the thread cache is. For details, see Section 5.2.4, "Server Status Variables".

- `thread_concurrency`

On Solaris, `mysqld` calls `thr_setconcurrency()` with this value. This function enables applications to give the threads system a hint about the desired number of threads that should be run at the same time.

- `thread_stack`

The stack size for each thread. Many of the limits detected by the `crash-me` test are dependent on this value. The default is large enough for normal operation. See Section 7.1.4, "The MySQL Benchmark Suite". The default is 192KB.

- `time_format`

This variable is not implemented.

- `time_zone`

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is 'SYSTEM' (which means, "use the value of `system_time_zone`"). The value can be specified explicitly at server startup with the `--default-time-zone` option. See Section 5.11.8, "MySQL Server Time Zone Support".

- `tmp_table_size`

If an in-memory temporary table exceeds this size, MySQL automatically converts it to an on-disk MyISAM table. Increase the value of `tmp_table_size` if you do many advanced GROUP BY queries and you have lots of memory.

- `tmpdir`

The directory used for temporary files and temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (':') on Unix and semicolon characters(';') on Windows, NetWare, and OS/2.

The multiple-directory feature can be used to spread the load between several physical disks. If the MySQL server is acting as a replication slave, you should not set `tmpdir` to point to a directory on a memory-based filesystem or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails. However, if you are using MySQL 4.0.0 or later, you can set the slave's temporary directory using the `slave_load_tmpdir` variable. In that case, the slave won't use the general `tmpdir` value and you can set `tmpdir` to a non-permanent location.

- `transaction_alloc_block_size`

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_prealloc_size`

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

- `tx_isolation`

The default transaction isolation level. Defaults to `REPEATABLE-READ`.

This variable is set by the `SET TRANSACTION ISOLATION LEVEL` statement. See Section 13.4.6, “`SET TRANSACTION Syntax`”. If you set `tx_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotes, with the space replaced by a dash. For example:

```
SET tx_isolation = 'READ-COMMITTED';
```

- `updatable_views_with_limit`

This variable controls whether updates can be made using a view that does not contain a primary key in the underlying table, if the update contains a `LIMIT` clause. (Such updates often are generated by GUI tools.) An update is an `UPDATE` or `DELETE` statement. Primary key here means a `PRIMARY KEY`, or a `UNIQUE` index in which no column can contain `NULL`.

The variable can have two values:

- 1 or `YES`: Issue a warning only (not an error message). This is the default value.
- 0 or `NO`: Prohibit the update.

This variable was added in MySQL 5.0.2.

- `version`

The version number for the server.

- `version_bdb`

The BDB storage engine version.

- `version_comment`

The configure script has a `--with-comment` option that allows a comment to be specified when building MySQL. This variable contains the value of that comment.

- `version_compile_machine`

The type of machine or architecture on which MySQL was built.

- `version_compile_os`

The type of operating system on which MySQL was built.

- `wait_timeout`

The number of seconds the server waits for activity on a non-interactive connection before closing it. This timeout applies only to TCP/IP connections, not to connections made via Unix socket files, named pipes, or shared memory.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

### 5.2.3. Using System Variables

The `mysql` server maintains many system variables that indicate how it is configured. Section 5.2.2, “Server System Variables”, describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

The server maintains two kinds of system variables. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes all global variables to their default values. These defaults can be changed by options specified on the command line or in an option file. (See Section 4.3, “Specifying Program Options”.)
- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, the client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

System variable values can be set globally at server startup by using options on the command line or in an option file. When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of K, M, or G (either uppercase or lowercase) to indicate a multiplier of 1024, 1024<sup>2</sup> or 1024<sup>3</sup>; that is, units of kilobytes, megabytes, or gigabytes, respectively. Thus, the following command starts the server with a query cache size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --query_cache_size=16M --max_allowed_packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
query_cache_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; 16M and 16m are equivalent, as are 1G and 1g.

If you want to restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, you can specify this maximum by using an option of the form `--maximum-var_name=value` at server startup. For example, to prevent the value of `query_cache_size` from being increased to more than 32MB at runtime, use the option `--maximum-query_cache_size=32M`.

Many system variables are dynamic and can be changed while the server runs by using the `SET`

statement. For a list, see Section 5.2.3.2, “Dynamic System Variables”. To change a system variable with SET, refer to it as *var\_name*, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by GLOBAL or @@global.. The SUPER privilege is required to set global variables.
- To indicate explicitly that a variable is a session variable, precede its name by SESSION, @@session., or @@. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.
- LOCAL and @@local. are synonyms for SESSION and @@session..
- If no modifier is present, SET changes the session variable.

A SET statement can contain multiple variable assignments, separated by commas. If you set several system variables, the most recent GLOBAL or SESSION modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

When you assign a value to a system variable with SET, you cannot use suffix letters in the value (as can be done with startup options). However, the value can take the form of an expression:

```
SET sort_buffer_size = 10 * 1024 * 1024;
```

The @@*var\_name* syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the SET GLOBAL statement).

To prevent incorrect usage, MySQL produces an error if you use SET GLOBAL with a variable that can only be used with SET SESSION or if you do not specify GLOBAL (or @@global.) when setting a global variable.

To set a SESSION variable to the GLOBAL value or a GLOBAL value to the compiled-in MySQL default value, use the DEFAULT keyword. For example, the following two statements are identical in setting the session value of max\_join\_size to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to DEFAULT. In such cases, use of DEFAULT results in an error.

You can refer to the values of specific global or session system variables in expressions by using one of the @@-modifiers. For example, you can retrieve values in a SELECT statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as @@var\_name (that is, when you do not specify @@global. or @@session.), MySQL returns the session value if it exists and the global value otherwise. (This differs from SET @@var\_name = value, which always refers to the session value.)

*Note:* Some system variables can be enabled with the SET statement by setting them to ON or 1, or disabled by setting them to OFF or 0. However, to set such a variable on the command line or in an option file, you must set it to 1 or 0; setting it to ON or OFF will not work. For example, on the command line, --delay\_key\_write=1 works but --delay\_key\_write=ON does not.

To display system variable names and values, use the SHOW VARIABLES statement.

```
mysql> SHOW VARIABLES;
```

Variable_name	Value
auto_increment_increment	1
auto_increment_offset	1
automatic_sp_privileges	ON
back_log	50
basedir	/
bdb_cache_size	8388600
bdb_home	/var/lib/mysql/
bdb_log_buffer_size	32768
bdb_logdir	
bdb_max_lock	10000
bdb_shared_data	OFF

version	5.0.19-Max
version_comment	MySQL Community Edition - Max (GPL)
version_compile_machine	i686
version_compile_os	pc-linux-gnu
wait_timeout	28800

With a LIKE clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a LIKE clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the ‘%’ wildcard character in a LIKE clause:

```
SHOW VARIABLES LIKE '%size%';  
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because ‘\_’ is a wildcard that matches any single character, you should escape it as ‘\\_’ to match it literally. In practice, this is rarely necessary.

For SHOW VARIABLES, if you specify neither GLOBAL nor SESSION, MySQL returns SESSION values.

The reason for requiring the GLOBAL keyword when setting GLOBAL-only variables but not when retrieving them is to prevent problems in the future. If we were to remove a SESSION variable that has the same name as a GLOBAL variable, a client with the SUPER privilege might accidentally change the GLOBAL variable rather than just the SESSION variable for its own connection. If we add a SESSION variable with the same name as a GLOBAL variable, a client that intends to change the GLOBAL variable might find only its own SESSION variable changed.

### 5.2.3.1. Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL 5.0 supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`
- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in Section 7.4.6, “The MyISAM Key Cache”.

To refer to a component of a structured variable instance, you can use a compound name in *instance\_name.component\_name* format. Examples:

```
hot_cache.key_buffer_size  
hot_cache.key_cache_block_size  
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.
- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.
- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache`` is.
- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@global.var_name` for referring to non-structured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]  
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K \  
--extra_cache.key_buffer_size=128K \  
--extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M \  
--hot_cache.key_buffer_size=2M \  
--cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;  
mysql> SET @@global.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@global.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a LIKE pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

### 5.2.3.2. Dynamic System Variables

Many server system variables are dynamic and can be set at runtime using SET GLOBAL or SET SESSION. You can also obtain their values using SELECT. See Section 5.2.3, “Using System Variables”.

The following table shows the full list of all dynamic system variables. The last column indicates for each variable whether GLOBAL or SESSION (or both) apply. The table also lists session options that can be set with the SET statement. Section 13.5.3, “SET Syntax”, discusses these options.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, ON or OFF. (If you set them on the command line or in an option file, use the numeric values.) Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration value corresponds to 0. This differs from ENUM columns, for which the first enumeration value corresponds to 1.

Variable Name	Value Type	Type
autocommit	boolean	SESSION
big_tables	boolean	SESSION
binlog_cache_size	numeric	GLOBAL
bulk_insert_buffer_size	numeric	GLOBAL   SESSION
character_set_client	string	GLOBAL   SESSION

## 5.2.4. Server Status Variables

The server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW STATUS` statement:

```
mysql> SHOW STATUS;
```

Variable_name	Value
Aborted_clients	0
Aborted_connects	0
Bytes_received	155372598
Bytes_sent	1176560426
..	
Connections	30023
Created_tmp_disk_tables	0
Created_tmp_files	3
Created_tmp_tables	2
..	
Threads_created	217
Threads_running	88
Uptime	1389872

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

The status variables have the following meanings. Variables with no version indicated were already present prior to MySQL 5.0. For information regarding their implementation history, see *MySQL 3.23, 4.0, 4.1 Reference Manual*.

- `Aborted_clients`

The number of connections that were aborted because the client died without closing the connec-

tion properly. See Section A.2.10, “Communication Errors and Aborted Connections”.

- `Aborted_connects`

The number of failed attempts to connect to the MySQL server. See Section A.2.10, “Communication Errors and Aborted Connections”.

- `Binlog_cache_disk_use`

The number of transactions that used the temporary binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store statements from the transaction.

- `Binlog_cache_use`

The number of transactions that used the temporary binary log cache.

- `Bytes_received`

The number of bytes received from all clients.

- `Bytes_sent`

The number of bytes sent to all clients.

- `Com_xxx`

The `Com_xxx` statement counter variables indicate the number of times each `xxx` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_insert` count `DELETE` and `INSERT` statements, respectively.

All of the `Com_stmt_xxx` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

The `Com_stmt_xxx` status variables were added in 5.0.8:

- `Com_stmt_prepare`
- `Com_stmt_execute`
- `Com_stmt_fetch`
- `Com_stmt_send_long_data`
- `Com_stmt_reset`
- `Com_stmt_close`

Those variables stand for prepared statement commands. Their names refer to the `COM_xxx` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older (available since MySQL 4.1.3) statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

- `Compression`

Whether the client connection uses compression in the client/server protocol. Added in MySQL 5.0.16.

- `Connections`  
The number of connection attempts (successful or not) to the MySQL server.
- `Created_tmp_disk_tables`  
The number of temporary tables on disk created automatically by the server while executing statements.
- `Created_tmp_files`  
How many temporary files mysqld has created.
- `Created_tmp_tables`  
The number of in-memory temporary tables created automatically by the server while executing statements. If `Created_tmp_disk_tables` is large, you may want to increase the `tmp_table_size` value to cause temporary tables to be memory-based instead of disk-based.
- `Delayed_errors`  
The number of rows written with `INSERT DELAYED` for which some error occurred (probably `duplicate key`).
- `Delayed_insert_threads`  
The number of `INSERT DELAYED` handler threads in use.
- `Delayed_writes`  
The number of `INSERT DELAYED` rows written.
- `Flush_commands`  
The number of executed `FLUSH` statements.
- `Handler_commit`  
The number of internal `COMMIT` statements.
- `Handler_discover`  
The MySQL server can ask the `NDB Cluster` storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered via this mechanism.
- `Handler_delete`  
The number of times that rows have been deleted from tables.
- `Handler_read_first`  
The number of times the first entry was read from an index. If this value is high, it suggests that the server is doing a lot of full index scans; for example, `SELECT col1 FROM foo`, assuming that `col1` is indexed.
- `Handler_read_key`  
The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.
- `Handler_read_next`  
The number of requests to read the next row in key order. This value is incremented if you are

querying an index column with a range constraint or if you are doing an index scan.

- `Handler_read_prev`

The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.
- `Handler_read_rnd`

The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that don't use keys properly.
- `Handler_read_rnd_next`

The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.
- `Handler_rollback`

The number of internal `ROLLBACK` statements.
- `Handler_update`

The number of requests to update a row in a table.
- `Handler_write`

The number of requests to insert a row in a table.
- `Innodb_buffer_pool_pages_data`

The number of pages containing data (dirty or clean). Added in MySQL 5.0.2.
- `Innodb_buffer_pool_pages_dirty`

The number of pages currently dirty. Added in MySQL 5.0.2.
- `Innodb_buffer_pool_pages_flushed`

The number of buffer pool page-flush requests. Added in MySQL 5.0.2.
- `Innodb_buffer_pool_pages_free`

The number of free pages. Added in MySQL 5.0.2.
- `Innodb_buffer_pool_pages_latched`

The number of latched pages in InnoDB buffer pool. These are pages currently being read or written or that cannot be flushed or removed for some other reason. Added in MySQL 5.0.2.
- `Innodb_buffer_pool_pages_misc`

The number of pages that are busy because they have been allocated for administrative overhead such as row locks or the adaptive hash index. This value can also be calculated as `Innodb_buffer_pool_pages_total - Innodb_buffer_pool_pages_free - Innodb_buffer_pool_pages_data`. Added in MySQL 5.0.2.
- `Innodb_buffer_pool_pages_total`

The total size of buffer pool, in pages. Added in MySQL 5.0.2.

- `Innodb_buffer_pool_read_ahead_rnd`

The number of “random” read-aheads initiated by InnoDB. This happens when a query scans a large portion of a table but in random order. Added in MySQL 5.0.2.
- `Innodb_buffer_pool_read_ahead_seq`

The number of sequential read-aheads initiated by InnoDB. This happens when InnoDB does a sequential full table scan. Added in MySQL 5.0.2.
- `Innodb_buffer_pool_read_requests`

The number of logical read requests InnoDB has done. Added in MySQL 5.0.2.
- `Innodb_buffer_pool_reads`

The number of logical reads that InnoDB could not satisfy from the buffer pool and had to do a single-page read. Added in MySQL 5.0.2.
- `Innodb_buffer_pool_wait_free`

Normally, writes to the InnoDB buffer pool happen in the background. However, if it is necessary to read or create a page and no clean pages are available, it is also necessary to wait for pages to be flushed first. This counter counts instances of these waits. If the buffer pool size has been set properly, this value should be small. Added in MySQL 5.0.2.
- `Innodb_buffer_pool_write_requests`

The number writes done to the InnoDB buffer pool. Added in MySQL 5.0.2.
- `Innodb_data_fsyncs`

The number of `fsync()` operations so far. Added in MySQL 5.0.2.
- `Innodb_data_pending_fsyncs`

The current number of pending `fsync()` operations. Added in MySQL 5.0.2.
- `Innodb_data_pending_reads`

The current number of pending reads. Added in MySQL 5.0.2.
- `Innodb_data_pending_writes`

The current number of pending writes. Added in MySQL 5.0.2.
- `Innodb_data_read`

The amount of data read so far, in bytes. Added in MySQL 5.0.2.
- `Innodb_data_reads`

The total number of data reads. Added in MySQL 5.0.2.
- `Innodb_data_writes`

The total number of data writes. Added in MySQL 5.0.2.
- `Innodb_data_written`

The amount of data written so far, in bytes. Added in MySQL 5.0.2.
- `Innodb_dblwr_writes`, `Innodb_dblwr_pages_written`

The number of doublewrite operations that have been performed and the number of pages that

have been written for this purpose. Added in MySQL 5.0.2. See Section 14.2.14.1, “InnoDB Disk I/O”.

- `InnoDB_log_waits`

The number of times that the log buffer was too small and a wait was required for it to be flushed before continuing. Added in MySQL 5.0.2.

- `InnoDB_log_write_requests`

The number of log write requests. Added in MySQL 5.0.2.

- `InnoDB_log_writes`

The number of physical writes to the log file. Added in MySQL 5.0.2.

- `InnoDB_os_log_fsyncs`

The number of `fsync()` writes done to the log file. Added in MySQL 5.0.2.

- `InnoDB_os_log_pending_fsyncs`

The number of pending log file `fsync()` operations. Added in MySQL 5.0.2.

- `InnoDB_os_log_pending_writes`

The number of pending log file writes. Added in MySQL 5.0.2.

- `InnoDB_os_log_written`

The number of bytes written to the log file. Added in MySQL 5.0.2.

- `InnoDB_page_size`

The compiled-in InnoDB page size (default 16KB). Many values are counted in pages; the page size allows them to be easily converted to bytes. Added in MySQL 5.0.2.

- `InnoDB_pages_created`

The number of pages created. Added in MySQL 5.0.2.

- `InnoDB_pages_read`

The number of pages read. Added in MySQL 5.0.2.

- `InnoDB_pages_written`

The number of pages written. Added in MySQL 5.0.2.

- `InnoDB_row_lock_current_waits`

The number of row locks currently being waited for. Added in MySQL 5.0.3.

- `InnoDB_row_lock_time`

The total time spent in acquiring row locks, in milliseconds. Added in MySQL 5.0.3.

- `InnoDB_row_lock_time_avg`

The average time to acquire a row lock, in milliseconds. Added in MySQL 5.0.3.

- `InnoDB_row_lock_time_max`

The maximum time to acquire a row lock, in milliseconds. Added in MySQL 5.0.3.

- `Innodb_row_lock_waits`  
The number of times a row lock had to be waited for. Added in MySQL 5.0.3.
- `Innodb_rows_deleted`  
The number of rows deleted from InnoDB tables. Added in MySQL 5.0.2.
- `Innodb_rows_inserted`  
The number of rows inserted into InnoDB tables. Added in MySQL 5.0.2.
- `Innodb_rows_read`  
The number of rows read from InnoDB tables. Added in MySQL 5.0.2.
- `Innodb_rows_updated`  
The number of rows updated in InnoDB tables. Added in MySQL 5.0.2.
- `Key_blocks_not_flushed`  
The number of key blocks in the key cache that have changed but have not yet been flushed to disk.
- `Key_blocks_unused`  
The number of unused blocks in the key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` in Section 5.2.2, “Server System Variables”.
- `Key_blocks_used`  
The number of used blocks in the key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.
- `Key_read_requests`  
The number of requests to read a key block from the cache.
- `Key_reads`  
The number of physical reads of a key block from disk. If `Key_reads` is large, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads/Key_read_requests`.
- `Key_write_requests`  
The number of requests to write a key block to the cache.
- `Key_writes`  
The number of physical writes of a key block to disk.
- `Last_query_cost`  
The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. This variable was added in MySQL 5.0.1, with a default value of -1. In MySQL 5.0.7, the default was changed to 0; also in version 5.0.7, the scope of `Last_query_cost` was changed to session rather than global.  
  
Prior to MySQL 5.0.16, this variable was not updated for queries served from the query cache.

- `Max_used_connections`  
The maximum number of connections that have been in use simultaneously since the server started.
- `Not_flushed_delayed_rows`  
The number of rows waiting to be written in `INSERT DELAY` queues.
- `Open_files`  
The number of files that are open.
- `Open_streams`  
The number of streams that are open (used mainly for logging).
- `Open_tables`  
The number of tables that are open.
- `Opened_tables`  
The number of tables that have been opened. If `Opened_tables` is big, your `table_cache` value is probably too small.
- `Qcache_free_blocks`  
The number of free memory blocks in the query cache.
- `Qcache_free_memory`  
The amount of free memory for the query cache.
- `Qcache_hits`  
The number of query cache hits.
- `Qcache_inserts`  
The number of queries added to the query cache.
- `Qcache_lowmem_prunes`  
The number of queries that were deleted from the query cache because of low memory.
- `Qcache_not_cached`  
The number of non-cached queries (not cacheable, or not cached due to the `query_cache_type` setting).
- `Qcache_queries_in_cache`  
The number of queries registered in the query cache.
- `Qcache_total_blocks`  
The total number of blocks in the query cache.
- `Questions`  
The number of statements that clients have sent to the server.
- `Rpl_status`

The status of fail-safe replication (not yet implemented).

- `Select_full_join`

The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- `Select_full_range_join`

The number of joins that used a range search on a reference table.

- `Select_range`

The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- `Select_range_check`

The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

- `Select_scan`

The number of joins that did a full scan of the first table.

- `Slave_open_temp_tables`

The number of temporary tables that the slave SQL thread currently has open.

- `Slave_running`

This is ON if this server is a slave that is connected to a master.

- `Slave_retried_transactions`

The total number of times since startup that the replication slave SQL thread has retried transactions. This variable was added in version 5.0.4.

- `Slow_launch_threads`

The number of threads that have taken more than `slow_launch_time` seconds to create.

- `Slow_queries`

The number of queries that have taken more than `long_query_time` seconds. See Section 5.12.4, “The Slow Query Log”.

- `Sort_merge_passes`

The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- `Sort_range`

The number of sorts that were done using ranges.

- `Sort_rows`

The number of sorted rows.

- `Sort_scan`

The number of sorts that were done by scanning the table.

- `Ssl_xxx`  
Variables used for SSL connections.
- `Table_locks_immediate`  
The number of times that a table lock was acquired immediately.
- `Table_locks_waited`  
The number of times that a table lock could not be acquired immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.
- `Threads_cached`  
The number of threads in the thread cache.
- `Threads_connected`  
The number of currently open connections.
- `Threads_created`  
The number of threads created to handle connections. If `Threads_created` is big, you may want to increase the `thread_cache_size` value. The cache miss rate can be calculated as `Threads_created/Connections`.
- `Threads_running`  
The number of threads that are not sleeping.
- `Uptime`  
The number of seconds that the server has been up.

## 5.2.5. The Server SQL Mode

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients. This capability enables each application to tailor the server's operating mode to its own requirements.

Modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

You can set the default SQL mode by starting `mysqld` with the `--sql-mode="modes"` option. `modes` is a list of different modes separated by comma (',' ) characters. The default value is empty (no modes set). The `modes` value also can be empty (`--sql-mode=""`) if you want to clear it explicitly.

You can change the SQL mode at runtime by using a `SET [GLOBAL|SESSION] sql_mode='modes'` statement to set the `sql_mode` system value. Setting the GLOBAL variable requires the SUPER privilege and affects the operation of all clients that connect from that time on. Setting the SESSION variable affects only the current client. Any client can change its own session `sql_mode` value at any time.

You can retrieve the current global or session `sql_mode` value with the following statements:

```
SELECT @@global.sql_mode;  
SELECT @@session.sql_mode;
```

The most important `sql_mode` values are probably these:

- ANSI

Change syntax and behavior to be more conformant to standard SQL.

- STRICT\_TRANS\_TABLES

If a value could not be inserted as given into a transactional table, abort the statement. For a non-transactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More detail is given later in this section. (Implemented in MySQL 5.0.2)

- TRADITIONAL

Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. **Note:** The INSERT/UPDATE aborts as soon as the error is noticed. This may not be what you want if you are using a non-transactional storage engine, because data changes made prior to the error are not be rolled back, resulting in a “partially done” update. (Added in MySQL 5.0.2)

When this manual refers to “strict mode,” it means a mode where at least one of STRICT\_TRANS\_TABLES or STRICT\_ALL\_TABLES is enabled.

The following list describes all supported modes:

- ALLOW\_INVALID\_DATES

Don't do full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This is very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation). This mode applies to DATE and DATETIME columns. It does not apply to TIMESTAMP columns, which always require a valid date.

This mode is implemented in MySQL 5.0.2. Before 5.0.2, this was the default MySQL date-handling mode. As of 5.0.2, the server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as '2004-04-31' are converted to '0000-00-00' and a warning is generated. With strict mode enabled, invalid dates generate an error. To allow such dates, enable ALLOW\_INVALID\_DATES.

- ANSI\_QUOTES

Treat ‘”’ as an identifier quote character (like the ‘`’ quote character) and not as a string quote character. You can still use ‘`’ to quote identifiers with this mode enabled. With ANSI\_QUOTES enabled, you cannot use double quotes to quote literal strings, because it is interpreted as an identifier.

- ERROR\_FOR\_DIVISION\_BY\_ZERO

Produce an error in strict mode (otherwise a warning) when a division by zero (or MOD(X, 0)) occurs during an INSERT or UPDATE. If this mode is not enabled, MySQL instead returns NULL for divisions by zero. For INSERT IGNORE or UPDATE IGNORE, MySQL generates a warning for divisions by zero, but the result of the operation is NULL. (Implemented in MySQL 5.0.2)

- HIGH\_NOT\_PRECEDENCE

From MySQL 5.0.2 on, the precedence of the NOT operator is such that expressions such as NOT a BETWEEN b AND c are parsed as NOT (a BETWEEN b AND c). Before MySQL 5.0.2, the expression is parsed as (NOT a) BETWEEN b AND c. The old higher-precedence

behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE SQL` mode. (Added in MySQL 5.0.2)

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
      -> 0
mysql> SET sql_mode = 'broken_not';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
      -> 1
```

- `IGNORE_SPACE`

Allow spaces between a function name and the `'` character. This forces all function names to be treated as reserved words. As a result, if you want to access any database, table, or column name that is a reserved word, you must quote it. For example, because there is a `USER()` function, the name of the `user` table in the `mysql` database and the `User` column in that table become reserved, so you must quote them:

```
SELECT "User" FROM mysql."user";
```

The `IGNORE_SPACE SQL` mode applies to built-in functions, not to stored routines. It is always allowable to have spaces after a routine name, regardless of whether `IGNORE_SPACE` is enabled.

- `NO_AUTO_CREATE_USER`

Prevent `GRANT` from automatically creating new users if it would otherwise do so, unless a non-empty password also is specified. (Added in MySQL 5.0.2)

- `NO_AUTO_VALUE_ON_ZERO`

`NO_AUTO_VALUE_ON_ZERO` affects handling of `AUTO_INCREMENT` columns. Normally, you generate the next sequence number for the column by inserting either `NULL` or `0` into it. `NO_AUTO_VALUE_ON_ZERO` suppresses this behavior for `0` so that only `NULL` generates the next sequence number.

This mode can be useful if `0` has been stored in a table's `AUTO_INCREMENT` column. (Storing `0` is not a recommended practice, by the way.) For example, if you dump the table with `mysql-dump` and then reload it, MySQL normally generates new sequence numbers when it encounters the `0` values, resulting in a table with contents different from the one that was dumped. Enabling `NO_AUTO_VALUE_ON_ZERO` before reloading the dump file solves this problem. `mysql-dump` now automatically includes in its output a statement that enables `NO_AUTO_VALUE_ON_ZERO`, to avoid this problem.

- `NO_BACKSLASH_ESCAPES`

Disable the use of the backslash character (`'\'`) as an escape character within strings. With this mode enabled, backslash becomes any ordinary character like any other. (Implemented in MySQL 5.0.1)

- `NO_DIR_IN_CREATE`

When creating a table, ignore all `INDEX DIRECTORY` and `DATA DIRECTORY` directives. This option is useful on slave replication servers.

- `NO_ENGINE_SUBSTITUTION`

Prevents automatic substitution of the default storage engine when a statement such as `CREATE TABLE` specifies a storage engine that is disabled or not compiled in. (Implemented in MySQL 5.0.8)

- `NO_FIELD_OPTIONS`

Do not print MySQL-specific column options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_KEY_OPTIONS`

Do not print MySQL-specific index options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_TABLE_OPTIONS`

Do not print MySQL-specific table options (such as `ENGINE`) in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_UNSIGNED_SUBTRACTION`

In integer subtraction operations, do not mark the result as `UNSIGNED` if one of the operands is unsigned. Note that this makes `BIGINT UNSIGNED` not 100% usable in all contexts. See Section 12.8, “Cast Functions and Operators”.

```
mysql>t; SET sql_mode = '';
mysql>t; SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
|          18446744073709551615 |
+-----+
mysql>t; SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql>t; SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
|                      -1 |
+-----+
```

- `NO_ZERO_DATE`

In strict mode, don't allow '0000-00-00' as a valid date. You can still insert zero dates with the `IGNORE` option. When not in strict mode, the date is accepted but a warning is generated. (Added in MySQL 5.0.2)

- `NO_ZERO_IN_DATE`

In strict mode, don't accept dates where the month or day part is 0. If used with the `IGNORE` option, MySQL inserts a '0000-00-00' date for any such date. When not in strict mode, the date is accepted but a warning is generated. (Added in MySQL 5.0.2)

- `ONLY_FULL_GROUP_BY`

Do not allow queries for which the `SELECT` list refers to non-aggregated columns that are not named in the `GROUP BY` clause. The following query is invalid with this mode enabled because `address` is not named in the `GROUP BY` clause:

```
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

As of MySQL 5.0.22, this mode also restricts references to non-aggregated columns in the `HAVING` clause that are not named in the `GROUP BY` clause.

- `PIPES_AS_CONCAT`

Treat `||` as a string concatenation operator (same as `CONCAT( )`) rather than as a synonym for `OR`.

- `REAL_AS_FLOAT`

Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`.

- `STRICT_ALL_TABLES`

Enable strict mode for all storage engines. Invalid data values are rejected. Additional detail follows. (Added in MySQL 5.0.2)

- `STRICT_TRANS_TABLES`

Enable strict mode for transactional storage engines, and when possible for non-transactional storage engines. Additional details follow. (Implemented in MySQL 5.0.2)

Strict mode controls how MySQL handles input values that are invalid or missing. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a column that has no explicit `DEFAULT` clause in its definition.

For transactional tables, an error occurs for invalid or missing values in a statement when either of the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` modes are enabled. The statement is aborted and rolled back.

For non-transactional tables, the behavior is the same for either mode, if the bad value occurs in the first row to be inserted or updated. The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict option is enabled:

- For `STRICT_ALL_TABLES`, MySQL returns an error and ignores the rest of the rows. However, in this case, the earlier rows still have been inserted or updated. This means that you might get a partial update, which might not be what you want. To avoid this, it's best to use single-row statements because these can be aborted without changing the table.
- For `STRICT_TRANS_TABLES`, MySQL converts an invalid value to the closest valid value for the column and insert the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in Section 11.1.4, "Data Type Default Values".

Strict mode disallows invalid date values such as `'2004-04-31'`. It does not disallow dates with zero parts such as `'2004-04-00'` or "zero" dates. To disallow these as well, enable the `NO_ZERO_IN_DATE` and `NO_ZERO_DATE` SQL modes in addition to strict mode.

If you are not using strict mode (that is, neither `STRICT_TRANS_TABLES` nor `STRICT_ALL_TABLES` is enabled), MySQL inserts adjusted values for invalid or missing values and produces warnings. In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`. See Section 13.5.4.25, "SHOW WARNINGS Syntax".

The following special modes are provided as shorthand for combinations of mode values from the preceding list. All are available in MySQL 5.0 beginning with version 5.0.0, except for `TRADITIONAL`, which was implemented in MySQL 5.0.2.

The descriptions include all mode values that are available in the most recent version of MySQL. For older versions, a combination mode does not include individual mode values that are not available except in newer versions.

- `ANSI`

Equivalent to `REAL_AS_FLOAT`, `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`.

Before MySQL 5.0.3, ANSI also includes `ONLY_FULL_GROUP_BY`. See Section 1.9.3, “Running MySQL in ANSI Mode”.

- DB2

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- MAXDB

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- MSSQL

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- MYSQL323

Equivalent to `NO_FIELD_OPTIONS`, `HIGH_NOT_PRECEDENCE`.

- MYSQL40

Equivalent to `NO_FIELD_OPTIONS`, `HIGH_NOT_PRECEDENCE`.

- ORACLE

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- POSTGRESQL

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- TRADITIONAL

Equivalent to `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, `NO_AUTO_CREATE_USER`.

## 5.2.6. The MySQL Server Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

Server shutdown can be initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

Error: Can't create thread to kill server

3. The server stops accepting new connections.

To prevent new activity from being initiated during shutdown, the server stops accepting new client connections. It does this by closing the network connections to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread that is associated with a client connection, the connection to the client is broken and the thread is marked as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see Section 13.5.5.3, “KILL Syntax”, in particular for the instructions about killed `REPAIR TABLE` or `OPTIMIZE TABLE` operations on MyISAM tables.

For threads that have an open transaction, the transaction is rolled back. Note that if a thread is updating a non-transactional table, an operation such as a multiple-row `UPDATE` or `INSERT` may leave the table partially updated, because the operation can terminate before completion.

If the server is a master replication server, threads associated with currently connected slaves are treated like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a slave replication server, the I/O and SQL threads, if active, are stopped before client threads are marked as killed. The SQL thread is allowed to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread was in the middle of a transaction at this point, the transaction is rolled back.

5. Storage engines are shut down or closed.

At this stage, the table cache is flushed and all open tables are closed.

Each storage engine performs any actions necessary for tables that it manages. For example, MyISAM flushes any pending index writes for a table. InnoDB flushes its buffer pool to disk (starting from 5.0.5: unless `innodb_fast_shutdown` is 2), writes the current LSN to the tablespace, and terminates its own internal threads.

6. The server exits.

## 5.3. The `mysqld-max` Extended MySQL Server

A MySQL-Max server is a version of the `mysqld` MySQL server that has been built to include additional features. The MySQL-Max distribution to use depends on your platform:

- For Windows, MySQL binary distributions include both the standard server (`mysqld.exe`) and the MySQL-Max server (`mysqld-max.exe`), so no special distribution is needed. Just use a regular Windows distribution. See Section 2.3, “Installing MySQL on Windows”.
- For Linux, if you install MySQL using RPM distributions, the MySQL-Max RPM presupposes that you have already installed the regular server RPM. Use the regular `MySQL-server` RPM first to install a standard server named `mysqld`, and then use the MySQL-Max RPM to install a server named `mysqld-max`. See Section 2.4, “Installing MySQL on Linux”, for more information on the Linux RPM packages.

- All other MySQL-Max distributions contain a single server that is named `mysqld` but that has the additional features included.

You can find the MySQL-Max binaries on the MySQL AB Web site at <http://dev.mysql.com/downloads/>.

MySQL AB builds the MySQL-Max servers by using the following configure options:

- `--with-server-suffix=-max`

This option adds a `-max` suffix to the `mysqld` version string.

- `--with-innodb`

This option enables support for the InnoDB storage engine. MySQL-Max servers always include InnoDB support. From MySQL 4.0 onward, InnoDB is included by default in all binary distributions, so a MySQL-Max server is not needed to obtain InnoDB support.

- `--with-bdb`

This option enables support for the Berkeley DB (BDB) storage engine on those platforms for which BDB is available. (See notes in the following discussion.)

- `--with-blackhole-storage-engine`

This option enables support for the BLACKHOLE storage engine.

- `--with-csv-storage-engine`

This option enables support for the CSV storage engine.

- `--with-example-storage-engine`

This option enables support for the EXAMPLE storage engine.

- `--with-federated-storage-engine`

This option enables support for the FEDERATED storage engine.

- `--with-ndbcluster`

This option enables support for the NDB Cluster storage engine on those platforms for which Cluster is available. (See notes in the following discussion.)

- `USE_SYMDIR`

This define is enabled to turn on database symbolic link support for Windows. From MySQL 4.0 onward, symbolic link support is enabled for all Windows servers, so a MySQL-Max server is not needed to take advantage of this feature.

MySQL-Max binary distributions are a convenience for those who wish to install precompiled programs. If you build MySQL using a source distribution, you can build your own Max-like server by enabling the same features at configuration time that the MySQL-Max binary distributions are built with.

MySQL-Max servers include the BerkeleyDB (BDB) storage engine whenever possible, but not all platforms support BDB.

Currently, MySQL Cluster is supported on Linux (on most platforms), Solaris, Mac OS X, and HP-UX only. Some users have reported success in using MySQL Cluster built from source on BSD operating systems, but these are not officially supported at this time. Note that, even for servers com-

piled with Cluster support, the NDB Cluster storage engine is not enabled by default. You must start the server with the `--ndbcluster` option to use it as part of a MySQL Cluster. (For details, see Section 15.4, “MySQL Cluster Configuration”.)

The following table shows the platforms for which MySQL-Max binaries include support for BDB and NDB Cluster.

System	BDB Support	NDB Support
AIX 5.2	N	N
HP-UX	Y	Y
Linux-IA-64	N	Y
Linux-Intel	Y	Y
Mac OS X	N	Y
NetWare	N	N
SCO 6	N	N
Solaris-SPARC	Y	Y
Solaris-Intel	N	Y
Solaris-AMD 64	Y	Y
Windows NT/2000/XP	Y	N

To find out which storage engines your server supports, use the `SHOW ENGINES` statement. (See Section 13.5.4.10, “SHOW ENGINES Syntax”.) For example:

```
mysql> SHOW ENGINES\G
***** 1. row *****
Engine: MyISAM
Support: DEFAULT
Comment: Default engine as of MySQL 3.23 with great performance
***** 2. row *****
Engine: MEMORY
Support: YES
Comment: Hash based, stored in memory, useful for temporary tables
***** 3. row *****
Engine: InnoDB
Support: YES
Comment: Supports transactions, row-level locking, and foreign keys
***** 4. row *****
Engine: BerkeleyDB
Support: NO
Comment: Supports transactions and page-level locking
***** 5. row *****
Engine: BLACKHOLE
Support: YES
Comment: /dev/null storage engine (anything you write to it disappears)
...

```

The precise output from `SHOW ENGINES` may vary according to the MySQL version used (and the features that are enabled). The `Support` values in the output indicate the server's level of support for each feature, as shown here:

Value	Meaning
YES	The feature is supported and is active.
NO	The feature is not supported.
DISABLED	The feature is supported but has been disabled.

A value of `NO` means that the server was compiled without support for the feature, so it cannot be

activated at runtime.

A value of `DISABLED` occurs either because the server was started with an option that disables the feature, or because not all options required to enable it were given. In the latter case, the error log file should contain a reason indicating why the option is disabled. See Section 5.12.1, “The Error Log”.

You might also see `DISABLED` for a storage engine if the server was compiled to support it, but was started with a `--skip-engine` option. For example, `--skip-innodb` disables the InnoDB engine. For the NDB Cluster storage engine, `DISABLED` means the server was compiled with support for MySQL Cluster, but was not started with the `--ndb-cluster` option.

All MySQL servers support MyISAM tables, because MyISAM is the default storage engine.

## 5.4. MySQL Server Startup Programs

This section describes several programs that are used to start `mysqld`, the MySQL server.

### 5.4.1. `mysqld_safe` — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix and NetWare. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log file. NetWare-specific behaviors are listed later in this section.

**Note:** To preserve backward compatibility with older versions of MySQL, MySQL binary distributions still include `safe_mysqld` as a symbolic link to `mysqld_safe`. However, you should not rely on this because it is removed as of MySQL 5.1.

By default, `mysqld_safe` tries to start an executable named `mysqld-max` if it exists, and `mysqld` otherwise. Be aware of the implications of this behavior:

- On Linux, the MySQL-Max RPM relies on this `mysqld_safe` behavior. The RPM installs an executable named `mysqld-max`, which causes `mysqld_safe` to automatically use that executable rather than `mysqld` from that point on.
- If you install a MySQL-Max distribution that includes a server named `mysqld-max`, and then upgrade later to a non-Max version of MySQL, `mysqld_safe` will still attempt to run the old `mysqld-max` server. If you perform such an upgrade, you should manually remove the old `mysqld-max` server to ensure that `mysqld_safe` runs the new `mysqld` server.

To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld` or `--mysqld-version` option to `mysqld_safe`. You can also use `-ledir` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See Section 5.2.1, “`mysqld` Command Options”.

All options specified to `mysqld_safe` on the command line are passed to `mysqld`. If you want to use any options that are specific to `mysqld_safe` and that `mysqld` doesn't support, do not specify them on the command line. Instead, list them in the `[mysqld_safe]` group of an option file. See Section 4.3.2, “Using Option Files”.

`mysqld_safe` reads all options from the `[mysqld]`, `[server]`, and `[mysqld_safe]` sections in option files. For backward compatibility, it also reads `[safe_mysqld]` sections, although you should rename such sections to `[mysqld_safe]` in MySQL 5.0 installations.

`mysqld_safe` supports the following options:

- `--help`

Display a help message and exit. (Added in MySQL 5.0.3)

- `--autoclose`

(NetWare only) On NetWare, `mysqld_safe` provides a screen presence. When you unload (shut down) the `mysqld_safe` NLM, the screen does not by default go away. Instead, it prompts for user input:

```
*<NLM has terminated; Press any key to close the screen>*
```

If you want NetWare to close the screen automatically instead, use the `--autoclose` option to `mysqld_safe`.

- `--basedir=path`

The path to the MySQL installation directory.

- `--core-file-size=size`

The size of the core file that `mysqld` should be able to create. The option value is passed to `ulimit -c`.

- `--datadir=path`

The path to the data directory.

- `--defaults-extra-file=path`

The name of an option file to be read in addition to the usual option files. This must be the first option on the command line if it is used. As of MySQL 5.0.6, if the file does not exist or is otherwise inaccessible, the server will exit with an error.

- `--defaults-file=file_name`

The name of an option file to be read instead of the usual option files. This must be the first option on the command line if it is used.

- `--ledir=path`

If `mysqld_safe` cannot find the server, use this option to indicate the pathname to the directory where the server is located.

- `--log-error=file_name`

Write the error log to the given file. See Section 5.12.1, “The Error Log”.

- `--mysqld=prog_name`

The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If `mysqld_safe` cannot find the server, use the `--ledir` option to indicate the pathname to the directory where the server is located.

- `--mysqld-version=suffix`

This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The basename is assumed to be `mysqld`. For example, if you use `--mysqld-version=max`, `mysqld_safe` starts the `mysqld-max` program in the `ledir` directory. If the argument to `--mysqld-version` is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

- `--nice=priority`

Use the `nice` program to set the server's scheduling priority to the given value.

- `--no-defaults`

Do not read any option files. This must be the first option on the command line if it is used.

- `--open-files-limit=count`

The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`. Note that you need to start `mysqld_safe` as `root` for this to work properly!

- `--pid-file=file_name`

The pathname of the process ID file.

- `--port=port_num`

The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--socket=path`

The Unix socket file that the server should use when listening for local connections.

- `--timezone=timezone`

Set the TZ time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

- `--user={user_name|user_id}`

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute `mysqld_safe` with the `--defaults-file` or `--defaults-extra-option` option to name an option file, the option must be the first one given on the command line or the option file will not be used. For example, this command will not use the named option file:

```
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See Section 2.1.5, “Installation Layouts”.) `mysqld_safe` expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which `mysqld_safe` is invoked). For binary distributions, `mysqld_safe` looks under its working directory for `bin` and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute `mysqld_safe` from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).
- If the server and databases cannot be found relative to the working directory, `mysqld_safe` attempts to locate them by absolute pathnames. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into

the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because `mysqld_safe` tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run `mysqld_safe` from the MySQL installation directory:

```
shell> cd mysql_installation_directory
shell> bin/mysqld_safe &
```

If `mysqld_safe` fails, even when invoked from the MySQL installation directory, you can specify the `--ledir` and `--datadir` options to indicate the directories in which the server and databases are located on your system.

Normally, you should not edit the `mysqld_safe` script. Instead, configure `mysqld_safe` by using command-line options or options in the `[mysqld_safe]` section of a `my.cnf` option file. In rare cases, it might be necessary to edit `mysqld_safe` to get it to start the server properly. However, if you do this, your modified version of `mysqld_safe` might be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.

On NetWare, `mysqld_safe` is a NetWare Loadable Module (NLM) that is ported from the original Unix shell script. It starts the server as follows:

1. Runs a number of system and option checks.
2. Runs a check on MyISAM tables.
3. Provides a screen presence for the MySQL server.
4. Starts `mysqld`, monitors it, and restarts it if it terminates in error.
5. Sends error messages from `mysqld` to the `host_name.err` file in the data directory.
6. Sends `mysqld_safe` screen output to the `host_name.safe` file in the data directory.

## 5.4.2. `mysql.server` — MySQL Server Startup Script

MySQL distributions on Unix include a script named `mysql.server`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the Mac OS X Startup Item for MySQL.

`mysql.server` can be found in the `support-files` directory under your MySQL installation directory or in a MySQL source distribution.

If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), the `mysql.server` script will be installed in the `/etc/init.d` directory with the name `mysql`. You need not install it manually. See Section 2.4, “Installing MySQL on Linux”, for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. Instructions are provided in Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

`mysql.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. For backward compatibility, it also reads `[mysql_server]` sections, although you should rename such sections to `[mysql.server]` when using MySQL 5.0.

### 5.4.3. `mysqld_multi` — Manage Multiple MySQL Servers

`mysqld_multi` is designed to manage several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status. The MySQL Instance Manager is an alternative means of managing multiple servers (see Section 5.5, “`mysqlmanager` — The MySQL Instance Manager”).

`mysqld_multi` searches for groups named `[mysqldN]` in `my.cnf` (or in the file named by the `--config-file` option). `N` can be any positive integer. This number is referred to in the following discussion as the option group number, or *GNR*. Group numbers distinguish option groups from one another and are used as arguments to `mysqld_multi` to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the `[mysqld]` group used for starting `mysqld`. (See, for example, Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see Section 5.13, “Running Multiple MySQL Servers on the Same Machine”.

To invoke `mysqld_multi`, use the following syntax:

```
shell> mysqld_multi [options] {start|stop|report} [GNR[,GNR] ...]
```

`start`, `stop`, and `report` indicate which operation to perform. You can perform the designated operation for a single server or multiple servers, depending on the *GNR* list that follows the option name. If there is no list, `mysqld_multi` performs the operation for all servers in the option file.

Each *GNR* value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the *GNR* for a group named `[mysqld17]` is 17. To specify a range of numbers, separate the first and last numbers by a dash. The *GNR* value `10-13` represents groups `[mysqld10]` through `[mysqld13]`. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the *GNR* list; anything after a whitespace character is ignored.

This command starts a single server using option group `[mysqld17]`:

```
shell> mysqld_multi start 17
```

This command stops several servers, using option groups `[mysqld8]` and `[mysqld10]` through `[mysqld13]`:

```
shell> mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
shell> mysqld_multi --example
```

`mysqld_multi` supports the following options:

- `--help`

Display a help message and exit.

- `--config-file=file_name`

Specify the name of an alternative option file. This affects where `mysqld_multi` looks for `[mysqldN]` option groups. Without this option, all options are read from the usual `my.cnf` file. The option does not affect where `mysqld_multi` reads its own options, which are always

taken from the `[mysqld_multi]` group in the usual `my.cnf` file.

- `--example`

Display a sample option file.

- `--log=filename`

Specify the name of the log file. If the file exists, log output is appended to it.

- `--mysqladmin=prog_name`

The `mysqladmin` binary to be used to stop servers.

- `--mysqld=prog_name`

The `mysqld` binary to be used. Note that you can specify `mysqld_safe` as the value for this option also. If you use `mysqld_safe` to start the server, you can include the `mysqld` or `ledir` options in the corresponding `[mysqldN]` option group. These options indicate the name of the server that `mysqld_safe` should start and the pathname of the directory where the server is located. (See the descriptions for these options in Section 5.4.1, “`mysqld_safe` — MySQL Server Startup Script”.) Example:

```
[mysqld38]
mysqld = mysqld-max
ledir  = /opt/local/mysql/libexec
```

- `--no-log`

Print log information to `stdout` rather than to the log file. By default, output goes to the log file.

- `--password=password`

The password of the MySQL account to use when invoking `mysqladmin`. Note that the password value is not optional for this option, unlike for other MySQL programs.

- `--silent`

Silent mode; disable warnings.

- `--tcp-ip`

Connect to each MySQL server via the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only via the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects `stop` and `report` operations.

- `--user=username`

The username of the MySQL account to use when invoking `mysqladmin`.

- `--verbose`

Be more verbose.

- `--version`

Display version information and exit.

Some notes about `mysqld_multi`:

- **Most important:** Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and *why* you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory does *not* give you extra performance in a threaded system. See Section 5.13, “Running Multiple MySQL Servers on the Same Machine”.
- **Important:** Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. *Do not* use the Unix `root` account for this, unless you *know* what you are doing. See Section 5.7.5, “How to Run MySQL as a Normal User”.
- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same username and password for each server. Also, make sure that the account has the SHUTDOWN privilege. If the servers that you want to manage have different usernames or passwords for the administrative accounts, you might want to create an account on each server that has the same username and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> GRANT SHUTDOWN ON *.*
-> TO 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
```

See Section 5.8.2, “How the Privilege System Works”. You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. Note that the hostname part of the account name must allow you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld`.
- The `--pid-file` option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `--mysqld=mysqld_safe`) Every `mysqld` should have its own process ID file. The advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` monitors its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault. Please note that the `mysqld_safe` script might require that you start it from a certain place. This means that you might have to change location to a certain directory before running `mysqld_multi`. If you have problems starting, please see the `mysqld_safe` script. Check especially the lines:

```
-----
MY_PWD=`pwd`
# Check if we are starting this relative (for the binary release)
if test -d $MY_PWD/data/mysql -a -f ./share/mysql/english/errmsg.sys -a \
-x ./bin/mysqld
-----
```

The test performed by these lines should be successful, or you might encounter problems. See Section 5.4.1, “`mysqld_safe` — MySQL Server Startup Script”.

- You might want to use the `--user` option for `mysqld`, but to do this you need to run the `mysqld_multi` script as the Unix `root` user. Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

The following example shows how you might set up an option file for use with `mysqld_multi`. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth [`mysqldN`] groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```
# This file should probably be in your home dir (~/.my.cnf)
# or /etc/my.cnf
# Version 2.1 by Jani Tolonen

[mysqld_multi]
mysqld      = /usr/local/bin/mysqld_safe
mysqldadmin = /usr/local/bin/mysqldadmin
user        = multi_admin
password    = multipass

[mysqld2]
socket      = /tmp/mysql.sock2
port        = 3307
pid-file    = /usr/local/mysql/var2/hostname.pid2
datadir     = /usr/local/mysql/var2
language    = /usr/local/share/mysql/english
user        = john

[mysqld3]
socket      = /tmp/mysql.sock3
port        = 3308
pid-file    = /usr/local/mysql/var3/hostname.pid3
datadir     = /usr/local/mysql/var3
language    = /usr/local/share/mysql/swedish
user        = monty

[mysqld4]
socket      = /tmp/mysql.sock4
port        = 3309
pid-file    = /usr/local/mysql/var4/hostname.pid4
datadir     = /usr/local/mysql/var4
language    = /usr/local/share/mysql/estonia
user        = tonu

[mysqld6]
socket      = /tmp/mysql.sock6
port        = 3311
pid-file    = /usr/local/mysql/var6/hostname.pid6
datadir     = /usr/local/mysql/var6
language    = /usr/local/share/mysql/japanese
user        = jani
```

See Section 4.3.2, “Using Option Files”.

## 5.5. mysqlmanager — The MySQL Instance Manager

`mysqlmanager` is the MySQL Instance Manager (IM). This program is a daemon running on a TCP/IP port that serves to monitor and manage MySQL Database Server instances. MySQL Instance Manager is available for Unix-like operating systems, and also on Windows as of MySQL 5.0.13.

MySQL Instance Manager is included in MySQL distributions from version 5.0.3, and can be used in place of the `mysqld_safe` script to start and stop the MySQL Server, *even from a remote host*. MySQL Instance Manager also implements the functionality (and most of the syntax) of the `mysqld_multi` script. A more detailed description of MySQL Instance Manager follows.

### 5.5.1. Starting the MySQL Server with MySQL Instance Manager

Normally, the `mysqld` MySQL Database Server is started with the `mysql.server` script, which usually resides in the `/etc/init.d/` folder. In MySQL 5.0.3, this script invokes `mysqlman-`

ager (the MySQL Instance Manager binary) to start MySQL. (In prior versions of MySQL the `mysqld_safe` script is used for this purpose.) Starting from MySQL 5.0.4, the behavior of the startup script was changed again to incorporate both setup schemes. In version 5.0.4, the startup script uses the old scheme (invoking `mysqld_safe`) by default, but one can set the `use_mysqld_safe` variable in the script to 0 (zero) to use the MySQL Instance Manager to start a server.

Starting with MySQL 5.0.19, you can instead modify the `my.cnf` file by adding `use-manager` to the `[mysql.server]` section:

```
[mysql.server]
use-manager
```

The Instance Manager's behavior in this case depends on the options given in the MySQL configuration file. If there is no configuration file, the MySQL Instance Manager creates a server instance named `mysqld` and attempts to start it with default (compiled-in) configuration values. This means that the IM cannot guess the placement of `mysqld` if it is not installed in the default location. If you have installed the MySQL server in a non-standard location, you should use a configuration file. See Section 2.1.5, "Installation Layouts".

If there is a configuration file, the IM reads it to find `[mysqldN]` sections (for example, `[mysqld1]`, `[mysqld2]`, and so forth). Each such section specifies an instance. When it starts, the Instance Manager attempts to start all server instances that it finds. By default, the Instance Manager stops all server instances when it shuts down.

## Warning

The `[mysqld]` section name is deprecated and should not be used in a configuration file.

Note that there is a special `--mysqld-path=path-to-mysqld-binary` option that is recognized only by the IM. Use this variable to let the IM know where the `mysqld` binary resides. You should also set `basedir` and `datadir` options for the server.

The typical startup/shutdown cycle for a MySQL server with the MySQL Instance Manager enabled is as follows:

1. The MySQL Instance Manager is started with `/etc/init.d/mysql` script.
2. The MySQL Instance Manager starts all instances and monitors them.
3. If a server instance fails the MySQL Instance Manager restarts it.
4. If the MySQL Instance Manager is shut down (for instance with the `/etc/init.d/mysql stop` command), all instances are shut down by the MySQL Instance Manager.

## 5.5.2. Connecting to the MySQL Instance Manager and Creating User Accounts

Communication with the MySQL Instance Manager is handled using the MySQL client-server protocol. As such, you can connect to the IM using the standard `mysql` client program, as well as the MySQL C API. The IM supports the version of the MySQL client-server protocol used by the client tools and libraries distributed along with MySQL 4.1 or later.

### 5.5.2.1. Instance Manager Users and Passwords

The Instance Manager stores its user information in a password file. The default name of the password file is `/etc/mysqlmanager.passwd`.

Password entries have the following format:

```
petr:*35110DC9B4D8140F5DE667E28C72DD2597B5C848
```

If there are no entries in the `/etc/mysqlmanager.password` file, you cannot connect to the Instance Manager.

To generate a new entry, invoke Instance Manager with the `--passwd` option. Then the output can be appended to the `/etc/mysqlmanager.password` file to add a new user. Here is an example:

```
shell> mysqlmanager --passwd >> /etc/mysqlmanager.password
Creating record for new user.
Enter user name: mike
Enter password: password
Re-type password: password
```

The preceding command causes the following line to be added to `/etc/mysqlmanager.password`:

```
mike:*00A51F3F48415C7D4E8908980D443C29C69B60C9
```

## Note

The Instance Manager must be restarted after adding/changing passwords.

### 5.5.2.2. MySQL Server Accounts for Status Monitoring

To monitor server status, the MySQL Instance Manager will attempt to connect to the MySQL server instance at regular intervals using the `MySQL_Instance_Manager@localhost` user account with a password of `check_connection`.

You are *not* required to create a `MySQL_Instance_M@localhost` user account in order for the MySQL Instance Manager to monitor server status, as a login failure is sufficient to identify that the server is operational. However, if the account does not exist, failed connection attempts are logged by the server to its general query log (see Section 5.12.2, “The General Query Log”).

### 5.5.3. MySQL Instance Manager Command Options

The MySQL Instance Manager supports a number of command line options. For a brief listing, invoke `mysqlmanager` with the `--help` option.

`mysqlmanager` supports the following options:

- `--help, -?`

Display a help message and exit.

- `--bind-address=IP`

The IP address to bind to.

- `--default-mysqld-path=path`

On Unix, the pathname of the MySQL Server binary, if no path was provided in the instance section. Example: `--default-mysqld-path=/usr/sbin/mysqld`

- `--defaults-file=file_name`

Read Instance Manager and MySQL Server settings from the given file. All configuration changes by the Instance Manager will be made to this file. This must be the first option on the command line if it is used.

- `--install`

On Windows, install Instance Manager as a Windows service. This option was added in MySQL 5.0.11.

- `--log=file_name`

The path to the IM log file. This is used with the `--run-as-service` option.

- `--monitoring-interval=seconds`

The interval in seconds for monitoring instances. The default value is 20 seconds. Instance Manager tries to connect to each monitored instance using the non-existing `MySQL_Instance_Manager` user account to check whether it is alive/not hanging. In the case of a failure to connect, IM performs several attempts to restart the instance. The `nonguarded` option in the appropriate instance section disables this behavior for a particular instance. The monitoring process will produce messages in the general query log similar to the following:

```
Access denied for user 'MySQL_Instance_M'@'localhost' (using password: YES)
```

- `--passwd, -P`

Prepare an entry for the password file and exit.

- `--password-file=file_name`

Look for the Instance Manager users and passwords in this file. The default file is `/etc/mysqlmanager.passwd`.

- `--pid-file=file_name`

The process ID file to use. By default, this file is named `mysqlmanager.pid`.

- `--port=port_num`

The TCP/IP port number to use for incoming connections. (The default port number assigned by IANA is 2273).

- `--print-defaults`

Print the current defaults and exit. This must be the first option on the command line if it is used.

- `--remove`

On Windows, removes Instance Manager as a Windows service. This assumes that Instance Manager has been run with `--install` previously. This option was added in MySQL 5.0.11.

- `--run-as-service`

On Unix, daemonize and start the angel process. The angel process is simple and unlikely to crash. It will restart the Instance Manager itself in case of a failure.

- `--socket=path`

On Unix, the socket file to use for incoming connections. By default, the file is named `/tmp/mysqlmanager.sock`.

- `--standalone`

On Windows, run Instance Manager in standalone mode. This option was added in MySQL 5.0.13.

- `--user=user_name`

On Unix, the username to start and run the `mysqlmanager` under. It is recommended to run `mysqlmanager` under the same user account used to run the `mysqld` server. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

- `--version, -V`

Output version information and exit.

- `--wait-timeout=N`

The number of seconds to wait for activity on a connection before closing it. The default is 28800 seconds (8 hours).

This option was added in MySQL 5.0.19. Before that, the timeout is 30 seconds and cannot be changed.

## 5.5.4. MySQL Instance Manager Configuration Files

Instance Manager uses the standard `my.cnf` file. It uses the `[manager]` section to read options for itself and the `[mysqldN]` sections to create instances. The `[manager]` section contains any of the options listed in Section 5.5.3, “MySQL Instance Manager Command Options”. Here is an example `[manager]` section:

```
# MySQL Instance Manager options section
[manager]
default-mysqld-path = /usr/local/mysql/libexec/mysqld
socket=/tmp/manager.sock
pid-file=/tmp/manager.pid
password-file = /home/cps/.mysqlmanager.passwd
monitoring-interval = 2
port = 1999
bind-address = 192.168.1.5
```

### Warning

The `[mysqld]` section name is deprecated and should not be used in a configuration file, instead `[mysqldN]` sections such as `[mysqld1]` should be used for specific instances.

Prior to MySQL 5.0.10, the MySQL Instance Manager read the same configuration files as the MySQL Server, including `/etc/my.cnf`, `~/my.cnf`, etc. As of MySQL 5.0.10, the MySQL Instance Manager reads and manages the `/etc/my.cnf` file only on Unix. On Windows, MySQL Instance Manager reads the `my.ini` file in the directory where Instance Manager is installed. The default option file location can be changed with the `--defaults-file=file_name` option.

Instance sections specify options given to each instance at startup. These are mainly common MySQL server options, but there are some IM-specific options:

- `mysqld-path = path`

The pathname to the `mysqld` server binary.

- `shutdown-delay = seconds`

The number of seconds IM should wait for the instance to shut down. The default value is 35 seconds. After the delay expires, the IM assumes that the instance is hanging and attempts to terminate it. If you use InnoDB with large tables, you should increase this value.

- `nonguarded`

This option should be specified if you want to disable IM monitoring functionality for a certain instance.

Here are some sample instance sections:

```
[mysqld1]
mysqld-path=/usr/local/mysql/libexec/mysqld
socket=/tmp/mysql.sock
port=3307
server_id=1
skip-stack-trace
core-file
skip-bdb
log-bin
log-error
log=mylog
log-slow-queries

[mysqld2]
nonguarded
port=3308
server_id=2
mysqld-path= /home/cps/mysql/trees/mysql-5.0/sql/mysqld
socket      = /tmp/mysql.sock5
pid-file    = /tmp/hostname.pid5
datadir=    /home/cps/mysql_data/data_dir1
language=/home/cps/mysql/trees/mysql-5.0/sql/share/english
log-bin
log=/tmp/fordel.log
```

## 5.5.5. Commands Recognized by the MySQL Instance Manager

Once you've set up a password file for the MySQL Instance Manager and the IM is running, you can connect to it. You can use the `mysql` client tool connect through a standard MySQL API:

```
mysql --port=2273 --host=mydomain.org --user=mysql -p
```

The following list of commands shows the MySQL Instance Manager currently accepts, with samples.

- `START INSTANCE instance_name`

This command attempts to start an instance.

```
mysql> START INSTANCE mysqld4;
Query OK, 0 rows affected (0,00 sec)
```

- `STOP INSTANCE instance_name`

This command attempts to stop an instance.

```
mysql> STOP INSTANCE mysqld4;
Query OK, 0 rows affected (0,00 sec)
```

- `SHOW INSTANCES`

Shows the names of all loaded instances.

```
mysql> SHOW INSTANCES;
+-----+-----+
| instance_name | status |
+-----+-----+
| mysqld3       | offline |
| mysqld4       | online  |
| mysqld2       | offline |
+-----+-----+
3 rows in set (0,04 sec)
```

- SHOW INSTANCE STATUS *instance\_name*

Shows the status and the version information for an instance.

```
mysql> SHOW INSTANCE STATUS mysqld3;
+-----+-----+-----+
| instance_name | status | version |
+-----+-----+-----+
| mysqld3       | online | unknown |
+-----+-----+-----+
1 row in set (0.00 sec)
```

- SHOW INSTANCE OPTIONS *instance\_name*

Shows the options used by an instance.

```
mysql> SHOW INSTANCE OPTIONS mysqld3;
+-----+-----+-----+
| option_name | value |
+-----+-----+-----+
| instance_name | mysqld3 |
| mysqld-path  | /home/cps/mysql/trees/mysql-4.1/sql/mysqld |
| port         | 3309   |
| socket       | /tmp/mysql.sock3 |
| pid-file     | hostname.pid3    |
| datadir      | /home/cps/mysql_data/data_dir1/ |
| language     | /home/cps/mysql/trees/mysql-4.1/sql/share/english |
+-----+-----+-----+
7 rows in set (0.01 sec)
```

- SHOW *instance\_name* LOG FILES

The command lists all log files used by the instance. The result set contains the path to the log file and the log file size. If no log file path is specified in the configuration file (for example, `log=/var/mysql.log`), the Instance Manager tries to guess its placement. If the IM is unable to guess the logfile placement you should specify the log file location explicitly by using the appropriate log option in the instance section of the configuration file.

```
mysql> SHOW mysqld LOG FILES;
+-----+-----+-----+
| Logfile      | Path | Filesize |
+-----+-----+-----+
| ERROR LOG    | /home/cps/var/mysql/owlet.err | 9186 |
| GENERAL LOG  | /home/cps/var/mysql/owlet.log | 471503 |
| SLOW LOG     | /home/cps/var/mysql/owlet-slow.log | 4463 |
+-----+-----+-----+
3 rows in set (0.01 sec)
```

- SHOW *instance\_name* LOG {ERROR | SLOW | GENERAL} *size[,offset\_from\_end]*

This command retrieves a portion of the specified log file. Because most users are interested in

the latest log messages, the *size* parameter defines the number of bytes you would like to retrieve starting from the log end. You can retrieve data from the middle of the log file by specifying the optional *offset\_from\_end* parameter. The following example retrieves 21 bytes of data, starting 23 bytes from the end of the log file and ending 2 bytes from the end of the log file:

```
mysql> SHOW mysqld LOG GENERAL 21, 2;
+-----+
| Log |
+-----+
| using password: YES |
+-----+
1 row in set (0.00 sec)
```

- `SET instance_name.option_name=option_value`

This command edits the specified instance's configuration file to change or add instance options. The IM assumes that the configuration file is located at `/etc/my.cnf`. You should check that the file exists and has appropriate permissions.

```
mysql> SET mysqld2.port=3322;
Query OK, 0 rows affected (0.00 sec)
```

Changes made to the configuration file do not take effect until the MySQL server is restarted. In addition, these changes are not stored in the instance manager's local cache of instance settings until a `FLUSH INSTANCES` command is executed.

- `UNSET instance_name.option_name`

This command removes an option from an instance's configuration file.

```
mysql> UNSET mysqld2.port;
Query OK, 0 rows affected (0.00 sec)
```

Changes made to the configuration file do not take effect until the MySQL server is restarted. In addition, these changes are not stored in the instance manager's local cache of instance settings until a `FLUSH INSTANCES` command is executed.

- `FLUSH INSTANCES`

This command forces IM to reread the configuration file and to refresh internal structures. This command should be performed after editing the configuration file. The command does not restart instances.

```
mysql> FLUSH INSTANCES;
Query OK, 0 rows affected (0.04 sec)
```

## 5.6. Installation-Related Programs

### 5.6.1. `mysql_fix_privilege_tables` — Upgrade MySQL System Tables

Some releases of MySQL introduce changes to the structure of the system tables in the `mysql` database to add new privileges or support new features. When you update to a new version of MySQL, you should update your system tables as well to make sure that their structure is up to date. Otherwise, there might be capabilities that you cannot take advantage of. First, make a backup of your `mysql` database, and then use the following procedure.

**Note:** As of MySQL 5.0.19, `mysql_fix_privilege_tables` is superseded by `mysql_upgrade`, which should be used instead. See Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

On Unix or Unix-like systems, update the system tables by running the `mysql_fix_privilege_tables` script:

```
shell> mysql_fix_privilege_tables
```

You must run this script while the server is running. It attempts to connect to the server running on the local host as `root`. If your `root` account requires a password, indicate the password on the command line like this:

```
shell> mysql_fix_privilege_tables --password=root_password
```

The `mysql_fix_privilege_tables` script performs any actions necessary to convert your system tables to the current format. You might see some `Duplicate column name` warnings as it runs; you can ignore them.

After running the script, stop the server and restart it.

On Windows systems, MySQL distributions include a `mysql_fix_privilege_tables.sql` SQL script that you can run using the `mysql` client. For example, if your MySQL installation is located at `C:\Program Files\MySQL\MySQL Server 5.0`, the commands look like this:

```
C:\> cd "C:\Program Files\MySQL\MySQL Server 5.0"
C:\> bin\mysql -u root -p mysql
mysql> SOURCE scripts/mysql_fix_privilege_tables.sql
```

The `mysql` command will prompt you for the `root` password; enter it when prompted.

If your installation is located in some other directory, adjust the pathnames appropriately.

As with the Unix procedure, you might see some `Duplicate column name` warnings as `mysql` processes the statements in the `mysql_fix_privilege_tables.sql` script; you can ignore them.

After running the script, stop the server and restart it.

## 5.6.2. `mysql_upgrade` — Check Tables for MySQL Upgrade

`mysql_upgrade` should be executed each time you upgrade MySQL. It checks all tables in all databases for incompatibilities with the current version of MySQL Server. If a table is found to have a possible incompatibility, it is checked. If any problems are found, the table is repaired. `mysql_upgrade` also upgrades the system tables so that you can take advantage of new privileges or capabilities that might have been added.

All checked and repaired tables are marked with the current MySQL version number. This ensures that next time you run `mysql_upgrade` with the same version of the server, it can tell whether there is any need to check or repair the table again.

`mysql_upgrade` also saves the MySQL version number in a file named `mysql_upgrade.info` in the data directory. This is used to quickly check if all tables have been checked for this release so that table-checking can be skipped. To ignore this file, use the `--force` option.

To check and repair tables and to upgrade the system tables, `mysql_upgrade` executes the following commands:

```
mysqlcheck --check-upgrade --all-databases --auto-repair
mysql_fix_privilege_tables
```

`mysql_upgrade` supersedes the older `mysql_fix_privilege_tables` script. In MySQL 5.0.19, `mysql_upgrade` was added as a shell script and worked only for Unix systems. As of MySQL 5.0.22, `mysql_upgrade` is an executable binary and is available on all systems. On systems older than those supporting `mysql_upgrade`, you can execute the `mysqlcheck` command manually, and then upgrade your system tables as described in Section 5.6.1, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.

For details about what is checked, see the description of the `FOR UPGRADE` option of the `CHECK TABLE` statement (see Section 13.5.2.3, “`CHECK TABLE` Syntax”).

To use `mysql_upgrade`, make sure that the server is running, and then invoke it like this:

```
shell> mysql_upgrade [options]
```

`mysql_upgrade` reads options from the command line and from the `[mysqld]` and `[mysql_upgrade]` groups in option files. It supports the following options:

- `--help`  
Display a short help message and exit.
- `--basedir=path`  
The path to the MySQL installation directory.
- `--datadir=path`  
The path to the data directory.
- `--force`  
Force execution of `mysqlcheck` even if `mysql_upgrade` has already been executed for the current version of MySQL. (In other words, this option causes the `mysql_upgrade.info` file to be ignored.)
- `--user=user_name, -u user_name`  
The MySQL username to use when connecting to the server. The default username is `root`.
- `--verbose`  
Verbose mode. Print more information about what the program does.

Other options are passed to `mysqlcheck` and to `mysql_fix_privilege_tables`. For example, it might be necessary to specify the `--password[=password]` option.

## 5.7. General Security Issues

This section describes some general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see Section 5.8, “The MySQL Access Privilege System”.

### 5.7.1. General Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the

most common security mistakes.

In discussing security, we emphasize the necessity of fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines whenever possible:

- **Do not ever give anyone (except MySQL root accounts) access to the user table in the mysql database!** This is critical.
- Learn the MySQL access privilege system. The GRANT and REVOKE statements are used for controlling access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

Checklist:

- Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL `root` user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a `root` password. See Section 2.10.3, “Securing the Initial MySQL Accounts”.
- Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.
- Do not store any plain-text passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `MD5 ( )`, `SHA1 ( )`, or some other one-way hashing function and store the hash value.
- Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Mary had a little lamb” results in a password of “Mhall”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence.
- Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

- Try to scan your ports from the Internet using a tool such as `nmap`. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. Another simple way to check whether or not your MySQL port is open is to try the following command from some remote machine, where `server_host` is the hostname or IP number of the host on which your MySQL server runs:

```
shell> telnet server_host 3306
```

If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open. If `telnet` hangs or the connection is refused, the port is blocked, which is how you want it to be.

- Do not trust any data entered by users of your applications. They can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like “;

`DROP DATABASE mysql;`". This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value 234, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotes around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing non-numeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is allowable to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Try to enter single and double quote marks ('' and '') in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding %22 (''), %23 ('#'), and %27 (') to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a username different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.
- Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:
  - MySQL C API: Use the `mysql_real_escape_string()` API call.
  - MySQL++: Use the `escape` and `quote` modifiers for query streams.
  - PHP: Use the `mysql_real_escape_string()` function (available as of PHP 4.3.0, prior to that PHP version use `mysql_escape_string()`, and prior to PHP 4.0.3, use `addslashes()`). Note that only `mysql_real_escape_string()` is character set-aware; the other functions can be "bypassed" when using (invalid) multi-byte character sets. In PHP 5, you can use the `mysqli` extension, which supports the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders.
  - Perl DBI: Use placeholders or the `quote()` method.
  - Ruby DBI: Use placeholders or the `quote()` method.
  - Java JDBC: Use a `PreparedStatement` object and placeholders.

Other programming interfaces might have similar capabilities.

- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to

everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections as of version 4.0. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.

- Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

```
shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
```

(This works under Linux and should work with small modifications under other systems.) Warning: If you do not see plaintext data, this doesn't always mean that the information actually is encrypted. If you need high security, you should consult with a security expert.

## 5.7.2. Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted in clear text over the connection. Password handling during the client connection sequence was upgraded in MySQL 4.1.1 to be very secure. If you are still using pre-4.1.1-style passwords, the encryption algorithm is not as strong as the newer algorithm. With some effort, a clever attacker who can sniff the traffic between the client and the server can crack the password. (See Section 5.8.9, “Password Hashing as of MySQL 4.1”, for a discussion of the different password handling methods.)

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See Section 5.9.7, “Using Secure Connections”. Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at <http://www.openssh.org/>, and a commercial SSH client at <http://www.ssh.com/>.

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any username to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all account have a password, connecting using another user's account becomes much more difficult.

For a discussion of methods for setting passwords, see Section 5.9.5, “Assigning Account Passwords”.

- Never run the MySQL server as the Unix `root` user. This is extremely dangerous, because any user with the `FILE` privilege is able to cause the server to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using the `--user=root` option.

`mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies the username in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

```
[mysqld]
user=mysql
```

This causes the server to start as the designated user whether you start it manually or by using

`mysqld_safe` or `mysql.server`. For more details, see Section 5.7.5, “How to Run MySQL as a Normal User”.

Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` username in the `user` table. *Username for MySQL accounts have nothing to do with usernames for Unix accounts.*

- Do not allow the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server's data directory then could delete any file in the system! See Section 7.6.1.2, “Using Symbolic Links for Tables on Unix”.
- Make sure that the only Unix user with read or write privileges in the database directories is the user that `mysqld` runs as.
- Do not grant the `PROCESS` or `SUPER` privilege to non-administrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is allowed to see the server process list might be able to see statements issued by other users such as `UPDATE user SET password=PASSWORD('not_secure')`.

`mysqld` reserves an extra connection for users who have the `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not grant the `FILE` privilege to non-administrative users. Any user that has this privilege can write a file anywhere in the filesystem with the privileges of the `mysqld` daemon. To make this a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

- If you do not trust your DNS, you should use IP numbers rather than hostnames in the grant tables. In any case, you should be very careful about creating grant table entries using hostname values that contain wildcards.
- If you want to restrict the number of connections allowed to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `GRANT` statement also supports resource control options for limiting the extent of server use allowed to an account. See Section 13.5.1.3, “GRANT Syntax”.

### 5.7.3. Security-Related `mysqld` Options

The following `mysqld` options affect security:

- `--allow-suspicious-udfs`

This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. For MySQL 5.0, this option was added in MySQL 5.0.3. See Section 24.2.4.6, “User-Defined Function Security Precautions”.

- `--local-infile[={0|1}]`

If you start the server with `--local-infile=0`, clients cannot use `LOCAL` in `LOAD DATA` statements. See Section 5.7.4, “Security Issues with `LOAD DATA LOCAL`”.

- `--old-passwords`

Force the server to generate short (pre-4.1) password hashes for new passwords. This is useful for compatibility when the server must support older client programs. See Section 5.8.9, “Password Hashing as of MySQL 4.1”.

- `--safe-show-database` (*OBSOLETE*)

In previous versions of MySQL, this option caused the `SHOW DATABASES` statement to display the names of only those databases for which the user had some kind of privilege. In MySQL 5.0, this option is no longer available as this is now the default behavior, and there is a `SHOW DATABASES` privilege that can be used to control access to database names on a per-account basis. See Section 13.5.1.3, “GRANT Syntax”.

- `--safe-user-create`

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` table. If you want a user to have the ability to create new users that have those privileges that the user has right to grant, you should grant the user the following privilege:

```
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--secure-auth`

Disallow authentication for accounts that have old (pre-4.1) passwords.

The `mysql` client also has a `--secure-auth` option, which prevents connections to a server if the server requires a password in old format for the client account.

- `--skip-grant-tables`

This option causes the server not to use the privilege system at all. This gives anyone with access to the server *unrestricted access to all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement. This option also suppresses loading of user-defined functions (UDFs).

- `--skip-name-resolve`

Hostnames are not resolved. All `Host` column values in the grant tables must be IP numbers or `localhost`.

- `--skip-networking`

Do not allow TCP/IP connections over the network. All connections to `mysqld` must be made via Unix socket files.

- `--skip-show-database`

With this option, the `SHOW DATABASES` statement is allowed only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. Without this option, `SHOW DATABASES` is allowed to all users, but displays each database name only if the user has the `SHOW DATABASES` privilege or some privilege for the database. Note that any global privilege is a privilege for the database.

## 5.7.4. Security Issues with `LOAD DATA LOCAL`

The `LOAD DATA` statement can load a file that is located on the server host, or it can load a file that is located on the client host when the `LOCAL` keyword is specified.

There are two potential security issues with supporting the `LOCAL` version of `LOAD DATA` statements:

- The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD DATA` statement. Such a server could access any file on the client host to which the client user has read access.
- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any command against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not the remote program being run by the user who connects to the Web server.

To deal with these problems, we changed how `LOAD DATA LOCAL` is handled as of MySQL 3.23.49 and MySQL 4.0.2 (4.0.13 on Windows):

- By default, all MySQL clients and libraries in binary distributions are compiled with the `--enable-local-infile` option, to be compatible with MySQL 3.23.48 and before.
- If you build MySQL from source but do not invoke `configure` with the `--enable-local-infile` option, `LOAD DATA LOCAL` cannot be used by any client unless it is written explicitly to invoke `mysql_options(... MYSQL_OPT_LOCAL_INFILE, 0)`. See Section 22.2.3.48, “`mysql_options()`”.
- You can disable all `LOAD DATA LOCAL` commands from the server side by starting `mysqld` with the `--local-infile=0` option.
- For the `mysql` command-line client, `LOAD DATA LOCAL` can be enabled by specifying the `--local-infile[=1]` option, or disabled with the `--local-infile=0` option. Similarly, for `mysqlimport`, the `--local` or `-L` option enables local data file loading. In any case, successful use of a local loading operation requires that the server is enabled to allow it.
- If you use `LOAD DATA LOCAL` in Perl scripts or other programs that read the `[client]` group from option files, you can add the `local-infile=1` option to that group. However, to keep this from causing problems for programs that do not understand `local-infile`, specify it using the `loose-` prefix:

```
[client]
loose-local-infile=1
```

- If `LOAD DATA LOCAL INFILE` is disabled, either in the server or the client, a client that attempts to issue such a statement receives the following error message:

```
ERROR 1148: The used command is not allowed with this MySQL version
```

## 5.7.5. How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Unix, the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it's running (use `mysqladmin shutdown`).
2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

```
shell> chown -R user_name /path/to/mysql/datadir
```

If you do not do this, the server will not be able to access databases or tables when it runs as `user_name`.

If directories or files within the MySQL data directory are symbolic links, you'll also need to follow those links and change the directories and files they point to. `chown -R` might not follow symbolic links for you.

3. Start the server as user `user_name`. If you are using MySQL 3.22 or later, another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` option. `mysqld` starts up, then switches to run as the Unix user `user_name` before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the username by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
user=user_name
```

If your Unix machine itself isn't secured, you should assign passwords to the MySQL `root` accounts in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See Section 2.10, "Post-Installation Setup and Testing".

## 5.8. The MySQL Access Privilege System

MySQL has an advanced but non-standard security and privilege system. The following discussion describes how it works.

### 5.8.1. What the Privilege System Does

The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`.

Additional functionality includes the ability to have anonymous users and to grant privileges for MySQL-specific functions such as `LOAD DATA INFILE` and administrative operations.

### 5.8.2. How the Privilege System Works

The MySQL privilege system ensures that all users may perform only the operations allowed to them. As a user, when you connect to a MySQL server, your identity is determined by *the host from which you connect* and *the username you specify*. When you issue requests after connecting, the system grants privileges according to your identity and *what you want to do*.

MySQL considers both your hostname and username in identifying you because there is little reason to assume that a given username belongs to the same person everywhere on the Internet. For example, the user `joe` who connects from `office.example.com` need not be the same person as the user `joe` who connects from `home.example.com`. MySQL handles this by allowing you to distinguish users on different hosts that happen to have the same name: You can grant one set of

privileges for connections by joe from office.example.com, and a different set of privileges for connections by joe from home.example.com.

MySQL access control involves two stages when you run a client program that connects to the server:

- Stage 1: The server checks whether it should allow you to connect.
- Stage 2: Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the SELECT privilege for the table or the DROP privilege for the database.

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. See Section 5.8.7, “When Privilege Changes Take Effect”, for details.

The server stores privilege information in the grant tables of the mysql database (that is, in the database named mysql). The MySQL server reads the contents of these tables into memory when it starts and re-reads them under the circumstances indicated in Section 5.8.7, “When Privilege Changes Take Effect”. Access-control decisions are based on the in-memory copies of the grant tables.

Normally, you manipulate the contents of the grant tables indirectly by using statements such as GRANT and REVOKE to set up accounts and control the privileges available to each one. See Section 13.5.1, “Account Management Statements”. The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients.

The server uses the user, db, and host tables in the mysql database at both stages of access control. The columns in the user and db tables are shown here. The host table is similar to the db table but has a specialized use as described in Section 5.8.6, “Access Control, Stage 2: Request Verification”.

Table Name	user	db
<b>Scope columns</b>	Host	Host
	User	Db
	Password	User
<b>Privilege columns</b>	Select_priv	Select_priv
	Insert_priv	Insert_priv
	Update_priv	Update_priv
	Delete_priv	Delete_priv
	Index_priv	Index_priv
	Alter_priv	Alter_priv
	Create_priv	Create_priv
	Drop_priv	Drop_priv
	Grant_priv	Grant_priv
	Create_view_priv	Create_view_priv
	Show_view_priv	Show_view_priv
	Create_routine_priv	Create_routine_priv
	Alter_routine_priv	Alter_routine_priv
	Execute_priv	Execute_priv
	Create_tmp_table_priv	Create_tmp_table_priv
	Lock_tables_priv	Lock_tables_priv

	References_priv	References_priv
	Reload_priv	
	Shutdown_priv	
	Process_priv	
	File_priv	
	Show_db_priv	
	Super_priv	
	Repl_slave_priv	
	Repl_client_priv	
<b>Security columns</b>	ssl_type	
	ssl_cipher	
	x509_issuer	
	x509_subject	
<b>Resource control columns</b>	max_questions	
	max_updates	
	max_connections	
	max_user_connections	

Execute\_priv was present in MySQL 5.0.0, but did not become operational until MySQL 5.0.3.

The Create\_view\_priv and Show\_view\_priv columns were added in MySQL 5.0.1.

The Create\_routine\_priv, Alter\_routine\_priv, and max\_user\_connections columns were added in MySQL 5.0.3.

During the second stage of access control, the server performs request verification to make sure that each client has sufficient privileges for each request that it issues. In addition to the user, db, and host grant tables, the server may also consult the tables\_priv and columns\_priv tables for requests that involve tables. The tables\_priv and columns\_priv tables provide finer privilege control at the table and column levels. They have the following columns:

Table Name	tables_priv	columns_priv
<b>Scope columns</b>	Host	Host
	Db	Db
	User	User
	Table_name	Table_name
		Column_name
<b>Privilege columns</b>	Table_priv	Column_priv
	Column_priv	
<b>Other columns</b>	Timestamp	Timestamp
	Grantor	

The Timestamp and Grantor columns currently are unused and are discussed no further here.

For verification of requests that involve stored routines, the server may consult the procs\_priv table. This table has the following columns:

Table Name	procs_priv
<b>Scope columns</b>	Host

	Db
	User
	Routine_name
	Routine_type
<b>Privilege columns</b>	Proc_priv
<b>Other columns</b>	Timestamp
	Grantor

The `procs_priv` table exists as of MySQL 5.0.3. The `Routine_type` column was added in MySQL 5.0.6. It is an ENUM column with values of 'FUNCTION' or 'PROCEDURE' to indicate the type of routine the row refers to. This column allows privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns currently are unused and are discussed no further here.

Each grant table contains scope columns and privilege columns:

- Scope columns determine the scope of each row (entry) in the tables; that is, the context in which the row applies. For example, a `user` table row with `Host` and `User` values of 'thomas.loc.gov' and 'bob' would be used for authenticating connections made to the server from the host `thomas.loc.gov` by a client that specifies a username of `bob`. Similarly, a `db` table row with `Host`, `User`, and `Db` column values of 'thomas.loc.gov', 'bob' and 'reports' would be used when `bob` connects from the host `thomas.loc.gov` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv` scope columns indicate the stored routine to which each row applies.
- Privilege columns indicate which privileges are granted by a table row; that is, what operations can be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. Section 5.8.6, "Access Control, Stage 2: Request Verification", describes the rules that are used to do this.

Scope columns contain strings. They are declared as shown here; the default value for each is the empty string:

Column Name	Type
Host	CHAR(60)
User	CHAR(16)
Password	CHAR(16)
Db	CHAR(64)
Table_name	CHAR(64)
Column_name	CHAR(64)
Routine_name	CHAR(64)

For access-checking purposes, comparisons of `Host` values are case-insensitive. `User`, `Password`, `Db`, and `Table_name` values are case sensitive. `Column_name` and `Routine_name` values are case insensitive.

In the `user`, `db`, and `host` tables, each privilege is listed in a separate column that is declared as `ENUM('N','Y') DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.

In the `tables_priv`, `columns_priv`, and `procs_priv` tables, the privilege columns are de-

clared as SET columns. Values in these columns can contain any combination of the privileges controlled by the table:

Table Name	Column Name	Possible Set Elements
tables_priv	Table_priv	'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view'
tables_priv	Column_priv	'Select', 'Insert', 'Update', 'References'
columns_priv	Column_priv	'Select', 'Insert', 'Update', 'References'
procs_priv	Proc_priv	'Execute', 'Alter Routine', 'Grant'

Briefly, the server uses the grant tables in the following manner:

- The user table scope columns determine whether to reject or allow incoming connections. For allowed connections, any privileges granted in the user table indicate the user's global (superuser) privileges. Any privilege granted in this table applies to *all* databases on the server.

**Note:** Because any global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with SHOW DATABASES or by examining the SCHEMATA table of INFORMATION\_SCHEMA.

- The db table scope columns determine which users can access which databases from which hosts. The privilege columns determine which operations are allowed. A privilege granted at the database level applies to the database and to all its tables.
- The host table is used in conjunction with the db table when you want a given db table row to apply to several hosts. For example, if you want a user to be able to use a database from several hosts in your network, leave the Host value empty in the user's db table row, then populate the host table with a row for each of those hosts. This mechanism is described more detail in Section 5.8.6, "Access Control, Stage 2: Request Verification".

**Note:** The host table must be modified directly with statements such as INSERT, UPDATE, and DELETE. It is not affected by statements such as GRANT and REVOKE that modify the grant tables indirectly. Most MySQL installations need not use this table at all.

- The tables\_priv and columns\_priv tables are similar to the db table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.
- The procs\_priv table applies to stored routines. A privilege granted at the routine level applies only to a single routine.

Administrative privileges (such as RELOAD or SHUTDOWN) are specified only in the user table. The reason for this is that administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. In fact, to determine whether you can perform an administrative operation, the server need consult only the user table.

The FILE privilege also is specified only in the user table. It is not an administrative privilege as such, but your ability to read or write files on the server host is independent of the database you are accessing.

The mysqld server reads the contents of the grant tables into memory when it starts. You can tell it to re-read the tables by issuing a FLUSH PRIVILEGES statement or executing a mysqladmin flush-privileges or mysqladmin reload command. Changes to the grant tables take ef-

fect as indicated in Section 5.8.7, “When Privilege Changes Take Effect”.

When you modify the contents of the grant tables, it is a good idea to make sure that your changes set up privileges the way you want. To check the privileges for a given account, use the `SHOW GRANTS` statement. (See Section 13.5.4.12, “`SHOW GRANTS` Syntax”.) For example, to determine the privileges that are granted to an account with `Host` and `User` values of `pc84.example.com` and `bob`, issue this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com' ;
```

For additional help in diagnosing privilege-related problems, see Section 5.8.8, “Causes of Access denied Errors”. For general advice on security issues, see Section 5.7, “General Security Issues”.

### 5.8.3. Privileges Provided by MySQL

Information about account privileges is stored in the `user`, `db`, `host`, `tables_priv`, `columns_priv`, and `procs_priv` tables in the `mysql` database. The MySQL server reads the contents of these tables into memory when it starts and re-reads them under the circumstances indicated in Section 5.8.7, “When Privilege Changes Take Effect”. Access-control decisions are based on the in-memory copies of the grant tables.

The names used in the `GRANT` and `REVOKE` statements to refer to privileges are shown in the following table, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies. Further information about the meaning of each privilege may be found at Section 13.5.1.3, “`GRANT` Syntax”.

Privilege	Column	Context
CREATE	Create_priv	databases, tables, or indexes
DROP	Drop_priv	databases or tables
GRANT OPTION	Grant_priv	databases, tables, or stored routines
REFERENCES	References_priv	databases or tables
ALTER	Alter_priv	tables
DELETE	Delete_priv	tables
INDEX	Index_priv	tables
INSERT	Insert_priv	tables
SELECT	Select_priv	tables
UPDATE	Update_priv	tables
CREATE VIEW	Create_view_priv	views
SHOW VIEW	Show_view_priv	views
ALTER ROUTINE	Alter_routine_priv	stored routines
CREATE ROUTINE	Create_routine_priv	stored routines
EXECUTE	Execute_priv	stored routines
FILE	File_priv	file access on server host
CREATE TEMPORARY TABLES	Create_tmp_table_priv	server administration
LOCK TABLES	Lock_tables_priv	server administration
CREATE USER	Create_user_priv	server administration
PROCESS	Process_priv	server administration
RELOAD	Reload_priv	server administration
REPLICATION CLIENT	Repl_client_priv	server administration
REPLICATION SLAVE	Repl_slave_priv	server administration
SHOW DATABASES	Show_db_priv	server administration

SHUTDOWN	Shutdown_priv	server administration
SUPER	Super_priv	server administration

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See Section 5.6.2, “mysql\_upgrade — Check Tables for MySQL Upgrade”.

CREATE VIEW and SHOW VIEW were added in MySQL 5.0.1. CREATE USER, CREATE ROUTINE, and ALTER ROUTINE were added in MySQL 5.0.3. Although EXECUTE was present in MySQL 5.0.0, it did not become operational until MySQL 5.0.3.

To create or alter stored routines if binary logging is enabled, you may also need the SUPER privilege, as described in Section 17.4, “Binary Logging of Stored Routines and Triggers”.

The CREATE and DROP privileges allow you to create new databases and tables, or to drop (remove) existing databases and tables. *If you grant the DROP privilege for the mysql database to a user, that user can drop the database in which the MySQL access privileges are stored.*

The SELECT, INSERT, UPDATE, and DELETE privileges allow you to perform operations on rows in existing tables in a database. INSERT is also required for the ANALYZE TABLE, OPTIMIZE TABLE, and REPAIR TABLE table-maintenance statements.

SELECT statements require the SELECT privilege only if they actually retrieve rows from a table. Some SELECT statements do not access tables and can be executed without permission for any database. For example, you can use the mysql client as a simple calculator to evaluate expressions that make no reference to tables:

```
SELECT 1+1;
SELECT PI()*2;
```

The INDEX privilege enables you to create or drop (remove) indexes. INDEX applies to existing tables. If you have the CREATE privilege for a table, you can include index definitions in the CREATE TABLE statement.

The ALTER privilege enables you to use ALTER TABLE to change the structure of or rename tables.

The CREATE ROUTINE privilege is needed for creating stored routines (functions and procedures). ALTER ROUTINE privilege is needed for altering or dropping stored routines, and EXECUTE is needed for executing stored routines.

The GRANT privilege enables you to give to other users those privileges that you yourself possess. It can be used for databases, tables, and stored routines.

The FILE privilege gives you permission to read and write files on the server host using the LOAD DATA INFILE and SELECT ... INTO OUTFILE statements. A user who has the FILE privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.) The FILE privilege also enables the user to create new files in any directory where the MySQL server has write access. As a security measure, the server will not overwrite existing files.

The remaining privileges are used for administrative operations. Many of them can be performed by using the mysqladmin program or by issuing SQL statements. The following table shows which mysqladmin commands each administrative privilege enables you to execute:

Privilege	Commands Permitted to Privilege Holders
RELOAD	flush-hosts, flush-logs, flush-privileges, flush-status, flush-tables, flush-threads, refresh, reload

SHUTDOWN	shutdown
PROCESS	processlist
SUPER	kill

The `reload` command tells the server to re-read the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-xxx` commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.

The `shutdown` command shuts down the server. There is no corresponding SQL statement.

The `processlist` command displays information about the threads executing within the server (that is, information about the statements being executed by clients). The `kill` command terminates server threads. You can always display or kill your own threads, but you need the `PROCESS` privilege to display threads initiated by other users and the `SUPER` privilege to kill them. See Section 13.5.5.3, “KILL Syntax”.

The `CREATE TEMPORARY TABLES` privilege enables the use of the keyword `TEMPORARY` in `CREATE TABLE` statements.

The `LOCK TABLES` privilege enables the use of explicit `LOCK TABLES` statements to lock tables for which you have the `SELECT` privilege. This includes the use of write locks, which prevents anyone else from reading the locked table.

The `REPLICATION CLIENT` privilege enables the use of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`.

The `REPLICATION SLAVE` privilege should be granted to accounts that are used by slave servers to connect to the current server as their master. Without this privilege, the slave cannot request updates that have been made to databases on the master server.

The `SHOW DATABASES` privilege allows the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option. Note that *any* global privilege is a privilege for the database.

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the `FILE` and administrative privileges:

- The `FILE` privilege can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server's data directory. The table can then be accessed using `SELECT` to transfer its contents to the client host.
- The `GRANT` privilege enables users to give their privileges to other users. Two users that have different privileges and with the `GRANT` privilege are able to combine privileges.
- The `ALTER` privilege may be used to subvert the privilege system by renaming tables.
- The `SHUTDOWN` privilege can be abused to deny service to other users entirely by terminating the server.
- The `PROCESS` privilege can be used to view the plain text of currently executing statements, including statements that set or change passwords.
- The `SUPER` privilege can be used to terminate other clients or change how the server operates.
- Privileges granted for the `mysql` database itself can be used to change passwords and other access privilege information. Passwords are stored encrypted, so a malicious user cannot simply

read them to know the plain text password. However, a user with write access to the `user` table `Password` column can change an account's password, and then connect to the MySQL server using that account.

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.
- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.
- A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

## 5.8.4. Connecting to the MySQL Server

MySQL client programs generally expect you to specify certain connection parameters when you want to access a MySQL server:

- The name of the host where the MySQL server is running
- Your username
- Your password

For example, the `mysql` client can be started as follows from a command-line prompt (indicated here by `shell>`):

```
shell> mysql -h host_name -u user_name -pyour_pass
```

Alternative forms of the `-h`, `-u`, and `-p` options are `--host=host_name`, `--user=user_name`, and `--password=your_pass`. Note that there is *no space* between `-p` or `--password=` and the password following it.

If you use a `-p` or `--password` option but do not specify the password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line. Any user on your system may be able to see a password specified on the command line by executing a command such as `ps auxww`. See Section 5.9.6, “Keeping Your Password Secure”.

MySQL client programs use default values for any connection parameter option that you do not specify:

- The default hostname is `localhost`.
- The default username is ODBC on Windows and your Unix login name on Unix.
- No password is supplied if neither `-p` nor `--password` is given.

Thus, for a Unix user with a login name of `joe`, all of the following commands are equivalent:

```
shell> mysql -h localhost -u joe
shell> mysql -h localhost
shell> mysql -u joe
shell> mysql
```

Other MySQL clients behave similarly.

You can specify different default values to be used when you make a connection so that you need not enter them on the command line each time you invoke a client program. This can be done in a couple of ways:

- You can specify connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

```
[client]
host=host_name
user=user_name
password=your_pass
```

Section 4.3.2, “Using Option Files”, discusses option files further.

- You can specify some connection parameters using environment variables. The host can be specified for `mysql` using `MYSQL_HOST`. The MySQL username can be specified using `USER` (this is for Windows and NetWare only). The password can be specified using `MYSQL_PWD`, although this is insecure; see Section 5.9.6, “Keeping Your Password Secure”. For a list of variables, see Appendix F, *Environment Variables*.

## 5.8.5. Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password. If not, the server denies access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL username

Identity checking is performed using the three `user` table scope columns (`Host`, `User`, and `Password`). The server accepts the connection only if the `Host` and `User` columns in some `user` table row match the client hostname and username and the client supplies the password specified in that row.

`Host` values in the `user` table may be specified as follows:

- A `Host` value may be a hostname or an IP number, or `'localhost'` to indicate the local host.
- You can use the wildcard characters `'%'` and `'_'` in `Host` column values. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, a `Host` value of `'%'` matches any hostname, whereas a value of `'%.mysql.com'` matches any host in the `mysql.com` domain.
- For `Host` values specified as IP numbers, you can specify a netmask indicating how many address bits to use for the network number. For example:

```
GRANT ALL PRIVILEGES ON db.* TO david@'192.58.197.0/255.255.255.0';
```

This allows `david` to connect from any client host having an IP number `client_ip` for

which the following condition is true:

```
client_ip & netmask = host_ip
```

That is, for the GRANT statement just shown:

```
client_ip & 255.255.255.0 = 192.58.197.0
```

IP numbers that satisfy this condition and can connect to the MySQL server are those in the range from 192.58.197.0 to 192.58.197.255.

Note: The netmask can only be used to tell the server to use 8, 16, 24, or 32 bits of the address. Examples:

- 192.0.0.0/255.0.0.0: anything on the 192 class A network
- 192.168.0.0/255.255.0.0: anything on the 192.168 class B network
- 192.168.1.0/255.255.255.0: anything on the 192.168.1 class C network
- 192.168.1.1: only this specific IP

The following netmask (28 bits) will not work:

```
192.168.0.1/255.255.255.240
```

- A blank `Host` value in a db table row means that its privileges should be combined with those in the row in the `host` table that matches the client hostname. The privileges are combined using an AND (intersection) operation, not OR (union). Section 5.8.6, “Access Control, Stage 2: Request Verification”, discusses use of the `host` table further.

A blank `Host` value in the other grant tables is the same as `'%'`.

Because you can use IP wildcard values in the `Host` column (for example, `'144.155.166.%'` to match every host on a subnet), someone could try to exploit this capability by naming a host `144.155.166.somewhere.com`. To foil such attempts, MySQL disallows matching on hostnames that start with digits and a dot. Thus, if you have a host named something like `1.2.foo.com`, its name never matches the `Host` column of the grant tables. An IP wildcard value can match only IP numbers, not hostnames.

In the `User` column, wildcard characters are not allowed, but you can specify a blank value, which matches any name. If the `user` table row that matches an incoming connection has a blank username, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank username is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `Password` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password.

Non-blank `Password` values in the `user` table represent encrypted passwords. MySQL does not store passwords in plaintext form for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the `PASSWORD()` function). The encrypted password then is used during the connection process when checking whether the password is correct. (This is done without the encrypted password ever traveling over the connection.) From MySQL's point of view, the encrypted password is the *real* password, so you should never give anyone access to it. In particular, *do not give non-administrative users read access to tables in the `mysql` database.*

MySQL 5.0 employs the stronger authentication method (first implemented in MySQL 4.1) that has better password protection during the connection process than in earlier versions. It is secure even if TCP/IP packets are sniffed or the `mysql` database is captured. Section 5.8.9, “Password Hashing as

of MySQL 4.1”, discusses password encryption further.

The following table shows how various combinations of `Host` and `User` values in the `user` table apply to incoming connections.

Host Value	User Value	Allowable Connections
'thomas.loc.gov'	'fred'	fred, connecting from thomas.loc.gov
'thomas.loc.gov'	' '	Any user, connecting from thomas.loc.gov
'%'	'fred'	fred, connecting from any host
'%'	' '	Any user, connecting from any host
'%.loc.gov'	'fred'	fred, connecting from any host in the loc.gov domain
'x.y.%'	'fred'	fred, connecting from x.y.net, x.y.com, x.y.edu, and so on (this is probably not useful)
'144.155.166.177'	'fred'	fred, connecting from the host with IP address 144.155.166.177
'144.155.166.%'	'fred'	fred, connecting from any host in the 144.155.166 class C subnet
'144.155.166.0/255.255.255.0'	'fred'	Same as previous example

It is possible for the client hostname and username of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from `thomas.loc.gov` by `fred`.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client hostname and username.

To see how this works, suppose that the `user` table looks like this:

```

+-----+-----+
| Host      | User      | ...
+-----+-----+
| %         | root      | ...
| %         | jeffrey   | ...
| localhost | root      | ...
| localhost |           | ...
+-----+-----+

```

When the server reads the table into memory, it orders the rows with the most-specific `Host` values first. Literal hostnames and IP numbers are the most specific. The pattern `'%'` means “any host” and is least specific. Rows with the same `Host` value are ordered with the most-specific `User` values first (a blank `User` value means “any user” and is least specific). For the `user` table just shown, the result after sorting looks like this:

```

+-----+-----+
| Host      | User      | ...
+-----+-----+
| localhost | root      | ...
| localhost |           | ...
| %         | jeffrey   | ...
+-----+-----+

```

```

| %          | root      | ...
+-----+-----+

```

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the rows from the table match: the one with `Host` and `User` values of `'localhost'` and `' '`, and the one with values of `'%'` and `'jeffrey'`. The `'localhost'` row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

```

+-----+-----+
| Host          | User      | ...
+-----+-----+
| %            | jeffrey   | ...
| thomas.loc.gov |          | ...
+-----+-----+

```

The sorted table looks like this:

```

+-----+-----+
| Host          | User      | ...
+-----+-----+
| thomas.loc.gov |          | ...
| %            | jeffrey   | ...
+-----+-----+

```

A connection by `jeffrey` from `thomas.loc.gov` is matched by the first row, whereas a connection by `jeffrey` from `whitehouse.gov` is matched by the second.

It is a common misconception to think that, for a given username, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is simply not true. The previous example illustrates this, where a connection from `thomas.loc.gov` by `jeffrey` is first matched not by the row containing `'jeffrey'` as the `User` column value, but by the row with no username. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a username when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` function. (See Section 12.9.3, “Information Functions”.) It returns a value in `user_name@host_name` format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:

```

mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| @localhost     |
+-----+

```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

Another thing you can do to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.

## 5.8.6. Access Control, Stage 2: Request Verification

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue via that connection, the server determines what operation you want to perform, then

checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `db`, `host`, `tables_priv`, `columns_priv`, or `procs_priv` tables. (You may find it helpful to refer to Section 5.8.2, “How the Privilege System Works”, which lists the columns present in each of the grant tables.)

The `user` table grants privileges that are assigned to you on a global basis and that apply no matter what the default database is. For example, if the `user` table grants you the `DELETE` privilege, you can delete rows from any table in any database on the server host! In other words, `user` table privileges are superuser privileges. It is wise to grant privileges in the `user` table only to superusers such as database administrators. For other users, you should leave all privileges in the `user` table set to 'N' and grant privileges at more specific levels only. You can grant privileges for particular databases, tables, columns, or routines.

The `db` and `host` tables grant database-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters ‘%’ and ‘\_’ can be used in the `Host` and `Db` columns of either table. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character (‘\_’) as part of a database name, specify it as ‘\\_’ in the `GRANT` statement.
- A ‘%’ `Host` value in the `db` table means “any host.” A blank `Host` value in the `db` table means “consult the `host` table for further information” (a process that is described later in this section).
- A ‘%’ or blank `Host` value in the `host` table means “any host.”
- A ‘%’ or blank `Db` value in either table means “any database.”
- A blank `User` value in either table matches the anonymous user.

The server reads the `db` and `host` tables into memory and sorts them at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns, and sorts the `host` table based on the `Host` and `Db` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching entries, it uses the first match that it finds.

The `tables_priv`, `columns_priv`, and `procs_priv` tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters ‘%’ and ‘\_’ can be used in the `Host` column. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator.
- A ‘%’ or blank `Host` value means “any host.”
- The `Db`, `Table_name`, and `Column_name` columns cannot contain wildcards or be blank.

The server sorts the `tables_priv`, `columns_priv`, and `procs_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as `SHUTDOWN` or `RELOAD`, the server checks only the `user` table row because that is the only table that specifies administrative privileges. The server grants access if the row allows the requested operation and denies access otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row doesn't grant the `SHUTDOWN` privilege to you, the server denies access without even checking the `db` or `host` tables. (They contain no

Shutdown\_priv column, so there is no need to do so.)

For database-related requests (INSERT, UPDATE, and so on), the server first checks the user's global (superuser) privileges by looking in the user table row. If the row allows the requested operation, access is granted. If the global privileges in the user table are insufficient, the server determines the user's database-specific privileges by checking the db and host tables:

1. The server looks in the db table for a match on the Host, Db, and User columns. The Host and User columns are matched to the connecting user's hostname and MySQL username. The Db column is matched to the database that the user wants to access. If there is no row for the Host and User, access is denied.
2. If there is a matching db table row and its Host column is not blank, that row defines the user's database-specific privileges.
3. If the matching db table row's Host column is blank, it signifies that the host table enumerates which hosts should be allowed access to the database. In this case, a further lookup is done in the host table to find a match on the Host and Db columns. If no host table row matches, access is denied. If there is a match, the user's database-specific privileges are computed as the intersection (*not* the union!) of the privileges in the db and host table entries; that is, the privileges that are 'Y' in both entries. (This way you can grant general privileges in the db table row and then selectively restrict them on a host-by-host basis using the host table entries.)

After determining the database-specific privileges granted by the db and host table entries, the server adds them to the global privileges granted by the user table. If the result allows the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in the tables\_priv and columns\_priv tables, adds those to the user's privileges, and allows or denies access based on the result. For stored routine operations, the server uses the procs\_priv table rather than tables\_priv and columns\_priv.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

It may not be apparent why, if the global user row privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an INSERT INTO ... SELECT statement, you need both the INSERT and the SELECT privileges. Your privileges might be such that the user table row grants one privilege and the db table row grants the other. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either table by itself; the privileges granted by the entries in both tables must be combined.

The host table is not affected by the GRANT or REVOKE statements, so it is unused in most MySQL installations. If you modify it directly, you can use it for some specialized purposes, such as to maintain a list of secure servers. For example, at TcX, the host table contains a list of all machines on the local network. These are granted all privileges.

You can also use the host table to indicate hosts that are *not* secure. Suppose that you have a machine public.your.domain that is located in a public area that you do not consider secure. You can allow access to all hosts on your network except that machine by using host table entries like this:

```
+-----+-----+-----+
| Host           | Db | ...
+-----+-----+-----+
```

```
| public.your.domain | % | ... (all privileges set to 'N')  
| %.your.domain     | % | ... (all privileges set to 'Y')  
+-----+-----+
```

Naturally, you should always test your changes to the grant tables (for example, by using `SHOW GRANTS`) to make sure that your access privileges are actually set up the way you think they are.

## 5.8.7. When Privilege Changes Take Effect

When `mysqld` starts, it reads all grant table contents into memory. The in-memory tables become effective for access control at that point.

When the server reloads the grant tables, privileges for existing client connections are affected as follows:

- Table and column privilege changes take effect with the client's next request.
- Database privilege changes take effect at the next `USE db_name` statement.
- Changes to global privileges and passwords take effect the next time the client connects.

If you modify the grant tables indirectly using statements such as `GRANT`, `REVOKE`, or `SET PASSWORD`, the server notices these changes and loads the grant tables into memory again immediately.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE`, your changes have no effect on privilege checking until you either restart the server or tell it to reload the tables. To reload the grant tables manually, issue a `FLUSH PRIVILEGES` statement or execute a `mysqladmin flush-privileges` or `mysqladmin reload` command.

If you change the grant tables directly but forget to reload them, your changes have *no effect* until you restart the server. This may leave you wondering why your changes do not seem to make any difference!

## 5.8.8. Causes of Access denied Errors

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not running, you cannot connect to it. For example, if you attempt to connect to the server and see a message such as one of those following, one cause might be that the server is not running:

```
shell> mysql  
ERROR 2003: Can't connect to MySQL server on 'host_name' (111)  
shell> mysql  
ERROR 2002: Can't connect to local MySQL server through socket  
'/tmp/mysql.sock' (111)
```

It might also be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` option to indicate the proper port number, or a `--socket` option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

```
shell> netstat -ln | grep mysql
```

- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM distributions on Linux), the installation process initializes the `mysql` database containing the grant tables. For distributions that do not do this, you must initialize the grant tables manually by running the `mysql_install_db` script. For details, see Section 2.10.2, “Unix Post-Installation Procedures”.

One way to determine whether you need to initialize the grant tables is to look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If you do not, execute the `mysql_install_db` script. After running this script and starting the server, test the initial privileges by executing this command:

```
shell> mysql -u root test
```

The server should let you connect without error.

- After a fresh installation, you should connect to the server and set up your users and their access permissions:

```
shell> mysql -u root mysql
```

The server should let you connect because the MySQL `root` user has no password initially. That is also a security risk, so setting the password for the `root` accounts is something you should do while you're setting up your other MySQL accounts. For instructions on setting the initial passwords, see Section 2.10.3, “Securing the Initial MySQL Accounts”.

- If you have updated an existing MySQL installation to a newer version, did you run the `mysql_upgrade` script? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.
- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
shell> mysql  
Client does not support authentication protocol requested  
by server; consider upgrading MySQL client
```

For information on how to deal with this, see Section 5.8.9, “Password Hashing as of MySQL 4.1”, and Section A.2.3, “Client does not support authentication protocol”.

- If you try to connect as `root` and get the following error, it means that you do not have a row in the `user` table with a `User` column value of `'root'` and that `mysqld` cannot resolve the hostname for your client:

```
Access denied for user ''@'unknown' to database mysql
```

In this case, you must restart the server with the `--skip-grant-tables` option and edit your `/etc/hosts` file or `\windows\hosts` file to add an entry for your host.

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check your environment and any applicable option files. For example, if you get `Access denied` when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the `--no-defaults` option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in Section 4.3.2, “Using Option Files”. Environment variables are listed in Appendix F, *Environment Variables*.

- If you get the following error, it means that you are using an incorrect root password:

```
shell> mysqladmin -u root -pxxxx ver  
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the `--no-defaults` option as described in the previous item.

For information on changing passwords, see Section 5.9.5, “Assigning Account Passwords”.

If you have lost or forgotten the root password, you can restart `mysqld` with `--skip-grant-tables` to change the password. See Section A.4.1, “How to Reset the Root Password”.

- If you change a password by using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must encrypt the password using the `PASSWORD()` function. If you do not use `PASSWORD()` for these statements, the password will not work. For example, the following statement sets a password, but fails to encrypt it, so the user is not able to connect afterward:

```
SET PASSWORD FOR 'abe'@'host_name' = 'eagle';
```

Instead, set the password like this:

```
SET PASSWORD FOR 'abe'@'host_name' = PASSWORD('eagle');
```

The `PASSWORD()` function is unnecessary when you specify a password using the `GRANT` or (beginning with MySQL 5.0.2) `CREATE USER` statements, or the `mysqladmin password` command. Each of those automatically uses `PASSWORD()` to encrypt the password. See Section 5.9.5, “Assigning Account Passwords”, and Section 13.5.1.1, “CREATE USER Syntax”.

- `localhost` is a synonym for your local hostname, and is also the default host to which clients try to connect if you specify no host explicitly.

To avoid this problem on such systems, you can use a `--host=127.0.0.1` option to name the server host explicitly. This will make a TCP/IP connection to the local `mysqld` server. You can also use TCP/IP by specifying a `--host` option that uses the actual hostname of the local host. In this case, the hostname must be specified in a `user` table row on the server host, even though you are running the client program on the same host as the server.

- If you get an `Access denied` error when trying to connect to the database with `mysql -u user_name`, you may have a problem with the `user` table. Check this by executing `mysql -u root mysql` and issuing this SQL statement:

```
SELECT * FROM user;
```

The result should include a row with the `Host` and `User` columns matching your computer's hostname and your MySQL username.

- The `Access denied` error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you

should have one row in the `user` table that exactly matches the hostname and username that were given in the error message. For example, if you get an error message that contains `using password: NO`, it means that you tried to log in without a password.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a `Host` value that matches the client host:

```
Host ... is not allowed to connect to this MySQL server
```

You can fix this by setting up an account for the combination of client hostname and username that you are using when trying to connect.

If you do not know the IP number or hostname of the machine from which you are connecting, you should put a row with `'%'` as the `Host` column value in the `user` table. After trying to connect from the client machine, use a `SELECT USER()` query to see how you really did connect. (Then change the `'%'` in the `user` table row to the actual hostname that shows up in the log. Otherwise, your system is left insecure because it allows connections from any host for the given username.)

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the `glibc` library than the one you are using. In this case, you should either upgrade your operating system or `glibc`, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a hostname when trying to connect, but get an error message where the hostname is not shown or is an IP number, it means that the MySQL server got an error when trying to resolve the IP number of the client host to a name:

```
shell> mysqladmin -u root -pXXXX -h some_hostname ver
Access denied for user 'root'@'' (using password: YES)
```

This indicates a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS hostname cache. See Section 7.5.6, “How MySQL Uses DNS”.

Some permanent solutions are:

- Determine what is wrong with your DNS server and fix it.
- Specify IP numbers rather than hostnames in the MySQL grant tables.
- Put an entry for the client machine name in `/etc/hosts` or `\windows\hosts`.
- Start `mysqld` with the `--skip-name-resolve` option.
- Start `mysqld` with the `--skip-host-cache` option.
- On Unix, if you are running the server and the client on the same machine, connect to `localhost`. Unix connections to `localhost` use a Unix socket file rather than TCP/IP.
- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the hostname `.` (period). Connections to `.` use a named pipe rather than TCP/IP.
- If `mysql -u root test` works but `mysql -h your_hostname -u root test` results in `Access denied` (where `your_hostname` is the actual hostname of the local host), you may not have the correct name for your host in the `user` table. A common problem here is that the `Host` value in the `user` table row specifies an unqualified hostname, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have an entry with host `'tcx'` in the `user` table, but your DNS tells MySQL that your hostname is `'tcx.subnet.se'`, the entry does not work. Try adding an entry to the

user table that contains the IP number of your host as the `Host` column value. (Alternatively, you could add an entry to the user table with a `Host` value that contains a wildcard; for example, `'tcx.%'`. However, use of hostnames ending with `'%'` is *insecure* and is *not* recommended!)

- If `mysql -u user_name test` works but `mysql -u user_name other_db_name` does not, you have not granted database access for `other_db_name` to the given user.
- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given username from the remote host.
- If you cannot figure out why you get `Access denied`, remove from the user table all entries that have `Host` values containing wildcards (entries that contain `'%'` or `'_'`). A very common error is to insert a new entry with `Host='%'` and `User='some_user'`, thinking that this allows you to specify `localhost` to connect from the same machine. The reason that this does not work is that the default privileges include an entry with `Host='localhost'` and `User=''`. Because that entry has a `Host` value `'localhost'` that is more specific than `'%'`, it is used in preference to the new entry when connecting from `localhost`! The correct procedure is to insert a second entry with `Host='localhost'` and `User='some_user'`, or to delete the entry with `Host='localhost'` and `User=''`. After deleting the entry, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables.
- If you get the following error, you may have a problem with the `db` or `host` table:

```
Access to database denied
```

If the entry selected from the `db` table has an empty value in the `Host` column, make sure that there are one or more corresponding entries in the `host` table specifying which hosts the `db` table entry applies to.

- If you are able to connect to the MySQL server, but get an `Access denied` message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA INFILE` statement, your entry in the user table does not have the `FILE` privilege enabled.
- If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to re-read the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` command, you won't need to specify the new password until after you flush the privileges, because the server won't know you've changed the password yet!
- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in Section 5.8.7, "When Privilege Changes Take Effect".
- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -pyour_pass db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=your_pass` syntax to specify the password. If you use the `-p --password` option with no password value, MySQL prompts you for the password.)
- For testing, start the `mysqld` server with the `--skip-grant-tables` option. Then you can change the MySQL grant tables and use the `mysqlaccess` script to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to start using the new grant tables. (Reloading the grant tables overrides the `--skip-grant-tables` option. This enables you to tell the server to begin using the grant tables again without stopping and restarting it.)

- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See Section E.1.2, “Creating Trace Files”.
- If you have any other problems with the MySQL grant tables and feel you must post the problem to the mailing list, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at Section 1.8, “How to Report Bugs or Problems”. In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`.

## 5.8.9. Password Hashing as of MySQL 4.1

MySQL user accounts are listed in the `user` table of the `mysql` database. Each MySQL account is assigned a password, although what is stored in the `Password` column of the `user` table is not the plaintext version of the password, but a hash value computed from it. Password hash values are computed by the `PASSWORD( )` function.

MySQL uses passwords in two phases of client/server communication:

- When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account that the client wants to use.
- After the client connects, it can (if it has sufficient privileges) set or change the password hashes for accounts listed in the `user` table. The client can do this by using the `PASSWORD( )` function to generate a password hash, or by using the `GRANT` or `SET PASSWORD` statements.

In other words, the server *uses* hash values during authentication when a client first attempts to connect. The server *generates* hash values if a connected client invokes the `PASSWORD( )` function or uses a `GRANT` or `SET PASSWORD` statement to set or change a password.

The password hashing mechanism was updated in MySQL 4.1 to provide better security and to reduce the risk of passwords being intercepted. However, this new mechanism is understood only by MySQL 4.1 (and newer) servers and clients, which can result in some compatibility problems. A 4.1 or newer client can connect to a pre-4.1 server, because the client understands both the old and new password hashing mechanisms. However, a pre-4.1 client that attempts to connect to a 4.1 or newer server may run into difficulties. For example, a 3.23 `mysql` client that attempts to connect to a 5.0 server may fail with the following error message:

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

Another common example of this phenomenon occurs for attempts to use the older PHP `mysql` extension after upgrading to MySQL 4.1 or newer. (See Section 22.3.1, “Common Problems with MySQL and PHP”.)

The following discussion describes the differences between the old and new password mechanisms, and what you should do if you upgrade your server but need to maintain backward compatibility with pre-4.1 clients. Additional information can be found in Section A.2.3, “Client does not support authentication protocol”. This information is of particular importance to PHP programmers migrating MySQL databases from version 4.0 or lower to version 4.1 or higher.

**Note:** This discussion contrasts 4.1 behavior with pre-4.1 behavior, but the 4.1 behavior described here actually begins with 4.1.1. MySQL 4.1.0 is an “odd” release because it has a slightly different mechanism than that implemented in 4.1.1 and up. Differences between 4.1.0 and more recent versions are described further in MySQL 3.23, 4.0, 4.1 Reference Manual.

Prior to MySQL 4.1, password hashes computed by the `PASSWORD()` function are 16 bytes long. Such hashes look like this:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| 6f8c114b58f2ce9e   |
+-----+
```

The `Password` column of the `user` table (in which these hashes are stored) also is 16 bytes long before MySQL 4.1.

As of MySQL 4.1, the `PASSWORD()` function has been modified to produce a longer 41-byte hash value:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-----+
```

Accordingly, the `Password` column in the `user` table also must be 41 bytes long to store these values:

- If you perform a new installation of MySQL 5.0, the `Password` column is made 41 bytes long automatically.
- Upgrading from MySQL 4.1 (4.1.1 or later in the 4.1 series) to MySQL 5.0 should not give rise to any issues in this regard because both versions use the same password hashing mechanism. If you wish to upgrade an older release of MySQL to version 5.0, you should upgrade to version 4.1 first, then upgrade the 4.1 installation to 5.0.

A widened `Password` column can store password hashes in both the old and new formats. The format of any given password hash value can be determined two ways:

- The obvious difference is the length (16 bytes versus 41 bytes).
- A second difference is that password hashes in the new format always begin with a '\*' character, whereas passwords in the old format never do.

The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the `Password` column:

- If the column is short, only short-hash authentication is used.
- If the column is long, it can hold either short or long hashes, and the server can use either format:
  - Pre-4.1 clients can connect, although because they know only about the old hashing mechan-

ism, they can authenticate only using accounts that have short hashes.

- 4.1 and later clients can authenticate using accounts that have short or long hashes.

Even for short-hash accounts, the authentication process is actually a bit more secure for 4.1 and later clients than for older clients. In terms of security, the gradient from least to most secure is:

- Pre-4.1 client authenticating with short password hash
- 4.1 or later client authenticating with short password hash
- 4.1 or later client authenticating with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `--old-passwords` option. A 4.1 or later server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and the `--old-passwords` option must not be given. These conditions apply as follows:

- The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot fit into it and generates only short hashes when a client performs password-changing operations using `PASSWORD()`, `GRANT`, or `SET PASSWORD`. This is the behavior that occurs if you have upgraded to 4.1 but have not yet run the `mysql_fix_privilege_tables` script to widen the `Password` column.
- If the `Password` column is wide, it can store either short or long password hashes. In this case, `PASSWORD()`, `GRANT`, and `SET PASSWORD` generate long hashes unless the server was started with the `--old-passwords` option. That option forces the server to generate short password hashes instead.

The purpose of the `--old-passwords` option is to enable you to maintain backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option doesn't affect authentication (4.1 and later clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that to occur, the account no longer could be used by pre-4.1 clients. Without the `--old-passwords` option, the following undesirable scenario is possible:

- An old client connects to an account that has a short password hash.
- The client changes its own password. Without `--old-passwords`, this results in the account having a long password hash.
- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the new hashing mechanism during authentication. (Once an account has a long password hash in the `user` table, only 4.1 and later clients can authenticate for it, because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is dangerous to run a 4.1 or newer server without using the `--old-passwords` option. By running the server with `--old-passwords`, password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of the `--old-passwords` option is that any passwords you create or change use

short hashes, even for 4.1 clients. Thus, you lose the additional security provided by long password hashes. If you want to create an account that has a long hash (for example, for use by 4.1 clients), you must do so while running the server without `--old-passwords`.

The following scenarios are possible for running a 4.1 or later server:

**Scenario 1:** Short `Password` column in user table:

- Only short hashes can be stored in the `Password` column.
- The server uses only short hashes during client authentication.
- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`, or `SET PASSWORD` use short hashes exclusively. Any change to an account's password results in that account having a short password hash.
- The `--old-passwords` option can be used but is superfluous because with a short `Password` column, the server generates only short password hashes anyway.

**Scenario 2:** Long `Password` column; server not started with `--old-passwords` option:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate using accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only using accounts that have short hashes.
- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`, or `SET PASSWORD` use long hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made via `GRANT`, `PASSWORD()`, or `SET PASSWORD` results in the account being given a long password hash. From that point on, no pre-4.1 client can authenticate to that account until the client upgrades to 4.1.

To deal with this problem, you can change a password in a special way. For example, normally you use `SET PASSWORD` as follows to change an account password:

```
SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('mypass');
```

To change the password but create a short hash, use the `OLD_PASSWORD()` function instead:

```
SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('mypass');
```

`OLD_PASSWORD()` is useful for situations in which you explicitly want to generate a short hash.

**Scenario 3:** Long `Password` column; 4.1 or newer server started with `--old-passwords` option:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate for accounts that have short or long hashes (but note that it is possible to create long hashes only when the server is started without `--old-passwords`).
- Pre-4.1 clients can authenticate only for accounts that have short hashes.
- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`,

or `SET PASSWORD` use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, you cannot create accounts that have long password hashes, because the `--old-passwords` option prevents generation of long hashes. Also, if you create an account with a long hash before using the `--old-passwords` option, changing the account's password while `--old-passwords` is in effect results in the account being given a short password, causing it to lose the security benefits of a longer hash.

The disadvantages for these scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.

In scenario 2, accounts with short hashes become inaccessible to pre-4.1 clients if you change their passwords without explicitly using `OLD_PASSWORD()`.

In scenario 3, `--old-passwords` prevents accounts with short hashes from becoming inaccessible, but password-changing operations cause accounts with long hashes to revert to short hashes, and you cannot change them back to long hashes while `--old-passwords` is in effect.

### 5.8.9.1. Implications of Password Hashing Changes for Application Programs

An upgrade to MySQL version 4.1 or later can cause compatibility issues for applications that use `PASSWORD()` to generate passwords for their own purposes. Applications really should not do this, because `PASSWORD()` should be used only to manage passwords for MySQL accounts. But some applications use `PASSWORD()` for their own purposes anyway.

If you upgrade to 4.1 or later from a pre-4.1 version of MySQL and run the server under conditions where it generates long password hashes, an application using `PASSWORD()` for its own passwords breaks. The recommended course of action in such cases is to modify the application to use another function, such as `SHA1()` or `MD5()`, to produce hashed values. If that is not possible, you can use the `OLD_PASSWORD()` function, which is provided to generate short hashes in the old format. However, you should note that `OLD_PASSWORD()` may one day no longer be supported.

If the server is running under circumstances where it generates short hashes, `OLD_PASSWORD()` is available but is equivalent to `PASSWORD()`.

PHP programmers migrating their MySQL databases from version 4.0 or lower to version 4.1 or higher should see Section 22.3, "MySQL PHP API".

## 5.9. MySQL User Account Management

This section describes how to set up accounts for clients of your MySQL server. It discusses the following topics:

- The meaning of account names and passwords as used in MySQL and how that compares to names and passwords used by your operating system
- How to set up new accounts and remove existing accounts
- How to change passwords
- Guidelines for using passwords securely
- How to use secure connections with SSL

### 5.9.1. MySQL Usernames and Passwords

A MySQL account is defined in terms of a username and the client host or hosts from which the user can connect to the server. The account also has a password. There are several distinctions between the way usernames and passwords are used by MySQL and the way they are used by your operating system:

- Usernames, as used by MySQL for authentication purposes, have nothing to do with usernames (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix username as the MySQL username, but that is for convenience only. The default can be overridden easily, because client programs allow any username to be specified with a `-u` or `--user` option. Because this means that anyone can attempt to connect to the server using any username, you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a username for an account that has no password is able to connect successfully to the server.
- MySQL usernames can be up to a maximum of 16 characters long. This limit is hard-coded in the MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database *does not work*.

**Note:** *You should never alter any of the tables in the `mysql` database in any manner whatsoever except by means of the procedure prescribed by MySQL AB that is described in Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”. Attempting to redefine MySQL's system tables in any other fashion results in undefined (and unsupported!) behavior.*

Operating system usernames are completely unrelated to MySQL usernames and may even be of a different maximum length. For example, Unix usernames typically are limited to eight characters.

- MySQL passwords have nothing to do with passwords for logging in to your operating system. There is no necessary connection between the password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.
- MySQL encrypts passwords using its own algorithm. This encryption is different from that used during the Unix login process. MySQL password encryption is the same as that implemented by the `PASSWORD()` SQL function. Unix password encryption is the same as that implemented by the `ENCRYPT()` SQL function. See the descriptions of the `PASSWORD()` and `ENCRYPT()` functions in Section 12.9.2, “Encryption and Compression Functions”. From version 4.1 on, MySQL employs a stronger authentication method that has better password protection during the connection process than in earlier versions. It is secure even if TCP/IP packets are sniffed or the `mysql` database is captured. (In earlier versions, even though passwords are stored in encrypted form in the `user` table, knowledge of the encrypted password value could be used to connect to the MySQL server.)

When you install MySQL, the grant tables are populated with an initial set of accounts. These accounts have names and access privileges that are described in Section 2.10.3, “Securing the Initial MySQL Accounts”, which also discusses how to assign passwords to them. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as `GRANT` and `REVOKE`. See Section 13.5.1, “Account Management Statements”.

When you connect to a MySQL server with a command-line client, you should specify the username and password for the account that you want to use:

```
shell> mysql --user=monty --password=guess db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u monty -pguess db_name
```

There must be *no space* between the `-p` option and the following password value. See Section 5.8.4, “Connecting to the MySQL Server”.

The preceding commands include the password value on the command line, which can be a security risk. See Section 5.9.6, “Keeping Your Password Secure”. To avoid this problem, specify the `--password` or `-p` option without any following password value:

```
shell> mysql --user=monty --password db_name
shell> mysql -u monty -p db_name
```

When the password option has no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `db_name` is *not* interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That is a problem with the system library, not with MySQL. Internally, MySQL doesn't have any limit for the length of the password. To work around the problem, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

## 5.9.2. Adding New User Accounts to MySQL

You can create MySQL accounts in two ways:

- By using statements intended for creating accounts, such as `CREATE USER` or `GRANT`
- By manipulating the MySQL grant tables directly with statements such as `INSERT`, `UPDATE`, or `DELETE`

The preferred method is to use account-creation statements because they are more concise and less error-prone. `CREATE USER` and `GRANT` are described in Section 13.5.1.1, “`CREATE USER` Syntax”, and Section 13.5.1.3, “`GRANT` Syntax”.

Another option for creating accounts is to use one of several available third-party programs that offer capabilities for MySQL account administration. `phpMyAdmin` is one such program.

The following examples show how to use the `mysql` client program to set up new users. These examples assume that privileges are set up according to the defaults described in Section 2.10.3, “Securing the Initial MySQL Accounts”. This means that to make changes, you must connect to the MySQL server as the MySQL `root` user, and the `root` account must have the `INSERT` privilege for the `mysql` database and the `RELOAD` administrative privilege.

First, use the `mysql` program to connect to the server as the MySQL `root` user:

```
shell> mysql --user=root mysql
```

If you have assigned a password to the `root` account, you'll also need to supply a `--password` or `-p` option for this `mysql` command and also for those later in this section.

After connecting to the server as `root`, you can add new accounts. The following statements use `GRANT` to set up four new accounts:

```
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'localhost'
-> IDENTIFIED BY 'some_pass' WITH GRANT OPTION;
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'%'
-> IDENTIFIED BY 'some_pass' WITH GRANT OPTION;
mysql> GRANT RELOAD,PROCESS ON *.* TO 'admin'@'localhost';
mysql> GRANT USAGE ON *.* TO 'dummy'@'localhost';
```

The accounts created by these `GRANT` statements have the following properties:

- Two of the accounts have a username of `monty` and a password of `some_pass`. Both accounts are superuser accounts with full privileges to do anything. One account (`'monty'@'localhost'`) can be used only when connecting from the local host. The other (`'monty'@'%'`) can be used to connect from any other host. Note that it is necessary to have both accounts for `monty` to be able to connect from anywhere as `monty`. Without the `localhost` account, the anonymous-user account for `localhost` that is created by `mysql_install_db` would take precedence when `monty` connects from the local host. As a result, `monty` would be treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific `Host` column value than the `'monty'@'%'` account and thus comes earlier in the `user` table sort order. (`user` table sorting is discussed in Section 5.8.5, “Access Control, Stage 1: Connection Verification”).
- One account has a username of `admin` and no password. This account can be used only by connecting from the local host. It is granted the `RELOAD` and `PROCESS` administrative privileges. These privileges allow the `admin` user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx` commands, as well as `mysqladmin processlist`. No privileges are granted for accessing any databases. You could add such privileges later by issuing additional `GRANT` statements.
- One account has a username of `dummy` and no password. This account can be used only by connecting from the local host. No privileges are granted. The `USAGE` privilege in the `GRANT` statement enables you to create an account without giving it any privileges. It has the effect of setting all the global privileges to `'N'`. It is assumed that you will grant specific privileges to the account later.

As an alternative to `GRANT`, you can create the same accounts directly by issuing `INSERT` statements and then telling the server to reload the grant tables using `FLUSH PRIVILEGES`:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user
->     VALUES('localhost','monty',PASSWORD('some_pass'),
->     'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO user
->     VALUES('%','monty',PASSWORD('some_pass'),
->     'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO user SET Host='localhost',User='admin',
->     Reload_priv='Y', Process_priv='Y';
mysql> INSERT INTO user (Host,User>Password)
->     VALUES('localhost','dummy','');
mysql> FLUSH PRIVILEGES;
```

The reason for using `FLUSH PRIVILEGES` when you create accounts with `INSERT` is to tell the server to re-read the grant tables. Otherwise, the changes go unnoticed until you restart the server. With `GRANT`, `FLUSH PRIVILEGES` is unnecessary.

The reason for using the `PASSWORD()` function with `INSERT` is to encrypt the password. The `GRANT` statement encrypts the password for you, so `PASSWORD()` is unnecessary.

The `'Y'` values enable privileges for the accounts. Depending on your MySQL version, you may have to use a different number of `'Y'` values in the first two `INSERT` statements. For the `admin` account, you may also employ the more readable extended `INSERT` syntax using `SET`.

In the `INSERT` statement for the `dummy` account, only the `Host`, `User`, and `Password` columns in the `user` table row are assigned values. None of the privilege columns are set explicitly, so MySQL assigns them all the default value of `'N'`. This is equivalent to what `GRANT USAGE` does.

Note that to set up a superuser account, it is necessary only to create a `user` table entry with the privilege columns set to `'Y'`. `user` table privileges are global, so no entries in any of the other grant tables are needed.

The next examples create three accounts and give them access to specific databases. Each of them has a username of `custom` and password of `obscure`.

To create the accounts with GRANT, use the following statements:

```
shell> mysql --user=root mysql
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
->     ON bankaccount.*
->     TO 'custom'@'localhost'
->     IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
->     ON expenses.*
->     TO 'custom'@'whitehouse.gov'
->     IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
->     ON customer.*
->     TO 'custom'@'server.domain'
->     IDENTIFIED BY 'obscure';
```

The three accounts can be used as follows:

- The first account can access the bankaccount database, but only from the local host.
- The second account can access the expenses database, but only from the host whitehouse.gov.
- The third account can access the customer database, but only from the host server.domain.

To set up the custom accounts without GRANT, use INSERT statements as follows to modify the grant tables directly:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user (Host,User,Password)
->     VALUES('localhost','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
->     VALUES('whitehouse.gov','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
->     VALUES('server.domain','custom',PASSWORD('obscure'));
mysql> INSERT INTO db
->     (Host,Db,User,Select_priv,Insert_priv,
->     Update_priv>Delete_priv>Create_priv>Drop_priv)
->     VALUES('localhost','bankaccount','custom',
->     'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
->     (Host,Db,User,Select_priv,Insert_priv,
->     Update_priv>Delete_priv>Create_priv>Drop_priv)
->     VALUES('whitehouse.gov','expenses','custom',
->     'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
->     (Host,Db,User,Select_priv,Insert_priv,
->     Update_priv>Delete_priv>Create_priv>Drop_priv)
->     VALUES('server.domain','customer','custom',
->     'Y','Y','Y','Y','Y','Y');
mysql> FLUSH PRIVILEGES;
```

The first three INSERT statements add user table entries that allow the user custom to connect from the various hosts with the given password, but grant no global privileges (all privileges are set to the default value of 'N'). The next three INSERT statements add db table entries that grant privileges to custom for the bankaccount, expenses, and customer databases, but only when accessed from the proper hosts. As usual when you modify the grant tables directly, you must tell the server to reload them with FLUSH PRIVILEGES so that the privilege changes take effect.

If you want to give a specific user access from all machines in a given domain (for example, mydomain.com), you can issue a GRANT statement that uses the '%' wildcard character in the host part of the account name:

```
mysql> GRANT ...
-> ON *.*
-> TO 'myname'@'%.mydomain.com'
-> IDENTIFIED BY 'mypass';
```

To do the same thing by modifying the grant tables directly, do this:

```
mysql> INSERT INTO user (Host,User,Password,...)
-> VALUES('%.mydomain.com','myname',PASSWORD('mypass'),...);
mysql> FLUSH PRIVILEGES;
```

### 5.9.3. Removing User Accounts from MySQL

To remove an account, use the `DROP USER` statement, which is described in Section 13.5.1.2, “`DROP USER` Syntax”.

### 5.9.4. Limiting Account Resources

One means of limiting use of MySQL server resources is to set the `max_user_connections` system variable to a non-zero value. However, this method is strictly global, and does not allow for management of individual accounts. In addition, it limits only the number of simultaneous connections made using a single account, and not what a client can do once connected. Both types of control are interest to many MySQL administrators, particularly those working for Internet Service Providers.

In MySQL 5.0, you can limit the following server resources for individual accounts:

- The number of queries that an account can issue per hour
- The number of updates that an account can issue per hour
- The number of times an account can connect to the server per hour

Any statement that a client can issue counts against the query limit. Only statements that modify databases or tables count against the update limit.

From MySQL 5.0.3 on, it is also possible to limit the number of simultaneous connections to the server on a per-account basis.

An account in this context is a single row in the `user` table. Each account is uniquely identified by its `User` and `Host` column values.

As a prerequisite for using this feature, the `user` table in the `mysql` database must contain the resource-related columns. Resource limits are stored in the `max_questions`, `max_updates`, `max_connections`, and `max_user_connections` columns. If your `user` table doesn't have these columns, it must be upgraded; see Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

To set resource limits with a `GRANT` statement, use a `WITH` clause that names each resource to be limited and a per-hour count indicating the limit value. For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue this statement:

```
mysql> GRANT ALL ON customer.* TO 'francis'@'localhost'
-> IDENTIFIED BY 'frank'
-> WITH MAX_QUERIES_PER_HOUR 20
->      MAX_UPDATES_PER_HOUR 10
->      MAX_CONNECTIONS_PER_HOUR 5
->      MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. If the `GRANT` statement has no `WITH` clause, the limits are each set to the default value of zero (that is, no limit). For `MAX_USER_CONNECTIONS`, the limit is an integer indicating the maximum number of simultaneous connections the account can make at any one time. If the limit is set to the default value of zero, the `max_user_connections` system variable determines the number of simultaneous connections for the account.

To set or change limits for an existing account, use a `GRANT USAGE` statement at the global level (`ON *.*`). The following statement changes the query limit for `francis` to 100:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'  
-> WITH MAX_QUERIES_PER_HOUR 100;
```

This statement leaves the account's existing privileges unchanged and modifies only the limit values specified.

To remove an existing limit, set its value to zero. For example, to remove the limit on how many times per hour `francis` can connect, use this statement:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'  
-> WITH MAX_CONNECTIONS_PER_HOUR 0;
```

Resource-use counting takes place when any account has a non-zero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, further connections for the account are rejected until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, further queries or updates are rejected until the hour is up. In all such cases, an appropriate error message is issued.

Resource counting is done per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a `FLUSH USER_RESOURCES` statement. The counts also can be reset by reloading the grant tables (for example, with a `FLUSH PRIVILEGES` statement or a `mysqladmin reload` command).
- The counts for an individual account can be set to zero by re-granting it any of its limits. To do this, use `GRANT USAGE` as described earlier and specify a limit value equal to the value that the account currently has.

Counter resets do not affect the `MAX_USER_CONNECTIONS` limit.

All counts begin at zero when the server starts; counts are not carried over through a restart.

## 5.9.5. Assigning Account Passwords

Passwords may be assigned from the command line by using the `mysqladmin` command:

```
shell> mysqladmin -u user_name -h host_name password "newpwd"
```

The account for which this command resets the password is the one with a `user` table row that matches `user_name` in the `User` column and the client host *from which you connect* in the `Host`

column.

Another way to assign a password to an account is to issue a `SET PASSWORD` statement:

```
mysql> SET PASSWORD FOR 'jeffrey'@'%' = PASSWORD('biscuit');
```

Only users such as `root` that have update access to the `mysql` database can change the password for other users. If you are not connected as an anonymous user, you can change your own password by omitting the `FOR` clause:

```
mysql> SET PASSWORD = PASSWORD('biscuit');
```

You can also use a `GRANT USAGE` statement at the global level (`ON *.*`) to assign a password to an account without affecting the account's current privileges:

```
mysql> GRANT USAGE ON *.* TO 'jeffrey'@'%' IDENTIFIED BY 'biscuit';
```

Although it is generally preferable to assign passwords using one of the preceding methods, you can also do so by modifying the `user` table directly:

- To establish a password when creating a new account, provide a value for the `Password` column:

```
shell> mysql -u root mysql
mysql> INSERT INTO user (Host,User,Password)
      -> VALUES('','%','jeffrey',PASSWORD('biscuit'));
mysql> FLUSH PRIVILEGES;
```

- To change the password for an existing account, use `UPDATE` to set the `Password` column value:

```
shell> mysql -u root mysql
mysql> UPDATE user SET Password = PASSWORD('bagel')
      -> WHERE Host = '%' AND User = 'francis';
mysql> FLUSH PRIVILEGES;
```

When you assign an account a non-empty password using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must use the `PASSWORD()` function to encrypt it. `PASSWORD()` is necessary because the `user` table stores passwords in encrypted form, not as plaintext. If you forget that fact, you are likely to set passwords like this:

```
shell> mysql -u root mysql
mysql> INSERT INTO user (Host,User,Password)
      -> VALUES('','%','jeffrey','biscuit');
mysql> FLUSH PRIVILEGES;
```

The result is that the literal value `'biscuit'` is stored as the password in the `user` table, not the encrypted value. When `jeffrey` attempts to connect to the server using this password, the value is encrypted and compared to the value stored in the `user` table. However, the stored value is the literal string `'biscuit'`, so the comparison fails and the server rejects the connection:

```
shell> mysql -u jeffrey -pbiscuit test
Access denied
```

If you assign passwords using the `GRANT ... IDENTIFIED BY` statement or the `mysqladmin password` command, they both take care of encrypting the password for you. In these cases, using `PASSWORD()` function is unnecessary.

**Note:** `PASSWORD()` encryption is different from Unix password encryption. See Section 5.9.1, “MySQL Usernames and Passwords”.

## 5.9.6. Keeping Your Password Secure

On an administrative level, you should never grant access to the `user` grant table to any non-administrative accounts.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method:

- Use a `-p` or `--password=your_pass` option on the command line. For example:

```
shell> mysql -u francis -pfrank db_name
```

This is convenient *but insecure*, because your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeroes during their initialization sequence. However, there is still a brief interval during which the value is visible. On some systems this strategy is ineffective, anyway, and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

- Use the `-p` or `--password` option with no password value specified. In this case, the client program solicits the password from the terminal:

```
shell> mysql -u francis -p db_name
Enter password: *****
```

The ‘\*’ characters indicate where you enter your password. The password is not displayed as you enter it.

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs non-interactively, there is no opportunity to enter the password from the terminal. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

```
[client]
password=your_pass
```

If you store your password in `.my.cnf`, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to 400 or 600. For example:

```
shell> chmod 600 .my.cnf
```

Section 4.3.2, “Using Option Files”, discusses option files in more detail.

- Store your password in the `MYSQL_PWD` environment variable. This method of specifying your MySQL password must be considered *extremely insecure* and should not be used. Some versions of `ps` include an option to display the environment of running processes. If you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which

users can examine process environments. See Appendix F, *Environment Variables*.

All in all, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

## 5.9.7. Using Secure Connections

MySQL supports secure (encrypted) connections between MySQL clients and the server using the Secure Sockets Layer (SSL) protocol. This section discusses how to use SSL connections. It also describes a way to set up SSH on Windows. For information on requiring users to use SSL connections, see Section 13.5.1.3, “GRANT Syntax”.

The standard configuration of MySQL is intended to be as fast as possible, so encrypted connections are not used by default. Doing so would make the client/server protocol much slower. Encrypting data is a CPU-intensive operation that requires the computer to do additional work and can delay other MySQL tasks. For applications that require the security provided by encrypted connections, the extra computation is warranted.

MySQL allows encryption to be enabled on a per-connection basis. You can choose a normal unencrypted connection or a secure encrypted SSL connection according the requirements of individual applications.

### 5.9.7.1. Basic SSL Concepts

To understand how MySQL uses SSL, it is necessary to explain some basic SSL and X509 concepts. People who are familiar with these can skip this part of the discussion.

By default, MySQL uses unencrypted connections between the client and the server. This means that someone with access to the network could watch all your traffic and look at the data being sent or received. They could even change the data while it is in transit between client and server. To improve security a little, you can compress client/server traffic by using the `--compress` option when invoking client programs. However, this does not foil a determined attacker.

When you need to move information over a network in a secure fashion, an unencrypted connection is unacceptable. Encryption is the way to make any kind of data unreadable. In fact, today's practice requires many additional security elements from encryption algorithms. They should resist many kind of known attacks such as changing the order of encrypted messages or replaying data twice.

SSL is a protocol that uses different encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect any data change, loss, or replay. SSL also incorporates algorithms that provide identity verification using the X509 standard.

X509 makes it possible to identify someone on the Internet. It is most commonly used in e-commerce applications. In basic terms, there should be some company called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can show the certificate to another party as proof of identity. A certificate consists of its owner's public key. Any data encrypted with this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

If you need more information about SSL, X509, or encryption, use your favorite Internet search engine to search for the keywords in which you are interested.

### 5.9.7.2. Using SSL Connections with OpenSSL

To use SSL connections between the MySQL server and client programs, your system must support either OpenSSL or (as of MySQL 5.0.10) yaSSL. This section covers OpenSSL. To use yaSSL, read Section 5.9.7.3, “Using SSL Connections with yaSSL”, instead.

To get secure connections to work with MySQL and OpenSSL, you must do the following:

1. Install the OpenSSL library if it has not already been installed. We have tested MySQL with OpenSSL 0.9.6. If you need OpenSSL, visit <http://www.openssl.org>.
2. When you configure MySQL, invoke the `configure` script with the `--with-vio` and `--with-openssl` options:

```
shell> ./configure --with-vio --with-openssl
```

3. Make sure that you have upgraded your grant tables to include the SSL-related columns in the `mysql.user` table. This is necessary if your grant tables date from a version prior to MySQL 4.0.0. The upgrade procedure is described in Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.
4. To check whether a running `mysqld` server supports OpenSSL, examine the value of the `have_openssl` system variable:

```
mysql> SHOW VARIABLES LIKE 'have_openssl';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_openssl  | YES   |
+-----+-----+
```

If the value is YES, the server supports OpenSSL connections.

### 5.9.7.3. Using SSL Connections with yaSSL

Using MySQL's built-in yaSSL support makes it easier to use secure connections. You don't have to install OpenSSL and perform the other steps described in Section 5.9.7.2, “Using SSL Connections with OpenSSL”. Also, both MySQL and yaSSL employ the same licensing model.

Currently, yaSSL support is available for these platforms:

- Linux/x86-64 Red Hat Enterprise 3.0
- Linux RHAS21 Itanium-2 with gcc, statically linked
- Linux Itanium-2 with gcc
- Windows (all builds)

To enable yaSSL when building MySQL from source, you should configure MySQL like this:

```
shell> ./configure --with-yassl
```

Note that yaSSL support on Unix platforms requires that either `/dev/urandom` or `/dev/random` be installed to retrieve true random numbers. For additional information (especially regarding yaSSL on Solaris versions prior to 2.8 and HP-UX), see Bug#13164 [<http://bugs.mysql.com/13164>].

To start the MySQL server with yaSSL support, use the same options as with OpenSSL support and identify the certificates needed to establish a secure connection:

```
shell> mysqld --ssl-ca=cacert.pem \  
            --ssl-cert=server-cert.pem \  
            --ssl-key=server-key.pem
```

- `--ssl-ca` identifies the Certificate Authority certificate.
- `--ssl-cert` identifies the server certificate.
- `--ssl-key` identifies the client certificate.

To establish a secure connection to a MySQL server with yaSSL support, start a client like this:

```
shell> mysql --ssl-ca=cacert.pem \  
         --ssl-cert=server-cert.pem \  
         --ssl-key=server-key.pem
```

In other words, the options are the same as for the server, and the Certificate Authority certificate has to be the same.

To establish a secure connection from an application program, use the `mysql_ssl_set()` API function to set the appropriate certificate options, before calling `mysql_real_connect()`. See Section 22.2.3.66, “`mysql_ssl_set()`”.

### 5.9.7.4. Setting Up SSL Certificates for MySQL

Here is an example of setting up SSL certificates for MySQL using OpenSSL:

```
DIR=`pwd`/openssl  
PRIV=$DIR/private  
  
mkdir $DIR $PRIV $DIR/newcerts  
cp /usr/share/ssl/openssl.cnf $DIR  
replace ./demoCA $DIR -- $DIR/openssl.cnf  
  
# Create necessary files: $database, $serial and $new_certs_dir  
# directory (optional)  
  
touch $DIR/index.txt  
echo "01" > $DIR/serial  
  
#  
# Generation of Certificate Authority(CA)  
#  
  
openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/cacert.pem \  
            -config $DIR/openssl.cnf  
  
# Sample output:  
# Using configuration from /home/monty/openssl/openssl.cnf  
# Generating a 1024 bit RSA private key  
# .....++++++  
# .....++++++  
# writing new private key to '/home/monty/openssl/private/cakey.pem'

openssl rsa -in $DIR/client-key.pem -out $DIR/client-key.pem

#
# Sign client cert
#

openssl ca -policy policy_anything -out $DIR/client-cert.pem \
    -config $DIR/openssl.cnf -infiles $DIR/client-req.pem

# Sample output:
# Using configuration from /home/monty/openssl/openssl.cnf
# Enter PEM pass phrase:
# Check that the request matches the signature
# Signature ok
# The Subjects Distinguished Name is as follows
# countryName          :PRINTABLE:'FI'
# organizationName     :PRINTABLE:'MySQL AB'
# commonName           :PRINTABLE:'MySQL user'
# Certificate is to be certified until Sep 13 16:45:17 2003 GMT
# (365 days)
# Sign the certificate? [y/n]:y
#
#
# 1 out of 1 certificate requests certified, commit? [y/n]y
# Write out database with 1 new entries
# Data Base Updated

#
# Create a my.cnf file that you can use to test the certificates
#

```

```
cnf=" "  
cnf="$cnf [client]"  
cnf="$cnf ssl-ca=$DIR/cacert.pem"  
cnf="$cnf ssl-cert=$DIR/client-cert.pem"  
cnf="$cnf ssl-key=$DIR/client-key.pem"  
cnf="$cnf [mysqld]"  
cnf="$cnf ssl-ca=$DIR/cacert.pem"  
cnf="$cnf ssl-cert=$DIR/server-cert.pem"  
cnf="$cnf ssl-key=$DIR/server-key.pem"  
echo $cnf | replace " " '  
' > $DIR/my.cnf
```

To test SSL connections, start the server as follows, where `$DIR` is the pathname to the directory where the sample `my.cnf` option file is located:

```
shell> mysqld --defaults-file=$DIR/my.cnf &
```

Then invoke a client program using the same option file:

```
shell> mysql --defaults-file=$DIR/my.cnf
```

If you have a MySQL source distribution, you can also test your setup by modifying the preceding `my.cnf` file to refer to the demonstration certificate and key files in the SSL directory of the distribution.

### 5.9.7.5. SSL Command Options

The following list describes options that are used for specifying the use of SSL, certificate files, and key files. They may be given on the command line or in an option file.

- `--ssl`

For the server, this option specifies that the server allows SSL connections. For a client program, it allows the client to connect to the server using SSL. This option is not sufficient in itself to cause an SSL connection to be used. You must also specify the `--ssl-ca`, `--ssl-cert`, and `--ssl-key` options.

This option is more often used in its opposite form to indicate that SSL should *not* be used. To do this, specify the option as `--skip-ssl` or `--ssl=0`.

Note that use of `--ssl` does not *require* an SSL connection. For example, if the server or client is compiled without SSL support, a normal unencrypted connection is used.

The secure way to ensure that an SSL connection is used is to create an account on the server that includes a `REQUIRE SSL` clause in the `GRANT` statement. Then use this account to connect to the server, with both a server and client that have SSL support enabled.

- `--ssl-ca=filename`

The path to a file with a list of trusted SSL CAs.

- `--ssl-capath=directory_name`

The path to a directory that contains trusted SSL CA certificates in PEM format.

- `--ssl-cert=filename`

The name of the SSL certificate file to use for establishing a secure connection.

- `--ssl-cipher=cipher_list`

A list of allowable ciphers to use for SSL encryption. *cipher\_list* has the same format as the `openssl ciphers` command.

Example: `--ssl-cipher=ALL:-AES:-EXP`

- `--ssl-key=file_name`

The name of the SSL key file to use for establishing a secure connection.

### 5.9.7.6. Connecting to MySQL Remotely from Windows with SSH

Here is a note that describes how to get a secure connection to a remote MySQL server with SSH (by David Carlson <dcarlson@mplcomm.com>):

1. Install an SSH client on your Windows machine. As a user, the best non-free one I have found is from SecureCRT from <http://www.vandyke.com/>. Another option is `f-secure` from <http://www.f-secure.com/>. You can also find some free ones on Google at [http://directory.google.com/Top/Computers/Security/Products\\_and\\_Tools/Cryptography/SSH/Clients/Windows/](http://directory.google.com/Top/Computers/Security/Products_and_Tools/Cryptography/SSH/Clients/Windows/).
2. Start your Windows SSH client. Set `Host_Name = yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value might not be the same as the username of your MySQL account.
3. Set up port forwarding. Either do a remote forward (Set `local_port: 3306`, `remote_host: yourmysqlservername_or_ip`, `remote_port: 3306`) or a local forward (Set `port: 3306`, `host: localhost`, `remote port: 3306`).
4. Save everything, otherwise you will have to redo it the next time.
5. Log in to your server with the SSH session you just created.
6. On your Windows machine, start some ODBC application (such as Access).
7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not `yourmysqlservername`.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

## 5.10. Backup and Recovery

This section discusses how to make database backups (full and incremental) and how to perform table maintenance. The syntax of the SQL statements described here is given in Chapter 13, *SQL Statement Syntax*. Much of the information here pertains primarily to MyISAM tables. Additional information about InnoDB backup procedures is given in Section 14.2.8, “Backing Up and Recovering an InnoDB Database”.

### 5.10.1. Database Backups

Because MySQL tables are stored as files, it is easy to do a backup. To get a consistent backup, do a `LOCK TABLES` on the relevant tables, followed by `FLUSH TABLES` for the tables. See Section 13.4.5, “`LOCK TABLES` and `UNLOCK TABLES` Syntax”, and Section 13.5.5.2, “`FLUSH TABLES` Syntax”. You need only a read lock; this allows other clients to continue to query the tables while you are making a copy of the files in the database directory. The `FLUSH TABLES` statement is needed to ensure that the all active index pages are written to disk before you start the backup.

To make an SQL-level backup of a table, you can use `SELECT INTO . . . OUTFILE`. For this

statement, the output file cannot already exist because allowing files to be overwritten would constitute a security risk. See Section 13.2.7, “SELECT Syntax”.

Another technique for backing up a database is to use the `mysqldump` program or the `mysql-hotcopy` script. See Section 8.11, “mysqldump — A Database Backup Program”, and Section 8.12, “mysqlhotcopy — A Database Backup Program”.

1. Create a full backup of your database:

```
shell> mysqldump --tab=/path/to/some/dir --opt db_name
```

Or:

```
shell> mysqlhotcopy db_name /path/to/some/dir
```

You can also create a binary backup simply by copying all table files (`*.frm`, `*.MYD`, and `*.MYI` files), as long as the server isn't updating anything. The `mysqlhotcopy` script uses this method. (But note that these methods do not work if your database contains InnoDB tables. InnoDB does not store table contents in database directories, and `mysqlhotcopy` works only for MyISAM tables.)

2. Stop `mysqld` if it is running, then start it with the `--log-bin[=file_name]` option. See Section 5.12.3, “The Binary Log”. The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you executed `mysqldump`.

For InnoDB tables, it is possible to perform an online backup that takes no locks on tables; see Section 8.11, “mysqldump — A Database Backup Program”.

MySQL supports incremental backups: You need to start the server with the `--log-bin` option to enable binary logging; see Section 5.12.3, “The Binary Log”. At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using `FLUSH LOGS`. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained further below. The next time you do a full backup, you should also rotate the binary log using `FLUSH LOGS`, `mysqldump --flush-logs`, or `mysqlhotcopy --flushlog`. See Section 8.11, “mysqldump — A Database Backup Program”, and Section 8.12, “mysqlhotcopy — A Database Backup Program”.

If your MySQL server is a slave replication server, then regardless of the backup method you choose, you should also back up the `master.info` and `relay-log.info` files when you back up your slave's data. These files are always needed to resume replication after you restore the slave's data. If your slave is subject to replicating `LOAD DATA INFILE` commands, you should also back up any `SQL_LOAD-*` files that may exist in the directory specified by the `--slave-load-tmpdir` option. (This location defaults to the value of the `tmpdir` variable if not specified.) The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations.

If you have to restore MyISAM tables, try to recover them using `REPAIR TABLE` or `myisamchk -r` first. That should work in 99.9% of all cases. If `myisamchk` fails, try the following procedure. Note that it works only if you have enabled binary logging by starting MySQL with the `--log-bin` option.

1. Restore the original `mysqldump` backup, or binary backup.
2. Execute the following command to re-run the updates in the binary logs:

```
shell> mysqlbinlog binlog.[0-9]* | mysql
```

In some cases, you may want to re-run only certain binary logs, from certain positions (usually you want to re-run all binary logs from the date of the restored backup, excepting possibly some incorrect statements). See Section 8.9, “mysqlbinlog — Utility for Processing Binary Log Files”, for more information on the `mysqlbinlog` utility and how to use it.

You can also make selective backups of individual files:

- To dump the table, use `SELECT * INTO OUTFILE 'file_name' FROM tbl_name`.
- To reload the table, use `LOAD DATA INFILE 'file_name' REPLACE ...`. To avoid duplicate rows, the table must have a `PRIMARY KEY` or a `UNIQUE` index. The `REPLACE` keyword causes old rows to be replaced with new ones when a new row duplicates an old row on a unique key value.

If you have performance problems with your server while making backups, one strategy that can help is to set up replication and perform backups on the slave rather than on the master. See Section 6.1, “Introduction to Replication”.

If you are using a Veritas filesystem, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.
2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

## 5.10.2. Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that allows you to recover data after several types of crashes:

- Operating system crash
- Power failure
- Filesystem crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` programs. You should include such options as necessary so that the MySQL server allows you to connect to it.

We assume that data is stored in the `InnoDB` storage engine, which has support for transactions and automatic crash recovery. We also assume that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL's disk data is available after a restart. The `InnoDB` data files might not contain consistent data due to the crash, but `InnoDB` reads its logs and finds in them the list of pending committed and non-committed transactions that have not been flushed to the data files. `InnoDB` automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. In-

formation about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of filesystem crashes or hardware problems, we can assume that the MySQL disk data is *not* available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that we must already have made backups. To make sure that is the case, we should design a backup policy.

### 5.10.2.1. Backup Policy

We all know that backups must be scheduled periodically. A full backups (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, InnoDB Hot Backup provides online non-blocking physical backup of the InnoDB data files, and `mysqldump` provides online logical backup. This discussion uses `mysqldump`.

Assume that we make a backup on Sunday at 1 p.m., when load is low. The following command makes a full backup of all our InnoDB tables in all databases:

```
shell> mysqldump --single-transaction --all-databases > backup_sunday_1_PM.sql
```

This is an online, non-blocking backup that does not disturb the reads and writes on the tables. We assumed earlier that our tables are InnoDB tables, so `--single-transaction` uses a consistent read and guarantees that data seen by `mysqldump` does not change. (Changes made by other clients to InnoDB tables are not seen by the `mysqldump` process.) If we do also have other types of tables, we must assume that they are not changed during the backup. For example, for the MyISAM tables in the `mysql` database, we must assume that no administrative changes are being made to MySQL accounts during the backup.

The resulting `.sql` file produced by `mysqldump` contains a set of SQL INSERT statements that can be used to reload the dumped tables at a later time.

Full backups are necessary, but they are not always convenient. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. After we have made the initial full backup, it is more efficient to make incremental backups. They are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. The MySQL server should always be started with the `--log-bin` option so that it stores these changes in a file while it up-

dates data. This option enables binary logging, so that the server writes each SQL statement that updates data into a file called a MySQL binary log. Looking at the data directory of a MySQL server that was started with the `--log-bin` option and that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem guilhem 1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem guilhem      4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem guilhem    79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem guilhem   508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem guilhem  998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem guilhem    361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS SQL` statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory. This file is used for replication.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, then any binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump` command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
        --all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, `gbichot2-bin.000007`. The resulting `.sql` file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the `mysqldump` command made a full backup, those lines mean two things:

- The `.sql` file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file or newer.
- All data changes logged after the backup are not present in the `.sql`, but are present in the `gbichot2-bin.000007` binary log file or newer.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. will be in the `gbichot2-bin.000007` file. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. will be in the `gbichot2-bin.000008` file (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
        --all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

**Note:** Deleting the MySQL binary logs with `mysqldump --delete-master-logs` can be

dangerous if your server is a replication master server, because slave servers might not yet fully have processed the contents of the binary log. The description for the `PURGE MASTER LOGS` statement explains what should be verified before deleting the MySQL binary logs. See Section 13.6.1.1, “`PURGE MASTER LOGS` Syntax”.

### 5.10.2.2. Using Backups for Recovery

Now, suppose that we have a catastrophic crash on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file at hand, and we could apply it using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash.

### 5.10.2.3. Backup Strategy Summary

In case of an operating system crash or power failure, InnoDB itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` option, or even `--log-bin=log_name`, where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
- Make periodic full backups, using the `mysqldump` command shown earlier in Section 5.10.2.1, “Backup Policy”, that makes an online, non-blocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

## 5.10.3. Point-in-Time Recovery

If a MySQL server was started with the `--log-bin` option to enable binary logging, you can use the `mysqlbinlog` utility to recover data from the binary log files, starting from a specified point in time (for example, since your last backup) until the present or another specified point in time. For information on enabling the binary log and using `mysqlbinlog`, see Section 5.12.3, “The Binary Log”, and Section 8.9, “`mysqlbinlog` — Utility for Processing Binary Log Files”.

To restore data from a binary log, you must know the location and name of the current binary log file. By default, the server creates binary log files in the data directory, but a pathname can be specified with the `--log-bin` option to place the files in a different location. Typically the option is given in an option file (that is, `my.cnf` or `my.ini`, depending on your system). It can also be given on the command line when the server is started. To determine the name of the current binary log

file, issue the following statement:

```
mysql> SHOW BINLOG EVENTS\G
```

If you prefer, you can execute the following command from the command line instead:

```
shell> mysql -u root -p -E -e "SHOW BINLOG EVENTS"
```

Enter the root password for your server when mysql prompts you for it.

### 5.10.3.1. Specifying Times for Recovery

To indicate the start and end times for recovery, specify the `--start-date` and `--stop-date` options for `mysqlbinlog`, in DATETIME format. As an example, suppose that exactly at 10:00 a.m. on April 20, 2005 an SQL statement was executed that deleted a large table. To restore the table and data, you could restore the previous night's backup, and then execute the following command:

```
shell> mysqlbinlog --stop-date="2005-04-20 9:59:59" \  
      /var/log/mysql/bin.123456 | mysql -u root -p
```

This command recovers all of the data up until the date and time given by the `--stop-date` option. If you did not detect the erroneous SQL statement that was entered until hours later, you will probably also want to recover the activity that occurred afterward. Based on this, you could run `mysqlbinlog` again with a start date and time, like so:

```
shell> mysqlbinlog --start-date="2005-04-20 10:01:00" \  
      /var/log/mysql/bin.123456 | mysql -u root -p
```

In this command, the SQL statements logged from 10:01 a.m. on will be re-executed. The combination of restoring of the previous night's dump file and the two `mysqlbinlog` commands restores everything up until one second before 10:00 a.m. and everything from 10:01 a.m. on. You should examine the log to be sure of the exact times to specify for the commands. To display the log file contents without executing them, use this command:

```
shell> mysqlbinlog /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

Then open the file with a text editor to examine it.

### 5.10.3.2. Specifying Positions for Recovery

Instead of specifying dates and times, the `--start-position` and `--stop-position` options for `mysqlbinlog` can be used for specifying log positions. They work the same as the start and stop date options, except that you specify log position numbers rather than dates. Using positions may enable you to be more precise about which part of the log to recover, especially if many transactions occurred around the same time as a damaging SQL statement. To determine the position numbers, run `mysqlbinlog` for a range of times near the time when the unwanted transaction was executed, but redirect the results to a text file for examination. This can be done like so:

```
shell> mysqlbinlog --start-date="2005-04-20 9:55:00" \  
      --stop-date="2005-04-20 10:05:00" \  
      /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

This command creates a small text file in the `/tmp` directory that contains the SQL statements around the time that the deleterious SQL statement was executed. Open this file with a text editor and look for the statement that you don't want to repeat. Determine the positions in the binary log for stopping and resuming the recovery and make note of them. Positions are labeled as `log_pos` followed by a number. After restoring the previous backup file, use the position numbers to process the binary log file. For example, you would use commands something like these:

```
shell> mysqlbinlog --stop-position="368312" /var/log/mysql/bin.123456 \  
      | mysql -u root -p  
  
shell> mysqlbinlog --start-position="368315" /var/log/mysql/bin.123456 \  
      | mysql -u root -p
```

The first command recovers all the transactions up until the stop position given. The second command recovers all transactions from the starting position given until the end of the binary log. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs will reflect the original times at which the transactions were executed.

## 5.10.4. Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see Section 8.3, “`myisamchk` — MyISAM Table-Maintenance Utility”.

You can use `myisamchk` to get information about your database tables or to check, repair, or optimize them. The following sections describe how to perform these operations and how to set up a table maintenance schedule.

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup *before* doing a repair or any maintenance operation that could make a lot of changes to a table

`myisamchk` operations that affect indexes can cause `FULLTEXT` indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in Section 8.3.1, “`myisamchk` General Options”.

In many cases, you may find it simpler to do MyISAM table maintenance using the SQL statements that perform operations that `myisamchk` can do:

- To check or repair MyISAM tables, use `CHECK TABLE` or `REPAIR TABLE`.
- To optimize MyISAM tables, use `OPTIMIZE TABLE`.
- To analyze MyISAM tables, use `ANALYZE TABLE`.

These statements can be used directly or by means of the `mysqlcheck` client program. One advantage of these statements over `myisamchk` is that the server does all the work. With `myisamchk`, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between `myisamchk` and the server. See Section 13.5.2.1, “`ANALYZE TABLE` Syntax”, Section 13.5.2.3, “`CHECK TABLE` Syntax”, Section 13.5.2.5, “`OPTIMIZE TABLE` Syntax”, and Section 13.5.2.6, “`REPAIR TABLE` Syntax”.

### 5.10.4.1. Using `myisamchk` for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

For an explanation of how MyISAM tables can become corrupted, see Section 14.1.4, “MyISAM Table Problems”.

If you run `mysqld` with external locking disabled (which is the default as of MySQL 4.0), you cannot reliably use `myisamchk` to check a table when `mysqld` is using the same table. If you can be certain that no one will access the tables through `mysqld` while you run `myisamchk`, you only have to execute `mysqladmin flush-tables` before you start checking the tables. If you cannot guarantee this, you must stop `mysqld` while you check the tables. If you run `myisamchk` to

check tables that `mysqld` is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use `myisamchk` to check tables at any time. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` to repair or optimize tables, you *must* always ensure that the `mysqld` server is not using the table (this also applies if external locking is disabled). If you don't stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

When performing crash recovery, it is important to understand that each MyISAM table `tbl_name` in a database corresponds to three files in the database directory:

File	Purpose
<code>tbl_name.frm</code>	Definition (format) file
<code>tbl_name.MYD</code>	Data file
<code>tbl_name.MYI</code>	Index file

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

`myisamchk` works by creating a copy of the `.MYD` data file row by row. It ends the repair stage by removing the old `.MYD` file and renaming the new file to the original file name. If you use `--quick`, `myisamchk` does not create a temporary `.MYD` file, but instead assumes that the `.MYD` file is correct and generates only a new index file without touching the `.MYD` file. This is safe, because `myisamchk` automatically detects whether the `.MYD` file is corrupt and aborts the repair if it is. You can also specify the `--quick` option twice to `myisamchk`. In this case, `myisamchk` does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the `.MYD` file. Normally the use of two `--quick` options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running `myisamchk`.

### 5.10.4.2. How to Check MyISAM Tables for Errors

To check a MyISAM table, use the following commands:

- `myisamchk tbl_name`

This finds 99.99% of all errors. What it cannot find is corruption that involves *only* the data file (which is very unusual). If you want to check a table, you should normally run `myisamchk` without options or with the `-s` (silent) option.

- `myisamchk -m tbl_name`

This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- `myisamchk -e tbl_name`

This does a complete and thorough check of all data (`-e` means “extended check”). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, `myisamchk` stops after the first error it finds. If you want to obtain more information, you can add the `-v` (verbose) option. This causes `myisamchk` to keep going, up through a maximum of 20 errors.

- `myisamchk -e -i tbl_name`

This is like the previous command, but the `-i` option tells `myisamchk` to print additional statistical information.

In most cases, a simple `myisamchk` command with no arguments other than the table name is sufficient to check a table.

### 5.10.4.3. How to Repair Tables

The discussion in this section describes how to use `myisamchk` on MyISAM tables (extensions `.MYI` and `.MYD`).

You can also (and should, if possible) use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See Section 13.5.2.3, “`CHECK TABLE` Syntax”, and Section 13.5.2.6, “`REPAIR TABLE` Syntax”.

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- `tbl_name.frm` is locked against change
- Can't find file `tbl_name.MYI` (Errcode: `nnn`)
- Unexpected end of file
- Record file is crashed
- Got error `nnn` from table handler

To get more information about the error, run `pererror nnn`, where `nnn` is the error number. The following example shows how to use `pererror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
shell> pererror 126 127 132 134 135 136 141 144 145
126 = Index file is crashed / Wrong file format
127 = Record-file is crashed
132 = Old database file
134 = Record was already deleted (or record file crashed)
135 = No more room in record file
136 = No more room in index file
141 = Duplicate unique key or constraint on write or update
144 = Table is crashed and last repair failed
145 = Table was marked as crashed and should be repaired
```

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use `ALTER TABLE` to increase the `MAX_ROWS` and `AVG_ROW_LENGTH` table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use `SHOW CREATE TABLE`.

For the other errors, you must repair your tables. `myisamchk` can usually detect and fix most problems that occur.

The repair process involves up to four stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that `mysqld` runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in Section 5.10.4.2, “How to Check MyISAM Tables for Errors”), or you want to use the extended features that `myisamchk` provides.

The options that you can use for table maintenance with `myisamchk` are described in Section 8.3, “`myisamchk` — MyISAM Table-Maintenance Utility”.

If you are going to repair a table from the command line, you must first stop the `mysqld` server. Note that when you do `mysqladmin shutdown` on a remote server, the `mysqld` server is still alive for a while after `mysqladmin` returns, until all statement-processing has stopped and all index changes have been flushed to disk.

### Stage 1: Checking your tables

Run `myisamchk *.MYI` or `myisamchk -e *.MYI` if you have more time. Use the `-s` (silent) option to suppress unnecessary information.

If the `mysqld` server is stopped, you should use the `--update-state` option to tell `myisamchk` to mark the table as “checked.”

You have to repair only those tables for which `myisamchk` announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

### Stage 2: Easy safe repair

First, try `myisamchk -r -q tbl_name` (`-r -q` means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use `myisamchk -r tbl_name` (`-r` means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

Note: If you want a repair operation to go much faster, you should set the values of the `sort_buffer_size` and `key_buffer_size` variables each to about 25% of your available memory when running `myisamchk`.

If you get unexpected errors when repairing (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

### Stage 3: Difficult repair

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

```
shell> mysql db_name
mysql> SET AUTOCOMMIT=1;
```

```
mysql> TRUNCATE TABLE tbl_name;  
mysql> quit
```

3. Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

You can also use the `REPAIR TABLE tbl_name USE_FRM SQL` statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `REPAIR TABLE`. See Section 13.5.2.6, “`REPAIR TABLE` Syntax”.

#### Stage 4: Very difficult repair

You should reach this stage only if the `.frm` description file has also crashed. That should never happen, because the description file is not changed after the table is created:

1. Restore the description file from a backup and go back to Stage 3. You can also restore the index file and go back to Stage 2. In the latter case, you should start with `myisamchk -r`.
2. If you do not have a backup but know exactly how the table was created, create a copy of the table in another database. Remove the new data file, and then move the `.frm` description and `.MYI` index files from the other database to your crashed database. This gives you new description and index files, but leaves the `.MYD` data file alone. Go back to Stage 2 and attempt to reconstruct the index file.

### 5.10.4.4. Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE SQL` statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See Section 13.5.2.5, “`OPTIMIZE TABLE` Syntax”.

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze, -a`
- `--sort-index, -S`
- `--sort-records=index_num, -R index_num`

For a full description of all available options, see Section 8.3, “`myisamchk` — MyISAM Table-Maintenance Utility”.

### 5.10.4.5. Getting Information About a Table

To obtain a description of a table or statistics about it, use the commands shown here. We explain some of the information in more detail later.

- `myisamchk -d tbl_name`

Runs `myisamchk` in “describe mode” to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- `myisamchk -d -v tbl_name`

Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about what it is doing.

- `myisamchk -eis tbl_name`

Shows only the most important information from a table. This operation is slow because it must read the entire table.

- `myisamchk -eiv tbl_name`

This is like `-eis`, but tells you what is being done.

Sample output for some of these commands follows. They are based on a table with these data and index file sizes:

```
-rw-rw-r--  1 monty    tcx      317235748 Jan 12 17:30 company.MYD
-rw-rw-r--  1 davida   tcx      96482304 Jan 12 18:35 company.MYI
```

Example of `myisamchk -d` output:

```
MyISAM file:      company.MYI
Record format:    Fixed length
Data records:     1403698 Deleted blocks:      0
Recordlength:    226
```

```
table description:
Key Start Len Index  Type
1    2     8  unique double
2   15    10  multip. text packed stripped
3   219    8  multip. double
4    63    10  multip. text packed stripped
5   167    2  multip. unsigned short
6   177    4  multip. unsigned long
7   155    4  multip. text
8   138    4  multip. unsigned long
9   177    4  multip. unsigned long
    193    1  text
```

Example of `myisamchk -d -v` output:

```
MyISAM file:      company
Record format:    Fixed length
File-version:     1
Creation time:    1999-10-30 12:12:51
Recover time:     1999-10-31 19:13:01
Status:           checked
Data records:     1403698 Deleted blocks:      0
Datafile parts:   1403698 Deleted data:      0
Datafile pointer (bytes): 3 Keyfile pointer (bytes): 3
Max datafile length: 3791650815 Max keyfile length: 4294967294
Recordlength:    226
```

```
table description:

```

Explanations for the types of information myisamchk produces are given here. “Keyfile” refers to the index file. “Record” and “row” are synonymous.

- MyISAM file  
Name of the MyISAM (index) file.
- File-version  
Version of MyISAM format. Currently always 2.
- Creation time  
When the data file was created.
- Recover time  
When the index/data file was last reconstructed.
- Data records  
How many rows are in the table.
- Deleted blocks  
How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 5.10.4.4, “Table Optimization”.
- Datafile parts  
For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as Data records.
- Deleted data  
How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See Section 5.10.4.4, “Table Optimization”.
- Datafile pointer

The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

- `Keyfile pointer`

The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- `Max datafile length`

How long the table data file can become, in bytes.

- `Max keyfile length`

How long the table index file can become, in bytes.

- `Recordlength`

How much space each row takes, in bytes.

- `Record format`

The format used to store table rows. The preceding examples use `Fixed length`. Other possible values are `Compressed` and `Packed`.

- `table description`

A list of all keys in the table. For each key, `myisamchk` displays some low-level information:

- `Key`

This key's number.

- `Start`

Where in the row this portion of the index starts.

- `Len`

How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column.

- `Index`

Whether a key value can exist multiple times in the index. Possible values are `unique` or `multip.` (multiple).

- `Type`

What data type this portion of the index has. This is a `MyISAM` data type with the possible values `packed`, `stripped`, or `empty`.

- `Root`

Address of the root index block.

- `Blocksize`

The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- `Rec/key`

This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

For the table shown in the examples, there are two `table description` lines for the ninth index. This indicates that it is a multiple-part index with two parts.

- `Keyblocks used`

What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, as for the table in the examples, the values are very high (very near the theoretical maximum).

- `Packed`

MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the third of the preceding examples, the fourth key is 10 characters long and a 60% reduction in space is achieved.

- `Max levels`

How deep the B-tree for this key is. Large tables with long key values get high values.

- `Records`

How many rows are in the table.

- `M.recordlength`

The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

- `Packed`

MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

- `Recordspace used`

What percentage of the data file is used.

- `Empty space`

What percentage of the data file is unused.

- `Blocks/Record`

Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See Section 5.10.4.4, "Table Optimization".

- `Recordblocks`

How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

- `Deleteblocks`

How many blocks (links) are deleted.

- `Recorddata`  
How many bytes in the data file are used.
- `Deleted data`  
How many bytes in the data file are deleted (unused).
- `Lost space`  
If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.
- `Linkdata`  
When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). `Linkdata` is the sum of the amount of storage used by all such pointers.

If a table has been compressed with `myisampack`, `myisamchk -d` prints additional information about each table column. See Section 8.5, “`myisampack` — Generate Compressed, Read-Only MyISAM Tables”, for an example of this information and a description of what it means.

#### 5.10.4.6. Setting Up a Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. See Section 13.5.2.3, “`CHECK TABLE` Syntax”, and Section 13.5.2.6, “`REPAIR TABLE` Syntax”.

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent`) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are “expected crashed tables.”) To check MyISAM tables automatically, start the server with the `--myisam-recover` option. See Section 5.2.1, “`mysqld` Command Options”.

You should also check your tables regularly during normal system operation. At MySQL AB, we run a cron job to check all our important tables once a week, using a line like this in a crontab file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that we can examine and repair them when needed.

Because we have not had any unexpectedly crashed tables (tables that become corrupted for reasons other than hardware trouble) for several years, once a week is more than sufficient for us.

We recommend that to start with, you execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours, until you come to trust MySQL as much as we do.

Normally, MySQL tables need little maintenance. If you are performing many updates to MyISAM tables with dynamic-sized rows (tables with `VARCHAR`, `BLOB`, or `TEXT` columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using `OPTIMIZE TABLE` on the tables in question. Alternatively, if you can stop the `mysqld` server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index --sort_buffer_size=16M */*.MYI
```

## 5.11. MySQL Localization and International Usage

This section describes how to configure the server to use different character sets. It also discusses how to set the server's time zone and enable per-connection time zone support.

### 5.11.1. The Character Set Used for Data and Sorting

By default, MySQL uses the `latin1` (cp1252 West European) character set and the `latin1_swedish_ci` collation that sorts according to Swedish/Finnish rules. These defaults are suitable for the United States and most of Western Europe.

All MySQL binary distributions are compiled with `--with-extra-charsets=complex`. This adds code to all standard programs that enables them to handle `latin1` and all multi-byte character sets within the binary. Other character sets are loaded from a character-set definition file when needed.

The character set determines what characters are allowed in identifiers. The collation determines how strings are sorted by the `ORDER BY` and `GROUP BY` clauses of the `SELECT` statement.

You can change the default server character set and collation with the `--character-set-server` and `--collation-server` options when you start the server. The collation must be a legal collation for the default character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.) See Section 5.2.1, “`mysqld` Command Options”.

The character sets available depend on the `--with-charset=charset_name` and `--with-extra-charsets=list-of-charsets | complex | all | none` options to configure, and the character set configuration files listed in `SHAREDIR/charsets/Index`. See Section 2.9.2, “Typical configure Options”.

If you change the character set when running MySQL, that may also change the sort order. Consequently, you must run `myisamchk -r -q --set-collation=collation_name` on all MyISAM tables, or your indexes may not be ordered correctly.

When a client connects to a MySQL server, the server indicates to the client what the server's default character set is. The client switches to this character set for this connection.

You should use `mysql_real_escape_string()` when escaping strings for an SQL query. `mysql_real_escape_string()` is identical to the old `mysql_escape_string()` function, except that it takes the MySQL connection handle as the first parameter so that the appropriate character set can be taken into account when escaping characters.

If the client is compiled with paths that differ from where the server is installed and the user who configured MySQL didn't include all character sets in the MySQL binary, you must tell the client where it can find the additional character sets it needs if the server runs with a different character set from the client. You can do this by specifying a `--character-sets-dir` option to indicate the path to the directory in which the dynamic MySQL character sets are stored. For example, you can put the following in an option file:

```
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets
```

You can force the client to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary, however.

### 5.11.1.1. Using the German Character Set

In MySQL 5.0, character set and collation are specified separately. This means that if you want German sort order, you should select the `latin1_german1_ci` or `latin1_german2_ci` collation. For example, to start the server with the `latin1_german1_ci` collation, use the `--character-set-server=latin1` and `--collation-server=latin1_german1_ci` options.

For information on the differences between these two collations, see Section 10.9.2, “West European Character Sets”.

### 5.11.2. Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can also be displayed in any of these other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish.

To start `mysqld` with a particular language for error messages, use the `--language` or `-L` option. The option value can be a language name or the full path to the error message file. For example:

```
shell> mysqld --language=swedish
```

Or:

```
shell> mysqld --language=/usr/local/share/swedish
```

The language name should be specified in lowercase.

By default, the language files are located in the `share/LANGUAGE` directory under the MySQL base directory.

You can also change the content of the error messages produced by the server. Details can be found in the MySQL Internals manual, available at <http://dev.mysql.com/doc/>. If you upgrade to a newer version of MySQL after changing the error messages, remember to repeat your changes after the upgrade.

### 5.11.3. Adding a New Character Set

This section discusses the procedure for adding a new character set to MySQL. You must have a MySQL source distribution to use these instructions. To choose the proper procedure, determine whether the character set is simple or complex:

- If the character set does not need to use special string collating routines for sorting and does not need multi-byte character support, it is simple.
- If it needs either of those features, it is complex.

For example, `latin1` and `danish` are simple character sets, whereas `big5` and `czech` are complex character sets.

In the following instructions, the name of the character set is represented by *MYSET*.

For a simple character set, do the following:

1. Add *MYSET* to the end of the `sql/share/charsets/Index` file. Assign a unique number to it.
2. Create the file `sql/share/charsets/MYSET.conf`. (You can use a copy of `sql/share/charsets/latin1.conf` as the basis for this file.)

The syntax for the file is very simple:

- Comments start with a '#' character and continue to the end of the line.
- Words are separated by arbitrary amounts of whitespace.
- When defining the character set, every word must be a number in hexadecimal format.
- The `ctype` array takes up the first 257 words. The `to_lower[]`, `to_upper[]` and `sort_order[]` arrays take up 256 words each after that.

See Section 5.11.4, "The Character Definition Arrays".

3. Add the character set name to the `CHARSETS_AVAILABLE` and `COMPILED_CHARSETS` lists in `configure.in`.
4. Reconfigure, recompile, and test.

For a complex character set, do the following:

1. Create the file `strings/ctype-MYSET.c` in the MySQL source distribution.
2. Add *MYSET* to the end of the `sql/share/charsets/Index` file. Assign a unique number to it.
3. Look at one of the existing `ctype-*.c` files (such as `strings/ctype-big5.c`) to see what needs to be defined. Note that the arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See Section 5.11.4, "The Character Definition Arrays".
4. Near the top of the file, place a special comment like this:

```
/*
 * This comment is parsed by configure to create ctype.c,
 * so don't change it unless you know what you are doing.
 *
 * .configure. number_MYSET=MYNUMBER
 * .configure. strxfrm_multiply_MYSET=N
 * .configure. mbmaxlen_MYSET=N
 */
```

The `configure` program uses this comment to include the character set into the MySQL library automatically.

The `strxfrm_multiply` and `mbmaxlen` lines are explained in the following sections. You need include them only if you need the string collating functions or the multi-byte character set functions, respectively.

5. You should then create some of the following functions:
  - `my_strncoll_MYSET()`
  - `my_strcoll_MYSET()`
  - `my_strxfrm_MYSET()`

- `my_like_range_MYSET()`

See Section 5.11.5, “String Collating Support”.

6. Add the character set name to the `CHARSETS_AVAILABLE` and `COMPILED_CHARSETS` lists in `configure.in`.
7. Reconfigure, recompile, and test.

The `sql/share/charsets/README` file includes additional instructions.

If you want to have the character set included in the MySQL distribution, mail a patch to the MySQL `internals` mailing list. See Section 1.7.1, “MySQL Mailing Lists”.

## 5.11.4. The Character Definition Arrays

`to_lower[]` and `to_upper[]` are simple arrays that hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```
to_lower['A'] should contain 'a'
to_upper['a'] should contain 'A'
```

`sort_order[]` is a map indicating how characters should be ordered for comparison and sorting purposes. Quite often (but not for all character sets) this is the same as `to_upper[]`, which means that sorting is case-insensitive. MySQL sorts characters based on the values of `sort_order[]` elements. For more complicated sorting rules, see the discussion of string collating in Section 5.11.5, “String Collating Support”.

`ctype[]` is an array of bit values, with one element for one character. (Note that `to_lower[]`, `to_upper[]`, and `sort_order[]` are indexed by character value, but `ctype[]` is indexed by character value + 1. This is an old legacy convention for handling EOF.)

You can find the following bitmask definitions in `m_ctype.h`:

```
#define _U      01      /* Uppercase */
#define _L      02      /* Lowercase */
#define _N      04      /* Numeral (digit) */
#define _S      010     /* Spacing character */
#define _P      020     /* Punctuation */
#define _C      040     /* Control character */
#define _B      0100    /* Blank */
#define _X      0200    /* hexadecimal digit */
```

The `ctype[]` entry for each character should be the union of the applicable bitmask values that describe the character. For example, 'A' is an uppercase character (`_U`) as well as a hexadecimal digit (`_X`), so `ctype['A'+1]` should contain the value:

```
_U + _X = 01 + 0200 = 0201
```

## 5.11.5. String Collating Support

If the sorting rules for your language are too complex to be handled with the simple `sort_order[]` table, you need to use the string collating functions.

The best documentation for this is the existing character sets. Look at the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets for examples.

You must specify the `strxfrm_multiply_MYSET=N` value in the special comment at the top of the file. `N` should be set to the maximum ratio the strings may grow during `my_strxfrm_MYSET`

(it must be a positive integer).

## 5.11.6. Multi-Byte Character Support

If you want to add support for a new character set that includes multi-byte characters, you need to use the multi-byte character functions.

The best documentation for this is the existing character sets. Look at the `eur_kr`, `gb2312`, `gbk`, `sjis`, and `ujis` character sets for examples. These are implemented in the `ctype-character-set_name.c` files in the `strings` directory.

You must specify the `mbmaxlen_MYSET=N` value in the special comment at the top of the source file. *N* should be set to the size in bytes of the largest character in the set.

## 5.11.7. Problems With Character Sets

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- Your program uses an incorrect path to determine where the character sets are stored. (Default `/usr/local/mysql/share/mysql/charsets`). This can be fixed by using the `--character-sets-dir` option when you run the program in question.
- The character set is a multi-byte character set that cannot be loaded dynamically. In this case, you must recompile the program with support for the character set.
- The character set is a dynamic character set, but you do not have a configure file for it. In this case, you should install the configure file for the character set from a new MySQL distribution.
- If your `Index` file does not contain the name for the character set, your program displays the following error message:

```
ERROR 1105: File '/usr/local/share/mysql/charsets/? .conf'
not found (Errcode: 2)
```

In this case, you should either get a new `Index` file or manually add the name of any missing character sets to the current file.

For MyISAM tables, you can check the character set name and number for a table with `myisamchk -dvv tbl_name`.

## 5.11.8. MySQL Server Time Zone Support

The MySQL server maintains several time zone settings:

- The system time zone. When the server starts, it attempts to determine the time zone of the host machine and uses it to set the `system_time_zone` system variable. The value does not change thereafter.
- The server's current time zone. The global `time_zone` system variable indicates the time zone the server currently is operating in. The initial value for `time_zone` is `'SYSTEM'`, which indicates that the server time zone is the same as the system time zone. The initial value can be specified explicitly with the `--default-time-zone=timezone` option. If you have the `SUPER` privilege, you can set the global value at runtime with this statement:

```
mysql> SET GLOBAL time_zone = timezone;
```

- Per-connection time zones. Each client that connects has its own time zone setting, given by the

session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

```
mysql> SET time_zone = timezone;
```

The current values of the global and client-specific time zones can be retrieved like this:

```
mysql> SELECT @@global.time_zone, @@session.time_zone;
```

`timezone` values can be given as strings indicating an offset from UTC, such as '+10:00' or '-6:00'. If the time zone information tables in the `mysql` database have been created and populated, you can also use named time zones, such as 'Europe/Helsinki', 'US/Eastern', or 'MET'. The value 'SYSTEM' can be used to indicate that the time zone should be the same as the system time zone. Time zone names are not case sensitive.

The MySQL installation procedure creates the time zone tables in the `mysql` database, but does not load them. You must do so manually. (If you are upgrading to MySQL 4.1.3 or later from an earlier version, you should create the tables by upgrading your `mysql` database. Use the instructions in Section 5.6.2, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.)

If your system has its own `zoneinfo` database (the set of files describing time zones), you should use the `mysql_tzinfo_to_sql` program for filling the time zone tables. Examples of such systems are Linux, FreeBSD, Sun Solaris, and Mac OS X. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system does not have a `zoneinfo` database, you can use the downloadable package described later in this section.

The `mysql_tzinfo_to_sql` program is used to load the time zone tables. On the command line, pass the `zoneinfo` directory pathname to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file, and to generate leap second information:

- To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke `mysql_tzinfo_to_sql` like this:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

- If your time zone needs to account for leap seconds, initialize the leap second information like this, where `tz_file` is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

If your system doesn't have a `zoneinfo` database (for example, Windows or HP-UX), you can use the package of pre-built time zone tables that is available for download at <http://dev.mysql.com/downloads/timezones.html>. This package contains `.frm`, `.MYD`, and `.MYI` files for the MyISAM time zone tables. These tables should be part of the `mysql` database, so you should place the files in the `mysql` subdirectory of your MySQL server's data directory. The server should be stopped while you do this.

**Warning:** Please don't use the downloadable package if your system has a `zoneinfo` database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime

handling between MySQL and other applications on your system.

For information about time zone settings in replication setup, please see Section 6.7, “Replication Features and Known Problems”.

## 5.12. MySQL Server Logs

MySQL has several different log files that can help you find out what is going on inside `mysqld`:

Log Type	Information Written to Log
The error log	Problems encountered starting, running, or stopping <code>mysqld</code>
The general query log	Established client connections and statements received from clients
The binary log	All statements that change data (also used for replication)
The slow log	All queries that took more than <code>long_query_time</code> seconds to execute or didn't use indexes

By default, all log files are created in the `mysqld` data directory. You can force `mysqld` to close and reopen the log files (or in some cases switch to a new log) by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement or execute `mysqladmin flush-logs` or `mysqladmin refresh`. See Section 13.5.5.2, “FLUSH Syntax”.

If you are using MySQL replication capabilities, slave replication servers maintain additional log files called relay logs. These are discussed in Chapter 6, *Replication*.

### 5.12.1. The Error Log

The error log file contains information indicating when `mysqld` was started and stopped and also any critical errors that occur while the server is running. If `mysqld` notices a table that needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if `mysqld` dies. The trace can be used to determine where `mysqld` died. See Section E.1.4, “Using a Stack Trace”.

If `mysqld` dies unexpectedly and `mysqld_safe` needs to restart it, `mysqld_safe` writes a `restarted mysqld` message to the error log.

You can specify where `mysqld` stores the error log file with the `--log-error[=file_name]` option. If no *file\_name* value is given, `mysqld` uses the name `host_name.err` and writes the file in the data directory. If you execute `FLUSH LOGS`, the error log is renamed with the suffix `-old` and `mysqld` creates a new empty log file. (No renaming occurs if the `--log-error` option was not given.)

If you do not specify `--log-error`, or (on Windows) if you use the `--console` option, errors are written to `stderr`, the standard error output. Usually this is your terminal.

On Windows, error output is always written to the `.err` file if `--console` is not given.

### 5.12.2. The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

`mysqld` writes statements to the query log in the order that it receives them. This may be different from the order in which they are executed. This is in contrast to the the binary log, for which statements are written after they are executed, but before any locks are released. (Also, the query log contains all statements, whereas the binary log does not contain statements that only select data.)

To enable the general query log, start `mysqld` with the `--log[=file_name]` or `-l [file_name]` option. If no *file\_name* value is given, the default name is *host\_name.log* in the data directory.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). On Unix, you can rename the file and create a new one by using the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> cp host_name-old.log backup-directory
shell> rm host_name-old.log
```

On Windows, you cannot rename the log file while the server has it open. You must stop the server and rename the file, and then restart the server to create a new log file.

### 5.12.3. The Binary Log

The binary log contains all statements that update data or potentially could have updated it (for example, a `DELETE` which matched no rows). Statements are stored in the form of “events” that describe the modifications. The binary log also contains information about how long each statement took that updated data.

**Note:** The binary log has replaced the old update log, which is no longer available as of MySQL 5.0. The binary log contains all information that is available in the update log in a more efficient format and in a manner that is transaction-safe. If you are using transactions, you must use the MySQL binary log for backups instead of the old update log.

The binary log does not contain statements that do not modify any data. If you want to log all statements (for example, to identify a problem query), use the general query log. See Section 5.12.2, “The General Query Log”.

The primary purpose of the binary log is to be able to update databases during a restore operation as fully as possible, because the binary log contains all updates done after a backup was made. The binary log is also used on master replication servers as a record of the statements to be sent to slave servers. See Chapter 6, *Replication*.

Running the server with the binary log enabled makes performance about 1% slower. However, the benefits of the binary log for restore operations and in allowing you to set up replication generally outweigh this minor performance decrement.

When started with the `--log-bin[=base_name]` option, `mysqld` writes a log file containing all SQL commands that update data. If no *base\_name* value is given, the default name is the name of the host machine followed by `-bin`. If the basename is given, but not as an absolute pathname, the server writes the file in the data directory. It is recommended that you specify a basename; see Section A.8.1, “Open Issues in MySQL”, for the reason.

If you supply an extension in the log name (for example, `--log-bin=base_name.extension`), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log basename. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new binary log file each time it starts or flushes the logs. The server also creates a new binary log file automatically when the current log's size reaches `max_binlog_size`. A binary log file may become larger than `max_binlog_size` if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, `mysqld` also creates a binary log index file that contains the names of all used binary log files. By default this has the same basename as the binary log file, with the extension `'.index'`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

Writes to the binary log file and binary log index file are handled in the same way as writes to MyISAM tables. See Section A.4.3, “How MySQL Handles a Full Disk”.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE MASTER LOGS`. See Section 13.5.5.5, “RESET Syntax”, and Section 13.6.1, “SQL Statements for Controlling Master Servers”.

The binary log format has some known limitations that can affect recovery from backups. See Section 6.7, “Replication Features and Known Problems”.

Binary logging for stored routines and triggers is done as described in Section 17.4, “Binary Logging of Stored Routines and Triggers”.

You can use the following options to `mysqld` to affect what is logged to the binary log. See also the discussion that follows this option list.

If you are using replication, the options described here affect which statements are sent by a master server to its slaves. There are also options for slave servers that control which statements received from the master to execute or ignore. For details, see Section 6.8, “Replication Startup Options”.

- `--binlog-do-db=db_name`

Tell the server to restrict binary logging to updates for which the default database is `db_name` (that is, the database selected by `USE`). All other databases that are not explicitly mentioned are ignored. If you use this option, you should ensure that you do updates only in the default database.

There is an exception to this for `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. The server uses the database named in the statement (not the default database) to decide whether it should log the statement.

An example of what does not work as you might expect: If the server is started with `binlog-do-db=sales`, and you run `USE prices; UPDATE sales.january SET amount=amount+1000;`, this statement is *not* written into the binary log.

To log multiple databases, use multiple options, specifying the option once for each database.

- `--binlog-ignore-db=db_name`

Tell the server to suppress binary logging of updates for which the default database is `db_name` (that is, the database selected by `USE`). If you use this option, you should ensure that you do updates only in the default database.

As with the `--binlog-do-db` option, there is an exception for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. The server uses the database named in the statement (not the default database) to decide whether it should log the statement.

An example of what does not work as you might expect: If the server is started with `binlog-ignore-db=sales`, and you run `USE prices; UPDATE sales.january SET amount=amount+1000;`, this statement *is* written into the binary log.

To ignore multiple databases, use multiple options, specifying the option once for each database.

The server evaluates the options for logging or ignoring updates to the binary log according to the following rules. As described previously, there is an exception for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, or *dropped* replaces the default database in the following rules.

1. Are there `--binlog-do-db` or `--binlog-ignore-db` rules?

- No: Write the statement to the binary log and exit.

- Yes: Go to the next step.
2. There are some rules (`--binlog-do-db`, `--binlog-ignore-db`, or both). Is there a default database (has any database been selected by `USE?`)?
    - No: Do *not* write the statement, and exit.
    - Yes: Go to the next step.
  3. There is a default database. Are there some `--binlog-do-db` rules?
    - Yes: Does the default database match any of the `--binlog-do-db` rules?
      - Yes: Write the statement and exit.
      - No: Do *not* write the statement, and exit.
    - No: Go to the next step.
  4. There are some `--binlog-ignore-db` rules. Does the default database match any of the `--binlog-ignore-db` rules?
    - Yes: Do not write the statement, and exit.
    - No: Write the query and exit.

For example, a slave running with only `--binlog-do-db=sales` does not write to the binary log any statement for which the default database is different from `sales` (in other words, `--binlog-do-db` can sometimes mean “ignore other databases”).

If you are using replication, you should not delete old binary log files until you are sure that no slave still needs to use them. For example, if your slaves never run more than three days behind, once a day you can execute `mysqladmin flush-logs` on the master and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE MASTER LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See Section 13.6.1, “SQL Statements for Controlling Master Servers”.

A client that has the `SUPER` privilege can disable binary logging of its own statements by using a `SET SQL_LOG_BIN=0` statement. See Section 13.5.3, “SET Syntax”.

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

See Section 8.9, “`mysqlbinlog` — Utility for Processing Binary Log Files”, for more information on the `mysqlbinlog` utility and how to use it. `mysqlbinlog` also can be used with relay log files because they are written using the same format as binary log files.

Binary logging is done immediately after a statement completes but before any locks are released or any commit is done. This ensures that the log is logged in execution order.

Updates to non-transactional tables are stored in the binary log immediately after execution. Within an uncommitted transaction, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change transactional tables such as `BDB` or `InnoDB` tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the `COMMIT` is executed. When the thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

Modifications to non-transactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to non-transactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` system variable (default 4GB) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this, it fails and rolls back.

If you are using the binary log, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statement. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation.

Note that the binary log format is different in MySQL 5.0 from previous versions of MySQL, due to enhancements in replication. See Section 6.5, “Replication Compatibility Between MySQL Versions”.

By default, the binary log is not synchronized to disk at each write. So if the operating system or machine (not only the MySQL server) crashes, there is a chance that the last statements of the binary log are lost. To prevent this, you can make the binary log be synchronized to disk after every *N* writes to the binary log, with the `sync_binlog` system variable. See Section 5.2.2, “Server System Variables”. 1 is the safest value for `sync_binlog`, but also the slowest. Even with `sync_binlog` set to 1, there is still the chance of an inconsistency between the table content and binary log content in case of a crash. For example, if you are using InnoDB tables and the MySQL server processes a `COMMIT` statement, it writes the whole transaction to the binary log and then commits this transaction into InnoDB. If the server crashes between those two operations, the transaction is rolled back by InnoDB at restart but still exists in the binary log. This problem can be solved with the `--innodb-safe-binlog` option, which adds consistency between the content of InnoDB tables and the binary log. (Note: `--innodb-safe-binlog` is unneeded as of MySQL 5.0; it was made obsolete by the introduction of XA transaction support.)

For this option to provide a greater degree of safety, the MySQL server should also be configured to synchronize the binary log and the InnoDB logs to disk at every transaction. The InnoDB logs are synchronized by default, and `sync_binlog=1` can be used to synchronize the binary log. The effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server cuts rolled back InnoDB transactions from the binary log. This ensures that the binary log reflects the exact data of InnoDB tables, and so, that the slave remains in synchrony with the master (not receiving a statement which has been rolled back).

Note that `--innodb-safe-binlog` can be used even if the MySQL server updates other storage engines than InnoDB. Only statements and transactions that affect InnoDB tables are subject to removal from the binary log at InnoDB's crash recovery. If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed InnoDB transaction. This should not happen if `sync_binlog=1` and the disk/filesystem do an actual sync when they are requested to (some don't), so the server prints an error message `The binary log <name> is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the master's data.

## 5.12.4. The Slow Query Log

The slow query log consists of all SQL statements that took more than `long_query_time` seconds to execute. The time to acquire the initial table locks is not counted as execution time. The minimum and default values of `long_query_time` are 1 and 10, respectively.

`mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released. Log order may be different from execution order.

To enable the slow query log, start `mysqld` with the `--log-slow-queries[=file_name]` option.

If no *file\_name* value is given, the default is the name of the host machine with a suffix of `-slow.log`. If a filename is given, but not as an absolute pathname, the server writes the file in the data directory.

The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can become a difficult task. To make this easier, you can process the slow query log using the `mysqldumpslow` command to summarize the queries that appear in the log. Use `mysqldumpslow --help` to see the options that this command supports.

In MySQL 5.0, queries that do not use indexes are logged in the slow query log if the `--log-queries-not-using-indexes` option is specified. See Section 5.2.1, “`mysqld` Command Options”.

In MySQL 5.0, the `--log-slow-admin-statements` server option enables you to request logging of slow administrative statements such as `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `ALTER TABLE` to the slow query log.

Queries handled by the query cache are not added to the slow query log, nor are queries that would not benefit from the presence of an index because the table has zero rows or one row.

## 5.12.5. Server Log Maintenance

MySQL Server can create a number of different log files that make it easy to see what is going on. See Section 5.12, “MySQL Server Logs”. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See Section 5.10.1, “Database Backups”.

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for this. If you installed MySQL from an RPM distribution, this script should have been installed automatically. You should be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all slaves.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

You can force MySQL to start using new log files by using `mysqladmin flush-logs` or by using the SQL statement `FLUSH LOGS`.

A log flushing operation does the following:

- If general query logging (`--log`) or slow query logging (`--log-slow-queries`) is used, the server closes and reopens the general query log file or slow query log file.
- If binary logging (`--log-bin`) is used, the server closes the current log file and opens a new log file with the next sequence number.

The server creates a new binary log file when you flush the logs. However, it just closes and reopens the general and slow query log files. To cause new files to be created on Unix, rename the current logs before flushing them. At flush time, the server will open new logs with the original names. For example, if the general and slow query logs are named `mysql.log` and `mysql-slow.log`, you can use a series of commands like this:

```
shell> cd mysql-data-directory
shell> mv mysql.log mysql.old
shell> mv mysql-slow.log mysql-slow.old
```

```
shell> mysqladmin flush-logs
```

At this point, you can make a backup of `mysql.old` and `mysql-slow.log` and then remove them from disk.

On Windows, you cannot rename log files while the server has them open. You must stop the server and rename them, and then restart the server to create new logs.

## 5.13. Running Multiple MySQL Servers on the Same Machine

In some cases, you might want to run multiple `mysqld` servers on the same machine. You might want to test a new MySQL release while leaving your existing production setup undisturbed. Or you might want to give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

To run multiple servers on a single machine, each server must have unique values for several operating parameters. These can be set on the command line or in option files. See Section 4.3, “Specifying Program Options”.

At least the following options must be different for each server:

- `--port=port_num`

`--port` controls the port number for TCP/IP connections.

- `--socket=path`

`--socket` controls the Unix socket file path on Unix and the name of the named pipe on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers that support named-pipe connections.

- `--shared-memory-base-name=name`

This option currently is used only on Windows. It designates the shared-memory name used by a Windows server to allow clients to connect via shared memory. It is necessary to specify distinct shared-memory names only for those servers that support shared-memory connections.

- `--pid-file=file_name`

This option is used only on Unix. It indicates the pathname of the file in which the server writes its process ID.

If you use the following log file options, they must be different for each server:

- `--log=file_name`
- `--log-bin=file_name`
- `--log-update=file_name`
- `--log-error=file_name`
- `--bdb-logdir=file_name`

Section 5.12.5, “Server Log Maintenance”, discusses the log file options further.

For better performance, you can specify the following options differently for each server, to spread the load between several physical disks:

- `--tmpdir=path`
- `--bdb-tmpdir=path`

Having different temporary directories is also recommended to make it easier to determine which MySQL server created any given temporary file.

With very limited exceptions, each server should use a different data directory, which is specified using the `--datadir=path` option.

**Warning:** Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log filenames that are unique to each server. Otherwise, the servers try to log to the same files. Please note that this kind of setup only works with MyISAM and MERGE tables, and not with any of the other storage engines.

The warning against sharing a data directory among servers also applies in an NFS environment. Allowing multiple MySQL servers to access a common data directory over NFS is a *very bad idea*.

- The primary problem is that NFS is the speed bottleneck. It is not meant for such use.
- Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

Make it easy for yourself: Forget about sharing a data directory among servers over NFS. A better solution is to have one computer that contains several CPUs and use an operating system that handles threads efficiently.

If you have multiple MySQL installations in different locations, you can specify the base installation directory for each server with the `--basedir=path` option to cause each server to use a different data directory, log files, and PID file. (The defaults for all these values are determined relative to the base directory). In that case, the only other options you need to specify are the `--socket` and `--port` options. For example, suppose that you install different versions of MySQL using tar file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` option to pass to `mysqld`, and you need specify only the `--socket` and `--port` options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by setting environment variables or by specifying appropriate command-line options. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` option is useful for this purpose.

## 5.13.1. Running Multiple Servers on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters. On Windows NT-based systems, you also have the option of installing several servers as Windows services and running them that way. General instructions for running MySQL servers from the command line or as services are given in Section 2.3, “Installing MySQL on Windows”. This section describes how to make sure that you start each server with different values for those startup options that must be unique per server, such as the data directory. These options are described in Section 5.13, “Running Multiple MySQL Servers on the Same Machine”.

### 5.13.1.1. Starting Multiple Windows Servers at the Command Line

To start multiple servers manually from the command line, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the filename with a `--defaults-file` option when you run it.

Suppose that you want to run `mysqld` on port 3307 with a data directory of `C:\mydata1`, and `mysqld-max` on port 3308 with a data directory of `C:\mydata2`. (To do this, make sure that before you start the servers, each data directory exists and has its own copy of the `mysql` database that contains the grant tables.) Then create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
port = 3308
```

Then start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld-max --defaults-file=C:\my-opts2.cnf
```

On NT, each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, you must connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 shutdown
```

Servers configured as just described allow clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to allow named-pipe connections, use the `mysqld-nt` or `mysqld-max-nt` servers and specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Then start the server this way:

```
C:\> C:\mysql\bin\mysqld-nt --defaults-file=C:\my-opts1.cnf
```

Modify `C:\my-opts2.cnf` similarly for use by the second server.

A similar procedure applies for servers that you want to support shared-memory connections. Enable such connections with the `--shared-memory` option and specify a unique shared-memory name for each server with the `--shared-memory-base-name` option.

## 5.13.1.2. Starting Multiple Windows Servers as Services

On NT-based systems, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in Section 2.3.11, “Starting MySQL as a Windows Service”.

You can also install multiple MySQL servers as services. In this case, you must make sure that each server uses a different service name in addition to all the other parameters that must be unique for each server.

For the following instructions, assume that you want to run the `mysqld-nt` server from two different versions of MySQL that are installed at `C:\mysql-4.1.8` and `C:\mysql-5.0.22`, respectively. (This might be the case if you're running 4.1.8 as your production server, but also want to conduct tests using 5.0.22.)

The following principles apply when installing a MySQL service with the `--install` or `--install-manual` option:

- If you specify no service name, the server uses the default service name of MySQL and the server reads options from the `[mysqld]` group in the standard option files.
- If you specify a service name after the `--install` option, the server ignores the `[mysqld]` option group and instead reads options from the group that has the same name as the service. The server reads options from the standard option files.
- If you specify a `--defaults-file` option after the service name, the server ignores the standard option files and reads options only from the `[mysqld]` group of the named file.

**Note:** Before MySQL 4.0.17, only a server installed using the default service name (MySQL) or one installed explicitly with a service name of `mysqld` read the `[mysqld]` group in the standard option files. As of 4.0.17, all servers read the `[mysqld]` group if they read the standard option files, even if they are installed using another service name. This allows you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group named after each service for use by the server installed with that service name.

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, be sure that you shut down and remove any existing MySQL services first.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 4.1.8 `mysqld-nt` using the service name of `mysqld1` and the 5.0.22 `mysqld-nt` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 4.1.8 and the `[mysqld2]` group for 5.0.22. For example, you can set up `C:\my.cnf` like this:

```
# options for mysqld1 service
[mysqld1]
basedir = C:/mysql-4.1.8
port = 3307
enable-named-pipe
socket = mypipe1

# options for mysqld2 service
[mysqld2]
basedir = C:/mysql-5.0.22
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows, using the full server pathnames to ensure that Windows registers

the correct executable program for each service:

```
C:\> C:\mysql-4.1.8\bin\mysqld-nt --install mysqld1
C:\> C:\mysql-5.0.22\bin\mysqld-nt --install mysqld2
```

To start the services, use the services manager, or use `NET START` with the appropriate service names:

```
C:\> NET START mysqld1
C:\> NET START mysqld2
```

To stop the services, use the services manager, or use `NET STOP` with the appropriate service names:

```
C:\> NET STOP mysqld1
C:\> NET STOP mysqld2
```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

With this approach, to specify options for the 4.1.8 `mysqld-nt`, create a file `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-4.1.8
port = 3307
enable-named-pipe
socket = mypipe1
```

For the 5.0.22 `mysqld-nt`, create a file `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.0.22
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

```
C:\> C:\mysql-4.1.8\bin\mysqld-nt --install mysqld1
--defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-5.0.22\bin\mysqld-nt --install mysqld2
--defaults-file=C:\my-opts2.cnf
```

To use a `--defaults-file` option when you install a MySQL server as a service, you must precede the option with the service name.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (MySQL), you can omit it.

## 5.13.2. Running Multiple Servers on Unix

The easiest way to run multiple servers on Unix is to compile them with different TCP/IP ports and Unix socket files so that each one is listening on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data

directory, log file, and PID file location for each server.

Assume that an existing 4.1.8 server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new 5.0.22 server to have different operating parameters, use a `configure` command something like this:

```
shell> ./configure --with-tcp-port=port_number \  
                --with-unix-socket-path=file_name \  
                --prefix=/usr/local/mysql-5.0.22
```

Here, *port\_number* and *file\_name* must be different from the default TCP/IP port number and Unix socket file pathname, and the `--prefix` value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket filename:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

Note that if you specify `localhost` as a hostname, `mysqladmin` defaults to using a Unix socket file connection rather than TCP/IP. From MySQL 4.1 onward, you can explicitly specify the connection protocol to use by using the `--protocol={TCP|SOCKET|PIPE|MEMORY}` option.

You don't have to compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=path` option to `mysqld_safe` so that the server uses a different data directory.

Another way to achieve a similar effect is to use environment variables to set the Unix socket filename and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock  
shell> MYSQL_TCP_PORT=3307  
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT  
shell> mysql_install_db --user=mysql  
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

Appendix F, *Environment Variables*, includes a list of other environment variables you can use to affect `mysqld`.

For automatic server execution, the startup script that is executed at boot time should execute the following command once for each server with an appropriate option file path for each command:

```
shell> mysqld_safe --defaults-file=file_name
```

Each option file should contain option values specific to a given server.

On Unix, the `mysqld_multi` script is another way to start multiple servers. See Section 5.4.3,

`mysqld_multi` — Manage Multiple MySQL Servers”.

### 5.13.3. Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect via TCP/IP to a remote server, with `--host=127.0.0.1 --port=port_number` to connect via TCP/IP to a local server, or with `--host=localhost --socket=file_name` to connect to a local server via a Unix socket file or a Windows named pipe.
- As of MySQL 4.1, start the client with `--protocol=tcp` to connect via TCP/IP, `--protocol=socket` to connect via a Unix socket file, `--protocol=pipe` to connect via a named pipe, or `--protocol=memory` to connect via shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.
- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See Appendix F, *Environment Variables*.
- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See Section 4.3.2, “Using Option Files”.
- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See Section 22.2.3, “C API Function Descriptions”.
- If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```
$dsn = "DBI:mysql:test;mysql_read_default_group=client;"
      . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);
```

See Section 22.4, “MySQL Perl API”.

Other programming interfaces may provide similar capabilities for reading option files.

## 5.14. The MySQL Query Cache

The query cache stores the text of a `SELECT` statement together with the corresponding result that was sent to the client. If an identical statement is received later, the server retrieves the results from the query cache rather than parsing and executing the statement again.

The query cache is extremely useful in an environment where you have tables that do not change very often and for which the server receives many identical queries. This is a typical situation for many Web servers that generate many dynamic pages based on database content.

**Note:** The query cache does not return stale data. When tables are modified, any relevant entries in the query cache are flushed.

**Note:** The query cache does not work in an environment where you have multiple `mysqld` servers updating the same `MyISAM` tables.

**Note:** The query cache is not used for server-side prepared statements. If you're using server-side prepared statements consider that these statement won't be satisfied by the query cache. See Section 22.2.4, "C API Prepared Statements".

Some performance data for the query cache follows. These results were generated by running the MySQL benchmark suite on a Linux Alpha 2×500MHz system with 2GB RAM and a 64MB query cache.

- If all the queries you are performing are simple (such as selecting a row from a table with one row), but still differ so that the queries cannot be cached, the overhead for having the query cache active is 13%. This could be regarded as the worst case scenario. In real life, queries tend to be much more complicated, so the overhead normally is significantly lower.
- Searches for a single row in a single-row table are 238% faster with the query cache than without it. This can be regarded as close to the minimum speedup to be expected for a query that is cached.

To disable the query cache at server startup, set the `query_cache_size` system variable to 0. By disabling the query cache code, there is no noticeable overhead. If you build MySQL from source, query cache capabilities can be excluded from the server entirely by invoking `configure` with the `--without-query-cache` option.

## 5.14.1. How the Query Cache Operates

This section describes how the query cache works when it is operational. Section 5.14.3, "Query Cache Configuration", describes how to control whether it is operational.

Incoming queries are compared to those in the query cache before parsing, so the following two queries are regarded as different by the query cache:

```
SELECT * FROM tbl_name
Select * from tbl_name
```

Queries must be *exactly* the same (byte for byte) to be seen as identical. In addition, query strings that are identical may be treated as different for other reasons. Queries that use different databases, different protocol versions, or different default character sets are considered different queries and are cached separately.

Before a query result is fetched from the query cache, MySQL checks that the user has `SELECT` privilege for all databases and tables involved. If this is not the case, the cached result is not used.

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See Section 5.14.4, "Query Cache Status and Maintenance".

If a table changes, all cached queries that use the table become invalid and are removed from the cache. This includes queries that use `MERGE` tables that map to the changed table. A table can be changed by many types of statements, such as `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, `ALTER TABLE`, `DROP TABLE`, or `DROP DATABASE`.

Transactional `InnoDB` tables that have been changed are invalidated when a `COMMIT` is performed.

The query cache also works within transactions when using `InnoDB` tables, making use of the table version number to detect whether its contents are still current.

In MySQL 5.0, queries generated by views are cached.

Before MySQL 5.0, a query that began with a leading comment could be cached, but could not be

fetches from the cache. This problem is fixed in MySQL 5.0.

The query cache works for `SELECT SQL_CALC_FOUND_ROWS ...` and `SELECT FOUND_ROWS()` type queries. `FOUND_ROWS()` returns the correct value even if the preceding query was fetched from the cache because the number of found rows is also stored in the cache.

A query cannot be cached if it contains any of the functions shown in the following table.

<code>BENCHMARK()</code>	<code>CONNECTION_ID()</code>	<code>CURDATE()</code>
<code>CURRENT_DATE()</code>	<code>CURRENT_TIME()</code>	<code>CURRENT_TIMESTAMP()</code>
<code>CURTIME()</code>	<code>DATABASE()</code>	<code>ENCRYPT()</code> with one parameter
<code>FOUND_ROWS()</code>	<code>GET_LOCK()</code>	<code>LAST_INSERT_ID()</code>
<code>LOAD_FILE()</code>	<code>MASTER_POS_WAIT()</code>	<code>NOW()</code>
<code>RAND()</code>	<code>RELEASE_LOCK()</code>	<code>SYSDATE()</code>
<code>UNIX_TIMESTAMP()</code> with no parameters	<code>USER()</code>	

A query also is not cached under these conditions:

- It refers to user-defined functions (UDFs).
- It refers to user variables.
- It refers to tables in the `mysql` system database.
- It is of any of the following forms:

```
SELECT ... IN SHARE MODE
SELECT ... FOR UPDATE
SELECT ... INTO OUTFILE ...
SELECT ... INTO DUMPFILE ...
SELECT * FROM ... WHERE autoincrement_col IS NULL
```

The last form is not cached because it is used as the ODBC workaround for obtaining the last insert ID value. See Section 23.1.14.1, “How to Get the Value of an `AUTO_INCREMENT` Column in ODBC”.

- It was issued as a prepared statement, even if no placeholders were employed. For example, the query used here is not cached:

```
char *my_sql_stmt = "SELECT a, b FROM table_c";
/* ... */
mysql_stmt_prepare(stmt, my_sql_stmt, strlen(my_sql_stmt));
```

See Section 22.2.4, “C API Prepared Statements”.

- It uses `TEMPORARY` tables.
- It does not use any tables.
- The user has a column-level privilege for any of the involved tables.

## 5.14.2. Query Cache `SELECT` Options

Two query cache-related options may be specified in `SELECT` statements:

- `SQL_CACHE`

The query result is cached if the value of the `query_cache_type` system variable is `ON` or `DEMAND`.

- `SQL_NO_CACHE`

The query result is not cached.

Examples:

```
SELECT SQL_CACHE id, name FROM customer;
SELECT SQL_NO_CACHE id, name FROM customer;
```

### 5.14.3. Query Cache Configuration

The `have_query_cache` server system variable indicates whether the query cache is available:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_query_cache | YES |
+-----+-----+
```

When using a standard MySQL binary, this value is always `YES`, even if query caching is disabled.

Several other system variables control query cache operation. These can be set in an option file or on the command line when starting `mysqld`. The query cache system variables all have names that begin with `query_cache_`. They are described briefly in Section 5.2.2, “Server System Variables”, with additional configuration information given here.

To set the size of the query cache, set the `query_cache_size` system variable. Setting it to 0 disables the query cache. The default size is 0, so the query cache is disabled by default.

When you set `query_cache_size` to a non-zero value, keep in mind that the query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value too small, you'll get a warning, as in this example:

```
mysql> SET GLOBAL query_cache_size = 40000;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
  Level: Warning
  Code: 1282
Message: Query cache failed to set size 39936; new query cache size is 0

mysql> SET GLOBAL query_cache_size = 41984;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| query_cache_size | 41984 |
+-----+-----+
```

If the query cache size is greater than 0, the `query_cache_type` variable influences how it works. This variable can be set to the following values:

- A value of 0 or OFF prevents caching or retrieval of cached results.
- A value of 1 or ON allows caching except of those statements that begin with SELECT SQL\_NO\_CACHE.
- A value of 2 or DEMAND causes caching of only those statements that begin with SELECT SQL\_CACHE.

Setting the GLOBAL `query_cache_type` value determines query cache behavior for all clients that connect after the change is made. Individual clients can control cache behavior for their own connection by setting the SESSION `query_cache_type` value. For example, a client can disable use of the query cache for its own queries like this:

```
mysql> SET SESSION query_cache_type = OFF;
```

To control the maximum size of individual query results that can be cached, set the `query_cache_limit` system variable. The default value is 1MB.

When a query that is to be cached, its result (the data sent to the client) is stored in the query cache during result retrieval. Therefore the data usually is not handled in one big chunk. The query cache allocates blocks for storing this data on demand, so when one block is filled, a new block is allocated. Because memory allocation operation is costly (timewise), the query cache allocates blocks with a minimum size given by the `query_cache_min_res_unit` system variable. When a query is executed, the last result block is trimmed to the actual data size so that unused memory is freed. Depending on the types of queries your server executes, you might find it helpful to tune the value of `query_cache_min_res_unit`:

- The default value of `query_cache_min_res_unit` is 4KB. This should be adequate for most cases.
- If you have a lot of queries with small results, the default block size may lead to memory fragmentation, as indicated by a large number of free blocks. Fragmentation can force the query cache to prune (delete) queries from the cache due to lack of memory. In this case, you should decrease the value of `query_cache_min_res_unit`. The number of free blocks and queries removed due to pruning are given by the values of the `Qcache_free_blocks` and `Qcache_lowmem_prunes` status variables.
- If most of your queries have large results (check the `Qcache_total_blocks` and `Qcache_queries_in_cache` status variables), you can increase performance by increasing `query_cache_min_res_unit`. However, be careful to not make it too large (see the previous item).

## 5.14.4. Query Cache Status and Maintenance

You can check whether the query cache is present in your MySQL server using the following statement:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_query_cache | YES   |
+-----+-----+
```

You can defragment the query cache to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The `RESET QUERY CACHE` statement removes all query results from the query cache. The `FLUSH TABLES` statement also does this.

To monitor query cache performance, use `SHOW STATUS` to view the cache status variables:

```
mysql> SHOW STATUS LIKE 'Qcache%';
+-----+-----+
| Variable_name          | Value          |
+-----+-----+
| Qcache_free_blocks    | 36             |
| Qcache_free_memory    | 138488        |
| Qcache_hits           | 79570         |
| Qcache_inserts        | 27087         |
| Qcache_lowmem_prunes  | 3114          |
| Qcache_not_cached     | 22989         |
| Qcache_queries_in_cache | 415           |
| Qcache_total_blocks   | 912           |
+-----+-----+
```

Descriptions of each of these variables are given in Section 5.2.4, “Server Status Variables”. Some uses for them are described here.

The total number of `SELECT` queries is given by this formula:

```
Com_select
+ Qcache_hits
+ queries with errors found by parser
```

The `Com_select` value is given by this formula:

```
Qcache_inserts
+ Qcache_not_cached
+ queries with errors found during the column-privileges check
```

The query cache uses variable-length blocks, so `Qcache_total_blocks` and `Qcache_free_blocks` may indicate query cache memory fragmentation. After `FLUSH QUERY CACHE`, only a single free block remains.

Every cached query requires a minimum of two blocks (one for the query text and one or more for the query results). Also, every table that is used by a query requires one block. However, if two or more queries use the same table, only one table block needs to be allocated.

The information provided by the `Qcache_lowmem_prunes` status variable can help you tune the query cache size. It counts the number of queries that have been removed from the cache to free up memory for caching new queries. The query cache uses a least recently used (LRU) strategy to decide which queries to remove from the cache. Tuning information is given in Section 5.14.3, “Query Cache Configuration”.

---

# Chapter 6. Replication

This chapter describes the various replication features provided by MySQL. It introduces replication concepts, shows how to set up replication servers, and serves as a reference to the available replication options. It also provides a list of frequently asked questions (with answers), and troubleshooting advice for solving replication problems.

For a description of the syntax of replication-related SQL statements, see Section 13.6, “Replication Statements”.

## 6.1. Introduction to Replication

MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of MySQL Cluster (see Chapter 15, *MySQL Cluster*).

In single-master replication, the master server writes updates to its binary log files and maintains an index of those files to keep track of log rotation. The binary log files serve as a record of updates to be sent to any slave servers. When a slave connects to its master, it informs the master of the position up to which the slave read the logs at its last successful update. The slave receives any updates that have taken place since that time, and then blocks and waits for the master to notify it of new updates.

A slave server can itself serve as a master if you want to set up chained replication servers.

Multiple-master replication is possible, but raises issues not present in single-master replication. See Section 6.13, “Auto-Increment in Multiple-Master Replication”.

When you are using replication, all updates to the tables that are replicated should be performed on the master server. Otherwise, you must always be careful to avoid conflicts between updates that users make to tables on the master and updates that they make to tables on the slave.

Replication offers benefits for robustness, speed, and system administration:

- Robustness is increased with a master/slave setup. In the event of problems with the master, you can switch to the slave as a backup.
- Better response time for clients can be achieved by splitting the load for processing client queries between the master and slave servers. `SELECT` queries may be sent to the slave to reduce the query processing load of the master. Statements that modify data should still be sent to the master so that the master and slave do not get out of synchrony. This load-balancing strategy is effective if non-updating queries dominate, but that is the normal case.
- Another benefit of using replication is that you can perform database backups using a slave server without disturbing the master. The master continues to process updates while the backup is being made. See Section 5.10.1, “Database Backups”.

## 6.2. Replication Implementation Overview

MySQL replication is based on the master server keeping track of all changes to your databases (updates, deletes, and so on) in its binary logs. Therefore, to use replication, you must enable binary logging on the master server. See Section 5.12.3, “The Binary Log”.

Each slave server receives from the master the saved updates that the master has recorded in its binary log, so that the slave can execute the same updates on its copy of the data.

It is *extremely* important to realize that the binary log is simply a record starting from the fixed point in time at which you enable binary logging. Any slaves that you set up need copies of the databases

on your master *as they existed at the moment you enabled binary logging on the master*. If you start your slaves with databases that are not in the same state as those on the master when the binary log was started, your slaves are quite likely to fail.

One way to copy the master's data to the slave is to use the `LOAD DATA FROM MASTER` statement. However, `LOAD DATA FROM MASTER` works only if all the tables on the master use the MyISAM storage engine. In addition, this statement acquires a global read lock, so no updates on the master are possible while the tables are being transferred to the slave. When we implement lock-free hot table backup, this global read lock will no longer be necessary.

Due to these limitations, we recommend that at this point you use `LOAD DATA FROM MASTER` only if the dataset on the master is relatively small, or if a prolonged read lock on the master is acceptable. Although the actual speed of `LOAD DATA FROM MASTER` may vary from system to system, a good rule of thumb for how long it takes is 1 second per 1MB of data. This is a rough estimate, but you should find it fairly accurate if both master and slave are equivalent to 700MHz Pentium CPUs in performance and are connected through a 100Mbps network.

After the slave has been set up with a copy of the master's data, it connects to the master and waits for updates to process. If the master fails, or the slave loses connectivity with your master, the slave keeps trying to connect periodically until it is able to resume listening for updates. The `--master-connect-retry` option controls the retry interval. The default is 60 seconds.

Each slave keeps track of where it left off when it last read from its master server. The master has no knowledge of how many slaves it has or which ones are up to date at any given time.

## 6.3. Replication Implementation Details

MySQL replication capabilities are implemented using three threads (one on the master server and two on the slave). When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs. The master creates a thread to send the binary log contents to the slave. This thread can be identified as the `Binlog Dump` thread in the output of `SHOW PROCESSLIST` on the master. The slave I/O thread reads the updates that the master `Binlog Dump` thread sends and copies them to local files, known as *relay logs*, in the slave's data directory. The third thread is the SQL thread, which the slave creates to read the relay logs and to execute the updates they contain.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one thread for each currently-connected slave, and each slave has its own I/O and SQL threads.

The slave uses two threads so that reading updates from the master and executing them can be separated into two independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
      Id: 2
     User: root
    Host: localhost:32931
       db: NULL
Command: Binlog Dump
```

```

Time: 94
State: Has sent all binlog to slave; waiting for binlog to
      be updated
Info: NULL

```

Here, thread 2 is a Binlog Dump replication thread for a connected slave. The State information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no Binlog Dump threads on a master server, this means that replication is not running — that is, that no slaves are currently connected.

On the slave server, the output from SHOW PROCESSLIST looks like this:

```

mysql> SHOW PROCESSLIST\G
***** 1. row *****
      Id: 10
      User: system user
      Host:
        db: NULL
Command: Connect
      Time: 11
      State: Waiting for master to send event
      Info: NULL
***** 2. row *****
      Id: 11
      User: system user
      Host:
        db: NULL
Command: Connect
      Time: 11
      State: Has read all relay log; waiting for the slave I/O
            thread to update it
      Info: NULL

```

This information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that the SHOW PROCESSLIST was run, both threads were idle, waiting for further updates.

The value in the Time column can show how late the slave is compared to the master. See Section 6.10, “Replication FAQ”.

## 6.3.1. Replication Master Thread States

The following list shows the most common states you may see in the State column for the master's Binlog Dump thread. If you see no Binlog Dump threads on a master server, this means that replication is not running — that is, that no slaves are currently connected.

- Sending binlog event to slave
 

Binary logs consist of *events*, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the slave.
- Finished reading one binlog; switching to next binlog
 

The thread has finished reading a binary log file and is opening the next one to send to the slave.
- Has sent all binlog to slave; waiting for binlog to be updated
 

The thread has read all outstanding updates from the binary logs and sent them to the slave. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the master.
- Waiting to finalize termination

A very brief state that occurs as the thread is stopping.

## 6.3.2. Replication Slave I/O Thread States

The following list shows the most common states you see in the `State` column for a slave server I/O thread. This state also appears in the `Slave_IO_State` column displayed by `SHOW SLAVE STATUS`, so you can get a good view of what is happening by using that statement.

- `Connecting to master`

The thread is attempting to connect to the master.

- `Checking master version`

A state that occurs very briefly, after the connection to the master is established.

- `Registering slave on master`

A state that occurs very briefly after the connection to the master is established.

- `Requesting binlog dump`

A state that occurs very briefly, after the connection to the master is established. The thread sends to the master a request for the contents of its binary logs, starting from the requested binary log filename and position.

- `Waiting to reconnect after a failed binlog dump request`

If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `--master-connect-retry` option.

- `Reconnecting after a failed binlog dump request`

The thread is trying to reconnect to the master.

- `Waiting for master to send event`

The thread has connected to the master and is waiting for binary log events to arrive. This can last for a long time if the master is idle. If the wait lasts for `slave_read_timeout` seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- `Queueing master event to the relay log`

The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- `Waiting to reconnect after a failed master event read`

An error occurred while reading (due to disconnection). The thread is sleeping for `master-connect-retry` seconds before attempting to reconnect.

- `Reconnecting after a failed master event read`

The thread is trying to reconnect to the master. When connection is established again, the state becomes `Waiting for master to send event`.

- `Waiting for the slave SQL thread to free enough relay log space`

You are using a non-zero `relay_log_space_limit` value, and the relay logs have grown

large enough that their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

- `Waiting for slave mutex on exit`

A state that occurs briefly as the thread is stopping.

### 6.3.3. Replication Slave SQL Thread States

The following list shows the most common states you may see in the `State` column for a slave server SQL thread:

- `Reading event from the relay log`

The thread has read an event from the relay log so that the event can be processed.

- `Has read all relay log; waiting for the slave I/O thread to update it`

The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.

- `Waiting for slave mutex on exit`

A very brief state that occurs as the thread is stopping.

The `State` column for the I/O thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and is executing it.

### 6.3.4. Replication Relay and Status Files

By default, relay logs filenames have the form `host_name-relay-bin.nnnnnn`, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with 000001. The slave uses an index file to track the relay log files currently in use. The default relay log index filename is `host_name-relay-bin.index`. By default, the slave server creates relay log files in its data directory. The default filenames can be overridden with the `--relay-log` and `--relay-log-index` server options. See Section 6.8, “Replication Startup Options”.

Relay logs have the same format as binary logs and can be read using `mysqlbinlog`. The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes too large. The meaning of “too large” is determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maxim-

um relay log file size.

A slave replication server creates two additional small files in the data directory. These *status files* are named `master.info` and `relay-log.info` by default. Their names can be changed by using the `--master-info-file` and `--relay-log-info-file` options. See Section 6.8, “Replication Startup Options”.

The two status files contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in Section 13.6.2, “SQL Statements for Controlling Slave Servers”. Because the status files are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two files to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The I/O thread updates the `master.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Description
1	Number of lines in the file
2	Master_Log_File
3	Read_Master_Log_Pos
4	Master_Host
5	Master_User
6	Password (not shown by <code>SHOW SLAVE STATUS</code> )
7	Master_Port
8	Connect_Retry
9	Master_SSL_Allowed
10	Master_SSL_CA_File
11	Master_SSL_CA_Path
12	Master_SSL_Cert
13	Master_SSL_Cipher
14	Master_SSL_Key

The SQL thread updates the `relay-log.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Description
1	Relay_Log_File
2	Relay_Log_Pos
3	Relay_Master_Log_File
4	Exec_Master_Log_Pos

When you back up the slave's data, you should back up these two status files as well, along with the relay log files. They are needed to resume replication after you restore the slave's data. If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master server.

If your slave is subject to replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The

directory location is specified using the `--slave-load-tmpdir` option. If this option is not specified, the directory location is the value of the `tmpdir` system variable.

## 6.4. How to Set Up Replication

This section briefly describes how to set up complete replication of a MySQL server. It assumes that you want to replicate all databases on the master and have not previously configured replication. You must shut down your master server briefly to complete the steps outlined here.

This procedure is written in terms of setting up a single slave, but you can repeat it to set up multiple slaves.

Although this method is the most straightforward way to set up a slave, it is not the only one. For example, if you have a snapshot of the master's data, and the master already has its server ID set and binary logging enabled, you can set up a slave without shutting down the master or even blocking updates to it. For more details, please see Section 6.10, “Replication FAQ”.

If you want to administer a MySQL replication setup, we suggest that you read this entire chapter through and try all statements mentioned in Section 13.6.1, “SQL Statements for Controlling Master Servers”, and Section 13.6.2, “SQL Statements for Controlling Slave Servers”. You should also familiarize yourself with the replication startup options described in Section 6.8, “Replication Startup Options”.

**Note:** This procedure and some of the replication SQL statements shown in later sections require the `SUPER` privilege.

1. Make sure that the versions of MySQL installed on the master and slave are compatible according to the table shown in Section 6.5, “Replication Compatibility Between MySQL Versions”. Ideally, you should use the most recent version of MySQL on both master and slave.

If you encounter a problem, please do not report it as a bug until you have verified that the problem is present in the latest MySQL release.

2. Set up an account on the master server that the slave server can use to connect. This account must be given the `REPLICATION SLAVE` privilege. If the account is used only for replication (which is recommended), you don't need to grant any additional privileges.

Suppose that your domain is `mydomain.com` and that you want to create an account with a username of `repl` such that slave servers can use the account to access the master server from any host in your domain using a password of `slavepass`. To create the account, use this `GRANT` statement:

```
mysql> GRANT REPLICATION SLAVE ON *.*  
-> TO 'repl'@'%mydomain.com' IDENTIFIED BY 'slavepass';
```

If you plan to use the `LOAD TABLE FROM MASTER` or `LOAD DATA FROM MASTER` statements from the slave host, you must grant this account additional privileges:

- Grant the account the `SUPER` and `RELOAD` global privileges.
- Grant the `SELECT` privilege for all tables that you want to load. Any master tables from which the account cannot `SELECT` will be ignored by `LOAD DATA FROM MASTER`.

For additional information about setting up user accounts and privileges, see Section 5.9, “MySQL User Account Management”.

3. Flush all the tables and block write statements by executing a `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

For InnoDB tables, note that `FLUSH TABLES WITH READ LOCK` also blocks `COMMIT` operations. When you have acquired a global read lock, you can start a filesystem snapshot of your InnoDB tables. Internally (inside the InnoDB storage engine) the snapshot won't be consistent (because the InnoDB caches are not flushed), but this is not a cause for concern, because InnoDB resolves this at startup and delivers a consistent result. This means that InnoDB can perform crash recovery when started on this snapshot, without corruption. However, there is no way to stop the MySQL server while insuring a consistent snapshot of your InnoDB tables.

Leave running the client from which you issue the `FLUSH TABLES` statement so that the read lock remains in effect. (If you exit the client, the lock is released.) Then take a snapshot of the data on your master server.

The easiest way to create a snapshot is to use an archiving program to make a binary backup of the databases in your master's data directory. For example, use `tar` on Unix, or `PowerArchiver`, `WinRAR`, `WinZip`, or any similar software on Windows. To use `tar` to create an archive that includes all databases, change location into the master server's data directory, then execute this command:

```
shell> tar -cvf /tmp/mysql-snapshot.tar .
```

If you want the archive to include only a database called `this_db`, use this command instead:

```
shell> tar -cvf /tmp/mysql-snapshot.tar ./this_db
```

Then copy the archive file to the `/tmp` directory on the slave server host. On that machine, change location into the slave's data directory, and unpack the archive file using this command:

```
shell> tar -xvf /tmp/mysql-snapshot.tar
```

You may not want to replicate the `mysql` database if the slave server has a different set of user accounts from those that exist on the master. In this case, you should exclude it from the archive. You also need not include any log files in the archive, or the `master.info` or `relay-log.info` files.

While the read lock placed by `FLUSH TABLES WITH READ LOCK` is in effect, read the value of the current binary log name and offset on the master:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.003 | 73       | test         | manual,mysql      |
+-----+-----+-----+-----+
```

The `File` column shows the name of the log and `Position` shows the offset within the file. In this example, the binary log file is `mysql-bin.003` and the offset is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

If the master has been running previously without binary logging enabled, the log name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string ( `' '` ) and 4.

After you have taken the snapshot and recorded the log name and offset, you can re-enable write activity on the master:

```
mysql> UNLOCK TABLES;
```

If you are using InnoDB tables, ideally you should use the InnoDB Hot Backup tool, which takes a consistent snapshot without acquiring any locks on the master server, and records the log name and offset corresponding to the snapshot to be later used on the slave. Hot Backup is an additional non-free (commercial) tool that is not included in the standard MySQL distribution. See the InnoDB Hot Backup home page at <http://www.innodb.com/manual.php> for detailed information.

Without the Hot Backup tool, the quickest way to take a binary snapshot of InnoDB tables is to shut down the master server and copy the InnoDB data files, log files, and table format files (.frm files). To record the current log file name and offset, you should issue the following statements before you shut down the server:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Then record the log name and the offset from the output of SHOW MASTER STATUS as was shown earlier. After recording the log name and the offset, shut down the server *without* unlocking the tables to make sure that the server goes down with the snapshot corresponding to the current log file and offset:

```
shell> mysqladmin -u root shutdown
```

An alternative that works for both MyISAM and InnoDB tables is to take an SQL dump of the master instead of a binary copy as described in the preceding discussion. For this, you can use `mysqldump --master-data` on your master and later load the SQL dump file into your slave. However, this is slower than doing a binary copy.

4. Make sure that the `[mysqld]` section of the `my.cnf` file on the master host includes a `log-bin` option. The section should also have a `server-id=master_id` option, where `master_id` must be a positive integer value from 1 to  $2^{32} - 1$ . For example:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

If those options are not present, add them and restart the server. The server cannot act as a replication master unless binary logging is enabled.

**Note:** For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should use `innodb_flush_log_at_trx_commit=1`, `sync_binlog=1`, and, before MySQL 5.0.3, `innodb_safe_binlog`, in the master `my.cnf` file. (`innodb_safe_binlog` is not needed from 5.0.3 on.)

5. Stop the server that is to be used as a slave and add the following lines to its `my.cnf` file:

```
[mysqld]
server-id=slave_id
```

The `slave_id` value, like the `master_id` value, must be a positive integer value from 1 to  $2^{32} - 1$ . In addition, it is necessary that the ID of the slave be different from the ID of the master. For example:

```
[mysqld]
server-id=2
```

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from each of the other slaves. Think of `server-id` values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

If you do not specify a `server-id` value, it is set to 1 if you have not defined `master-host`; otherwise it is set to 2. Note that in the case of `server-id` omission, a master refuses connections from all slaves, and a slave refuses to connect to a master. Thus, omitting `server-id` is good only for backup with a binary log.

6. If you made a binary backup of the master server's data, copy it to the slave server's data directory before starting the slave. Make sure that the privileges on the files and directories are correct. The system account that you use to run the slave server must be able to read and write the files, just as on the master.

If you made a backup using `mysqldump`, start the slave first. The dump file is loaded in a later step.

7. Start the slave server. If it has been replicating previously, start the slave server with the `--skip-slave-start` option so that it doesn't immediately try to connect to its master. You also may want to start the slave server with the `--log-warnings` option to get more messages in the error log about problems (for example, network or connection problems). The option is enabled by default, but aborted connections are not logged to the error log unless the option value is greater than 1.

8. If you made a backup of the master server's data using `mysqldump`, load the dump file into the slave server:

```
shell> mysql -u root -p < dump_file.sql
```

9. Execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master_host_name',
->     MASTER_USER='replication_user_name',
->     MASTER_PASSWORD='replication_password',
->     MASTER_LOG_FILE='recorded_log_file_name',
->     MASTER_LOG_POS=recorded_log_position;
```

The following table shows the maximum allowable length for the string-valued options:

MASTER_HOST	60
MASTER_USER	16
MASTER_PASSWORD	32
MASTER_LOG_FILE	255

10. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do *not* remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

**Note:** The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See Section 6.8, “Replication Startup Options”, for more details.

Once you have a snapshot of the master, you can use it to set up other slaves by following the slave portion of the procedure just described. You do not need to take another snapshot of the master; you can use the same one for each slave.

## 6.5. Replication Compatibility Between MySQL Versions

The binary log format as implemented in MySQL 5.0 is considerably different from that used in previous versions. Major changes were made in MySQL 5.0.3 (for improvements to handling of character sets and `LOAD DATA INFILE`) and 5.0.4 (for improvements to handling of time zones).

We recommend using the most recent MySQL version available because replication capabilities are continually being improved. We also recommend using the same version for both the master and the slave. We recommend upgrading masters and slaves running alpha or beta versions to new (production) versions. Replication from a 5.0.3 master to a 5.0.2 slave will fail; from a 5.0.4 master to a 5.0.3 slave will also fail. In general, slaves running MySQL 5.0.x can be used with older masters (even those running MySQL 3.23, 4.0, or 4.1), but not the reverse.

**Note:** You *cannot* replicate from a master that uses a newer binary log format to a slave that uses an older format (for example, from MySQL 5.0 to MySQL 4.1.) This has significant implications for upgrading replication servers, as described in Section 6.6, “Upgrading a Replication Setup”.

The preceding information pertains to replication compatibility at the protocol level. However, there can be other constraints, such as SQL-level compatibility issues. For example, a 5.0 master cannot replicate to a 4.1 slave if the replicated statements use SQL features available in 5.0 but not in 4.1. These and other issues are discussed in Section 6.7, “Replication Features and Known Problems”.

## 6.6. Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

### 6.6.1. Upgrading Replication to 5.0

This section applies to upgrading replication from MySQL 3.23, 4.0, or 4.1 to MySQL 5.0. A 4.0 server should be 4.0.3 or newer.

When you upgrade a master to 5.0 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.0.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.0.x version, restart it, and restart replication. The 5.0 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.0 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.0.x release as

the slaves, and restart it. The 5.0 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.0 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master following the upgrade are in 5.0 format. These too are recognized by the 5.0 slaves.

In other words, there are no measures to take when upgrading to MySQL 5.0, except that the slaves must be MySQL 5.0 before you can upgrade the master to 5.0. Note that downgrading from 5.0 to older versions does not work so simply: You must ensure that any 5.0 binary logs or relay logs have been fully processed, so that you can remove them before proceeding with the downgrade.

## 6.7. Replication Features and Known Problems

In general, replication compatibility at the SQL level requires that any features used be supported by both the master and the slave servers. If you use a feature on a master server that is available only as of a given version of MySQL, you cannot replicate to a slave that is older than that version. Such incompatibilities are likely to occur between series, so that, for example, you cannot replicate from MySQL 5.0 to 4.1. However, these incompatibilities also can occur for within-series replication. For example, the `SLEEP()` function is available in MySQL 5.0.12 and up. If you use this function on the master server, you cannot replicate to a slave server that is older than MySQL 5.0.12.

If you are planning to use replication between 5.0 and a previous version of MySQL you should consult the edition of the MySQL Reference Manual corresponding to the earlier release series for information regarding the replication characteristics of that series.

The following list provides details about what is supported and what is not. Additional InnoDB-specific information about replication is given in Section 14.2.6.5, “InnoDB and MySQL Replication”.

Replication issues with regard to stored routines and triggers is described in Section 17.4, “Binary Logging of Stored Routines and Triggers”.

- **Known issue:** In MySQL 5.0.17, the syntax for `CREATE TRIGGER` changed to include a `DEFINER` clause for specifying which access privileges to check at trigger invocation time. (See Section 18.1, “`CREATE TRIGGER` Syntax”, for more information.) However, if you attempt to replicate from a master server older than MySQL 5.0.17 to a slave running MySQL 5.0.17 through 5.0.19, replication of `CREATE TRIGGER` statements fails on the slave with a `Definer not fully qualified` error. A workaround is to create triggers on the master using a version-specific comment embedded in each `CREATE TRIGGER` statement:

```
CREATE /*!50017 DEFINER = 'root'@'localhost' */ TRIGGER ... ;
```

`CREATE TRIGGER` statements written this way will replicate to newer slaves, which pick up the `DEFINER` clause from the comment and execute successfully.

This slave problem is fixed as of MySQL 5.0.20.

- Replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly.

However, adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
```

```
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE T2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

**Important:** To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also Section A.7.1, “Problems with `ALTER TABLE`”.

- The `USER()`, `UUID()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave.
- As of MySQL 5.0.13, the `SYSDATE()` function is no longer equivalent to `NOW()`. Implications are that `SYSDATE()` is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is non-deterministic. To avoid this, you can start the server with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`.
- User privileges are replicated only if the `mysql` database is replicated. That is, the `GRANT`, `REVOKE`, `SET PASSWORD`, `CREATE USER`, and `DROP USER` statements take effect on the slave only if the replication setup includes the `mysql` database.

If you're replicating all databases, but don't want statements that affect user privileges to be replicated, set up the slave to not replicate the `mysql` database, using the `--replicate-wild-ignore-table=mysql.%` option. The slave will recognize that issuing privilege-related SQL statements won't have an effect, and thus not execute those statements.

- The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on master. Therefore, these functions should not be used to insert into a master's table because the content on the slave would differ. (For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...)).`)
- The `FOREIGN_KEY_CHECKS`, `SQL_MODE`, `UNIQUE_CHECKS`, and `SQL_AUTO_IS_NULL` variables are all replicated in MySQL 5.0. The `storage_engine` system variable (also known as `table_type`) is not yet replicated, which is a good thing for replication between different storage engines.
- Starting from MySQL 5.0.3 (master and slave), replication works even if the master and slave have different global character set variables. Starting from MySQL 5.0.4 (master and slave), replication works even if the master and slave have different global time zone variables.
- The following applies to replication between MySQL servers that use different character sets:
  1. If the master uses MySQL 4.1, you must *always* use the same *global* character set and collation on the master and the slave, regardless of the MySQL version running on the slave. (These are controlled by the `--character-set-server` and `--collation-server` options.) Otherwise, you may get duplicate-key errors on the

slave, because a key that is unique in the master character set might not be unique in the slave character set. Note that this is not a cause for concern when master and slave are both MySQL 5.0 or later.

2. If the master is older than MySQL 4.1.3, the character set of any client should never be made different from its global value because this character set change is not known to the slave. In other words, clients should not use `SET NAMES`, `SET CHARACTER SET`, and so forth. If both the master and the slave are 4.1.3 or newer, clients can freely set session values for character set variables because these settings are written to the binary log and so are known to the slave. That is, clients can use `SET NAMES` or `SET CHARACTER SET` or can set variables such as `collation_client` or `collation_server`. However, clients are prevented from changing the *global* value of these variables; as stated previously, the master and slave must always have identical global character set values.
  3. If you have databases on the master with character sets that differ from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that tables in those databases do not implicitly rely on the database default character set (see Bug#2326 [<http://bugs.mysql.com/2326>]). A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.
- If the master uses MySQL 4.1, the same system time zone should be set for both master and slave. Otherwise some statements will not be replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. You can set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. Both master and slave should also have the same default connection time zone setting; that is, the `--default-time-zone` parameter should have the same value for both master and slave. Note that this is not necessary when the master is MySQL 5.0 or later.
  - `CONVERT_TZ(..., ..., @@global.time_zone)` is not properly replicated. `CONVERT_TZ(..., ..., @@session.time_zone)` is properly replicated only if the master and slave are from MySQL 5.0.4 or newer.
  - Session variables are not replicated properly when used in statements that update tables. For example, `SET MAX_JOIN_SIZE=1000` followed by `INSERT INTO mytable VALUES(@@MAX_JOIN_SIZE)` will not insert the same data on the master and the slave. This does not apply to the common sequence of `SET TIME_ZONE=...` followed by `INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone))`, which replicates correctly as of MySQL 5.0.4.
  - It is possible to replicate transactional tables on the master using non-transactional tables on the slave. For example, you can replicate an InnoDB master table as a MyISAM slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN/COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.
  - Update statements that refer to user-defined variables (that is, variables of the form `@var_name`) are replicated correctly in MySQL 5.0. However, this is not true for versions prior to 4.1. Note that user variable names are case insensitive starting in MySQL 5.0. You should take this into account when setting up replication between MySQL 5.0 and older versions.
  - Slaves can connect to masters using SSL.
  - Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.
  - In MySQL 5.0 (starting from 5.0.3), there is a global system variable `slave_transaction_retries`: If the replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because it exceeded the InnoDB `innodb_lock_wait_timeout` or the NDBCluster `TransactionDeadlockDetection-`

Timeout or TransactionInactiveTimeout value, the transaction automatically retries slave\_transaction\_retries times before stopping with an error. The default value is 10. Starting from MySQL 5.0.4, the total retry count can be seen in the output of SHOW STATUS; see Section 5.2.4, “Server Status Variables”.

- If a DATA DIRECTORY or INDEX DIRECTORY table option is used in a CREATE TABLE statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host filesystem or if it exists but is not accessible to the slave server. MySQL supports an sql\_mode option called NO\_DIR\_IN\_CREATE. If the slave server is run with this SQL mode enabled, it ignores the DATA DIRECTORY and INDEX DIRECTORY table options when replicating CREATE TABLE statements. The result is that MyISAM data and index files are created in the table's database directory.
- It is possible for the data on the master and slave to become different if a statement is designed in such a way that the data modification is non-deterministic; that is, left to the will of the query optimizer. (This is in general not a good practice, even outside of replication.) For a detailed explanation of this issue, see Section A.8.1, “Open Issues in MySQL”.
- *The following applies only if either the master or the slave is running MySQL version 5.0.3 or older:* If on the master a LOAD DATA INFILE is interrupted (integrity constraint violation, killed connection, and so on), the slave skips the LOAD DATA INFILE entirely. This means that if this command permanently inserted or updated table records before being interrupted, these modifications are not replicated to the slave.
- Some forms of the FLUSH statement are not logged because they could cause problems if replicated to a slave: FLUSH LOGS, FLUSH MASTER, FLUSH SLAVE, and FLUSH TABLES WITH READ LOCK. For a syntax example, see Section 13.5.5.2, “FLUSH Syntax”. The FLUSH TABLES, ANALYZE TABLE, OPTIMIZE TABLE, and REPAIR TABLE statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data. However, this can cause difficulties under certain circumstances. If you replicate the privilege tables in the mysql database and update those tables directly without using GRANT, you must issue a FLUSH PRIVILEGES on the slaves to put the new privileges into effect. In addition, if you use FLUSH TABLES when renaming a MyISAM table that is part of a MERGE table, you must issue FLUSH TABLES manually on the slaves. These statements are written to the binary log unless you specify NO\_WRITE\_TO\_BINLOG or its alias LOCAL.
- MySQL supports only one master and many slaves. In the future we plan to add a voting algorithm for changing the master automatically in the event of problems with the current master. We also plan to introduce agent processes to help perform load balancing by sending SELECT queries to different slaves.
- When a server shuts down and restarts, its MEMORY (HEAP tables become empty. The master replicates this effect to slaves as follows: The first time that the master uses each MEMORY table after startup, it logs an event that notifies the slaves that the table needs to be emptied by writing a DELETE statement for that table to the binary log. See Section 14.4, “The MEMORY (HEAP) Storage Engine”, for more information.
- Temporary tables are replicated except in the case where you shut down the slave server (not just the slave threads) and you have replicated temporary tables that are used in updates that have not yet been executed on the slave. If you shut down the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:
  1. Issue a STOP SLAVE statement.
  2. Use SHOW STATUS to check the value of the Slave\_open\_temp\_tables variable.
  3. If the value is 0, issue a mysqladmin shutdown command to stop the slave.
  4. If the value is not 0, restart the slave threads with START SLAVE.

5. Repeat the procedure later until the `Slave_open_temp_tables` variable is 0 and you can stop the slave.

- The syntax for multiple-table `DELETE` statements that use table aliases changed between MySQL 4.0 and 4.1. In MySQL 4.0, you should use the true table name to refer to any table from which rows should be deleted:

```
DELETE test FROM test AS t1, test2 WHERE ...
```

In MySQL 4.1, you must use the alias:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

If you use such `DELETE` statements, the change in syntax means that a 4.0 master cannot replicate to 4.1 (or higher) slaves.

- It is safe to connect servers in a circular master/slave relationship if you use the `--log-slave-updates` option. That means that you can create a setup such as this:

```
A -> B -> C -> A
```

However, many statements do not work correctly in this kind of setup unless your client code is written to take care of the potential problems that can occur from updates that occur in different sequence on different servers.

Server IDs are encoded in binary log events, so server A knows when an event that it reads was originally created by itself and does not execute the event (unless server A was started with the `--replicate-same-server-id` option, which is meaningful only in rare cases). Thus, there are no infinite loops. This type of circular setup works only if you perform no conflicting updates between the tables. In other words, if you insert data in both A and C, you should never insert a row in A that may have a key that conflicts with a row inserted in C. You should also not update the same rows on two servers if the order in which the updates are applied is significant.

- If a statement on a slave produces an error, the slave SQL thread terminates, and the slave writes a message to its error log. You should then connect to the slave manually and determine the cause of the problem. (`SHOW SLAVE STATUS` is useful for this.) Then fix the problem (for example, you might need to create a non-existent table) and run `START SLAVE`.
- It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `--master-connect-retry` option. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See Section 5.2.2, “Server System Variables”.
- Shutting down the slave (cleanly) is also safe because it keeps track of where it left off. Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the system went down. Your system fault tolerance is greatly increased if you have a good uninterruptible power supply. Unclean shutdowns of the master may cause inconsistencies between the content of tables and the binary log in master; this can be avoided by using `InnoDB` tables and the `--innodb-safe-binlog` option on the master. See Section 5.12.3, “The Binary Log”.

**Note:** `--innodb-safe-binlog` is unneeded as of MySQL 5.0.3, having been made obsolete by the introduction of XA transaction support.

- A crash on the master side can result in the master's binary log having a final position less than the most recent position read by the slave, due to the master's binary log file not being flushed.

This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

- Due to the non-transactional nature of MyISAM tables, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave thread exits and waits for the database administrator to decide what to do about it unless the error code is legitimate and execution of the statement results in the same error code on the slave. If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.
- If you update transactional tables from non-transactional tables inside a `BEGIN/COMMIT` sequence, updates to the binary log may be out of synchrony with table states if the non-transactional table is updated before the transaction commits. This occurs because the transaction is written to the binary log only when it is committed.
- In situations where transactions mix updates to transactional and non-transactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the non-transactional table before the first connection's transaction is complete, statements can be logged out of order, because the second connection's update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.
- Floating-point values are approximate, so comparisons involving them are inexact. This is true for operations that use floating-point values explicitly, or values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See Section 12.1.2, “Type Conversion in Expression Evaluation”, and Section A.5.8, “Problems with Floating-Point Comparisons”.

## 6.8. Replication Startup Options

This section describes the options that you can use on slave replication servers. You can specify these options either on the command line or in an option file.

On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to  $2^{32} - 1$ , and each ID must be different from every other ID. Example: `server-id=3`

Options that you can use on the master server for controlling binary logging are described in Section 5.12.3, “The Binary Log”.

Some slave server replication options are handled in a special way, in the sense that each is ignored if a `master.info` file exists when the slave starts and contains a value for the option. The following options are handled this way:

- `--master-host`
- `--master-user`
- `--master-password`
- `--master-port`
- `--master-connect-retry`
- `--master-ssl`

- `--master-ssl-ca`
- `--master-ssl-capath`
- `--master-ssl-cert`
- `--master-ssl-cipher`
- `--master-ssl-key`

The `master.info` file format in MySQL 5.0 includes values corresponding to the SSL options. In addition, the file format includes as its first line the number of lines in the file. (See Section 6.3.4, “Replication Relay and Status Files”.) If you upgrade an older server (before MySQL 4.1.1) to a newer version, the new server upgrades the `master.info` file to the new format automatically when it starts. However, if you downgrade a newer server to an older version, you should remove the first line manually before starting the older server for the first time.

If no `master.info` file exists when the slave server starts, it uses the values for those options that are specified in option files or on the command line. This occurs when you start the server as a replication slave for the very first time, or when you have run `RESET SLAVE` and then have shut down and restarted the slave.

If the `master.info` file exists when the slave server starts, the server uses its contents and ignores any options that correspond to the values listed in the file. Thus, if you start the slave server with different values of the startup options that correspond to values in the `master.info` file, the different values have no effect, because the server continues to use the `master.info` file. To use different values, you must either restart after removing the `master.info` file or (preferably) use the `CHANGE MASTER TO` statement to reset the values while the slave is running.

Suppose that you specify this option in your `my.cnf` file:

```
[mysqld]
master-host=some_host
```

The first time you start the server as a replication slave, it reads and uses that option from the `my.cnf` file. The server then records the value in the `master.info` file. The next time you start the server, it reads the master host value from the `master.info` file only and ignores the value in the option file. If you modify the `my.cnf` file to specify a different master host of `some_other_host`, the change still has no effect. You should use `CHANGE MASTER TO` instead.

Because the server gives an existing `master.info` file precedence over the startup options just described, you might prefer not to use startup options for these values at all, and instead specify them by using the `CHANGE MASTER TO` statement. See Section 13.6.2.1, “CHANGE MASTER TO Syntax”.

This example shows a more extensive use of startup options to configure a slave server:

```
[mysqld]
server-id=2
master-host=db-master.mycompany.com
master-port=3306
master-user=pertinax
master-password=freitag
master-connect-retry=60
report-host=db-slave.mycompany.com
```

The following list describes startup options for controlling replication. Many of these options can be reset while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts.

- `--log-slave-updates`

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

A -> B -> C

Here, A serves as the master for the slave B, and B serves as the master for the slave C. For this to work, B must be both a master *and* a slave. You must start both A and B with `--log-bin` to enable binary logging, and B with the `--log-slave-updates` option so that updates received from A are logged by B to its binary log.

- `--log-warnings[=level]`

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled by default; to disable it, use `--skip-log-warnings`. Aborted connections are not logged to the error log unless the value is greater than 1.

- `--master-connect-retry=seconds`

The number of seconds that the slave thread sleeps before trying to reconnect to the master in case the master goes down or the connection is lost. The value in the `master.info` file takes precedence if it can be read. If not set, the default is 60.

- `--master-host=host_name`

The hostname or IP number of the master replication server. The value in `master.info` takes precedence if it can be read. If no master host is specified, the slave thread does not start.

- `--master-info-file=file_name`

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory.

- `--master-password=password`

The password of the account that the slave thread uses for authentication when it connects to the master. The value in the `master.info` file takes precedence if it can be read. If not set, an empty password is assumed.

- `--master-port=port_number`

The TCP/IP port number that the master is listening on. The value in the `master.info` file takes precedence if it can be read. If not set, the compiled-in setting is assumed (normally 3306).

- `--master-retry-count=count`

The number of times that the slave tries to connect to the master before giving up.

- `--master-ssl, --master-ssl-ca=file_name, --master-ssl-capath=directory_name,  
--master-ssl-cert=file_name,  
--master-ssl-cipher=cipher_list, --master-ssl-key=file_name`

These options are used for setting up a secure replication connection to the master server using SSL. Their meanings are the same as the corresponding `--ssl, --ssl-ca, --ssl-capath, --ssl-cert, --ssl-cipher, --ssl-key` options that are described in Section 5.9.7.5, “SSL Command Options”. The values in the `master.info` file take precedence if they can be

read.

- `--master-user=user_name`

The username of the account that the slave thread uses for authentication when it connects to the master. This account must have the `REPLICATION SLAVE` privilege. The value in the `master.info` file takes precedence if it can be read. If the master username is not set, the name `test` is assumed.

- `--max-relay-log-size=size`

The size at which the server rotates relay log files automatically. For more information, see Section 6.3.4, “Replication Relay and Status Files”.

- `--read-only`

Cause the slave to allow no updates except from slave threads or from users having the `SUPER` privilege. This enables you to ensure that a slave server accepts no updates from clients. As of MySQL 5.0.16, this option does not apply to `TEMPORARY` tables.

- `--relay-log=file_name`

The name for the relay log. The default name is `host_name-relay-bin.nnnnnn`, where `host_name` is the name of the slave server host and `nnnnnn` indicates that relay logs are created in numbered sequence. You can specify the option to create hostname-independent relay log names, or if your relay logs tend to be big (and you don't want to decrease `max_relay_log_size`) and you need to put them in some area different from the data directory, or if you want to increase speed by balancing load between disks.

- `--relay-log-index=file_name`

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- `--relay-log-info-file=file_name`

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- `--relay-log-purge={0|1}`

Disable or enable automatic purging of relay logs as soon as they are not needed any more. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--relay-log-space-limit=size`

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit.” This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs, because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to temporarily ignore `--relay-log-space-limit`.

- `--replicate-do-db=db_name`

Tell the slave to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times,

once for each database. Note that this does not replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while having selected a different database or no database.

An example of what does not work as you might expect: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See Section 6.9, “How Servers Evaluate Replication Rules”.

- `--replicate-do-table=db_name.tbl_name`

Tell the slave thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-do-db`. See Section 6.9, “How Servers Evaluate Replication Rules”.

- `--replicate-ignore-db=db_name`

Tells the slave to not replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database to ignore, use this option multiple times, once for each database. You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See Section 6.9, “How Servers Evaluate Replication Rules”.

An example of what does not work as you might expect: If the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See Section 6.9, “How Servers Evaluate Replication Rules”.

- `--replicate-ignore-table=db_name.tbl_name`

Tells the slave thread to not replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See Section 6.9, “How Servers Evaluate Replication Rules”.

- `--replicate-rewrite-db=from_name->to_name`

Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. This does not work for cross-database updates. The database name translation is done *before* the `--replicate-*` rules are tested.

If you use this option on the command line and the ‘>’ character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. Note that by default the slave I/O thread does not even write binary log events to the relay log if they have the slave's server id (this optimization helps save disk usage). So if you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the ‘%’ and ‘\_’ wildcard characters, which have the same meaning as for the LIKE pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See Section 6.9, “How Servers Evaluate Replication Rules”.

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is %, it matches any table name and the option also applies to database-level statements (CREATE DATABASE, DROP DATABASE, and ALTER DATABASE). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `mylownAABCdb` database, you should escape the ‘\_’ and ‘%’ characters like this: `--replicate-wild-do-table=my\_own\%db`. If you're using the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the bash shell, you would need to type `--replicate-wild-do-table=my\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See Section 6.9, “How Servers Evaluate Replication Rules”.

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=slave_name`

The hostname or IP number of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP number of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-port=slave_port_num`

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a non-default port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

- `--skip-slave-start`

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it.

- `--slave-load-tmpdir=file_name`

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some filesystem that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that filesystem.

The directory specified by this option should be located in a disk-based filesystem (not a memory-based filesystem) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `--master-connect-retry` option.

- `--slave-skip-errors=[err_code1,err_code2,...|all]`

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. Appendix B, *Error Codes and Messages*, lists server error codes.

You can also (but should not) use the very non-recommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
```

## 6.9. How Servers Evaluate Replication Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master side, decisions about which statements to log are based on the `--binlog-do-db` and `--binlog-ignore-db` options that control binary logging. For a description of the rules that servers use in evaluating these options, see Section 5.12.3, “The Binary Log”.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See Section 6.8, “Replication Startup Options”.) The slave evaluates these options using the following procedure, which first checks the database-level options and then the table-level options.

In the simplest case, when there are no `--replicate-*` options, the procedure yields the result that the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given. In general, to make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and non-wildcard options.

### Stage 1. Check the database options.

At this stage, the slave checks whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that specify database-specific conditions:

- *No*: Permit the statement and proceed to the table-checking stage.
- *Yes*: Test the options using the same rules as for the `--binlog-do-db` and `--binlog-ignore-db` options to determine whether to permit or ignore the statement. What is the result of the test?
  - *Permit*: Do not execute the statement immediately. Defer the decision and proceed to the table-checking stage.
  - *Ignore*: Ignore the statement and exit.

This stage can permit a statement for further option-checking, or cause it to be ignored. However, statements that are permitted at this stage are not actually executed yet. Instead, they pass to the following stage that checks the table options.

### Stage 2. Check the table options.

First, as a preliminary condition, the slave checks whether the statement occurs within a stored function or (prior to MySQL 5.0.12) a stored procedure. If so, execute the statement and exit. (Stored procedures are exempt from this test as of MySQL 5.0.12 because procedure logging occurs at the level of statements that are executed within the routine rather than at the `CALL` level.)

Next, the slave checks for table options and evaluates them. If the server reaches this point, it executes all statements if there are no table options. If there are “do” table options, the statement must match one of them if it is to be executed; otherwise, it is ignored. If there are any “ignore” options, all statements are executed except those that match any `ignore` option. The following steps describe how this evaluation occurs in more detail.

1. Are there any `--replicate-*-table` options?

- *No*: There are no table restrictions, so all statements match. Execute the statement and exit.
  - *Yes*: There are table restrictions. Evaluate the tables to be updated against them. There might be multiple tables to update, so loop through the following steps for each table looking for a matching option (first the non-wild options, and then the wild options). Only tables that are to be updated are compared to the options. For example, if the statement is `INSERT INTO sales SELECT * FROM prices`, only `sales` is compared to the options). If several tables are to be updated (multiple-table statement), the first table that matches “do” or “ignore” wins. That is, the server checks the first table against the options. If no decision could be made, it checks the second table against the options, and so on.
2. Are there any `--replicate-do-table` options?
    - *No*: Proceed to the next step.
    - *Yes*: Does the table match any of them?
      - *No*: Proceed to the next step.
      - *Yes*: Execute the statement and exit.
  3. Are there any `--replicate-ignore-table` options?
    - *No*: Proceed to the next step.
    - *Yes*: Does the table match any of them?
      - *No*: Proceed to the next step.
      - *Yes*: Ignore the statement and exit.
  4. Are there any `--replicate-wild-do-table` options?
    - *No*: Proceed to the next step.
    - *Yes*: Does the table match any of them?
      - *No*: Proceed to the next step.
      - *Yes*: Execute the statement and exit.
  5. Are there any `--replicate-wild-ignore-table` options?
    - *No*: Proceed to the next step.
    - *Yes*: Does the table match any of them?
      - *No*: Proceed to the next step.
      - *Yes*: Ignore the statement and exit.
  6. No `--replicate-*-table` option was matched. Is there another table to test against these options?
    - *No*: We have now tested all tables to be updated and could not match any option. Are there `--replicate-do-table` or `--replicate-wild-do-table` options?
      - *No*: There were no “do” table options, so no explicit “do” match is required. Execute the statement and exit.
      - *Yes*: There were “do” table options, so the statement is executed only with an explicit match to one of them. Ignore the statement and exit.

- *Yes*: Loop.

Examples:

- No `--replicate-*` options at all

The slave executes all statements that it receives from the master.

- `--replicate-*-db` options, but no table options

The slave permits or ignores statements using the database options. Then it executes all statements permitted by those options because there are no table restrictions.

- `--replicate-*-table` options, but no database options

All statements are permitted at the database-checking stage because there are no database conditions. The slave executes or ignores statements based on the table options.

- A mix of database and table options

The slave permits or ignores statements using the database options. Then it evaluates all statements permitted by those options according to the table options. In some cases, this process can yield what might seem a counterintuitive result. Consider the following set of options:

```
[mysqld]
replicate-do-db      = db1
replicate-do-table   = db2.mytbl2
```

Suppose that `db1` is the default database and the slave receives this statement:

```
INSERT INTO mytbl1 VALUES(1,2,3);
```

The database is `db1`, which matches the `--replicate-do-db` option at the database-checking stage. The algorithm then proceeds to the table-checking stage. If there were no table options, the statement would be executed. However, because the options include a “do” table option, the statement must match if it is to be executed. The statement does not match, so it is ignored. (The same would happen for any table in `db1`.)

## 6.10. Replication FAQ

**Q:** How do I configure a slave if the master is running and I do not want to stop it?

**A:** There are several possibilities. If you have taken a snapshot backup of the master at some point and recorded the binary log filename and offset (from the output of `SHOW MASTER STATUS`) corresponding to the snapshot, use the following procedure:

1. Make sure that the slave is assigned a unique server ID.
2. Execute the following statement on the slave, filling in appropriate values for each option:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master_host_name',
->     MASTER_USER='master_user_name',
->     MASTER_PASSWORD='master_pass',
->     MASTER_LOG_FILE='recorded_log_file_name',
->     MASTER_LOG_POS=recorded_log_position;
```

3. Execute `START SLAVE` on the slave.

If you do not have a backup of the master server, here is a quick procedure for creating one. All steps should be performed on the master host.

1. Issue this statement to acquire a global read lock:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

2. With the lock still in place, execute this command (or a variation of it):

```
shell> tar zcf /tmp/backup.tar.gz /var/lib/mysql
```

3. Issue this statement and record the output, which you will need later:

```
mysql> SHOW MASTER STATUS;
```

4. Release the lock:

```
mysql> UNLOCK TABLES;
```

An alternative to using the preceding procedure to make a binary copy is to make an SQL dump of the master. To do this, you can use `mysqldump --master-data` on your master and later load the SQL dump into your slave. However, this is slower than making a binary copy.

Regardless of which of the two methods you use, afterward follow the instructions for the case when you have a snapshot and have recorded the log filename and offset. You can use the same snapshot to set up several slaves. Once you have the snapshot of the master, you can wait to set up a slave as long as the binary logs of the master are left intact. The two practical limitations on the length of time you can wait are the amount of disk space available to retain binary logs on the master and the length of time it takes the slave to catch up.

You can also use `LOAD DATA FROM MASTER`. This is a convenient statement that transfers a snapshot to the slave and adjusts the log filename and offset all at once. Be warned, however, that it works only for MyISAM tables and it may hold a read lock for a long time. It is not yet implemented as efficiently as we would like. If you have large tables, the preferred method is still to make a binary snapshot on the master server after executing `FLUSH TABLES WITH READ LOCK`.

**Q:** Does the slave need to be connected to the master all the time?

**A:** No, it does not. The slave can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in synchrony with the master unless you take some special measures.

**Q:** How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?

**A:** You can read the `Seconds_Behind_Master` column in `SHOW SLAVE STATUS`. See Section 6.3, “Replication Implementation Details”.

When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp. (This is why `TIMESTAMP` is well replicated.) In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the slave SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see `Time`

values like 3600 for the slave SQL thread in `SHOW PROCESSLIST`. This is because the slave is executing statements that are one hour old.

**Q:** How do I force the master to block updates until the slave catches up?

**A:** Use the following procedure:

1. On the master, execute these statements:

```
mysql> FLUSH TABLES WITH READ LOCK;  
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the log filename and offset) from the output of the `SHOW` statement.

2. On the slave, issue the following statement, where the arguments to the `MASTER_POS_WAIT()` function are the replication coordinate values obtained in the previous step:

```
mysql> SELECT MASTER_POS_WAIT('log_name', log_offset);
```

The `SELECT` statement blocks until the slave reaches the specified log file and offset. At that point, the slave is in synchrony with the master and the statement returns.

3. On the master, issue the following statement to allow the master to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

**Q:** What issues should I be aware of when setting up two-way replication?

**A:** MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different from what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention, because the updates originating on another server are serialized in one slave thread. Even this benefit might be offset by network delays.

**Q:** How can I use replication to improve performance of my system?

**A:** You should set up one server as the master and direct all writes to it. Then configure as many slaves as you have the budget and rackspace for, and distribute the reads among the master and the slaves. You can also start the slaves with the `--skip-innodb`, `--skip-bdb`, `--low-priority-updates`, and `--delay-key-write=ALL` options to get speed improvements on the slave end. In this case, the slave uses non-transactional MyISAM tables instead of InnoDB and BDB tables to get more speed by eliminating transactional overhead.

**Q:** What should I do to prepare client code in my own applications to use performance-enhancing replication?

**A:** If the part of your code that is responsible for database access has been properly abstracted/

modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to it clean up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

**Q:** When and how much can MySQL replication improve the performance of my system?

**A:** MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by adding more slaves until you either run out of network bandwidth, or your update load grows to the point that the master cannot handle it.

To determine how many slaves you can use before the added benefits begin to level out, and how much you can improve performance of your site, you need to know your query patterns, and to determine empirically by benchmarking the relationship between the throughput for reads (reads per second, or `reads`) and for writes (`writes`) on a typical master and a typical slave. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that `reads` is  $1200 - 2 \times \text{writes}$ . In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Let us suppose that the master and each slave have the same capacity, and that we have one master and  $N$  slaves. Then we have for each server (master or slave):

$$\text{reads} = 1200 - 2 \times \text{writes}$$

$$\text{reads} = 9 \times \text{writes} / (N + 1) \text{ (reads are split, but writes go to all servers)}$$

$$9 \times \text{writes} / (N + 1) + 2 \times \text{writes} = 1200$$

$$\text{writes} = 1200 / (2 + 9/(N+1))$$

The last equation indicates the maximum number of writes for  $N$  slaves, given a maximum possible read rate of 1,200 per minute and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If  $N = 0$  (which means we have no replication), our system can handle about  $1200/11 = 109$  writes per second.
- If  $N = 1$ , we get up to 184 writes per second.
- If  $N = 8$ , we get up to 400 writes per second.
- If  $N = 17$ , we get up to 480 writes per second.
- Eventually, as  $N$  approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

Note that these computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add  $N$  replication slaves. However, answering the following questions should help you decide whether and by how much replication will improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
- For how many slaves do you have bandwidth available on your network?

**Q:** How can I use replication to provide redundancy or high availability?

**A:** With the currently available features, you would have to set up a master and a slave (or several slaves), and to write a script that monitors the master to check whether it is up. Then instruct your applications and the slaves to change master in case of failure. Some suggestions:

- To tell a slave to change its master, use the `CHANGE MASTER TO` statement.
- A good way to keep your applications informed as to the location of the master is by having a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to dynamically update your DNS.
- Run your slaves with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master as soon as you issue `STOP SLAVE; RESET MASTER`, and `CHANGE MASTER TO` statement on the other slaves. For example, assume that you have the following setup:

In this diagram, `M` means the master, `S` the slaves, `WC` the clients issuing database writes and reads; clients that issue only database reads are not represented, because they need not switch. `S1`, `S2`, and `S3` are slaves running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `M` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `S1`, all `WC` should be redirected to `S1`, which will log updates to its binary log. `S2` and `S3` should then replicate from `S1`.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. Suppose that S1 has `--log-slave-updates` enabled. Then it will write updates that it receives from M to its own binary log. When S2 changes from M to S1 as its master, it may receive updates from S1 that it has already received from M

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave S1 being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves S2 and S3, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='S1'` (where 'S1' represents the real hostname of S1). To `CHANGE MASTER`, add all information about how to connect to S1 from S2 or S3 (*user, password, port*). In `CHANGE MASTER`, there is no need to specify the name of S1's binary log or binary log position to read from: We know it is the first binary log and position 4, which are the defaults for `CHANGE MASTER`. Finally, use `START SLAVE` on S2 and S3.

Then instruct all WC to direct their statements to S1. From that point on, all updates statements sent by WC to S1 are written to the binary log of S1, which then contains every update statement sent to S1 since M died.

The result is this configuration:

When M is up again, you must issue on it the same `CHANGE MASTER` as that issued on S2 and S3, so that M becomes a slave of S1 and picks up all the WC writes that it missed while it was down. To make M a master again (because it is the most powerful machine, for example), use the preceding procedure as if S1 was unavailable and M was to be the new master. During this procedure, do not forget to run `RESET MASTER` on M before making S1, S2, and S3 slaves of M. Otherwise, they may pick up old WC writes from before the point at which M became unavailable.

Note that there is no synchronization between the different slaves to a master. Some slaves might be ahead of others. This means that the concept outlined in the previous example might not work. In practice, however, the relay logs of different slaves will most likely not be far behind the master, so it would work, anyway (but there is no guarantee).

**Q:** How do I prevent `GRANT` and `REVOKE` statements from replicating to slave machines?

**A:** Start the server with the `--replicate-wild-ignore-table=mysql.%` option.

**Q:** Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on Mac OS X and Windows)?

**A:** Yes.

**Q:** Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?

A: Yes.

## 6.11. Troubleshooting Replication

If you have followed the instructions, and your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is non-zero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` and `--server-id` options.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the `I/O` and `SQL` threads and check their `State` column to see what they display. See Section 6.3, “Replication Implementation Details”. If the `I/O` thread state says `Connecting to master`, verify the privileges for the replication user on the master, the master hostname, your DNS setup, whether the master is actually running, and whether it is reachable from the slave.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Section 6.7, “Replication Features and Known Problems”. If it is a bug, see Section 6.12, “How to Report Replication Bugs or Problems”, for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.
  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
  3. If you decide that you can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL SQL_SLAVE_SKIP_COUNTER = N;  
mysql> START SLAVE;
```

The value of `N` should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL,

please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

## 6.12. How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in Section 1.8, “How to Report Bugs or Problems”. If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
  - All binary logs from the master
  - All binary logs from the slave
  - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
  - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
  - Error logs from the master and the slave
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_pos` and `log_file` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog -j log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at Section 1.8, “How to Report Bugs or Problems”.

## 6.13. Auto-Increment in Multiple-Master Replication

When multiple servers are configured as replication masters, special steps must be taken to prevent

key collisions when using `AUTO_INCREMENT` columns, otherwise multiple masters may attempt to use the same `AUTO_INCREMENT` value when inserting rows.

The `auto_increment_increment` and `auto_increment_offset` system variables help to accommodate multiple-master replication with `AUTO_INCREMENT` columns. Each of these variables has a default and minimum value of 1, and a maximum value of 65,535. They were introduced in MySQL 5.0.2.

These two variables effect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the increment between successive `AUTO_INCREMENT` values.
- `auto_increment_offset` determines the starting point for `AUTO_INCREMENT` column values.

By choosing non-conflicting values for these variables on different masters, servers in a multiple-master configuration will not use conflicting `AUTO_INCREMENT` values when inserting new rows into the same table. To set up  $N$  master servers, set the variables like this:

- Set `auto_increment_increment` to  $N$  on each master.
- Set each of the  $N$  masters to have a different `auto_increment_offset`, using the values 1, 2, ...,  $N$ .

For additional information about `auto_increment_increment` and `auto_increment_offset`, see Section 5.2.2, “Server System Variables”.

---

# Chapter 7. Optimization

Optimization is a complex task because ultimately it requires understanding of the entire system to be optimized. Although it may be possible to perform some local optimizations with little knowledge of your system or application, the more optimal you want your system to become, the more you must know about it.

This chapter tries to explain and give some examples of different ways to optimize MySQL. Remember, however, that there are always additional ways to make the system even faster, although they may require increasing effort to achieve.

## 7.1. Optimization Overview

The most important factor in making a system fast is its basic design. You must also know what kinds of processing your system is doing, and what its bottlenecks are. In most cases, system bottlenecks arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.
- Disk reading and writing. When the disk is at the correct position, we need to read the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.
- CPU cycles. When we have the data in main memory, we need to process it to get our result. Having small tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.
- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

### 7.1.1. MySQL Design Limitations and Tradeoffs

When using the `MyISAM` storage engine, MySQL uses extremely fast table locking that allows multiple readers or a single writer. The biggest problem with this storage engine occurs when you have a steady stream of mixed updates and slow selects on a single table. If this is a problem for certain tables, you can use another storage engine for them. See Chapter 14, *Storage Engines and Table Types*.

MySQL can work with both transactional and non-transactional tables. To make it easier to work smoothly with non-transactional tables (which cannot roll back if something goes wrong), MySQL has the following rules. Note that these rules apply *only* when not running in strict SQL mode or if you use the `IGNORE` specifier for `INSERT` or `UPDATE`.

- All columns have default values.
- If you insert an inappropriate or out-of-range value into a column, MySQL sets the column to the “best possible value” instead of reporting an error. For numerical values, this is 0, the smallest possible value or the largest possible value. For strings, this is either the empty string or as much of the string as can be stored in the column.
- All calculated expressions return a value that can be used instead of signaling an error condition. For example, `1/0` returns `NULL`.

To change the preceding behaviors, you can enable stricter data handling by setting the server SQL mode appropriately. For more information about data handling, see Section 1.9.6, “How MySQL Deals with Constraints”, Section 5.2.5, “The Server SQL Mode”, and Section 13.2.4, “INSERT Syntax”.

## 7.1.2. Designing Applications for Portability

Because all SQL servers implement different parts of standard SQL, it takes work to write portable database applications. It is very easy to achieve portability for very simple selects and inserts, but becomes more difficult the more capabilities you require. If you want an application that is fast with many database systems, it becomes even more difficult.

All database systems have some weak points. That is, they have different design compromises that lead to different behavior.

To make a complex application portable, you need to determine which SQL servers it must work with, and then determine what features those servers support. You can use the MySQL `crash-me` program to find functions, types, and limits that you can use with a selection of database servers. `crash-me` does not check for every possible feature, but it is still reasonably comprehensive, performing about 450 tests. An example of the type of information `crash-me` can provide is that you should not use column names that are longer than 18 characters if you want to be able to use Informix or DB2.

The `crash-me` program and the MySQL benchmarks are all very database independent. By taking a look at how they are written, you can get a feeling for what you must do to make your own applications database independent. The programs can be found in the `sql-bench` directory of MySQL source distributions. They are written in Perl and use the DBI database interface. Use of DBI in itself solves part of the portability problem because it provides database-independent access methods. See Section 7.1.4, “The MySQL Benchmark Suite”.

If you strive for database independence, you need to get a good feeling for each SQL server's bottlenecks. For example, MySQL is very fast in retrieving and updating rows for MyISAM tables, but has a problem in mixing slow readers and writers on the same table. Oracle, on the other hand, has a big problem when you try to access rows that you have recently updated (until they are flushed to disk). Transactional database systems in general are not very good at generating summary tables from log tables, because in this case row locking is almost useless.

To make your application *really* database independent, you should define an easily extendable interface through which you manipulate your data. For example, C++ is available on most systems, so it makes sense to use a C++ class-based interface to the databases.

If you use some feature that is specific to a given database system (such as the REPLACE statement, which is specific to MySQL), you should implement the same feature for other SQL servers by coding an alternative method. Although the alternative might be slower, it enables the other servers to perform the same tasks.

With MySQL, you can use the `/*! */` syntax to add MySQL-specific keywords to a statement. The code inside `/*! */` is treated as a comment (and ignored) by most other SQL servers. For information about writing comments, see Section 9.4, “Comment Syntax”.

If high performance is more important than exactness, as for some Web applications, it is possible to create an application layer that caches all results to give you even higher performance. By letting old results expire after a while, you can keep the cache reasonably fresh. This provides a method to handle high load spikes, in which case you can dynamically increase the cache size and set the expiration timeout higher until things get back to normal.

In this case, the table creation information should contain information about the initial cache size and how often the table should normally be refreshed.

An attractive alternative to implementing an application cache is to use the MySQL query cache. By enabling the query cache, the server handles the details of determining whether a query result can be reused. This simplifies your application. See Section 5.14, “The MySQL Query Cache”.

### 7.1.3. What We Have Used MySQL For

This section describes an early application for MySQL.

During MySQL initial development, the features of MySQL were made to fit our largest customer, which handled data warehousing for a couple of the largest retailers in Sweden.

From all stores, we got weekly summaries of all bonus card transactions, and were expected to provide useful information for the store owners to help them find how their advertising campaigns were affecting their own customers.

The volume of data was quite huge (about seven million summary transactions per month), and we had data for 4–10 years that we needed to present to the users. We got weekly requests from our customers, who wanted instant access to new reports from this data.

We solved this problem by storing all information per month in compressed “transaction tables.” We had a set of simple macros that generated summary tables grouped by different criteria (product group, customer id, store, and so on) from the tables in which the transactions were stored. The reports were Web pages that were dynamically generated by a small Perl script. This script parsed a Web page, executed the SQL statements in it, and inserted the results. We would have used PHP or `mod_perl` instead, but they were not available at the time.

For graphical data, we wrote a simple tool in C that could process SQL query results and produce GIF images based on those results. This tool also was dynamically executed from the Perl script that parses the Web pages.

In most cases, a new report could be created simply by copying an existing script and modifying the SQL query that it used. In some cases, we needed to add more columns to an existing summary table or generate a new one. This also was quite simple because we kept all transaction-storage tables on disk. (This amounted to about 50GB of transaction tables and 200GB of other customer data.)

We also let our customers access the summary tables directly with ODBC so that the advanced users could experiment with the data themselves.

This system worked well and we had no problems handling the data with quite modest Sun Ultra SPARCstation hardware (2×200MHz). Eventually the system was migrated to Linux.

### 7.1.4. The MySQL Benchmark Suite

This benchmark suite is meant to tell any user what operations a given SQL implementation performs well or poorly. You can get a good idea for how the benchmarks work by looking at the code and results in the `sql-bench` directory in any MySQL source distribution.

Note that this benchmark is single-threaded, so it measures the minimum time for the operations performed. We plan to add multi-threaded tests to the benchmark suite in the future.

To use the benchmark suite, the following requirements must be satisfied:

- The benchmark suite is provided with MySQL source distributions. You can either download a released distribution from <http://dev.mysql.com/downloads/>, or use the current development source tree. (See Section 2.9.3, “Installing from the Development Source Tree”.)
- The benchmark scripts are written in Perl and use the Perl DBI module to access database servers, so DBI must be installed. You also need the server-specific DBD drivers for each of the servers you want to test. For example, to test MySQL, PostgreSQL, and DB2, you must have the `DBD: :mysql`, `DBD: :Pg`, and `DBD: :DB2` modules installed. See Section 2.14, “Perl Installation Notes”.

After you obtain a MySQL source distribution, you can find the benchmark suite located in its `sql-bench` directory. To run the benchmark tests, build MySQL, and then change location into the `sql-bench` directory and execute the `run-all-tests` script:

```
shell> cd sql-bench
shell> perl run-all-tests --server=server_name
```

*server\_name* should be the name of one of the supported servers. To get a list of all options and supported servers, invoke this command:

```
shell> perl run-all-tests --help
```

The `crash-me` script also is located in the `sql-bench` directory. `crash-me` tries to determine what features a database system supports and what its capabilities and limitations are by actually running queries. For example, it determines:

- What data types are supported
- How many indexes are supported
- What functions are supported
- How big a query can be
- How big a VARCHAR column can be

You can find the results from `crash-me` for many different database servers at <http://dev.mysql.com/tech-resources/crash-me.php>. For more information about benchmark results, visit <http://dev.mysql.com/tech-resources/benchmarks/>.

## 7.1.5. Using Your Own Benchmarks

You should definitely benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

For examples of portable benchmark programs, look at those in the MySQL benchmark suite. See Section 7.1.4, “The MySQL Benchmark Suite”. You can take any program from this suite and modify it for your own needs. By doing this, you can try different solutions to your problem and test which really is fastest for you.

Another free benchmark suite is the Open Source Database Benchmark, available at <http://osdb.sourceforge.net/>.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, you should put some effort into benchmarking your whole application under the worst possible load. You can use Super Smack, available at <http://jeremy.zawodny.com/mysql/super-smack/>. As suggested by its name, it can bring a system to its knees, so make sure to use it only on your development systems.

## 7.2. Optimizing SELECT and Other Statements

First, one factor affects all statements: The more complex your permissions setup, the more overhead you have. Using simpler permissions when you issue GRANT statements enables MySQL to re-

duce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the `tables_priv` and `columns_priv` tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, it may be worth the time to use a simplified grant structure to reduce permission-checking overhead.

If your problem is with a specific MySQL expression or function, you can perform a timing test by invoking the `BENCHMARK()` function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count, expression)`. The return value is always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
+-----+
| BENCHMARK(1000000,1+1) |
+-----+
|                          0 |
+-----+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

All MySQL functions should be highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

## 7.2.1. Optimizing Queries with `EXPLAIN`

```
EXPLAIN tbl_name
```

Or:

```
EXPLAIN [EXTENDED] SELECT select_options
```

The `EXPLAIN` statement can be used either as a synonym for `DESCRIBE` or as a way to obtain information about how MySQL executes a `SELECT` statement:

- `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` or `SHOW COLUMNS FROM tbl_name`.
- When you precede a `SELECT` statement with the keyword `EXPLAIN`, MySQL displays information from the optimizer about the query execution plan. That is, MySQL explains how it would process the `SELECT`, including information about how tables are joined and in which order.

This section describes the second use of `EXPLAIN` for obtaining query execution plan information. For a description of the `DESCRIBE` and `SHOW COLUMNS` statements, see Section 13.3.1, “`DESCRIBE Syntax`”, and Section 13.5.4.3, “`SHOW COLUMNS Syntax`”.

With the help of `EXPLAIN`, you can see where you should add indexes to tables to get a faster `SELECT` that uses indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To force the optimizer to use a join order corresponding to the order in which the tables are named in the `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`.

If you have a problem with indexes not being used when you believe that they should be, you should run `ANALYZE TABLE` to update table statistics such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.5.2.1, “`ANALYZE TABLE Syntax`”.

`EXPLAIN` returns a row of information for each table used in the `SELECT` statement. The tables are listed in the output in the order that MySQL would read them while processing the query. MySQL

resolves all joins using a *single-sweep multi-join* method. This means that MySQL reads a row from the first table, and then finds a matching row in the second table, the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

When the `EXTENDED` keyword is used, `EXPLAIN` produces extra information that can be viewed by issuing a `SHOW WARNINGS` statement following the `EXPLAIN` statement. This information displays how the optimizer qualifies table and column names in the `SELECT` statement, what the `SELECT` looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process.

Each output row from `EXPLAIN` provides information about one table, and each row contains the following columns:

- `id`

The `SELECT` identifier. This is the sequential number of the `SELECT` within the query.

- `select_type`

The type of `SELECT`, which can be any of those shown in the following table:

<code>SIMPLE</code>	Simple <code>SELECT</code> (not using <code>UNION</code> or subqueries)
<code>PRIMARY</code>	Outermost <code>SELECT</code>
<code>UNION</code>	Second or later <code>SELECT</code> statement in a <code>UNION</code>
<code>DEPENDENT UNION</code>	Second or later <code>SELECT</code> statement in a <code>UNION</code> , dependent on outer query
<code>UNION RESULT</code>	Result of a <code>UNION</code> .
<code>SUBQUERY</code>	First <code>SELECT</code> in subquery
<code>DEPENDENT SUB-QUERY</code>	First <code>SELECT</code> in subquery, dependent on outer query
<code>DERIVED</code>	Derived table <code>SELECT</code> (subquery in <code>FROM</code> clause)

`DEPENDENT` typically signifies the use of a correlated subquery. See Section 13.2.8.7, “Correlated Subqueries”.

- `table`

The table to which the row of output refers.

- `type`

The join type. The different join types are listed here, ordered from the best type to the worst:

- `system`

The table has only one row (= system table). This is a special case of the `const` join type.

- `const`

The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. `const` tables are very fast because they are read only once.

`const` is used when you compare all parts of a `PRIMARY KEY` or `UNIQUE` index to constant values. In the following queries, `tbl_name` can be used as a `const` table:

```
SELECT * FROM tbl_name WHERE primary_key=1;
```

```
SELECT * FROM tbl_name
```

```
WHERE primary_key_part1=1 AND primary_key_part2=2;
```

- `eq_ref`

One row is read from this table for each combination of rows from the previous tables. Other than the `system` and `const` types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a `PRIMARY KEY` or `UNIQUE` index.

`eq_ref` can be used for indexed columns that are compared using the `=` operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an `eq_ref` join to process `ref_table`:

```
SELECT * FROM ref_table,other_table
WHERE ref_table.key_column=other_table.column;
```

```
SELECT * FROM ref_table,other_table
WHERE ref_table.key_column_part1=other_table.column
AND ref_table.key_column_part2=1;
```

- `ref`

All rows with matching index values are read from this table for each combination of rows from the previous tables. `ref` is used if the join uses only a leftmost prefix of the key or if the key is not a `PRIMARY KEY` or `UNIQUE` index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

`ref` can be used for indexed columns that are compared using the `=` or `<=>` operator. In the following examples, MySQL can use a `ref` join to process `ref_table`:

```
SELECT * FROM ref_table WHERE key_column=expr;
```

```
SELECT * FROM ref_table,other_table
WHERE ref_table.key_column=other_table.column;
```

```
SELECT * FROM ref_table,other_table
WHERE ref_table.key_column_part1=other_table.column
AND ref_table.key_column_part2=1;
```

- `ref_or_null`

This join type is like `ref`, but with the addition that MySQL does an extra search for rows that contain `NULL` values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a `ref_or_null` join to process `ref_table`:

```
SELECT * FROM ref_table
WHERE key_column=expr OR key_column IS NULL;
```

See Section 7.2.7, “IS NULL Optimization”.

- `index_merge`

This join type indicates that the Index Merge optimization is used. In this case, the `key` column in the output row contains a list of indexes used, and `key_len` contains a list of the longest key parts for the indexes used. For more information, see Section 7.2.6, “Index Merge Optimization”.

- `unique_subquery`

This type replaces `ref` for some `IN` subqueries of the following form:

```
value IN (SELECT primary_key FROM single_table WHERE some_expr)
```

`unique_subquery` is just an index lookup function that replaces the subquery completely for better efficiency.

- `index_subquery`

This join type is similar to `unique_subquery`. It replaces `IN` subqueries, but it works for non-unique indexes in subqueries of the following form:

```
value IN (SELECT key_column FROM single_table WHERE some_expr)
```

- `range`

Only rows that are in a given range are retrieved, using an index to select the rows. The `key` column in the output row indicates which index is used. The `key_len` contains the longest key part that was used. The `ref` column is `NULL` for this type.

`range` can be used when a key column is compared to a constant using any of the `=`, `<>`, `>`, `>=`, `<`, `<=`, `IS NULL`, `<=>`, `BETWEEN`, or `IN` operators:

```
SELECT * FROM tbl_name
WHERE key_column = 10;
```

```
SELECT * FROM tbl_name
WHERE key_column BETWEEN 10 and 20;
```

```
SELECT * FROM tbl_name
WHERE key_column IN (10,20,30);
```

```
SELECT * FROM tbl_name
WHERE key_part1= 10 AND key_part2 IN (10,20,30);
```

- `index`

This join type is the same as `ALL`, except that only the index tree is scanned. This usually is faster than `ALL` because the index file usually is smaller than the data file.

MySQL can use this join type when the query uses only columns that are part of a single index.

- `ALL`

A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked `const`, and usually *very* bad in all other cases. Normally, you can avoid `ALL` by adding indexes that allow row retrieval from the table based on constant values or column values from earlier tables.

- `possible_keys`

The `possible_keys` column indicates which indexes MySQL can choose from use to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from `EXPLAIN`. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

If this column is `NULL`, there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the `WHERE` clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index

and check the query with `EXPLAIN` again. See Section 13.1.2, “ALTER TABLE Syntax”.

To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

- `key`

The `key` column indicates the key (index) that MySQL actually decided to use. The key is `NULL` if no index was chosen. To force MySQL to use or ignore an index listed in the `possible_keys` column, use `FORCE INDEX`, `USE INDEX`, or `IGNORE INDEX` in your query. See Section 13.2.7, “SELECT Syntax”.

For MyISAM and BDB tables, running `ANALYZE TABLE` helps the optimizer choose better indexes. For MyISAM tables, `myisamchk --analyze` does the same. See Section 13.5.2.1, “ANALYZE TABLE Syntax”, and Section 5.10.4, “Table Maintenance and Crash Recovery”.

- `key_len`

The `key_len` column indicates the length of the key that MySQL decided to use. The length is `NULL` if the `key` column says `NULL`. Note that the value of `key_len` enables you to determine how many parts of a multiple-part key MySQL actually uses.

- `ref`

The `ref` column shows which columns or constants are compared to the index named in the `key` column to select rows from the table.

- `rows`

The `rows` column indicates the number of rows MySQL believes it must examine to execute the query.

- `Extra`

This column contains additional information about how MySQL resolves the query. Here is an explanation of the values that can appear in this column:

- `Distinct`

MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

- `Not exists`

MySQL was able to do a `LEFT JOIN` optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the `LEFT JOIN` criteria. Here is an example of the type of query that can be optimized this way:

```
SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
WHERE t2.id IS NULL;
```

Assume that `t2.id` is defined as `NOT NULL`. In this case, MySQL scans `t1` and looks up the rows in `t2` using the values of `t1.id`. If MySQL finds a matching row in `t2`, it knows that `t2.id` can never be `NULL`, and does not scan through the rest of the rows in `t2` that have the same `id` value. In other words, for each row in `t1`, MySQL needs to do only a single lookup in `t2`, regardless of how many rows actually match in `t2`.

- `range checked for each record (index map: N)`

MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a `range` or `index_merge` access method to retrieve rows. This is not very fast, but is faster than performing a join with no in-

dex at all. The applicability criteria are as described in Section 7.2.5, “Range Optimization”, and Section 7.2.6, “Index Merge Optimization”, with the exception that all column values for the preceding table are known and considered to be constants.

- `Using filesort`

MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the `WHERE` clause. The keys then are sorted and the rows are retrieved in sorted order. See Section 7.2.12, “`ORDER BY` Optimization”.

- `Using index`

The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

- `Using temporary`

To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains `GROUP BY` and `ORDER BY` clauses that list columns differently.

- `Using where`

A `WHERE` clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the `Extra` value is not `Using where` and the table join type is `ALL` or `index`.

If you want to make your queries as fast as possible, you should look out for `Extra` values of `Using filesort` and `Using temporary`.

- `Using sort_union(...)`, `Using union(...)`, `Using intersect(...)`

These indicate how index scans are merged for the `index_merge` join type. See Section 7.2.6, “Index Merge Optimization”, for more information.

- `Using index for group-by`

Similar to the `Using index` way of accessing a table, `Using index for group-by` indicates that MySQL found an index that can be used to retrieve all columns of a `GROUP BY` or `DISTINCT` query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see Section 7.2.13, “`GROUP BY` Optimization”.

- `Using where with pushed condition`

This item applies to `NDB Cluster` tables *only*. It means that MySQL Cluster is using *condition pushdown* to improve the efficiency of a direct comparison (`=`) between a non-indexed column and a constant. In such cases, the condition is “pushed down” to the cluster’s data nodes where it is evaluated in all partitions simultaneously. This eliminates the need to send non-matching rows over the network, and can speed up such queries by a factor of 5 to 10 times over cases where condition pushdown could be but is not used.

Suppose that you have a Cluster table defined as follows:

```
CREATE TABLE t1 (
  a INT,
  b INT,
  KEY(a)
) ENGINE=NDBCLUSTER;
```

In this case, condition pushdown can be used with a query such as this one:

```
SELECT a,b FROM t1 WHERE b = 10;
```

This can be seen in the output of EXPLAIN SELECT, as shown here:

```
mysql> EXPLAIN SELECT a,b FROM t1 WHERE b = 10\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
       type: ALL
possible_keys: NULL
      key: NULL
     key_len: NULL
      ref: NULL
       rows: 10
  Extra: Using where with pushed condition
```

Condition pushdown *cannot* be used with either of these two queries:

```
SELECT a,b FROM t1 WHERE a = 10;
SELECT a,b FROM t1 WHERE b + 1 = 10;
```

With regard to the first of these two queries, condition pushdown is not applicable because an index exists on column a. In the case of the second query, a condition pushdown cannot be employed because the comparison involving the non-indexed column b is an indirect one. (However, it would apply if you were to reduce  $b + 1 = 10$  to  $b = 9$  in the WHERE clause.)

However, a condition pushdown may also be employed when an indexed column is compared with a constant using a > or < operator:

```
mysql> EXPLAIN SELECT a,b FROM t1 WHERE a<2\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
       type: range
possible_keys: a
      key: a
     key_len: 5
      ref: NULL
       rows: 2
  Extra: Using where with pushed condition
```

With regard to condition pushdown, keep in mind that:

- Condition pushdown is relevant to MySQL Cluster *only*, and does not occur when executing queries against tables using any other storage engine.
- Condition pushdown capability is not used by default. To enable it, you can start mysqld with the `--engine-condition-pushdown` option, or execute the following statement:

```
SET engine_condition_pushdown=On;
```

**Note:** Condition pushdown is not supported for columns of any of the BLOB or TEXT types.

Condition pushdown, Using where with pushed condition, and engine\_condition\_pushdown were all introduced in MySQL 5.0 Cluster.

You can get a good indication of how good a join is by taking the product of the values in the rows column of the EXPLAIN output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the max\_join\_size system variable, this row product also is used to determine which multiple-table SELECT statements to execute and which to abort. See Section 7.5.2, “Tuning Server Parameters”.

The following example shows how a multiple-table join can be optimized progressively based on the information provided by EXPLAIN.

Suppose that you have the SELECT statement shown here and that you plan to examine it using EXPLAIN:

```
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn,
              tt.ProjectReference, tt.EstimatedShipDate,
              tt.ActualShipDate, tt.ClientID,
              tt.ServiceCodes, tt.RepetitiveID,
              tt.CurrentProcess, tt.CurrentDPPerson,
              tt.RecordVolume, tt.DPPrinted, et.COUNTRY,
              et_1.COUNTRY, do.CUSTNAME
FROM tt, et, et AS et_1, do
WHERE tt.SubmitTime IS NULL
      AND tt.ActualPC = et.EMPLOYID
      AND tt.AssignedPC = et_1.EMPLOYID
      AND tt.ClientID = do.CUSTNMBR;
```

For this example, make the following assumptions:

- The columns being compared have been declared as follows:

Table	Column	Data Type
tt	ActualPC	CHAR(10)
tt	AssignedPC	CHAR(10)
tt	ClientID	CHAR(10)
et	EMPLOYID	CHAR(15)
do	CUSTNMBR	CHAR(15)

- The tables have the following indexes:

Table	Index
tt	ActualPC
tt	AssignedPC
tt	ClientID
et	EMPLOYID (primary key)
do	CUSTNMBR (primary key)

- The tt.ActualPC values are not evenly distributed.

Initially, before any optimizations have been performed, the EXPLAIN statement produces the following information:

```

table type possible_keys key key_len ref rows Extra
et ALL PRIMARY NULL NULL NULL 74
do ALL PRIMARY NULL NULL NULL 2135
et_1 ALL PRIMARY NULL NULL NULL 74
tt ALL AssignedPC, NULL NULL NULL 3872
      ClientID,
      ActualPC
      range checked for each record (key map: 35)

```

Because `type` is `ALL` for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is  $74 \times 2135 \times 74 \times 3872 = 45,268,558,720$  rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. `tt.ActualPC` is declared as `CHAR(10)` and `et.EMPLOYID` is `CHAR(15)`, so there is a length mismatch.

To fix this disparity between column lengths, use `ALTER TABLE` to lengthen `ActualPC` from 10 characters to 15 characters:

```
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now `tt.ActualPC` and `et.EMPLOYID` are both `VARCHAR(15)`. Executing the `EXPLAIN` statement again produces this result:

```

table type possible_keys key key_len ref rows Extra
tt ALL AssignedPC, NULL NULL NULL 3872 Using
      ClientID, where
      ActualPC
do ALL PRIMARY NULL NULL NULL 2135
      range checked for each record (key map: 1)
et_1 ALL PRIMARY NULL NULL NULL 74
      range checked for each record (key map: 1)
et eq_ref PRIMARY PRIMARY 15 tt.ActualPC 1

```

This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
->      MODIFY ClientID VARCHAR(15);
```

After that modification, `EXPLAIN` produces the output shown here:

```

table type possible_keys key key_len ref rows Extra
et ALL PRIMARY NULL NULL NULL 74
tt ref AssignedPC, ActualPC 15 et.EMPLOYID 52 Using
      ClientID, where
      ActualPC
et_1 eq_ref PRIMARY PRIMARY 15 tt.AssignedPC 1
do eq_ref PRIMARY PRIMARY 15 tt.ClientID 1

```

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the `tt.ActualPC` column are evenly distributed, and that is not the case for the `tt` table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and EXPLAIN produces this result:

table	type	possible_keys	key	key_len	ref	rows	Extra
tt	ALL	AssignedPC ClientID, ActualPC	NULL	NULL	NULL	3872	Using where
et	eq_ref	PRIMARY	PRIMARY	15	tt.ActualPC	1	
et_1	eq_ref	PRIMARY	PRIMARY	15	tt.AssignedPC	1	
do	eq_ref	PRIMARY	PRIMARY	15	tt.ClientID	1	

Note that the rows column in the output from EXPLAIN is an educated guess from the MySQL join optimizer. You should check whether the numbers are even close to the truth by comparing the rows product with the actual number of rows that the query returns. If the numbers are quite different, you might get better performance by using STRAIGHT\_JOIN in your SELECT statement and trying to list the tables in a different order in the FROM clause.

## 7.2.2. Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row:  $\log(\text{row\_count}) / \log(\text{index\_block\_length} / 3 \times 2 / (\text{index\_length} + \text{data\_pointer\_length})) + 1$ .

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with an index length of three bytes (the size of MEDIUMINT), the formula indicates  $\log(500,000) / \log(1024/3 \times 2 / (3+4)) + 1 = 4$  seeks.

This index would require storage of about  $500,000 \times 7 \times 3/2 = 5.2\text{MB}$  (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

Note that the preceding discussion does not mean that your application performance slowly degenerates by  $\log N$ . As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by  $\log N$ ). To avoid this, increase the key cache size as the data grows. For MyISAM tables, the key cache size is controlled by the key\_buffer\_size system variable. See Section 7.5.2, "Tuning Server Parameters".

## 7.2.3. Speed of SELECT Queries

In general, when you want to make a slow SELECT . . . WHERE query faster, the first thing to check is whether you can add an index. All references between different tables should usually be done with indexes. You can use the EXPLAIN statement to determine which indexes are used for a SELECT. See Section 7.2.1, "Optimizing Queries with EXPLAIN", and Section 7.4.5, "How MySQL Uses Indexes".

Some general tips for speeding up queries on MyISAM tables:

- To help MySQL better optimize queries, use ANALYZE TABLE or run myisamchk -analyze on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a non-constant expression. You can check the result from the table analysis by using

SHOW INDEX FROM *tbl\_name* and examining the Cardinality value. `myisamchk --description --verbose` shows index distribution information.

- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.

## 7.2.4. WHERE Clause Optimization

This section discusses optimizations that can be made for processing WHERE clauses. The examples use SELECT statements, but the same optimizations apply for WHERE clauses in DELETE and UPDATE statements.

Work on the MySQL optimizer is ongoing, so this section is incomplete. MySQL performs a great many optimizations, not all of which are documented here.

Some of the optimizations performed by MySQL follow:

- Removal of unnecessary parentheses:

```
((a AND b) AND c OR (((a AND b) AND (c AND d))))
-> (a AND b AND c) OR (a AND b AND c AND d)
```

- Constant folding:

```
(a<b AND b=c) AND a=5
-> b>5 AND b=c AND a=5
```

- Constant condition removal (needed because of constant folding):

```
(B>=5 AND B=5) OR (B=6 AND 5=5) OR (B=7 AND 5=6)
-> B=5 OR B=6
```

- Constant expressions used by indexes are evaluated only once.
- COUNT(\*) on a single table without a WHERE is retrieved directly from the table information for MyISAM and MEMORY tables. This is also done for any NOT NULL expression when used with only one table.
- Early detection of invalid constant expressions. MySQL quickly detects that some SELECT statements are impossible and returns no rows.
- HAVING is merged with WHERE if you do not use GROUP BY or aggregate functions (COUNT(), MIN(), and so on).
- For each table in a join, a simpler WHERE is constructed to get a fast WHERE evaluation for the table and also to skip rows as soon as possible.
- All constant tables are read first before any other tables in the query. A constant table is any of the following:
  - An empty table or a table with one row.
  - A table that is used with a WHERE clause on a PRIMARY KEY or a UNIQUE index, where all index parts are compared to constant expressions and are defined as NOT NULL.

All of the following tables are used as constant tables:

```
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
  WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in ORDER BY and GROUP BY clauses come from the same table, that table is preferred first when joining.
- If there is an ORDER BY clause and a different GROUP BY clause, or if the ORDER BY or GROUP BY contains columns from tables other than the first table in the join queue, a temporary table is created.
- If you use the SQL\_SMALL\_RESULT option, MySQL uses an in-memory temporary table.
- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.
- In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.
- Before each row is output, those that do not match the HAVING clause are skipped.

Some examples of queries that are very fast:

```
SELECT COUNT(*) FROM tbl_name;

SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;

SELECT MAX(key_part2) FROM tbl_name
  WHERE key_part1=constant;

SELECT ... FROM tbl_name
  ORDER BY key_part1,key_part2,... LIMIT 10;

SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;
```

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are numeric:

```
SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;

SELECT COUNT(*) FROM tbl_name
  WHERE key_part1=val1 AND key_part2=val2;

SELECT key_part2 FROM tbl_name GROUP BY key_part1;
```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```
SELECT ... FROM tbl_name
  ORDER BY key_part1,key_part2,... ;

SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

## 7.2.5. Range Optimization

The range access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections give a detailed description of how intervals are extracted from the WHERE clause.

### 7.2.5.1. The Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the WHERE clause, so we speak of *range conditions* rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both BTREE and HASH indexes, comparison of a key part with a constant value is a range condition when using the =, <=>, IN, IS NULL, or IS NOT NULL operators.
- For BTREE indexes, comparison of a key part with a constant value is a range condition when using the >, <, >=, <=, BETWEEN, !=, or <> operators, or LIKE 'pattern' (where 'pattern' does not start with a wildcard).
- For all types of indexes, multiple range conditions combined with OR or AND form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a const or system table from the same join
- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the WHERE clause:

```
SELECT * FROM t1
  WHERE key_col > 1
     AND key_col < 10;

SELECT * FROM t1
  WHERE key_col = 1
     OR key_col IN (15,18,20);

SELECT * FROM t1
  WHERE key_col LIKE 'ab%'
     OR key_col BETWEEN 'bar' AND 'foo';
```

Note that some non-constant values may be converted to constants during the constant propagation phase.

MySQL tries to extract range conditions from the WHERE clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where key1 is an indexed column and nonkey is not indexed:

```
SELECT * FROM t1 WHERE
  (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
  (key1 < 'bar' AND nonkey = 4) OR
  (key1 < 'uux' AND key1 > 'z');
```

The extraction process for key `key1` is as follows:

1. Start with original `WHERE` clause:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z')
```

2. Remove `nonkey = 4` and `key1 LIKE '%b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Having replaced them with `TRUE`, we get:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
(key1 < 'bar' AND TRUE) OR
(key1 < 'uux' AND key1 > 'z')
```

3. Collapse conditions that are always true or false:

- `(key1 LIKE 'abcde%' OR TRUE)` is always true
- `(key1 < 'uux' AND key1 > 'z')` is always false

Replacing these conditions with constants, we get:

```
(key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
```

Removing unnecessary `TRUE` and `FALSE` constants, we obtain:

```
(key1 < 'abc') OR (key1 < 'bar')
```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

```
(key1 < 'bar')
```

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the `WHERE` clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full `WHERE` clause.

The range condition extraction algorithm can handle nested `AND/OR` constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in `WHERE` clause.

### 7.2.5.2. The Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following set of key tuples listed in key order:

<code>key_part1</code>	<code>key_part2</code>	<code>key_part3</code>
NULL	1	'abc'
NULL	1	'xyz'
NULL	2	'foo'

1	1	'abc'
1	1	'xyz'
1	2	'abc'
2	1	'aaa'

The condition `key_part1 = 1` defines this interval:

```
(1, -inf, -inf) <= (key_part1, key_part2, key_part3) < (1, +inf, +inf)
```

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition `key_part3 = 'abc'` does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For HASH indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

```
key_part1 cmp const1
AND key_part2 cmp const2
AND ...
AND key_partN cmp constN;
```

Here, `const1`, `const2`, ... are constants, `cmp` is one of the `=`, `<=>`, or `IS NULL` comparison operators, and the conditions cover all index parts. (That is, there are  $N$  conditions, one for each part of an  $N$ -part index.) For example, the following is a range condition for a three-part HASH index:

```
key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'
```

For the definition of what is considered to be a constant, see Section 7.2.5.1, “The Range Access Method for Single-Part Indexes”.

- For a BTREE index, an interval might be usable for conditions combined with AND, where each condition compares a key part with a constant value using `=`, `<=>`, `IS NULL`, `>`, `<`, `>=`, `<=`, `!=`, `<>`, `BETWEEN`, or `LIKE 'pattern'` (where `'pattern'` does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if `<>` or `!=` is used). For example, for this condition:

```
key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10
```

The single interval is:

```
('foo', 10, 10) < (key_part1, key_part2, key_part3) < ('foo', +inf, +inf)
```

It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value `('foo', 11, 0)`, which does not satisfy the original condition.

- If conditions that cover sets of rows contained within intervals are combined with OR, they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with AND, they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

```
(key_part1 = 1 AND key_part2 < 2) OR (key_part1 > 5)
```

The intervals are:

```
(1,-inf) < (key_part1,key_part2) < (1,2)
(5,-inf) < (key_part1,key_part2)
```

In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The `key_len` column in the `EXPLAIN` output indicates the maximum length of the key prefix used.

In some cases, `key_len` may indicate that a key part was used, but that might be not what you would expect. Suppose that `key_part1` and `key_part2` can be `NULL`. Then the `key_len` column displays two key part lengths for the following condition:

```
key_part1 >= 1 AND key_part2 < 2
```

But, in fact, the condition is converted to this:

```
key_part1 >= 1 AND key_part2 IS NOT NULL
```

Section 7.2.5.1, “The Range Access Method for Single-Part Indexes”, describes how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index. Analogous steps are performed for range conditions on multiple-part indexes.

## 7.2.6. Index Merge Optimization

The *Index Merge* method is used to retrieve rows with several range scans and to merge their results into one. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans.

**Note:** If you have upgraded from a previous version of MySQL, you should be aware that this type of join optimization is first introduced in MySQL 5.0, and represents a significant change in behavior with regard to indexes. (Formerly, MySQL was able to use at most only one index for each referenced table.)

In `EXPLAIN` output, the Index Merge method appears as `index_merge` in the `type` column. In this case, the `key` column contains a list of indexes used, and `key_len` contains a list of the longest key parts for those indexes.

Examples:

```
SELECT * FROM tbl_name WHERE key_part1 = 10 OR key_part2 = 20;

SELECT * FROM tbl_name
  WHERE (key_part1 = 10 OR key_part2 = 20) AND non_key_part=30;

SELECT * FROM t1, t2
  WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%')
  AND t2.key1=t1.some_col;

SELECT * FROM t1, t2
  WHERE t1.key1=1
  AND (t2.key1=t1.some_col OR t2.key2=t1.some_col2);
```

The Index Merge method has several access algorithms (seen in the `Extra` field of `EXPLAIN` output):

- Using `intersect(...)`

- Using `union(...)`
- Using `sort_union(...)`

The following sections describe these methods in greater detail.

**Note:** The Index Merge optimization algorithm has the following known deficiencies:

- If a range scan is possible on some key, an Index Merge is not considered. For example, consider this query:

```
SELECT * FROM t1 WHERE (goodkey1 < 10 OR goodkey2 < 20) AND badkey < 30;
```

For this query, two plans are possible:

- An Index Merge scan using the `(goodkey1 < 10 OR goodkey2 < 20)` condition.
- A range scan using the `badkey < 30` condition.

However, the optimizer considers only the second plan. If that is not what you want, you can make the optimizer consider Index Merge by using `IGNORE INDEX` or `FORCE INDEX`. The following queries are executed using Index Merge:

```
SELECT * FROM t1 FORCE INDEX(goodkey1,goodkey2)
  WHERE (goodkey1 < 10 OR goodkey2 < 20) AND badkey < 30;
```

```
SELECT * FROM t1 IGNORE INDEX(badkey)
  WHERE (goodkey1 < 10 OR goodkey2 < 20) AND badkey < 30;
```

- If your query has a complex WHERE clause with deep AND/OR nesting and MySQL doesn't choose the optimal plan, try distributing terms using the following identity laws:

$$(x \text{ AND } y) \text{ OR } z = (x \text{ OR } z) \text{ AND } (y \text{ OR } z)$$

$$(x \text{ OR } y) \text{ AND } z = (x \text{ AND } z) \text{ OR } (y \text{ AND } z)$$

- Index Merge is not applicable to fulltext indexes. We plan to extend it to cover these in a future MySQL release.

The choice between different possible variants of the Index Merge access method and other access methods is based on cost estimates of various available options.

### 7.2.6.1. The Index Merge Intersection Access Algorithm

This access algorithm can be employed when a WHERE clause was converted to several range conditions on different keys combined with AND, and each condition is one of the following:

- In this form, where the index has exactly *N* parts (that is, all index parts are covered):
 

```
key_part1=const1 AND key_part2=const2 ... AND key_partN=constN
```
- Any range condition over a primary key of an InnoDB or BDB table.

Examples:

```
SELECT * FROM innodb_table WHERE primary_key < 10 AND key_coll=20;
```

```
SELECT * FROM tbl_name
  WHERE (key1_part1=1 AND key1_part2=2) AND key2=2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved (EXPLAIN output contains `Using index` in `Extra` field in this case). Here is an example of such a query:

```
SELECT COUNT(*) FROM t1 WHERE key1=1 AND key2=1;
```

If the used indexes don't cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over a primary key of an InnoDB or BDB table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

### 7.2.6.2. The Index Merge Union Access Algorithm

The applicability criteria for this algorithm are similar to those for the Index Merge method intersection algorithm. The algorithm can be employed when the table's WHERE clause was converted to several range conditions on different keys combined with OR, and each condition is one of the following:

- In this form, where the index has exactly *N* parts (that is, all index parts are covered):  

```
key_part1=const1 AND key_part2=const2 ... AND key_partN=constN
```
- Any range condition over a primary key of an InnoDB or BDB table.
- A condition for which the Index Merge method intersection algorithm is applicable.

Examples:

```
SELECT * FROM t1 WHERE key1=1 OR key2=2 OR key3=3;
```

```
SELECT * FROM innodb_table WHERE (key1=1 AND key2=2) OR
  (key3='foo' AND key4='bar') AND key5=5;
```

### 7.2.6.3. The Index Merge Sort-Union Access Algorithm

This access algorithm is employed when the WHERE clause was converted to several range conditions combined by OR, but for which the Index Merge method union algorithm is not applicable.

Examples:

```
SELECT * FROM tbl_name WHERE key_col1 < 10 OR key_col2 < 20;
```

```
SELECT * FROM tbl_name
  WHERE (key_col1 > 10 OR key_col2 = 20) AND nonkey_col=30;
```

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

## 7.2.7. IS NULL Optimization

MySQL can perform the same optimization on `col_name IS NULL` that it can use for

*col\_name* = *constant\_value*. For example, MySQL can use indexes and ranges to search for NULL with IS NULL.

Examples:

```
SELECT * FROM tbl_name WHERE key_col IS NULL;
SELECT * FROM tbl_name WHERE key_col <=> NULL;
SELECT * FROM tbl_name
  WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a WHERE clause includes a *col\_name* IS NULL condition for a column that is declared as NOT NULL, that expression is optimized away. This optimization does not occur in cases when the column might produce NULL anyway; for example, if it comes from a table on the right side of a LEFT JOIN.

MySQL can also optimize the combination *col\_name* = *expr* AND *col\_name* IS NULL, a form that is common in resolved subqueries. EXPLAIN shows *ref\_or\_null* when this optimization is used.

This optimization can handle one IS NULL for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns a and b of table t2:

```
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;
SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;
SELECT * FROM t1, t2
  WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;
SELECT * FROM t1, t2
  WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);
SELECT * FROM t1, t2
  WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
  OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

*ref\_or\_null* works by first doing a read on the reference key, and then a separate search for rows with a NULL key value.

Note that the optimization can handle only one IS NULL level. In the following query, MySQL uses key lookups only on the expression (t1.a=t2.a AND t2.a IS NULL) and is not able to use the key part on b:

```
SELECT * FROM t1, t2
  WHERE (t1.a=t2.a AND t2.a IS NULL)
  OR (t1.b=t2.b AND t2.b IS NULL);
```

## 7.2.8. DISTINCT Optimization

DISTINCT combined with ORDER BY needs a temporary table in many cases.

Because DISTINCT may use GROUP BY, you should be aware of how MySQL works with columns in ORDER BY or HAVING clauses that are not part of the selected columns. See Section 12.10.3, “GROUP BY and HAVING with Hidden Fields”.

In most cases, a DISTINCT clause can be considered as a special case of GROUP BY. For example, the following two queries are equivalent:

```
SELECT DISTINCT c1, c2, c3 FROM t1 WHERE c1 > const;
```

```
SELECT c1, c2, c3 FROM t1 WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to `GROUP BY` queries can be also applied to queries with a `DISTINCT` clause. Thus, for more details on the optimization possibilities for `DISTINCT` queries, see Section 7.2.13, “`GROUP BY` Optimization”.

When combining `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that `t1` is used before `t2` (which you can check with `EXPLAIN`), MySQL stops reading from `t2` (for any particular row in `t1`) when it finds the first row in `t2`:

```
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

## 7.2.9. LEFT JOIN and RIGHT JOIN Optimization

MySQL implements an `A LEFT JOIN B join_condition` as follows:

- Table `B` is set to depend on table `A` and all tables on which `A` depends.
- Table `A` is set to depend on all tables (except `B`) that are used in the `LEFT JOIN` condition.
- The `LEFT JOIN` condition is used to decide how to retrieve rows from table `B`. (In other words, any condition in the `WHERE` clause is not used.)
- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependence, MySQL issues an error.
- All standard `WHERE` optimizations are performed.
- If there is a row in `A` that matches the `WHERE` clause, but there is no row in `B` that matches the `ON` condition, an extra `B` row is generated with all columns set to `NULL`.
- If you use `LEFT JOIN` to find rows that do not exist in some table and you have the following test: `col_name IS NULL` in the `WHERE` part, where `col_name` is a column that is declared as `NOT NULL`, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the `LEFT JOIN` condition.

The implementation of `RIGHT JOIN` is analogous to that of `LEFT JOIN` with the roles of the tables reversed.

The join optimizer calculates the order in which tables should be joined. The table read order forced by `LEFT JOIN` or `STRAIGHT_JOIN` helps the join optimizer do its work much more quickly, because there are fewer table permutations to check. Note that this means that if you do a query of the following type, MySQL does a full scan on `b` because the `LEFT JOIN` forces it to be read before `d`:

```
SELECT *
  FROM a JOIN b LEFT JOIN c ON (c.key=a.key) LEFT JOIN d ON (d.key=a.key)
 WHERE b.key=d.key;
```

The fix in this case is reverse the order in which `a` and `b` are listed in the `FROM` clause:

```
SELECT *
  FROM b JOIN a LEFT JOIN c ON (c.key=a.key) LEFT JOIN d ON (d.key=a.key)
 WHERE b.key=d.key;
```

For a `LEFT JOIN`, if the `WHERE` condition is always false for the generated `NULL` row, the `LEFT JOIN` is changed to a normal join. For example, the `WHERE` clause would be false in the following query if `t2.column1` were `NULL`:

```
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to a normal join:

```
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

This can be made faster because MySQL can use table `t2` before table `t1` if doing so would result in a better query plan. To force a specific table order, use `STRAIGHT_JOIN`.

## 7.2.10. Nested Join Optimization

As of MySQL 5.0.1, the syntax for expressing joins allows nested joins. The following discussion refers to the join syntax described in Section 13.2.7.1, “JOIN Syntax”.

The syntax of *table\_factor* is extended in comparison with the SQL Standard. The latter accepts only *table\_reference*, not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of *table\_reference* items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
                        ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
                        ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, `CROSS JOIN` is a syntactic equivalent to `INNER JOIN` (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause; `CROSS JOIN` is used otherwise.

In versions of MySQL prior to 5.0.1, parentheses in *table\_references* were just omitted and all join operations were grouped to the left. In general, parentheses can be ignored in join expressions containing only inner join operations.

After removing parentheses and grouping operations to the left, the join expression:

```
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
  ON t1.a=t2.a
```

transforms into the expression:

```
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
  ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables `t1`, `t2`, and `t3` have the following state:

- Table `t1` contains rows (1), (2)
- Table `t2` contains row (1,101)
- Table `t3` contains row (101)

In this case, the first expression returns a result set including the rows (1,1,101,101), (2,NULL,NULL,NULL), whereas the second expression returns the rows (1,1,101,101), (2,NULL,NULL,101):

```
mysql> SELECT *
-> FROM t1
-> LEFT JOIN
-> (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
-> ON t1.a=t2.a;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	NULL

```
mysql> SELECT *
-> FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
-> LEFT JOIN t3
-> ON t2.b=t3.b OR t2.b IS NULL;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	101

In the following example, an outer join operation is used together with an inner join operation:

```
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```
t1 LEFT JOIN t2 ON t1.a=t2.a, t3.
```

For the given table states, the two expressions return different sets of rows:

```
mysql> SELECT *
-> FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	NULL

```
mysql> SELECT *
-> FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
```

a	a	b	b
1	1	101	101
2	NULL	NULL	101

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:

```
(t1, t2) LEFT JOIN t3 ON P(t2.b, t3.b)
```

is equivalent to this expression:

```
t1, t2 LEFT JOIN t3 ON P(t2.b, t3.b)
```

for any tables  $t_1, t_2, t_3$  and any condition  $P$  over attributes  $t_2.b$  and  $t_3.b$ .

Whenever the order of execution of the join operations in a join expression (*join\_table*) is not from left to right, we talk about nested joins. Consider the following queries:

```
SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
WHERE t1.a > 1
```

```
SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1
```

Those queries are considered to contain these nested joins:

```
t2 LEFT JOIN t3 ON t2.b=t3.b
t2, t3
```

The nested join is formed in the first query with a left join operation, whereas in the second query it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression will dictate the same order of execution for join operations. For the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. (In our extended syntax the parentheses in  $(t_2, t_3)$  of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because `LEFT JOIN` and `ON` would play the role of the left and right delimiters for the expression  $(t_2, t_3)$ .)

The preceding examples demonstrate these points:

- For join expressions involving only inner joins (and not outer joins), parentheses can be removed. You can remove parentheses and evaluate left to right (or, in fact, you can evaluate the tables in any order).
- The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall by what algorithmic schema the nested-loop join executes a query. Suppose that we have a join query over 3 tables  $T_1, T_2, T_3$  of the form:

```
SELECT * FROM T1 INNER JOIN T2 ON P1(T1, T2)
INNER JOIN T3 ON P2(T2, T3)
WHERE P(T1, T2, T3).
```

Here,  $P_1(T_1, T_2)$  and  $P_2(T_2, T_3)$  are some join conditions (on expressions), whereas  $P(t_1, t_2, t_3)$  is a condition over columns of tables  $T_1, T_2, T_3$ .

The nested-loop join algorithm would execute this query in the following manner:

```

FOR each row t1 in T1 {
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}

```

The notation `t1||t2||t3` means “a row constructed by concatenating the columns of rows `t1`, `t2`, and `t3`.” In some of the following examples, `NULL` where a row name appears means that `NULL` is used for each column of that row. For example, `t1||t2||NULL` means “a row constructed by concatenating the columns of rows `t1` and `t2`, and `NULL` for each column of `t3`.”

Now let's consider a query with nested outer joins:

```

SELECT * FROM T1 LEFT JOIN
          (T2 LEFT JOIN T3 ON P2(T2,T3))
          ON P1(T1,T2)
WHERE P(T1,T2,T3).

```

For this query, we modify the nested-loop pattern to get:

```

FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f2=TRUE;
    }
    IF (!f2) {
      IF P(t1,t2,NULL) {
        t:=t1||t2||NULL; OUTPUT t;
      }
      f1=TRUE;
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}

```

In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by `NULL` values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In our example, the outer join table expressed by the following expression is embedded:

```

(T2 LEFT JOIN T3 ON P2(T2,T3))

```

Note that for the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```

FOR each row t3 in T3 {
  FOR each row t2 in T2 such that P2(t2,t3) {
    FOR each row t1 in T1 such that P1(t1,t2) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}

```

For the queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer will evaluate two different nestings:

```

SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
WHERE P(T1,T2,T3)

```

The nestings are these:

```

FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t1,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f1:=TRUE
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}

```

and:

```

FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t3 in T3 such that P2(t1,t3) {
    FOR each row t2 in T2 such that P1(t1,t2) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f1:=TRUE
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}

```

In both nestings, T1 must be processed in the outer loop because it is used in an outer join. T2 and T3 are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, T2 and T3 can be processed in either order.

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our WHERE condition  $P(T1, T2, T3)$  can be represented by a conjunctive formula:

$P(T1, T2, T2) = C1(T1) \text{ AND } C2(T2) \text{ AND } C3(T3).$

In this case, MySQL actually uses the following nested-loop schema for the execution of the query with inner joins:

```
FOR each row t1 in T1 such that C1(t1) {
  FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2) {
    FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
```

You see that each of the conjuncts  $C1(T1)$ ,  $C2(T2)$ ,  $C3(T3)$  are pushed out of the most inner loop to the most outer loop where it can be evaluated. If  $C1(T1)$  is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table  $T1$  passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the `WHERE` condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we have to introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

For our example with outer joins with:

$P(T1, T2, T3) = C1(T1) \text{ AND } C(T2) \text{ AND } C3(T3)$

the nested-loop schema using guarded pushed-down conditions looks like this:

```
FOR each row t1 in T1 such that C1(t1) {
  BOOL f1:=FALSE;
  FOR each row t2 in T2
    such that P1(t1,t2) AND (f1?C2(t2):TRUE) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3
      such that P2(t2,t3) AND (f1&&f2?C3(t3):TRUE) {
        IF (f1&&f2?TRUE:(C2(t2) AND C3(t3))) {
          t:=t1||t2||t3; OUTPUT t;
        }
        f2=TRUE;
        f1=TRUE;
      }
    }
  IF (!f2) {
    IF (f1?TRUE:C2(t2) && P(t1,t2,NULL)) {
      t:=t1||t2||NULL; OUTPUT t;
    }
    f1=TRUE;
  }
}
IF (!f1 && P(t1,NULL,NULL)) {
  t:=t1||NULL||NULL; OUTPUT t;
}
```

In general, pushed-down predicates can be extracted from join conditions such as  $P1(T1, T2)$  and  $P(T2, T3)$ . In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the `NULL`-complemented row generated by the corresponding outer join operation.

Note that access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the `WHERE` condition. (We could use conditional key access in this

case, but this technique is not employed yet in MySQL 5.0.)

## 7.2.11. Outer Join Simplification

Table expressions in the FROM clause of a query are simplified in many cases.

At the parser stage, queries with right outer joins operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed according to the following rule:

$$(T1, \dots) \text{ RIGHT JOIN } (T2, \dots) \text{ ON } P(T1, \dots, T2, \dots) = \\ (T2, \dots) \text{ LEFT JOIN } (T1, \dots) \text{ ON } P(T1, \dots, T2, \dots)$$

All inner join expressions of the form `T1 INNER JOIN T2 ON P(T1, T2)` are replaced by the list `T1, T2, P(T1, T2)` being joined as a conjunct to the WHERE condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for join queries with outer join operation, it takes into consideration only the plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer options are limited because only such plans enables us to execute queries with outer joins operations by the nested loop schema.

Suppose that we have a query of the form:

```
SELECT * T1 LEFT JOIN T2 ON P1(T1, T2)
WHERE P(T1, T2) AND R(T2)
```

with `R(T2)` narrowing greatly the number of matching rows from table `T2`. If we executed the query as it is, the optimizer would have no other choice besides to access table `T1` before table `T2` that may lead to a very inefficient execution plan.

Fortunately, MySQL converts such a query into a query without an outer join operation if the WHERE condition is null-rejected. A condition is called null-rejected for an outer join operation if it evaluates to `FALSE` or to `UNKNOWN` for any `NULL`-complemented row built for the operation.

Thus, for this outer join:

```
T1 LEFT JOIN T2 ON T1.A=T2.A
```

Conditions such as these are null-rejected:

```
T2.B IS NOT NULL,
T2.B > 3,
T2.C <= T1.C,
T2.B < 2 OR T2.C > 1
```

Conditions such as these are not null-rejected:

```
T2.B IS NULL,
T1.B < 3 OR T2.B IS NOT NULL,
T1.B < 3 OR T2.B > 3
```

The general rules for checking whether a condition is null-rejected for an outer join operation are simple. A condition is null-rejected in the following cases:

- If it is of the form `A IS NOT NULL`, where `A` is an attribute of any of the inner tables
- If it is a predicate containing a reference to an inner table that evaluates to `UNKNOWN` when one of its arguments is `NULL`

- If it is a conjunction containing a null-rejected condition as a conjunct
- If it is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
        LEFT JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

the WHERE condition is null-rejected for the second outer join operation but is not null-rejected for the first one.

If the WHERE condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, the preceding query is replaced with the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
        INNER JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

For the original query, the optimizer would evaluate plans compatible with only one access order T1, T2, T3. For the replacing query, it additionally considers the access sequence T3, T1, T2.

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
        LEFT JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

will be first converted to the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
        INNER JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

which is equivalent to the query:

```
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

Now the remaining outer join operation can be replaced by an inner join, too, because the condition T3.B=T2.B is null-rejected and we get a query without outer joins at all:

```
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes we succeed in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```
SELECT * FROM T1 LEFT JOIN
        (T2 LEFT JOIN T3 ON T3.B=T2.B)
        ON T2.A=T1.A
WHERE T3.C > 0
```

is converted to:

```
SELECT * FROM T1 LEFT JOIN
      (T2 INNER JOIN T3 ON T3.B=T2.B)
      ON T2.A=T1.A
WHERE T3.C > 0,
```

That can be rewritten only to the form still containing the embedding outer join operation:

```
SELECT * FROM T1 LEFT JOIN
      (T2,T3)
      ON (T2.A=T1.A AND T3.B=T2.B)
WHERE T3.C > 0.
```

When trying to convert an embedded outer join operation in a query, we must take into account the join condition for the embedding outer join together with the WHERE condition. In the query:

```
SELECT * FROM T1 LEFT JOIN
      (T2 LEFT JOIN T3 ON T3.B=T2.B)
      ON T2.A=T1.A AND T3.C=T1.C
WHERE T3.D > 0 OR T1.D > 0
```

the WHERE condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join `T2.A=T1.A AND T3.C=T1.C` is null-rejected. So the query can be converted to:

```
SELECT * FROM T1 LEFT JOIN
      (T2, T3)
      ON T2.A=T1.A AND T3.C=T1.C AND T3.B=T2.B
WHERE T3.D > 0 OR T1.D > 0
```

The algorithm that converts outer join operations into inner joins was implemented in full measure, as it has been described here, in MySQL 5.0.1. MySQL 4.1 performs only some simple conversions.

## 7.2.12. ORDER BY Optimization

In some cases, MySQL can use an index to satisfy an ORDER BY clause without doing any extra sorting.

The index can also be used even if the ORDER BY does not match the index exactly, as long as all of the unused portions of the index and all the extra ORDER BY columns are constants in the WHERE clause. The following queries use the index to resolve the ORDER BY part:

```
SELECT * FROM t1
  ORDER BY key_part1,key_part2,... ;

SELECT * FROM t1
  WHERE key_part1=constant
  ORDER BY key_part2;

SELECT * FROM t1
  ORDER BY key_part1 DESC, key_part2 DESC;

SELECT * FROM t1
  WHERE key_part1=1
  ORDER BY key_part1 DESC, key_part2 DESC;
```

In some cases, MySQL *cannot* use indexes to resolve the ORDER BY, although it still uses indexes to find the rows that match the WHERE clause. These cases include the following:

- You use ORDER BY on different keys:

```
SELECT * FROM t1 ORDER BY key1, key2;
```

- You use ORDER BY on non-consecutive parts of a key:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key_part2;
```

- You mix ASC and DESC:

```
SELECT * FROM t1 ORDER BY key_part1 DESC, key_part2 ASC;
```

- The key used to fetch the rows is not the same as the one used in the ORDER BY:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key1;
```

- You are joining many tables, and the columns in the ORDER BY are not all from the first non-constant table that is used to retrieve rows. (This is the first table in the EXPLAIN output that does not have a `const` join type.)
- You have different ORDER BY and GROUP BY expressions.
- The type of table index used does not store rows in order. For example, this is true for a HASH index in a MEMORY table.

With `EXPLAIN SELECT ... ORDER BY`, you can check whether MySQL can use indexes to resolve the query. It cannot if you see `Using filesort` in the `Extra` column. See Section 7.2.1, “Optimizing Queries with EXPLAIN”.

A `filesort` optimization is used that records not only the sort key value and row position, but the columns required for the query as well. This avoids reading the rows twice. The `filesort` algorithm works like this:

1. Read the rows that match the WHERE clause.
2. For each row, record a tuple of values consisting of the sort key value and row position, and also the columns required for the query.
3. Sort the tuples by sort key value
4. Retrieve the rows in sorted order, but read the required columns directly from the sorted tuples rather than by accessing the table a second time.

This algorithm represents a significant improvement over that used in some older versions of MySQL.

To avoid a slowdown, this optimization is used only if the total size of the extra columns in the sort tuple does not exceed the value of the `max_length_for_sort_data` system variable. (A symptom of setting the value of this variable too high is that you should see high disk activity and low CPU activity.)

If you want to increase ORDER BY speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, you can try the following strategies:

- Increase the size of the `sort_buffer_size` variable.
- Increase the size of the `read_rnd_buffer_size` variable.

- Change `tmpdir` to point to a dedicated filesystem with large amounts of empty space. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (':') on Unix and semicolon characters(';') on Windows, NetWare, and OS/2. You can use this feature to spread the load across several directories. *Note:* The paths should be for directories in filesystems that are located on different *physical* disks, not different partitions on the same disk.

By default, MySQL sorts all `GROUP BY col1, col2, ...` queries as if you specified `ORDER BY col1, col2, ...` in the query as well. If you include an `ORDER BY` clause explicitly that contains the same column list, MySQL optimizes it away without any speed penalty, although the sorting still occurs. If a query includes `GROUP BY` but you want to avoid the overhead of sorting the result, you can suppress sorting by specifying `ORDER BY NULL`. For example:

```
INSERT INTO foo
SELECT a, COUNT(*) FROM bar GROUP BY a ORDER BY NULL;
```

## 7.2.13. GROUP BY Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and to avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for `GROUP BY` are that all `GROUP BY` columns reference attributes from the same index, and that the index stores its keys in order (for example, this is a `BTREE` index and not a `HASH` index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a `GROUP BY` query via index access, as detailed in the following sections. In the first method, the grouping operation is applied together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.

### 7.2.13.1. Loose index scan

The most efficient way to process `GROUP BY` is when the index is used to directly retrieve the group fields. With this access method, MySQL uses the property of some index types that the keys are ordered (for example, `BTREE`). This property enables use of lookup groups in an index without having to consider all keys in the index that satisfy all `WHERE` conditions. This access method considers only a fraction of the keys in an index, so it is called a *loose index scan*. When there is no `WHERE` clause, a loose index scan reads as many keys as the number of groups, which may be a much smaller number than that of all keys. If the `WHERE` clause contains range predicates (see the discussion of the `range` join type in Section 7.2.1, “Optimizing Queries with `EXPLAIN`”), a loose index scan looks up the first key of each group that satisfies the range conditions, and again reads the least possible number of keys. This is possible under the following conditions:

- The query is over a single table.
- The `GROUP BY` includes the first consecutive parts of the index. (If, instead of `GROUP BY`, the query has a `DISTINCT` clause, all distinct attributes refer to the beginning of the index.)
- The only aggregate functions used (if any) are `MIN()` and `MAX()`, and all of them refer to the same column.
- Any other parts of the index than those from the `GROUP BY` referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of `MIN()` or `MAX()` functions.

The EXPLAIN output for such queries shows `Using index for group-by` in the Extra column.

The following queries fall into this category, assuming that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`:

```
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1;
SELECT c1, c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > const GROUP BY c1, c2;
SELECT c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT c1, c2 FROM t1 WHERE c3 = const GROUP BY c1, c2;
```

The following queries cannot be executed with this quick select method, for the reasons given:

- There are aggregate functions other than `MIN()` or `MAX()`, for example:

```
SELECT c1, SUM(c2) FROM t1 GROUP BY c1;
```

- The fields in the `GROUP BY` clause do not refer to the beginning of the index, as shown here:

```
SELECT c1,c2 FROM t1 GROUP BY c2, c3;
```

- The query refers to a part of a key that comes after the `GROUP BY` part, and for which there is no equality with a constant, an example being:

```
SELECT c1,c3 FROM t1 GROUP BY c1, c2;
```

## 7.2.13.2. Tight index scan

A tight index scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a loose index scan are not met, it is still possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, we term it a *tight index scan*. Notice that with a tight index scan, the group-operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there is a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the `GROUP BY` key. The constants from the equality conditions fill in any “gaps” in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If we require sorting of the `GROUP BY` result, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

The following queries do not work with the loose index scan access method described earlier, but still work with the tight index scan access method (assuming that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`).

- There is a gap in the `GROUP BY`, but it is covered by the condition `c2 = 'a'`:

```
SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
```

- The `GROUP BY` does not begin with the first part of the key, but there is a condition that provides a constant for that part:

```
SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
```

## 7.2.14. LIMIT Optimization

In some cases, MySQL handles a query differently when you are using `LIMIT row_count` and not using `HAVING`:

- If you are selecting only a few rows with `LIMIT`, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.
- If you use `LIMIT row_count` with `ORDER BY`, MySQL ends the sorting as soon as it has found the first `row_count` rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the `LIMIT` clause must be selected, and most or all of them must be sorted, before it can be ascertained that the first `row_count` rows have been found. In either case, after the initial rows have been found, there is no need to sort any remainder of the result set, and MySQL does not do so.
- When combining `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.
- In some cases, a `GROUP BY` can be resolved by reading the key in order (or doing a sort on the key) and then calculating summaries until the key value changes. In this case, `LIMIT row_count` does not calculate any unnecessary `GROUP BY` values.
- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using `SQL_CALC_FOUND_ROWS`.
- `LIMIT 0` quickly returns an empty set. This can be useful for checking the validity of a query. When using one of the MySQL APIs, it can also be employed for obtaining the types of the result columns. (This trick does not work in the MySQL Monitor (the `mysql` program), which merely displays `Empty set` in such cases; you should instead use `SHOW COLUMNS` or `DESCRIBE` for this purpose.)
- When the server uses temporary tables to resolve the query, it uses the `LIMIT row_count` clause to calculate how much space is required.

## 7.2.15. How to Avoid Table Scans

The output from `EXPLAIN` shows `ALL` in the `type` column when MySQL uses a table scan to resolve a query. This usually happens under the following conditions:

- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.
- There are no usable restrictions in the `ON` or `WHERE` clause for indexed columns.
- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See Section 7.2.4, “`WHERE` Clause Optimization”.
- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key it probably will do many key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See Section 13.5.2.1, “ANALYZE TABLE Syntax”.
- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

See Section 13.2.7, “SELECT Syntax”.

- Start `mysqld` with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.2.2, “Server System Variables”.

## 7.2.16. Speed of INSERT Statements

The time required for inserting a row is determined by the following factors, where the numbers indicate approximate proportions:

- Connecting: (3)
- Sending query to server: (2)
- Parsing query: (2)
- Inserting row: (1 × size of row)
- Inserting indexes: (1 × number of indexes)
- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by  $\log N$ , assuming B-tree indexes.

You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use `INSERT` statements with multiple `VALUES` lists to insert several rows at a time. This is considerably faster (many times faster in some cases) than using separate single-row `INSERT` statements. If you are adding data to a non-empty table, you can tune the `bulk_insert_buffer_size` variable to make data insertion even faster. See Section 5.2.2, “Server System Variables”.
- If you are inserting a lot of rows from different clients, you can get higher speed by using the `INSERT DELAYED` statement. See Section 13.2.4.2, “INSERT DELAYED Syntax”.
- For a MyISAM table, you can use concurrent inserts to add rows at the same time that `SELECT` statements are running if there are no deleted rows in middle of the table. See Section 7.3.3, “Concurrent Inserts”.
- When loading a table from a text file, use `LOAD DATA INFILE`. This is usually 20 times faster than using `INSERT` statements. See Section 13.2.5, “LOAD DATA INFILE Syntax”.

- With some extra work, it is possible to make `LOAD DATA INFILE` run even faster for a MyISAM table when the table has many indexes. Use the following procedure:
  1. Optionally create the table with `CREATE TABLE`.
  2. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.
  3. Use `myisamchk --keys-used=0 -rq /path/to/db/tbl_name`. This removes all use of indexes for the table.
  4. Insert data into the table with `LOAD DATA INFILE`. This does not update any indexes and therefore is very fast.
  5. If you intend only to read from the table in the future, use `myisampack` to compress it. See Section 14.1.3.3, “Compressed Table Characteristics”.
  6. Re-create the indexes with `myisamchk -rq /path/to/db/tbl_name`. This creates the index tree in memory before writing it to disk, which is much faster than updating the index during `LOAD DATA INFILE` because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.
  7. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

Note that `LOAD DATA INFILE` performs the preceding optimization automatically if the MyISAM table into which you insert data is empty. The main difference is that you can let `myisamchk` allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the `LOAD DATA INFILE` statement.

You can also disable or enable the indexes for a MyISAM table by using the following statements rather than `myisamchk`. If you use these statements, you can skip the `FLUSH TABLE` operations:

```
ALTER TABLE tbl_name DISABLE KEYS;
ALTER TABLE tbl_name ENABLE KEYS;
```

- To speed up `INSERT` operations that are performed with multiple statements for non-transactional tables, lock your tables:

```
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
...
UNLOCK TABLES;
```

This benefits performance because the index buffer is flushed to disk only once, after all `INSERT` statements have completed. Normally, there would be as many index buffer flushes as there are `INSERT` statements. Explicit locking statements are not needed if you can insert all rows with a single `INSERT`.

To obtain faster insertions, for transactional tables, you should use `START TRANSACTION` and `COMMIT` instead of `LOCK TABLES`.

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. For example:

1. Connection 1 does 1000 inserts
2. Connections 2, 3, and 4 do 1 insert
3. Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40%

faster.

INSERT, UPDATE, and DELETE operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five inserts or updates in a row. If you do very many inserts in a row, you could do a `LOCK TABLES` followed by an `UNLOCK TABLES` once in a while (each 1,000 rows or so) to allow other threads access to the table. This would still result in a nice performance gain.

INSERT is still much slower for loading data than `LOAD DATA INFILE`, even when using the strategies just outlined.

- To increase performance for MyISAM tables, for both `LOAD DATA INFILE` and INSERT, enlarge the key cache by increasing the `key_buffer_size` system variable. See Section 7.5.2, “Tuning Server Parameters”.

## 7.2.17. Speed of UPDATE Statements

An update statement is optimized like a SELECT query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a MyISAM table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use `OPTIMIZE TABLE` occasionally. See Section 13.5.2.5, “OPTIMIZE TABLE Syntax”.

## 7.2.18. Speed of DELETE Statements

The time required to delete individual rows is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the `key_buffer_size` system variable. See Section 7.5.2, “Tuning Server Parameters”.

To delete all rows from a table, `TRUNCATE TABLE tbl_name` is faster than `DELETE FROM tbl_name`. See Section 13.2.9, “TRUNCATE Syntax”.

## 7.2.19. Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- Use persistent connections to the database to avoid connection overhead. If you cannot use persistent connections and you are initiating many new connections to the database, you may want to change the value of the `thread_cache_size` variable. See Section 7.5.2, “Tuning Server Parameters”.
- Always check whether all your queries really use the indexes that you have created in the tables. In MySQL, you can do this with the `EXPLAIN` statement. See Section 7.2.1, “Optimizing Queries with EXPLAIN”.
- Try to avoid complex SELECT queries on MyISAM tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.
- With MyISAM tables that have no deleted rows in the middle, you can insert rows at the end at the same time that another query is reading from the table. If it is important to be able to do this, you should consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. See Section 14.1, “The MyISAM Storage Engine”.

- To fix any compression issues that may have occurred with ARCHIVE tables, you can use `OPTIMIZE TABLE`. See Section 14.8, “The ARCHIVE Storage Engine”.
- Use `ALTER TABLE ... ORDER BY expr1, expr2, ...` if you usually retrieve rows in *expr1*, *expr2*, ... order. By using this option after extensive changes to the table, you may be able to get higher performance.
- In some cases, it may make sense to introduce a column that is “hashed” based on information from other columns. If this column is short and reasonably unique, it may be much faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:

```
SELECT * FROM tbl_name
WHERE hash_col=MD5(CONCAT(col1,col2))
AND col1='constant' AND col2='constant';
```

- For MyISAM tables that change frequently, you should try to avoid all variable-length columns (VARCHAR, BLOB, and TEXT). The table uses dynamic row format if it includes even a single variable-length column. See Chapter 14, *Storage Engines and Table Types*.
- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a MyISAM table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See Chapter 14, *Storage Engines and Table Types*.
- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

```
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```

This is very important when you use MySQL storage engines such as MyISAM that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- If you need to collect statistics from large log tables, use summary tables instead of scanning the entire log table. Maintaining the summaries should be much faster than trying to calculate statistics “live.” Regenerating new summary tables from the logs when things change (depending on business decisions) is faster than changing the running application.
- If possible, you should classify reports as “live” or as “statistical,” where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.
- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.
- In some cases, it is convenient to pack and store data into a BLOB column. In this case, you must provide code in your application to pack and unpack information, but this may save a lot of accesses at some stage. This is practical when you have data that does not conform well to a rows-and-columns table structure.
- Normally, you should try to keep all data non-redundant (observing what is referred to in database theory as *third normal form*). However, there may be situations in which it can be advantageous to duplicate information or create summary tables to gain more speed.
- Stored routines or UDFs (user-defined functions) may be a good way to gain performance for some tasks. See Chapter 17, *Stored Procedures and Functions*, and Section 24.2, “Adding New Functions to MySQL”, for more information.

- You can always gain something by caching queries or answers in your application and then performing many inserts or updates together. If your database system supports table locks (as do MySQL and Oracle), this should help to ensure that the index cache is only flushed once after all updates. You can also take advantage of MySQL's query cache to achieve similar results; see Section 5.14, "The MySQL Query Cache".
- Use `INSERT DELAYED` when you do not need to know when your data is written. This reduces the overall insertion impact because many rows can be written with a single disk write.
- Use `INSERT LOW_PRIORITY` when you want to give `SELECT` statements higher priority than your inserts.
- Use `SELECT HIGH_PRIORITY` to get retrievals that jump the queue. That is, the `SELECT` is executed even if there is another client waiting to do a write.
- Use multiple-row `INSERT` statements to store many rows with one SQL statement. Many SQL servers support this, including MySQL.
- Use `LOAD DATA INFILE` to load large amounts of data. This is faster than using `INSERT` statements.
- Use `AUTO_INCREMENT` columns to generate unique values.
- Use `OPTIMIZE TABLE` once in a while to avoid fragmentation with dynamic-format MyISAM tables. See Section 14.1.3, "MyISAM Table Storage Formats".
- Use `MEMORY (HEAP)` tables when possible to get more speed. See Section 14.4, "The `MEMORY (HEAP)` Storage Engine". `MEMORY` tables are useful for non-critical data that is accessed often, such as information about the last displayed banner for users who don't have cookies enabled in their Web browser. User sessions are another alternative available in many Web application environments for handling volatile state data.
- With Web servers, images and other binary assets should normally be stored as files. That is, store only a reference to the file rather than the file itself in the database. Most Web servers are better at caching files than database contents, so using files is generally faster.
- Columns with identical information in different tables should be declared to have identical data types so that joins based on the corresponding columns will be faster.
- Try to keep column names simple. For example, in a table named `customer`, use a column name of `name` instead of `customer_name`. To make your names portable to other SQL servers, you should keep them shorter than 18 characters.
- If you need really high speed, you should take a look at the low-level interfaces for data storage that the different SQL servers support. For example, by accessing the MySQL MyISAM storage engine directly, you could get a speed increase of two to five times compared to using the SQL interface. To be able to do this, the data must be on the same server as the application, and usually it should only be accessed by one process (because external file locking is really slow). One could eliminate these problems by introducing low-level MyISAM commands in the MySQL server (this could be one easy way to get more performance if needed). By carefully designing the database interface, it should be quite easy to support this type of optimization.
- If you are using numerical data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you need not parse your text files to find line and column boundaries.
- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replication servers to split up the load. To avoid slowing down the master while making backups, you can make backups using a slave server. See Chapter 6, *Replication*.
- Declaring a MyISAM table with the `DELAY_KEY_WRITE=1` table option makes index updates

faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you should ensure that the table is okay by running the server with the `--myisam-recover` option, or by running `myisamchk` before restarting the server. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)

## 7.3. Locking Issues

### 7.3.1. Locking Methods

MySQL uses table-level locking for `MyISAM` and `MEMORY` tables, page-level locking for `BDB` tables, and row-level locking for `InnoDB` tables.

In many cases, you can make an educated guess about which locking type is best for an application, but generally it is difficult to say that a given lock type is better than another. Everything depends on the application and different parts of an application may require different lock types.

To decide whether you want to use a storage engine with row-level locking, you should look at what your application does and what mix of select and update statements it uses. For example, most Web applications perform many selects, relatively few deletes, updates based mainly on key values, and inserts into a few specific tables. The base MySQL `MyISAM` setup is very well tuned for this.

Table locking in MySQL is deadlock-free for storage engines that use table-level locking. Deadlock avoidance is managed by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order.

The table-locking method MySQL uses for `WRITE` locks works as follows:

- If there are no locks on the table, put a write lock on it.
- Otherwise, put the lock request in the write lock queue.

The table-locking method MySQL uses for `READ` locks works as follows:

- If there are no write locks on the table, put a read lock on it.
- Otherwise, put the lock request in the read lock queue.

When a lock is released, the lock is made available to the threads in the write lock queue and then to the threads in the read lock queue. This means that if you have many updates for a table, `SELECT` statements wait until there are no more updates.

You can analyze the table lock contention on your system by checking the `Table_locks_waited` and `Table_locks_immediate` status variables:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Table_locks_immediate | 1151552 |
| Table_locks_waited | 15324 |
+-----+-----+
```

If a `MyISAM` table contains no free blocks in the middle, rows always are inserted at the end of the data file. In this case, you can freely mix concurrent `INSERT` and `SELECT` statements for a `MyISAM` table without locks. That is, you can insert rows into a `MyISAM` table at the same time other cli-

ents are reading from it. (Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are re-enabled automatically when all holes have been filled with new data.)

If you want to perform many INSERT and SELECT operations on a table when concurrent inserts are not possible, you can insert rows in a temporary table and update the real table with the rows from the temporary table once in a while. This can be done with the following code:

```
mysql> LOCK TABLES real_table WRITE, insert_table WRITE;
mysql> INSERT INTO real_table SELECT * FROM insert_table;
mysql> TRUNCATE TABLE insert_table;
mysql> UNLOCK TABLES;
```

InnoDB uses row locks and BDB uses page locks. For these two storage engines, deadlocks are possible because they automatically acquire locks during the processing of SQL statements, not at the start of the transaction.

Advantages of row-level locking:

- Fewer lock conflicts when accessing different rows in many threads.
- Fewer changes for rollbacks.
- Possible to lock a single row for a long time.

Disadvantages of row-level locking:

- Requires more memory than page-level or table-level locks.
- Slower than page-level or table-level locks when used on a large part of the table because you must acquire many more locks.
- Definitely much slower than other locks if you often do GROUP BY operations on a large part of the data or if you must scan the entire table frequently.

Table locks are superior to page-level or row-level locks in the following cases:

- Most statements for the table are reads.
- A mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:

```
UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
DELETE FROM tbl_name WHERE unique_key_col=key_value;
```

- SELECT combined with concurrent INSERT statements, and very few UPDATE or DELETE statements.
- Many scans or GROUP BY operations on the entire table without any writers.

With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level or page-level locking:

- Versioning (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different

views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”

- Copy on demand is in many cases superior to page-level or row-level locking. However, in the worst case, it can use much more memory than using normal locks.
- Instead of using row-level locks, you can employ application-level locks, such as `GET_LOCK()` and `RELEASE_LOCK()` in MySQL. These are advisory locks, so they work only in well-behaved applications. (See Section 12.9.4, “Miscellaneous Functions”.)

## 7.3.2. Table Locking Issues

To achieve a very high lock speed, MySQL uses table locking (instead of page, row, or column locking) for all storage engines except InnoDB and BDB.

For InnoDB and BDB tables, MySQL uses only table locking if you explicitly lock the table with `LOCK TABLES`. For these storage engines, we recommend that you not use `LOCK TABLES` at all, because InnoDB uses automatic row-level locking and BDB uses page-level locking to ensure transaction isolation.

For large tables, table locking is much better than row locking for most applications, but there are some pitfalls:

- Table locking enables many threads to read from a table at the same time, but if a thread wants to write to a table, it must first get exclusive access. During the update, all other threads that want to access this particular table must wait until the update is done.
- Table updates normally are considered to be more important than table retrievals, so they are given higher priority. This should ensure that updates to a table are not “starved” even if there is heavy `SELECT` activity for the table.
- Table locking causes problems in cases such as when a thread is waiting because the disk is full and free space needs to become available before the thread can proceed. In this case, all threads that want to access the problem table are also put in a waiting state until more disk space is made available.

Table locking is also disadvantageous under the following scenario:

- A client issues a `SELECT` that takes a long time to run.
- Another client then issues an `UPDATE` on the same table. This client waits until the `SELECT` is finished.
- Another client issues another `SELECT` statement on the same table. Because `UPDATE` has higher priority than `SELECT`, this `SELECT` waits for the `UPDATE` to finish, *and* for the first `SELECT` to finish.

The following items describe some ways to avoid or reduce contention caused by table locking:

- Try to get the `SELECT` statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.
- Start `mysqld` with `--low-priority-updates`. This gives all statements that update (modify) a table lower priority than `SELECT` statements. In this case, the second `SELECT` statement in the preceding scenario would execute before the `UPDATE` statement, and would not need to wait for the first `SELECT` to finish.

- You can specify that all updates issued in a specific connection should be done with low priority by using the `SET LOW_PRIORITY_UPDATES=1` statement. See Section 13.5.3, “SET Syntax”.
- You can give a specific `INSERT`, `UPDATE`, or `DELETE` statement lower priority with the `LOW_PRIORITY` attribute.
- You can give a specific `SELECT` statement higher priority with the `HIGH_PRIORITY` attribute. See Section 13.2.7, “SELECT Syntax”.
- You can start `mysqld` with a low value for the `max_write_lock_count` system variable to force MySQL to temporarily elevate the priority of all `SELECT` statements that are waiting for a table after a specific number of inserts to the table occur. This allows `READ` locks after a certain number of `WRITE` locks.
- If you have problems with `INSERT` combined with `SELECT`, you might want to consider switching to `MyISAM` tables, which support concurrent `SELECT` and `INSERT` statements. (See Section 7.3.3, “Concurrent Inserts”.)
- If you mix inserts and deletes on the same table, `INSERT DELAYED` may be of great help. See Section 13.2.4.2, “INSERT DELAYED Syntax”.
- If you have problems with mixed `SELECT` and `DELETE` statements, the `LIMIT` option to `DELETE` may help. See Section 13.2.1, “DELETE Syntax”.
- Using `SQL_BUFFER_RESULT` with `SELECT` statements can help to make the duration of table locks shorter. See Section 13.2.7, “SELECT Syntax”.
- You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

Here are some tips concerning table locks in MySQL:

- Concurrent users are not a problem if you do not mix updates with selects that need to examine many rows in the same table.
- You can use `LOCK TABLES` to increase speed, because many updates within a single lock is much faster than updating without locks. Splitting table contents into separate tables may also help.
- If you encounter speed problems with table locks in MySQL, you may be able to improve performance by converting some of your tables to `InnoDB` or `BDB` tables. See Section 14.2, “The InnoDB Storage Engine”, and Section 14.5, “The BDB (BerkeleyDB) Storage Engine”.

### 7.3.3. Concurrent Inserts

For a `MyISAM` table, you can use concurrent inserts to add rows at the same time that `SELECT` statements are running if there are no deleted rows in middle of the table.

Under circumstances where concurrent inserts can be used, there is seldom any need to use the `DELAYED` modifier for `INSERT` statements. See Section 13.2.4.2, “INSERT DELAYED Syntax”.

If you are using the binary log, concurrent inserts are converted to normal inserts for `CREATE . . . SELECT` or `INSERT . . . SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation.

With `LOAD DATA INFILE`, if you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. Using this option affects the perform-

ance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

## 7.4. Optimizing Database Structure

### 7.4.1. Design Choices

MySQL keeps row data and index data in separate files. Many (almost all) other database systems mix row and index data in the same file. We believe that the MySQL choice is better for a very wide range of modern systems.

Another way to store the row data is to keep the information for each column in a separate area (examples are SDBM and Focus). This causes a performance hit for every query that accesses more than one column. Because this degenerates so quickly when more than one column is accessed, we believe that this model is not good for general-purpose databases.

The more common case is that the index and data are stored together (as in Oracle/Sybase, et al). In this case, you find the row information at the leaf page of the index. The good thing with this layout is that it, in many cases, depending on how well the index is cached, saves a disk read. The bad things with this layout are:

- Table scanning is much slower because you have to read through the indexes to get at the data.
- You cannot use only the index table to retrieve data for a query.
- You use more space because you must duplicate indexes from the nodes (you cannot store the row in the nodes).
- Deletes degenerate the table over time (because indexes in nodes are usually not updated on delete).
- It is more difficult to cache only the index data.

### 7.4.2. Make Your Data as Small as Possible

One of the most basic optimizations is to design your tables to take as little space on the disk as possible. This can result in huge improvements because disk reads are faster, and smaller tables normally require less main memory while their contents are being actively processed during query execution. Indexing also is a lesser resource burden if done on smaller columns.

MySQL supports many different storage engines (table types) and row formats. For each table, you can decide which storage and indexing method to use. Choosing the proper table format for your application may give you a big performance gain. See Chapter 14, *Storage Engines and Table Types*.

You can get better performance for a table and minimize storage space by using the techniques listed here:

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory. For example, use the smaller integer types if possible to get smaller tables. `MEDIUMINT` is often a better choice than `INT` because a `MEDIUMINT` column uses 25% less space.
- Declare columns to be `NOT NULL` if possible. It makes everything faster and you save one bit per column. If you really need `NULL` in your application, you should definitely use it. Just avoid having it on all columns by default.
- For `MyISAM` tables, if you do not have any variable-length columns (`VARCHAR`, `TEXT`, or `BLOB` columns), a fixed-size row format is used. This is faster but unfortunately may waste some space. See Section 14.1.3, “`MyISAM` Table Storage Formats”. You can hint that you want to have fixed length rows even if you have `VARCHAR` columns with the `CREATE TABLE` op-

tion `ROW_FORMAT=FIXED`.

- Starting with MySQL 5.0.3, InnoDB tables use a more compact storage format. In earlier versions of MySQL, InnoDB rows contain some redundant information, such as the number of columns and the length of each column, even for fixed-size columns. By default, tables are created in the compact format (`ROW_FORMAT=COMPACT`). If you wish to downgrade to older versions of MySQL, you can request the old format with `ROW_FORMAT=REDUNDANT`.

The compact InnoDB format also changes how CHAR columns containing UTF-8 data are stored. With `ROW_FORMAT=REDUNDANT`, a UTF-8 `CHAR(N)` occupies  $3 \times N$  bytes, given that the maximum length of a UTF-8 encoded character is three bytes. Many languages can be written primarily using single-byte UTF-8 characters, so a fixed storage length often wastes space. With `ROW_FORMAT=COMPACT` format, InnoDB allocates a variable amount of storage in the range from  $N$  to  $3 \times N$  bytes for these columns by stripping trailing spaces if necessary. The minimum storage length is kept as  $N$  bytes to facilitate in-place updates in typical cases.

- The primary index of a table should be as short as possible. This makes identification of each row easy and efficient.
- Create only the indexes that you really need. Indexes are good for retrieval but bad when you need to store data quickly. If you access a table mostly by searching on a combination of columns, create an index on them. The first part of the index should be the column most used. If you *always* use many columns when selecting from the table, you should use the column with more duplicates first to obtain better compression of the index.
- If it is very likely that a string column has a unique prefix on the first number of characters, it's better to index only this prefix, using MySQL's support for creating an index on the leftmost part of the column (see Section 13.1.4, "CREATE INDEX Syntax"). Shorter indexes are faster, not only because they require less disk space, but because they give also you more hits in the index cache, and thus fewer disk seeks. See Section 7.5.2, "Tuning Server Parameters".
- In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic-format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.

### 7.4.3. Column Indexes

All MySQL data types can be indexed. Use of indexes on the relevant columns is the best way to improve the performance of `SELECT` operations.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See Chapter 14, *Storage Engines and Table Types*. All storage engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

With `col_name(N)` syntax in an index specification, you can create an index that uses only the first  $N$  characters of a string column. Indexing only a prefix of column values in this way can make the index file much smaller. When you index a BLOB or TEXT column, you *must* specify a prefix length for the index. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for InnoDB tables). Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE` statements is interpreted as number of characters. *Be sure to take this into account when specifying a prefix length for a column that uses a multi-byte character set.*

You can also create FULLTEXT indexes. These are used for full-text searches. Only the MyISAM storage engine supports FULLTEXT indexes and only for CHAR, VARCHAR, and TEXT columns. Indexing always takes place over the entire column and partial (column prefix) indexing is not supported. For details, see Section 12.7, "Full-Text Search Functions".

You can also create indexes on spatial data types. Currently, only MyISAM supports R-tree indexes on spatial types. As of MySQL 5.0.16, other storage engines use B-trees for indexing spatial types (except for ARCHIVE and NDBCLUSTER, which do not support spatial type indexing).

The MEMORY storage engine uses HASH indexes by default, but also supports BTREE indexes.

## 7.4.4. Multiple-Column Indexes

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 15 columns. For certain data types, you can index a prefix of the column (see Section 7.4.3, “Column Indexes”).

A multiple-column index can be considered a sorted array containing values that are created by concatenating the values of the indexed columns.

MySQL uses multiple-column indexes in such a way that queries are fast when you specify a known quantity for the first column of the index in a WHERE clause, even if you do not specify values for the other columns.

Suppose that a table has the following specification:

```
CREATE TABLE test (  
  id          INT NOT NULL,  
  last_name   CHAR(30) NOT NULL,  
  first_name  CHAR(30) NOT NULL,  
  PRIMARY KEY (id),  
  INDEX name (last_name,first_name)  
);
```

The name index is an index over the last\_name and first\_name columns. The index can be used for queries that specify values in a known range for last\_name, or for both last\_name and first\_name. Therefore, the name index is used in the following queries:

```
SELECT * FROM test WHERE last_name='Widenius';  
  
SELECT * FROM test  
  WHERE last_name='Widenius' AND first_name='Michael';  
  
SELECT * FROM test  
  WHERE last_name='Widenius'  
  AND (first_name='Michael' OR first_name='Monty');  
  
SELECT * FROM test  
  WHERE last_name='Widenius'  
  AND first_name >='M' AND first_name < 'N';
```

However, the name index is *not* used in the following queries:

```
SELECT * FROM test WHERE first_name='Michael';  
  
SELECT * FROM test  
  WHERE last_name='Widenius' OR first_name='Michael';
```

The manner in which MySQL uses indexes to improve query performance is discussed further in Section 7.4.5, “How MySQL Uses Indexes”.

## 7.4.5. How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can

quickly determine the position to seek to in the middle of the data file without having to look at all the data. If a table has 1,000 rows, this is at least 100 times faster than reading sequentially. If you need to access most of the rows, it is faster to read sequentially, because this minimizes disk seeks.

Most MySQL indexes (`PRIMARY KEY`, `UNIQUE`, `INDEX`, and `FULLTEXT`) are stored in B-trees. Exceptions are that indexes on spatial data types use R-trees, and that `MEMORY` tables also support hash indexes.

Strings are automatically prefix- and end-space compressed. See Section 13.1.4, “`CREATE INDEX Syntax`”.

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in `MEMORY` tables) are described at the end of this section.

MySQL uses indexes for these operations:

- To find the rows matching a `WHERE` clause quickly.
- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows.
- To retrieve rows from other tables when performing joins.
- To find the `MIN()` or `MAX()` value for a specific indexed column `key_col`. This is optimized by a preprocessor that checks whether you are using `WHERE key_part_N = constant` on all key parts that occur before `key_col` in the index. In this case, MySQL does a single key lookup for each `MIN()` or `MAX()` expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

```
SELECT MIN(key_part2),MAX(key_part2)
FROM tbl_name WHERE key_part1=10;
```

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable key (for example, `ORDER BY key_part1, key_part2`). If all key parts are followed by `DESC`, the key is read in reverse order. See Section 7.2.12, “`ORDER BY Optimization`”.
- In some cases, a query can be optimized to retrieve values without consulting the data rows. If a query uses only columns from a table that are numeric and that form a leftmost prefix for some key, the selected values may be retrieved from the index tree for greater speed:

```
SELECT key_part3 FROM tbl_name
WHERE key_part1=1
```

Suppose that you issue the following `SELECT` statement:

```
mysql> SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;
```

If a multiple-column index exists on `col1` and `col2`, the appropriate rows can be fetched directly. If separate single-column indexes exist on `col1` and `col2`, the optimizer tries to find the most restrictive index by deciding which index finds fewer rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to find rows. For example, if you have a three-column index on (`col1`, `col2`, `col3`), you have indexed search capabilities on (`col1`), (`col1`, `col2`), and (`col1`, `col2`, `col3`).

MySQL cannot use a partial index if the columns do not form a leftmost prefix of the index. Suppose that you have the `SELECT` statements shown here:

```
SELECT * FROM tbl_name WHERE col1=val1;
SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;
```

```
SELECT * FROM tbl_name WHERE col2=val2;
SELECT * FROM tbl_name WHERE col2=val2 AND col3=val3;
```

If an index exists on (col1, col2, col3), only the first two queries use the index. The third and fourth queries do involve indexed columns, but (col2) and (col2, col3) are not leftmost prefixes of (col1, col2, col3).

A B-tree index can be used for column comparisons in expressions that use the =, >, >=, <, <=, or BETWEEN operators. The index also can be used for LIKE comparisons if the argument to LIKE is a constant string that does not start with a wildcard character. For example, the following SELECT statements use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%ck%';
```

In the first statement, only rows with 'Patrick' <= key\_col < 'Patrickl' are considered. In the second statement, only rows with 'Pat' <= key\_col < 'Pau' are considered.

The following SELECT statements do not use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;
```

In the first statement, the LIKE value begins with a wildcard character. In the second statement, the LIKE value is not a constant.

If you use ... LIKE '%string%' and string is longer than three characters, MySQL uses the *Turbo Boyer-Moore algorithm* to initialize the pattern for the string and then uses this pattern to perform the search more quickly.

A search using col\_name IS NULL employs indexes if col\_name is indexed.

Any index that does not span all AND levels in the WHERE clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every AND group.

The following WHERE clauses use indexes:

```
... WHERE index_part1=1 AND index_part2=2 AND other_column=3
      /* index = 1 OR index = 2 */
... WHERE index=1 OR A=10 AND index=2
      /* optimized like "index_part1='hello'" */
... WHERE index_part1='hello' AND index_part3=5
      /* Can use index on index1 but not on index2 or index3 */
... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
```

These WHERE clauses do *not* use indexes:

```
      /* index_part1 is not used */
... WHERE index_part2=1 AND index_part3=2

      /* Index is not used in both parts of the WHERE clause */
... WHERE index=1 OR A=10

      /* No index spans all rows */
... WHERE index_part1=1 OR index_part2=10
```

Sometimes MySQL does not use an index, even if one is available. One circumstance under which this occurs is when the optimizer estimates that using the index would require MySQL to access a very large percentage of the rows in the table. (In this case, a table scan is likely to be much faster because it requires fewer seeks.) However, if such a query uses LIMIT to retrieve only some of the rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return

in the result.

Hash indexes have somewhat different characteristics from those just discussed:

- They are used only for equality comparisons that use the = or <=> operators (but are *very* fast). They are not used for comparison operators such as < that find a range of values.
- The optimizer cannot use a hash index to speed up ORDER BY operations. (This type of index cannot be used to search for the next entry in order.)
- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a MyISAM table to a hash-indexed MEMORY table.
- Only whole keys can be used to search for a row. (With a B-tree index, any leftmost prefix of the key can be used to find rows.)

## 7.4.6. The MyISAM Key Cache

To minimize disk I/O, the MyISAM storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the *key cache* (or *key buffer*) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.
- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system filesystem cache.

This section first describes the basic operation of the MyISAM key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

- Access to the key cache no longer is serialized among threads. Multiple threads can access the cache concurrently.
- You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the `key_buffer_size` system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the `key_buffer_size` value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native filesystem buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the MyISAM index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are non-leaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new in-

dex block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an *LRU (Least Recently Used)* strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains a special queue (*LRU chain*) of all used blocks. When a block is accessed, it is placed at the end of the queue. When blocks need to be replaced, blocks at the beginning of the queue are the least recently used and become the first candidates for eviction.

### 7.4.6.1. Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:

- A buffer that is not being updated can be accessed by multiple threads.
- A buffer that is being updated causes threads that need to use it to wait until the update is complete.
- Multiple threads can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

### 7.4.6.2. Multiple Key Caches

Shared access to the key cache improves performance but does not eliminate contention among threads entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given MyISAM table. By default, all MyISAM table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the `CACHE INDEX` statement (see Section 13.5.5.1, “`CACHE INDEX Syntax`”). For example, the following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

Table	Op	Msg_type	Msg_text
test.t1	assign_to_keycache	status	OK
test.t2	assign_to_keycache	status	OK
test.t3	assign_to_keycache	status	OK

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a `SET GLOBAL` parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

Note that you cannot destroy the default key cache. Any attempt to do this will be ignored:

```
mysql> SET GLOBAL key_buffer_size = 0;

mysql> SHOW VARIABLES LIKE 'key_buffer_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| key_buffer_size | 8384512 |
+-----+-----+
```

Key cache variables are structured system variables that have a name and components. For `keycache1.key_buffer_size`, `keycache1` is the cache variable name and `key_buffer_size` is the cache component. See Section 5.2.3.1, “Structured System Variables”, for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, we recommend a strategy that uses three key caches:

- A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.
- A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.
- A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.
- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to non-leaf nodes of the index B-tree remain in the cache.
- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read in from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

`CACHE INDEX` sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an `init-file` option that names a file containing `CACHE INDEX` statements to be executed. For example:

```
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysqld_init.sql
```

The statements in `mysqld_init.sql` are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to

hot\_cache and cold\_cache:

```
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

### 7.4.6.3. Midpoint Insertion Strategy

By default, the key cache management system uses the LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the *midpoint insertion strategy*.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sub-chain and a warm sub-chain. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not “too short,” always containing at least `key_cache_division_limit` percent of the key cache blocks. `key_cache_division_limit` is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sub-chain. After a certain number of hits (accesses of the block), it is promoted to the hot sub-chain. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sub-chain is placed at the end of the chain. The block then circulates within this sub-chain. If the block stays at the beginning of the sub-chain for a long enough time, it is demoted to the warm chain. This time is determined by the value of the `key_cache_age_threshold` component of the key cache.

The threshold value prescribes that, for a key cache containing  $N$  blocks, the block at the beginning of the hot sub-chain not accessed within the last  $N \times \text{key\_cache\_age\_threshold} / 100$  hits is to be moved to the beginning of the warm sub-chain. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sub-chain.

The midpoint insertion strategy allows you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sub-chain during an index scan operation as well.

### 7.4.6.4. Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its non-leaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading allows you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks will stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table  | Op          | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+-----+-----+-----+-----+
```

+-----+-----+-----+-----+

The `IGNORE LEAVES` modifier causes only blocks for the non-leaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the non-leaf nodes from `t2`.

If an index has been assigned to a key cache using a `CACHE INDEX` statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

### 7.4.6.5. Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the `key_cache_block_size` variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

Currently, you cannot control the size of the index blocks in a table. This size is set by the server when the `.MYI` index file is created, depending on the size of the keys in the indexes present in the table definition. In most cases, it is set equal to the I/O buffer size.

### 7.4.6.6. Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the `key_buffer_size` or `key_cache_block_size` key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native filesystem caching. Filesystem caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of filesystem caching for the indexes ceases.

### 7.4.7. MyISAM Index Statistics Collection

Storage engines collect statistics about tables for use by the optimizer. Table statistics are based on value groups, where a value group is a set of rows with the same key prefix value. For optimizer purposes, an important statistic is the average value group size.

MySQL uses the average value group size in the following ways:

- To estimate how many rows must be read for each `ref` access
- To estimate how many row a partial join will produce; that is, the number of rows that an operation of this form will produce:

```
(...) JOIN tbl_name ON tbl_name.key = expr
```

As the average value group size for an index increases, the index is less useful for those two purposes because the average number of rows per lookup increases: For the index to be good for optimization purposes, it is best that each index value target a small number of rows in the table. When a given index value yields a large number of rows, the index is less useful and MySQL is less likely to use it.

The average value group size is related to table cardinality, which is the number of value groups. The `SHOW INDEX` statement displays a cardinality value based on  $N/S$ , where  $N$  is the number of rows in the table and  $S$  is the average value group size. That ratio yields an approximate number of value groups in the table.

For a join based on the `<=>` comparison operator, `NULL` is not treated differently from any other value: `NULL <=> NULL`, just as `N <=> N` for any other  $N$ .

However, for a join based on the `=` operator, `NULL` is different from non-`NULL` values: `expr1 = expr2` is not true when `expr1` or `expr2` (or both) are `NULL`. This affects `ref` accesses for comparisons of the form `tbl_name.key = expr`: MySQL will not access the table if the current value of `expr` is `NULL`, because the comparison cannot be true.

For `=` comparisons, it does not matter how many `NULL` values are in the table. For optimization purposes, the relevant value is the average size of the non-`NULL` value groups. However, MySQL does not currently allow that average size to be collected or used.

For MyISAM tables, you have some control over collection of table statistics by means of the `myisam_stats_method` system variable. This variable has two possible values, which differ as follows:

- When `myisam_stats_method` is `nulls_equal`, all `NULL` values are treated as identical (that is, they all form a single value group).

If the `NULL` value group size is much higher than the average non-`NULL` value group size, this method skews the average value group size upward. This makes index appear to the optimizer to be less useful than it really is for joins that look for non-`NULL` values. Consequently, the `nulls_equal` method may cause the optimizer not to use the index for `ref` accesses when it should.

- When `myisam_stats_method` is `nulls_unequal`, `NULL` values are not considered the same. Instead, each `NULL` value forms a separate value group of size 1.

If you have many `NULL` values, this method skews the average value group size downward. If the average non-`NULL` value group size is large, counting `NULL` values each as a group of size 1 causes the optimizer to overestimate the value of the index for joins that look for non-`NULL` values. Consequently, the `nulls_unequal` method may cause the optimizer to use this index for `ref` lookups when other methods may be better.

If you tend to use many joins that use `<=>` rather than `=`, `NULL` values are not special in comparisons and one `NULL` is equal to another. In this case, `nulls_equal` is the appropriate statistics method.

The `myisam_stats_method` system variable has global and session values. Setting the global value affects MyISAM statistics collection for all MyISAM tables. Setting the session value affects statistics collection only for the current client connection. This means that you can force a table's statistics to be regenerated with a given method without affecting other clients by setting the session value of `myisam_stats_method`.

To regenerate table statistics, you can use any of the following methods:

- Set `myisam_stats_method`, and then issue a `CHECK TABLE` statement
- Execute `myisamchk --stats_method=method_name --analyze`

- Change the table to cause its statistics to go out of date (for example, insert a row and then delete it), and then set `myisam_stats_method` and issue an `ANALYZE TABLE` statement

Some caveats regarding the use of `myisam_stats_method`:

- You can force table statistics to be collected explicitly, as just described. However, MySQL may also collect statistics automatically. For example, if during the course of executing statements for a table, some of those statements modify the table, MySQL may collect statistics. (This may occur for bulk inserts or deletes, or some `ALTER TABLE` statements, for example.) If this happens, the statistics are collected using whatever value `myisam_stats_method` has at the time. Thus, if you collect statistics using one method, but `myisam_stats_method` is set to the other method when a table's statistics are collected automatically later, the other method will be used.
- There is no way to tell which method was used to generate statistics for a given MyISAM table.
- `myisam_stats_method` applies only to MyISAM tables. Other storage engines have only one method for collecting table statistics. Usually it is closer to the `nulls_equal` method.

## 7.4.8. How MySQL Opens and Closes Tables

When you execute a `mysqladmin status` command, you should see something like this:

```
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
```

The `Open tables` value of 12 can be somewhat puzzling if you have only six tables.

MySQL is multi-threaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client threads having different states on the same table, the table is opened independently by each concurrent thread. This uses additional memory but normally increases performance. With MyISAM tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all threads.)

The `table_cache`, `max_connections`, and `max_tmp_tables` system variables affect the maximum number of files the server keeps open. If you increase one or more of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems allow you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

`table_cache` is related to `max_connections`. For example, for 200 concurrent running connections, you should have a table cache size of at least  $200 \times N$ , where  $N$  is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the `table_cache` setting. If `table_cache` is set too high, MySQL may run out of file descriptors and refuse connections, fail to perform queries, and be very unreliable. You also have to take into account that the MyISAM storage engine needs two file descriptors for each unique open table. You can increase the number of file descriptors available to MySQL using the `--open-files-limit` startup option to `mysqld`. See Section A.2.17, “File Not Found”.

The cache of open tables is kept at a level of `table_cache` entries. The default value is 64; this can be changed with the `--table_cache` option to `mysqld`. Note that MySQL may temporarily open more tables than this to execute queries.

MySQL closes an unused table and removes it from the table cache under the following circum-

stances:

- When the cache is full and a thread tries to open a table that is not in the cache.
- When the cache contains more than `table_cache` entries and a table in the cache is no longer being used by any threads.
- When a table flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables that are not currently in use are released, beginning with the table least recently used.
- If a new table needs to be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary.

When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any MyISAM table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See Section 13.2.3, “HANDLER Syntax”.

You can determine whether your table cache is too small by checking the `mysqld` status variable `Opened_tables`:

```
mysql> SHOW STATUS LIKE 'Opened_tables';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Opened_tables | 2741  |
+-----+-----+
```

If the value is very large, even when you have not issued many `FLUSH TABLES` statements, you should increase the table cache size. See Section 5.2.2, “Server System Variables”, and Section 5.2.4, “Server Status Variables”.

## 7.4.9. Drawbacks to Creating Many Tables in the Same Database

If you have many MyISAM tables in the same database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by making the table cache larger.

## 7.5. Optimizing the MySQL Server

## 7.5.1. System Factors and Startup Parameter Tuning

We start with system-level factors, because some of these decisions must be made very early to achieve large performance gains. In other cases, a quick look at this section may suffice. However, it is always nice to have a sense of how much can be gained by changing factors that apply at this level.

The operating system to use is very important. To get the best use of multiple-CPU machines, you should use Solaris (because its threads implementation works well) or Linux (because the 2.4 and later kernels have good SMP support). Note that older Linux kernels have a 2GB filesize limit by default. If you have such a kernel and a need for files larger than 2GB, you should get the Large File Support (LFS) patch for the ext2 filesystem. Other filesystems such as ReiserFS and XFS do not have this 2GB limitation.

Before using MySQL in production, we advise you to test it on your intended platform.

Other tips:

- If you have enough RAM, you could remove all swap devices. Some operating systems use a swap device in some contexts even if you have free memory.
- Avoid external locking. Since MySQL 4.0, the default has been for external locking to be disabled on all systems. The `--external-locking` and `--skip-external-locking` options explicitly enable and disable external locking.

Note that disabling external locking does not affect MySQL's functionality as long as you run only one server. Just remember to take down the server (or lock and flush the relevant tables) before you run `myisamchk`. On some systems it is mandatory to disable external locking because it does not work, anyway.

The only case in which you cannot disable external locking is when you run multiple MySQL *servers* (not clients) on the same data, or if you run `myisamchk` to check (not repair) a table without telling the server to flush and lock the tables first. Note that using multiple MySQL servers to access the same data concurrently is generally *not* recommended, except when using MySQL Cluster.

The `LOCK TABLES` and `UNLOCK TABLES` statements use internal locking, so you can use them even if external locking is disabled.

## 7.5.2. Tuning Server Parameters

You can determine the default buffer sizes used by the `mysqld` server using this command:

```
shell> mysqld --verbose --help
```

This command produces a list of all `mysqld` options and configurable system variables. The output includes the default variable values and looks something like this:

```
back_log                50
binlog_cache_size       32768
bulk_insert_buffer_size 8388608
connect_timeout         5
date_format              (No default value)
datetime_format         (No default value)
default_week_format     0
delayed_insert_limit    100
delayed_insert_timeout  300
delayed_queue_size      1000
expire_logs_days        0
flush_time              1800
ft_max_word_len         84
```

ft_min_word_len	4
ft_query_expansion_limit	20

updatable_views_with_limit 1
wait_timeout              28800

```

For a `mysqld` server that is currently running, you can see the current values of its system variables by connecting to it and issuing this statement:

```
mysql> SHOW VARIABLES;
```

You can also see some statistical and status indicators for a running server by issuing this statement:

```
mysql> SHOW STATUS;
```

System variable and status information also can be obtained using `mysqladmin`:

```

shell> mysqladmin variables
shell> mysqladmin extended-status

```

For a full description of all system and status variables, see Section 5.2.2, “Server System Variables”, and Section 5.2.4, “Server Status Variables”.

MySQL uses algorithms that are very scalable, so you can usually run with very little memory. However, normally you get better performance by giving MySQL more memory.

When tuning a MySQL server, the two most important variables to configure are `key_buffer_size` and `table_cache`. You should first feel confident that you have these set appropriately before trying to change any other variables.

The following examples indicate some typical variable values for different runtime configurations.

- If you have at least 256MB of memory and many tables and want maximum performance with a moderate number of clients, you should use something like this:

```

shell> mysqld_safe --key_buffer_size=64M --table_cache=256 \
          --sort_buffer_size=4M --read_buffer_size=1M &

```

- If you have only 128MB of memory and only a few tables, but you still do a lot of sorting, you can use something like this:

```
shell> mysqld_safe --key_buffer_size=16M --sort_buffer_size=1M
```

If there are very many simultaneous connections, swapping problems may occur unless `mysqld` has been configured to use very little memory for each connection. `mysqld` performs better if you have enough memory for all connections.

- With little memory and lots of connections, use something like this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=100K \  
--read_buffer_size=100K &
```

Or even this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=16K \  
--table_cache=32 --read_buffer_size=8K \  
--net_buffer_length=1K &
```

If you are performing `GROUP BY` or `ORDER BY` operations on tables that are much larger than your available memory, you should increase the value of `read_rnd_buffer_size` to speed up the reading of rows following sorting operations.

When you have installed MySQL, the `support-files` directory contains some different `my.cnf` sample files: `my-huge.cnf`, `my-large.cnf`, `my-medium.cnf`, and `my-small.cnf`. You can use these as a basis for optimizing your system. (On Windows, look in the MySQL installation directory.)

If you specify an option on the command line for `mysqld` or `mysqld_safe`, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file.

To see the effects of a parameter change, do something like this:

```
shell> mysqld --key_buffer_size=32M --verbose --help
```

The variable values are listed near the end of the output. Make sure that the `--verbose` and `--help` options are last. Otherwise, the effect of any options listed after them on the command line are not reflected in the output.

For information on tuning the InnoDB storage engine, see Section 14.2.11, “InnoDB Performance Tuning Tips”.

### 7.5.3. Controlling Query Optimizer Performance

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the difference in performance between “good” and “bad” plans can be orders of magnitude (that is, seconds versus hours or even days), most query optimizers, including that of MySQL, perform a more or less exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the number of possible plans investigated by the MySQL optimizer grows exponentially with the number of tables referenced in a query. For small numbers of tables (typically less than 7–10) this is not a problem. However, when larger queries are submitted, the time spent in query optimization may easily become the major bottleneck in the server's performance.

MySQL 5.0.1 introduces a more flexible method for query optimization that allows the user to control how exhaustive the optimizer is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled via two system variables:

- The `optimizer_prune_level` variable tells the optimizer to skip certain plans based on estimates of the number of rows accessed for each table. Our experience shows that this kind of “educated guess” rarely misses optimal plans, and may dramatically reduce query compilation times. That is why this option is on (`optimizer_prune_level=1`) by default. However, if you believe that the optimizer missed a better query plan, this option can be switched off (`optimizer_prune_level=0`) with the risk that query compilation may take much longer. Note that, even with the use of this heuristic, the optimizer still explores a roughly exponential number of plans.
- The `optimizer_search_depth` variable tells how far into the “future” of each incomplete plan the optimizer should look to evaluate whether it should be expanded further. Smaller values of `optimizer_search_depth` may result in orders of magnitude smaller query compilation times. For example, queries with 12, 13, or more tables may easily require hours and even days to compile if `optimizer_search_depth` is close to the number of tables in the query. At the same time, if compiled with `optimizer_search_depth` equal to 3 or 4, the optimizer may compile in less than a minute for the same query. If you are unsure of what a reasonable value is for `optimizer_search_depth`, this variable can be set to 0 to tell the optimizer to determine the value automatically.

## 7.5.4. How Compiling and Linking Affects the Speed of MySQL

Most of the following tests were performed on Linux with the MySQL benchmarks, but they should give some indication for other operating systems and workloads.

You obtain the fastest executables when you link with `-static`.

On Linux, it is best to compile the server with `pgcc` and `-O3`. You need about 200MB memory to compile `sql_yacc.cc` with these options, because `gcc` or `pgcc` needs a great deal of memory to make all functions inline. You should also set `CXX=gcc` when configuring MySQL to avoid inclusion of the `libstdc++` library, which is not needed. Note that with some versions of `pgcc`, the resulting binary runs only on true Pentium processors, even if you use the compiler option indicating that you want the resulting code to work on all x586-type processors (such as AMD).

By using a better compiler and compilation options, you can obtain a 10–30% speed increase in applications. This is particularly important if you compile the MySQL server yourself.

When we tested both the Cygnus CodeFusion and Fujitsu compilers, neither was sufficiently bug-free to allow MySQL to be compiled with optimizations enabled.

The standard MySQL binary distributions are compiled with support for all character sets. When you compile MySQL yourself, you should include support only for the character sets that you are going to use. This is controlled by the `--with-charset` option to `configure`.

Here is a list of some measurements that we have made:

- If you use `pgcc` and compile everything with `-O6`, the `mysqld` server is 1% faster than with `gcc 2.95.2`.
- If you link dynamically (without `-static`), the result is 13% slower on Linux. Note that you still can use a dynamically linked MySQL library for your client applications. It is the server that is most critical for performance.
- For a connection from a client to a server running on the same host, if you connect using TCP/IP rather than a Unix socket file, performance is 7.5% slower. (On Unix, if you connect to the hostname `localhost`, MySQL uses a socket file by default.)

- For TCP/IP connections from a client to a server, connecting to a remote server on another host is 8–11% slower than connecting to a server on the same host, even for connections over 100Mb/s Ethernet.
- When running our benchmark tests using secure connections (all data encrypted with internal SSL support) performance was 55% slower than with unencrypted connections.
- If you compile with `--with-debug=full`, most queries are 20% slower. Some queries may take substantially longer; for example, the MySQL benchmarks run 35% slower. If you use `--with-debug` (without `=full`), the speed decrease is only 15%. For a version of `mysqld` that has been compiled with `--with-debug=full`, you can disable memory checking at runtime by starting it with the `--skip-safemalloc` option. The execution speed should then be close to that obtained when configuring with `--with-debug`.
- On a Sun UltraSPARC-IIe, a server compiled with Forte 5.0 is 4% faster than one compiled with gcc 3.2.
- On a Sun UltraSPARC-IIe, a server compiled with Forte 5.0 is 4% faster in 32-bit mode than in 64-bit mode.
- Compiling with gcc 2.95.2 for UltraSPARC with the `-mcpu=v8 -Wa,-xarch=v8plusa` options gives 4% more performance.
- On Solaris 2.5.1, MIT-pthreads is 8–12% slower than Solaris native threads on a single processor. With greater loads or more CPUs, the difference should be larger.
- Compiling on Linux-x86 using gcc without frame pointers (`-fomit-frame-pointer` or `-fomit-frame-pointer -ffixed-ebp`) makes `mysqld` 1–4% faster.

Binary MySQL distributions for Linux that are provided by MySQL AB used to be compiled with `pgcc`. We had to go back to regular `gcc` due to a bug in `pgcc` that would generate binaries that do not run on AMD. We will continue using `gcc` until that bug is resolved. In the meantime, if you have a non-AMD machine, you can build a faster binary by compiling with `pgcc`. The standard MySQL Linux binary is linked statically to make it faster and more portable.

## 7.5.5. How MySQL Uses Memory

The following list indicates some of the ways that the `mysqld` server uses memory. Where applicable, the name of the system variable relevant to the memory use is given:

- The key buffer (variable `key_buffer_size`) is shared by all threads; other buffers used by the server are allocated as needed. See Section 7.5.2, “Tuning Server Parameters”.
- Each connection uses some thread-specific space:
  - A stack (default 192KB, variable `thread_stack`)
  - A connection buffer (variable `net_buffer_length`)
  - A result buffer (variable `net_buffer_length`)

The connection buffer and result buffer are dynamically enlarged up to `max_allowed_packet` when needed. While a query is running, a copy of the current query string is also allocated.

- All threads share the same base memory.
- When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.

- Only compressed MyISAM tables are memory mapped. This is because the 32-bit memory space of 4GB is not large enough for most big tables. When systems with a 64-bit address space become more common, we may add general support for memory mapping.
- Each request that performs a sequential scan of a table allocates a *read buffer* (variable `read_buffer_size`).
- When reading rows in an arbitrary sequence (for example, following a sort), a *random-read buffer* (variable `read_rnd_buffer_size`) may be allocated in order to avoid disk seeks.
- All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain BLOB columns are stored on disk.

If an internal heap table exceeds the size of `tmp_table_size`, MySQL handles this automatically by changing the in-memory heap table to a disk-based MyISAM table as necessary. You can also increase the temporary table size by setting the `tmp_table_size` option to `mysqld`, or by setting the SQL option `SQL_BIG_TABLES` in the client program. See Section 13.5.3, “SET Syntax”.

- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See Section A.4.4, “Where MySQL Stores Temporary Files”.
- Almost all parsing and calculating is done in a local memory store. No memory overhead is needed for small items, so the normal slow memory allocation and freeing is avoided. Memory is allocated only for unexpectedly large strings. This is done with `malloc()` and `free()`.
- For each MyISAM table that is opened, the index file is opened once; the data file is opened once for each concurrently running thread. For each concurrent thread, a table structure, column structures for each column, and a buffer of size  $3 \times N$  are allocated (where  $N$  is the maximum row length, not counting BLOB columns). A BLOB column requires five to eight bytes plus the length of the BLOB data. The MyISAM storage engine maintains one extra row buffer for internal use.
- For each table having BLOB columns, a buffer is enlarged dynamically to read in larger BLOB values. If you scan a table, a buffer as large as the largest BLOB value is allocated.
- Handler structures for all in-use tables are saved in a cache and managed as a FIFO. By default, the cache has 64 entries. If a table has been used by two running threads at the same time, the cache contains two entries for the table. See Section 7.4.8, “How MySQL Opens and Closes Tables”.
- A `FLUSH TABLES` statement or `mysqladmin flush-tables` command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. `FLUSH TABLES` does not return until all tables have been closed.

`ps` and other system status programs may report that `mysqld` uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of `ps` counts the unused memory between stacks as used memory. You can verify this by checking available swap with `swap -s`. We test `mysqld` with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

## 7.5.6. How MySQL Uses DNS

When a new client connects to `mysqld`, `mysqld` spawns a new thread to handle the request. This thread first checks whether the hostname is in the hostname cache. If not, the thread attempts to resolve the hostname:

- If the operating system supports the thread-safe `gethostbyaddr_r()` and `gethostbyname_r()` calls, the thread uses them to perform hostname resolution.

- If the operating system does not support the thread-safe calls, the thread locks a mutex and calls `gethostbyaddr()` and `gethostbyname()` instead. In this case, no other thread can resolve hostnames that are not in the hostname cache until the first thread unlocks the mutex.

You can disable DNS hostname lookups by starting `mysqld` with the `--skip-name-resolve` option. However, in this case, you can use only IP numbers in the MySQL grant tables.

If you have a very slow DNS and many hosts, you can get more performance by either disabling DNS lookups with `--skip-name-resolve` or by increasing the `HOST_CACHE_SIZE` define (default value: 128) and recompiling `mysqld`.

You can disable the hostname cache by starting the server with the `--skip-host-cache` option. To clear the hostname cache, issue a `FLUSH HOSTS` statement or execute the `mysqladmin flush-hosts` command.

To disallow TCP/IP connections entirely, start `mysqld` with the `--skip-networking` option.

## 7.6. Disk Issues

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.
- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:

- Using symbolic links

This means that, for MyISAM tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See Section 7.6.1, “Using Symbolic Links”.

- Striping

Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the  $N$ -th block on the  $(N \text{ MOD } \textit{number\_of\_disks})$  disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See Section 7.1.5, “Using Your Own Benchmarks”.

The speed difference for striping is *very* dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

- For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need  $2 \times N$  drives to hold  $N$  drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.
- A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID  $N$  disk. RAID  $N$  can be a problem if you have many writes, due to the time required to update the parity bits.
- On Linux, you can get much more performance by using `hdparm` to configure your disk's interface. (Up to 100% under load is not uncommon.) The following `hdparm` options should be

quite good for MySQL, and probably for many other applications:

```
hdparm -m 16 -d 1
```

Note that performance and reliability when using this command depend on your hardware, so we strongly suggest that you test your system thoroughly after using `hdparm`. Please consult the `hdparm` manual page for more information. If `hdparm` is not used wisely, filesystem corruption may result, so back up everything before experimenting!

- You can also set the parameters for the filesystem that the database uses:

If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your filesystems with the `-o noatime` option. That skips updates to the last access time in inodes on the filesystem, which avoids some disk seeks.

On many operating systems, you can set a filesystem to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you more performance without sacrificing too much reliability. (This flag is on by default on Linux.)

## 7.6.1. Using Symbolic Links

You can move tables and databases from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disk.

The recommended way to do this is simply to symlink databases to a different disk. Symlink tables only as a last resort.

### 7.6.1.1. Using Symbolic Links for Databases on Unix

On Unix, the way to symlink a database is first to create a directory on some disk where you have free space and then to create a symlink to it from the MySQL data directory.

```
shell> mkdir /dr1/databases/test
shell> ln -s /dr1/databases/test /path/to/datadir
```

MySQL does not support linking one directory to multiple databases. Replacing a database directory with a symbolic link works as long as you do not make a symbolic link between databases. Suppose that you have a database `db1` under the MySQL data directory, and then make a symlink `db2` that points to `db1`:

```
shell> cd /path/to/datadir
shell> ln -s db1 db2
```

The result is that, or any table `tbl_a` in `db1`, there also appears to be a table `tbl_a` in `db2`. If one client updates `db1.tbl_a` and another client updates `db2.tbl_a`, problems are likely to occur.

However, if you really need to do this, it is possible by altering the source file `mysys/my_symlink.c`, in which you should look for the following statement:

```
if (!(MyFlags & MY_RESOLVE_LINK) ||
    (!lstat(filename, &stat_buff) && S_ISLNK(stat_buff.st_mode)))
```

Change the statement to this:

```
if (1)
```

## 7.6.1.2. Using Symbolic Links for Tables on Unix

You should not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`). You can check whether your system supports symbolic links by issuing a `SHOW VARIABLES LIKE 'have_symlink'` statement.

Symlinks are fully supported only for MyISAM tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links.

The handling of symbolic links for MyISAM tables works as follows:

- In the data directory, you always have the table format (`.frm`) file, the data (`.MYD`) file, and the index (`.MYI`) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks. The format file cannot.
- You can symlink the data file and the index file independently to different directories.
- You can instruct a running MySQL server to perform the symlinking by using the `DATA DIRECTORY` and `INDEX DIRECTORY` options to `CREATE TABLE`. See Section 13.1.5, “CREATE TABLE Syntax”. Alternatively, symlinking can be accomplished manually from the command line using `ln -s` if `mysqld` is not running.
- `myisamchk` does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located.
- **Note:** When you drop a table that is using symlinks, *both the symlink and the file to which the symlink points are dropped*. This is an extremely good reason why you should *not* run `mysqld` as the system `root` or allow system users to have write access to MySQL database directories.
- If you rename a table with `ALTER TABLE ... RENAME` and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you use `ALTER TABLE ... RENAME` to move a table to another database, the table is moved to the other database directory. The old symlinks and the files to which they pointed are deleted. In other words, the new table is not symlinked.
- If you are not using symlinks, you should use the `--skip-symbolic-links` option to `mysqld` to ensure that no one can use `mysqld` to drop or rename a file outside of the data directory.

Table symlink operations that are not yet supported:

- `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.
- `BACKUP TABLE` and `RESTORE TABLE` do not respect symbolic links.
- The `.frm` file must *never* be a symbolic link (as indicated previously, only the data and index files can be symbolic links). Attempting to do this (for example, to make synonyms) produces incorrect results. Suppose that you have a database `db1` under the MySQL data directory, a table `tbl1` in this database, and in the `db1` directory you make a symlink `tbl2` that points to `tbl1`:

```
shell> cd /path/to/datadir/db1
shell> ln -s tbl1.frm tbl2.frm
shell> ln -s tbl1.MYD tbl2.MYD
shell> ln -s tbl1.MYI tbl2.MYI
```

Problems result if one thread reads `db1.tbl1` and another thread updates `db1.tbl2`:

- The query cache is “fooled” (it has no way of knowing that `tbl1` has not been updated, so it returns outdated results).
- `ALTER` statements on `tbl2` fail.

### 7.6.1.3. Using Symbolic Links for Databases on Windows

Symbolic links are enabled by default for all Windows servers. This enables you to put a database directory on a different disk by setting up a symbolic link to it. This is similar to the way that database symbolic links work on Unix, although the procedure for setting up the link is different. If you do not need symbolic links, you can disable them using the `--skip-symbolic-links` option.

On Windows, create a symbolic link to a MySQL database by creating a file in the data directory that contains the path to the destination directory. The file should be named `db_name.sym`, where `db_name` is the database name.

Suppose that the MySQL data directory is `C:\mysql\data` and you want to have database `foo` located at `D:\data\foo`. Set up a symlink using this procedure

1. Make sure that the `D:\data\foo` directory exists by creating it if necessary. If you already have a database directory named `foo` in the data directory, you should move it to `D:\data`. Otherwise, the symbolic link will be ineffective. To avoid problems, make sure that the server is not running when you move the database directory.
2. Create a text file `C:\mysql\data\foo.sym` that contains the pathname `D:\data\foo\`.

After this, all tables created in the database `foo` are created in `D:\data\foo`. *Note that the symbolic link is not used if a directory with the same name as the database exists in the MySQL data directory.*

---

# Chapter 8. Client and Utility Programs

There are many different MySQL client programs that connect to the server to access databases or perform administrative tasks. Other utilities are available as well. These do not establish a client connection with the server but perform MySQL-related operations.

This chapter provides a brief overview of these programs and then a more detailed description of each one. Each program's description indicates its invocation syntax and the options that it understands. See Chapter 4, *Using MySQL Programs*, for general information on invoking programs and specifying program options.

## 8.1. Overview of Client and Utility Programs

The following list briefly describes the MySQL client programs and utilities:

- `myisam_ftdump`

A utility that displays information about full-text indexes in MyISAM tables. See Section 8.2, “`myisam_ftdump` — Display Full-Text Index information”.

- `myisamchk`

A utility to describe, check, optimize, and repair MyISAM tables. See Section 8.3, “`myisamchk` — MyISAM Table-Maintenance Utility”.

- `myisamlog`

A utility that processes the contents of a MyISAM log file. See Section 8.4, “`myisamlog` — Display MyISAM Log File Contents”.

- `myisampack`

A utility that compresses MyISAM tables to produce smaller read-only tables. See Section 8.5, “`myisampack` — Generate Compressed, Read-Only MyISAM Tables”.

- `mysql`

The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See Section 8.6, “`mysql` — The MySQL Command-Line Tool”.

- `mysqlaccess`

A script that checks the access privileges for a hostname, username, and database combination. See Section 8.7, “`mysqlaccess` — Client for Checking Access Privileges”.

- `mysqladmin`

A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See Section 8.8, “`mysqladmin` — Client for Administering a MySQL Server”.

- `mysqlbinlog`

A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See Section 8.9, “`mysqlbinlog` — Utility for Processing Binary Log Files”.

- `mysqlcheck`

A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See Section 8.10, “`mysqlcheck` — A Table Maintenance and Repair Program”.

- `mysqldump`

A client that dumps a MySQL database into a file as SQL statements or as tab-separated text files. See Section 8.11, “`mysqldump` — A Database Backup Program”.

- `mysqlhotcopy`

A utility that quickly makes backups of MyISAM tables while the server is running. See Section 8.12, “`mysqlhotcopy` — A Database Backup Program”.

- `mysqlimport`

A client that imports text files into their respective tables using `LOAD DATA INFILE`. See Section 8.13, “`mysqlimport` — A Data Import Program”.

- `mysqlshow`

A client that displays information about databases, tables, columns, and indexes. See Section 8.14, “`mysqlshow` — Display Database, Table, and Column Information”.

- `mysql_zap`

A utility that kills processes that match a pattern. Section 8.15, “`mysql_zap` — Kill Processes That Match a Pattern”.

- `pererror`

A utility that displays the meaning of system or MySQL error codes. See Section 8.16, “`pererror` — Explain Error Codes”.

- `replace`

A utility program that performs string replacement in the input text. See Section 8.17, “`replace` — A String-Replacement Utility”.

MySQL AB also provides a number of GUI tools for administering and otherwise working with MySQL servers. For basic information about these, see Chapter 4, *Using MySQL Programs*.

Each MySQL program takes many different options. Most programs provide a `--help` option that you can use to get a full description of the program's different options. For example, try `mysql -help`.

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables:

<code>MYSQL_UNIX_PORT</code>	The default Unix socket file; used for connections to <code>localhost</code>
<code>MYSQL_TCP_PORT</code>	The default port number; used for TCP/IP connections
<code>MYSQL_PWD</code>	The default password
<code>MYSQL_DEBUG</code>	Debug trace options when debugging
<code>TMPDIR</code>	The directory where temporary tables and files are created

Use of `MYSQL_PWD` is insecure. See Section 5.9.6, “Keeping Your Password Secure”.

You can override the default option values or values specified in environment variables for all standard programs by specifying options in an option file or on the command line. See Section 4.3, “Specifying Program Options”.

## 8.2. `myisam_ftdump` — Display Full-Text Index information

`myisam_ftdump` displays information about FULLTEXT indexes in MyISAM tables. It reads the MyISAM index file directly, so it must be run on the server host where the table is located

Invoke `myisam_ftdump` like this:

```
shell> myisam_ftdump [options] tbl_name index_num
```

The `tbl_name` argument should be the name of a MyISAM table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the pathname to the table's database directory. Index numbers begin with 0.

Example: Suppose that the `test` database contains a table named `mytexttable1` that has the following definition:

```
CREATE TABLE mytexttable
(
  id   INT NOT NULL,
  txt  TEXT NOT NULL,
  PRIMARY KEY (id),
  FULLTEXT (txt)
);
```

The index on `id` is index 0 and the FULLTEXT index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
shell> myisam_ftdump mytexttable 1
```

If the pathname to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that pathname. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
shell> myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

`myisam_ftdump` understands the following options:

- `--help, -h -?`  
Display a help message and exit.
- `--count, -c`  
Calculate per-word statistics (counts and global weights).
- `--dump, -d`  
Dump the index, including data offsets and word weights.
- `--length, -l`  
Report the length distribution.
- `--stats, -s`  
Report global index statistics. This is the default operation if no other operation is specified.

- `--verbose, -v`

Verbose mode. Print more output about what the program does.

## 8.3. `myisamchk` — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes).

Invoke `myisamchk` like this:

```
shell> myisamchk [options] tbl_name ...
```

The *options* specify what you want `myisamchk` to do. They are described in the following sections. You can also get a list of options by invoking `myisamchk --help`.

With no options, `myisamchk` simply checks your table as the default operation. To get more information or to tell `myisamchk` to take corrective action, specify options as described in the following discussion.

*tbl\_name* is the database table you want to check or repair. If you run `myisamchk` somewhere other than in the database directory, you must specify the path to the database directory, because `myisamchk` has no idea where the database is located. In fact, `myisamchk` doesn't actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the `myisamchk` command line if you wish. You can also specify a table by naming its index file (the file with the `.MYI` suffix). This allows you to specify all tables in a directory by using the pattern `*.MYI`. For example, if you are in a database directory, you can check all the MyISAM tables in that directory like this:

```
shell> myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
shell> myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
shell> myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all MyISAM tables is:

```
shell> myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

If you want to check all MyISAM tables and repair any that are corrupted, you can use the following command:

```
shell> myisamchk --silent --force --fast --update-state \  
--key_buffer_size=64M --sort_buffer_size=64M \  
--read_buffer_size=1M --write_buffer_size=1M \  
/path/to/datadir/*/*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with `myisamchk`, see Section 8.3.5, “`myisamchk` Memory Usage”.

You must ensure that no other program is using the tables while you are running `myisamchk`. Otherwise, when you run `myisamchk`, it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the `mysqld` server) that hasn't yet closed the file or that has died without closing the file properly.

If `mysqld` is running, you must force it to flush any table modifications that are still buffered in memory by using `FLUSH TABLES`. You should then ensure that no one is using the tables while you are running `myisamchk`. The easiest way to avoid this problem is to use `CHECK TABLE` instead of `myisamchk` to check tables.

### 8.3.1. `myisamchk` General Options

The options described in this section can be used for any type of table maintenance operation performed by `myisamchk`. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- `--help, -?`

Display a help message and exit.

- `--debug=debug_options, -# debug_options`

Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`.

- `--silent, -s`

Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make `myisamchk` very silent.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This can be used with `-d` and `-e`. Use `-v` multiple times (`-vv`, `-vvv`) for even more output.

- `--version, -V`

Display version information and exit.

- `--wait, -w`

Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. Note that if you are running `mysqld` with external locking disabled, the table can be locked only by another `myisamchk` command.

You can also set the following variables by using `--var_name=value` syntax:

Variable	Default Value
<code>decode_bits</code>	9
<code>ft_max_word_len</code>	version-dependent
<code>ft_min_word_len</code>	4
<code>ft_stopword_file</code>	built-in list
<code>key_buffer_size</code>	523264

<code>myisam_block_size</code>	1024
<code>read_buffer_size</code>	262136
<code>sort_buffer_size</code>	2097144
<code>sort_key_blocks</code>	16
<code>stats_method</code>	<code>nulls_unequal</code>
<code>write_buffer_size</code>	262136

The possible `myisamchk` variables and their default values can be examined with `myisamchk -help`:

`sort_buffer_size` is used when the keys are repaired by sorting keys, which is the normal case when you use `--recover`.

`key_buffer_size` is used when you are checking the table with `--extend-check` or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

- You use `--safe-recover`.
- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks.

`stats_method` influences how `NULL` values are treated for index statistics collection when the `-analyze` option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in Section 5.2.2, “Server System Variables”, and Section 7.4.7, “MyISAM Index Statistics Collection”. For MySQL 5.0, `stats_method` was added in MySQL 5.0.14. For older versions, the statistics collection method is equivalent to `nulls_equal`.

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes. `ft_stopword_file` names the stopword file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in MyISAM index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

## 8.3.2. `myisamchk` Check Options

`myisamchk` supports the following options for table checking operations:

- `--check, -c`

Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- `--check-only-changed, -C`

Check only tables that have changed since the last check.

- `--extend-check, -e`

Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, `myisamchk` or `myisamchk --medium-check` should be able to determine whether there are any errors in the table.

If you are using `--extend-check` and have plenty of memory, setting the `key_buffer_size` variable to a large value helps the repair operation run faster.

- `--fast, -F`

Check only tables that haven't been closed properly.

- `--force, -f`

Do a repair operation automatically if `myisamchk` finds any errors in the table. The repair type is the same as that specified with the `--recover` or `-r` option.

- `--information, -i`

Print informational statistics about the table that is checked.

- `--medium-check, -m`

Do a check that is faster than an `--extend-check` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--read-only, -T`

Don't mark the table as checked. This is useful if you use `myisamchk` to check a table that is in use by some other application that doesn't use locking, such as `mysqld` when run with external locking disabled.

- `--update-state, -U`

Store information in the `.MYI` file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the `--check-only-changed` option, but you shouldn't use this option if the `mysqld` server is using the table and you are running it with external locking disabled.

### 8.3.3. `myisamchk` Repair Options

`myisamchk` supports the following options for table repair operations:

- `--backup, -B`  
Make a backup of the `.MYD` file as `file_name-time.BAK`
- `--character-sets-dir=path`  
The directory where character sets are installed. See Section 5.11.1, “The Character Set Used for Data and Sorting”.
- `--correct-checksum`  
Correct the checksum information for the table.
- `--data-file-length=len, -D len`  
Maximum length of the data file (when re-creating data file when it is “full”).
- `--extend-check, -e`  
Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Don't use this option unless you are desperate.
- `--force, -f`  
Overwrite old intermediate files (files with names like `tbl_name.TMD`) instead of aborting.
- `--keys-used=val, -k val`  
For `myisamchk`, the option value is a bit-value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r`.
- `--max-record-length=len`  
Skip rows larger than the given length if `myisamchk` cannot allocate memory to hold them.
- `--parallel-recover, -p`  
Uses the same technique as `-r` and `-n`, but creates all the keys in parallel, using different threads. *This is beta-quality code. Use at your own risk!*
- `--quick, -q`  
Achieve a faster repair by not modifying the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.
- `--recover, -r`  
Do a repair that can fix almost any problem except unique keys that aren't unique (which is an extremely unlikely error with MyISAM tables). If you want to recover a table, this is the option to try first. You should try `--safe-recover` only if `myisamchk` reports that the table can't

be recovered using `--recover`. (In the unlikely case that `--recover` fails, the data file remains intact.)

If you have lots of memory, you should increase the value of `sort_buffer_size`.

- `--safe-recover, -o`

Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `--recover`, but can handle a couple of very unlikely cases that `--recover` cannot. This recovery method also uses much less disk space than `--recover`. Normally, you should repair first with `--recover`, and then with `--safe-recover` only if `--recover` fails.

If you have lots of memory, you should increase the value of `key_buffer_size`.

- `--set-character-set=name`

Change the character set used by the table indexes. This option was replaced by `--set-collation` in MySQL 5.0.3.

- `--set-collation=name`

Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name. This option was added in MySQL 5.0.3.

- `--sort-recover, -n`

Force `myisamchk` to use sorting to resolve the keys even if the temporary files would be very large.

- `--tmpdir=path, -t path`

Path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. `tmpdir` can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (':') on Unix and the semicolon (;) on Windows, NetWare, and OS/2.

- `--unpack, -u`

Unpack a table that was packed with `myisampack`.

## 8.3.4. Other `myisamchk` Options

`myisamchk` supports the following options for actions other than table checks and repairs:

- `--analyze, -a`

Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a `myisamchk --description --verbose tbl_name` command or the `SHOW INDEX FROM tbl_name` statement.

- `--block-search=offset, -b offset`

Find the record that a block at the given offset belongs to.

- `--description, -d`

Print some descriptive information about the table.

- `--set-auto-increment [=value], -A [value]`

Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If *value* is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

- `--sort-index, -S`

Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=N, -R N`

Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

### 8.3.5. `myisamchk` Memory Usage

Memory allocation is important when you run `myisamchk`. `myisamchk` uses no more memory than its memory-related variables are set to. If you are going to use `myisamchk` on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get `myisamchk` to operate faster. For example, if you have more than 32MB RAM, you could use options such as these (in addition to any other options you might specify):

```
shell> myisamchk --sort_buffer_size=16M --key_buffer_size=16M \  
--read_buffer_size=1M --write_buffer_size=1M ...
```

Using `--sort_buffer_size=16M` should probably be enough for most cases.

Be aware that `myisamchk` uses temporary files in `TMPDIR`. If `TMPDIR` points to a memory filesystem, you may easily get out of memory errors. If this happens, run `myisamchk` with the `-tmpdir=path` option to specify some directory located on a filesystem that has more space.

When repairing, `myisamchk` also needs a lot of disk space:

- Double the size of the data file (the original file and a copy). This space is not needed if you do a repair with `--quick`; in this case, only the index file is re-created. This space is needed on the same filesystem as the original data file! (The copy is created in the same directory as the original.)
- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space is needed on the same filesystem as the original index file!
- When using `--recover` or `--sort-recover` (but not when using `--safe-recover`), you need space for a sort buffer. The following formula yields the amount of space required:

$$(largest\_key + row\_pointer\_length) \times number\_of\_rows \times 2$$

You can check the length of the keys and the `row_pointer_length` with `myisamchk -dv tbl_name`. This space is allocated in the temporary directory (specified by `TMPDIR` or `-tmpdir=path`).

If you have a problem with disk space during repair, you can try `--safe-recover` instead of `-recover`.

## 8.4. `myisamlog` — Display MyISAM Log File Contents

`myisamlog` processes the contents of a MyISAM log file.

Invoke `myisamlog` like this:

```
shell> myisamlog [options] [log_file [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` understands the following options:

- `-?`, `-I`  
Display a help message and exit.
- `-c N`  
Execute only *N* commands.
- `-f N`  
Specify the maximum number of open files.
- `-i`  
Display extra information before exiting.
- `-o offset`  
Specify the starting offset.
- `-p N`  
Remove *N* components from path.
- `-r`  
Perform a recovery operation.
- `-R record_pos_file record_pos`  
Specify record position file and record position.
- `-u`  
Perform an update operation.

- `-v`  
Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.
- `-w write_file`  
Specify the write file.
- `-V`  
Display version information.

## 8.5. `myisampack` — Generate Compressed, Read-Only MyISAM Tables

The `myisampack` utility compresses MyISAM tables. `myisampack` works by compressing each column in the table separately. Usually, `myisampack` packs the data file 40%-70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses `mmap()` when possible to perform memory mapping on compressed tables. If `mmap()` does not work, MySQL falls back to normal read/write file operations.

Please note the following:

- If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.
- After packing a table, it becomes read-only. This is generally intended (such as when accessing packed tables on a CD). Allowing writes to a packed table is on our TODO list, but with low priority.
- `myisampack` can pack BLOB or TEXT columns. (The older `pack_isam` program for ISAM tables did not have this capability.)

Invoke `myisampack` like this:

```
shell> myisampack [options] file_name ...
```

Each filename argument should be the name of an index (`.MYI`) file. If you are not in the database directory, you should specify the pathname to the file. It is permissible to omit the `.MYI` extension.

After you compress a table with `myisampack`, you should use `myisamchk -rq` to rebuild its indexes. Section 8.3, “`myisamchk` — MyISAM Table-Maintenance Utility”.

`myisampack` supports the following options:

- `--help, -?`  
Display a help message and exit.
- `--backup, -b`

Make a backup of each table's data file using the name *tbl\_name*.OLD.

- `--character-sets-dir=path`

The directory where character sets are installed. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. The *debug\_options* string often is `'d:t:o,file_name'`.

- `--force, -f`

Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of `mysampack` exists. (`mysampack` creates an intermediate file named *tbl\_name*.TMD in the database directory while it compresses the table. If you kill `mysampack`, the .TMD file might not be deleted.) Normally, `mysampack` exits with an error if it finds that *tbl\_name*.TMD exists. With `--force`, `mysampack` packs the table anyway.

- `--join=big_tbl_name, -j big_tbl_name`

Join all tables named on the command line into a single table *big\_tbl\_name*. All tables that are to be combined *must* have identical structure (same column names and types, same indexes, and so forth).

- `--packlength=len, -p len`

Specify the row length storage size, in bytes. The value should be 1, 2, or 3. `mysampack` stores all rows with length pointers of 1, 2, or 3 bytes. In most normal cases, `mysampack` can determine the correct length value before it begins packing the file, but it may notice during the packing process that it could have used a shorter length. In this case, `mysampack` prints a note that you could use a shorter row length the next time you pack the same file.

- `--silent, -s`

Silent mode. Write output only when errors occur.

- `--test, -t`

Do not actually pack the table, just test packing it.

- `--tmpdir=path, -T path`

Use the named directory as the location where `mysampack` creates temporary files.

- `--verbose, -v`

Verbose mode. Write information about the progress of the packing operation and its result.

- `--version, -V`

Display version information and exit.

- `--wait, -w`

Wait and retry if the table is in use. If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `mysampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
shell> ls -l station.*
```

```
-rw-rw-r-- 1 monty my 994128 Apr 17 19:00 station.MYD
-rw-rw-r-- 1 monty my 53248 Apr 17 19:00 station.MYI
-rw-rw-r-- 1 monty my 5767 Apr 17 19:00 station.frm
```

shell> **myisamchk -dvv station**

```

56	827	4	no zeros, zerofill(2)	2	9
57	831	4	no zeros, zerofill(1)	2	9

mysampack displays the following kinds of information:

- normal
 

The number of columns for which no extra packing is used.
- empty-space
 

The number of columns containing values that are only spaces. These occupy one bit.
- empty-zero
 

The number of columns containing values that are only binary zeros. These occupy one bit.
- empty-fill
 

The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a BIGINT column (eight bytes) can be stored as a TINYINT column (one byte) if all its values are in the range from -128 to 127.
- pre-space
 

The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.
- end-space
 

The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.
- table-lookup

The column had only a small number of different values, which were converted to an ENUM before Huffman compression.

- `zero`

The number of columns for which all values are zero.

- `Original trees`

The initial number of Huffman trees.

- `After join`

The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, `mysamchk -dvv` prints additional information about each column:

- `Type`

The data type. The value may contain any of the following descriptors:

- `constant`

All rows have the same value.

- `no endspace`

Do not store endspace.

- `no endspace, not_always`

Do not store endspace and do not do endspace compression for all values.

- `no endspace, no empty`

Do not store endspace. Do not store empty values.

- `table-lookup`

The column was converted to an ENUM.

- `zerofill(N)`

The most significant *N* bytes in the value are always 0 and are not stored.

- `no zeros`

Do not store zeros.

- `always zero`

Zero values are stored using one bit.

- `Huff tree`

The number of the Huffman tree associated with the column.

- `Bits`

The number of bits used in the Huffman tree.

After you run `myisampack`, you must run `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
shell> myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack` option to `myisamchk`.

## 8.6. mysql — The MySQL Command-Line Tool

`mysql` is a simple SQL shell (with GNU `readline` capabilities). It supports interactive and non-interactive use. When used interactively, query results are presented in an ASCII-table format. When used non-interactively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
shell> mysql db_name
```

Or:

```
shell> mysql --user=user_name --password=your_password db_name
```

Then type an SQL statement, end it with `;`, `\g`, or `\G` and press Enter.

You can execute SQL statements in a script file (batch file) like this:

```
shell> mysql db_name < script.sql > output.tab
```

### 8.6.1. mysql Options

`mysql` supports the following options:

- `--help, -?`

Display a help message and exit.

- `--auto-rehash`

Enable automatic rehashing. This option is on by default, which enables table and column name completion. Use `--skip-auto-rehash` to disable rehashing. That causes `mysql` to start faster, but you must issue the `rehash` command if you want to use table and column name completion.

- `--batch, -B`

Print results using tab as the column separator, with each row on a new line. With this option,

mysql does not use the history file.

- `--character-sets-dir=path`

The directory where character sets are installed. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

- `--column-names`

Write column names in results.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--database=db_name, -D db_name`

The database to use. This is useful primarily in an option file.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. The *debug\_options* string often is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysql.trace'`.

- `--debug-info, -T`

Print some debugging information when the program exits.

- `--default-character-set=charset_name`

Use *charset\_name* as the default character set. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

- `--delimiter=str`

Set the statement delimiter. The default is the semicolon character (`;`).

- `--execute=statement, -e statement`

Execute the statement and quit. The default output format is like that produced with `--batch`. See Section 4.3.1, “Using Options on the Command Line”, for some examples.

- `--force, -f`

Continue even if an SQL error occurs.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--html, -H`

Produce HTML output.

- `--ignore-spaces, -i`

Ignore spaces after function names. The effect of this is described in the discussion for the `IGNORE_SPACE` SQL mode (see Section 5.2.5, “The Server SQL Mode”).

- `--line-numbers`

Write line numbers for errors. Disable this with `--skip-line-numbers`.

- `--local-infile[={0|1}]`

Enable or disable LOCAL capability for LOAD DATA INFILE. With no value, the option enables LOCAL. The option may be given as `--local-infile=0` or `--local-infile=1` to explicitly disable or enable LOCAL. Enabling LOCAL has no effect if the server does not also support it.

- `--named-commands, -G`

Enable named mysql commands. Long-format commands are allowed, not just short-format commands. For example, `quit` and `\q` both are recognized. Use `--skip-named-commands` to disable named commands. See Section 8.6.2, “mysql Commands”.

- `--no-auto-rehash, -A`

Deprecated form of `--skip-auto-rehash`. See the description for `--auto-rehash`.

- `--no-beep, -b`

Do not beep when errors occur.

- `--no-named-commands, -g`

Disable named commands. Use the `\*` form only, or use named commands only at the beginning of a line ending with a semicolon (`;`). mysql starts with this option *enabled* by default. However, even with this option, long-format commands still work from the first line. See Section 8.6.2, “mysql Commands”.

- `--no-pager`

Deprecated form of `--skip-pager`. See the `--pager` option.

- `--no-tee`

Do not copy output to a file. Section 8.6.2, “mysql Commands”, discusses tee files further.

- `--one-database, -o`

Ignore statements except those for the default database named on the command line. This is useful for skipping updates to other databases in the binary log.

- `--pager [=command]`

Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat` [`> filename`], and so forth. This option works only on Unix. It does not work in batch mode. To disable paging, use `--skip-pager`. Section 8.6.2, “mysql Commands”, discusses output paging further.

- `--password [=password], -p [password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, you are prompted for one.

Specifying a password on the command line should be considered insecure. See Section 5.9.6, “Keeping Your Password Secure”.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--prompt=format_str`

Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in Section 8.6.2, “mysql Commands”.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use.

- `--quick, -q`

Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

- `--raw, -r`

Write column values without escape conversion. Often used with the `--batch` option.

- `--reconnect`

If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use `--skip-reconnect`.

- `--safe-updates, --i-am-a-dummy, -U`

Allow only those `UPDATE` and `DELETE` statements that specify which rows to modify by using key values. If you have set this option in an option file, you can override it by using `--safe-updates` on the command line. See Section 8.6.4, “mysql Tips”, for more information about this option.

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1.1) format. This prevents connections except for servers that use the newer password format.

- `--show-warnings`

Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode. This option was added in MySQL 5.0.6.

- `--sigint-ignore`

Ignore `SIGINT` signals (typically the result of typing Control-C).

- `--silent, -s`

Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

- `--skip-column-names, -N`

Do not write column names in results.

- `--skip-line-numbers, -L`

Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--table, -t`

Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- `--tee=filename`

Append a copy of output to the given file. This option does not work in batch mode. in Section 8.6.2, “mysql Commands”, discusses tee files further.

- `--unbuffered, -n`

Flush the buffer after each query.

- `--user=username, -u username`

The MySQL username to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

- `--version, -V`

Display version information and exit.

- `--vertical, -E`

Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

- `--wait, -w`

If the connection cannot be established, wait and retry instead of aborting.

- `--xml, -X`

Produce XML output.

You can also set the following variables by using `--var_name=value` syntax:

- `connect_timeout`

The number of seconds before connection timeout. (Default value is 0.)

- `max_allowed_packet`

The maximum packet length to send to or receive from the server. (Default value is 16MB.)

- `max_join_size`

The automatic limit for rows in a join when using `--safe-updates`. (Default value is 1,000,000.)

- `net_buffer_length`

The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- `select_limit`

The automatic limit for `SELECT` statements when using `--safe-updates`. (Default value is 1,000.)

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. *This syntax is deprecated.*

On Unix, the `mysql` client writes a record of executed statements to a history file. By default, the history file is named `.mysql_history` and is created in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.

If you do not want to maintain a history file, first remove `.mysql_history` if it exists, and then use either of the following techniques:

- Set the `MYSQL_HISTFILE` variable to `/dev/null`. To cause this setting to take effect each time you log in, put the setting in one of your shell's startup files.
- Create `.mysql_history` as a symbolic link to `/dev/null`:

```
shell> ln -s /dev/null $HOME/.mysql_history
```

You need do this only once.

## 8.6.2. `mysql` Commands

`mysql` sends each SQL statement that you issue to the server to be executed. There is also a set of commands that `mysql` itself interprets. For a list of these commands, type `help` or `\h` at the `mysql>` prompt:

```
mysql> help
```

List of all MySQL commands:

Note that all text commands must be first on line and end with ';'.

```
?          (\?) Synonym for `help'.
clear      (\c) Clear command.
connect    (\r) Reconnect to the server. Optional arguments are db and host.
delimiter (\d) Set statement delimiter. NOTE: Takes the rest of the line as
            new delimiter.
edit       (\e) Edit command with $EDITOR.
ego        (\G) Send command to mysql server, display result vertically.
exit       (\q) Exit mysql. Same as quit.
go         (\g) Send command to mysql server.
help       (\h) Display this help.
nopager    (\n) Disable pager, print to stdout.
notee      (\t) Don't write into outfile.
pager      (\P) Set PAGER [to_pager]. Print the query results via PAGER.
print      (\p) Print current command.
prompt     (\R) Change your mysql prompt.
quit       (\q) Quit mysql.
rehash     (\#) Rebuild completion hash.
source     (\.) Execute an SQL script file. Takes a file name as an argument.
status     (\s) Get status information from the server.
system     (\!) Execute a system shell command.
tee        (\T) Set outfile [to_outfile]. Append everything into given
            outfile.
use        (\u) Use another database. Takes database name as argument.
charset    (\C) Switch to another charset. Might be needed for processing binlog
warnings   (\W) Show warnings after every statement.
nowarning  (\w) Don't show warnings after every statement.
```

Each command has both a long and short form. The long form is not case sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

In the `delimiter` command, you should avoid the use of the backslash (`\`) character because that is the escape character for MySQL.

The `edit`, `nopager`, `pager`, and `system` commands work only in Unix.

The `status` command provides some information about the connection and the server you are using. If you are running in `--safe-updates` mode, `status` also prints the values for the `mysql` variables that affect your queries.

To log queries and their output, use the `tee` command. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. You can enable this feature on the command line with the `--tee` option, or interactively with the `tee` command. The `tee` file can be disabled interactively with the `notee` command. Executing `tee` again re-enables logging. Without a parameter, the previous file is used. Note that `tee` flushes query results to the file after each statement, just before `mysql` prints its next prompt.

By using the `--pager` option, it is possible to browse or search query results in interactive mode with Unix programs such as `less`, `more`, or any other similar program. If you specify no value for the option, `mysql` checks the value of the `PAGER` environment variable and sets the pager to that. Output paging can be enabled interactively with the `pager` command and disabled with `nopager`. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or `stdout` if no pager was specified.

Output paging works only in Unix because it uses the `popen()` function, which does not exist on Windows. For Windows, the `tee` option can be used instead to save query output, although this is not as convenient as `pager` for browsing output in some situations.

Here are a few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

```
mysql> pager cat > /tmp/log.txt
```

You can also pass any options for the program that you want to use as your pager:

```
mysql> pager less -n -i -S
```

- In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

```
shell> man less
```

- You can specify very complex pager commands for handling query output:

```
mysql> pager cat | tee /dr1/tmp/res.txt \  
      | tee /dr2/tmp/res2.txt | less -n -i -S
```

In this example, the command would send query results to two files in two different directories on two different filesystems mounted on `/dr1` and `/dr2`, yet still display the results onscreen via `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be

turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

The default `mysql>` prompt can be reconfigured. The string for defining the prompt can contain the following special sequences:

Option	Description
<code>\v</code>	The server version
<code>\d</code>	The default database
<code>\h</code>	The server host
<code>\p</code>	The current TCP/IP port or socket file
<code>\u</code>	Your username
<code>\U</code>	Your full <code>user_name@host_name</code> account name
<code>\\</code>	A literal <code>'\'</code> backslash character
<code>\n</code>	A newline character
<code>\t</code>	A tab character
<code>\ </code>	A space (a space follows the backslash)
<code>\_</code>	A space
<code>\R</code>	The current time, in 24-hour military time (0-23)
<code>\r</code>	The current time, standard 12-hour time (1-12)
<code>\m</code>	Minutes of the current time
<code>\y</code>	The current year, two digits
<code>\Y</code>	The current year, four digits
<code>\D</code>	The full current date
<code>\s</code>	Seconds of the current time
<code>\w</code>	The current day of the week in three-letter format (Mon, Tue, ...)
<code>\P</code>	am/pm
<code>\o</code>	The current month in numeric format
<code>\O</code>	The current month in three-letter format (Jan, Feb, ...)
<code>\c</code>	A counter that increments for each statement you issue
<code>\S</code>	Semicolon
<code>\'</code>	Single quote
<code>\"</code>	Double quote

`'\'` followed by any other letter just becomes that letter.

If you specify the `prompt` command with no argument, `mysql` resets the prompt to the default of `mysql>`.

You can set the prompt in several ways:

- *Use an environment variable.* You can set the `MYSQL_PS1` environment variable to a prompt string. For example:

```
shell> export MYSQL_PS1="(\u@\h) [\d]> "
```

- *Use a command-line option.* You can set the `--prompt` option on the command line to `mysql`. For example:

```
shell> mysql --prompt="(\u@\h) [\d]> "
(user@host) [database]>
```

- *Use an option file.* You can set the `prompt` option in the `[mysql]` group of any MySQL option file, such as `/etc/my.cnf` or the `.my.cnf` file in your home directory. For example:

```
[mysql]
prompt=(\u@\h) [\d]>\_
```

In this example, note that the backslashes are doubled. If you set the prompt using the `prompt` option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of allowable prompt options and the set of special escape sequences that are recognized in option files. (These sequences are listed in Section 4.3.2, “Using Option Files”.) The overlap may cause you problems if you use single backslashes. For example, `\s` is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `HH:MM:SS` format:

```
[mysql]
prompt="\r:\m:\s> "
```

- *Set the prompt interactively.* You can change your prompt interactively by using the `prompt` (or `\R`) command. For example:

```
mysql> prompt (\u@\h) [\d]>\_
PROMPT set to '(\u@\h) [\d]>\_'
(user@host) [database]>
(user@host) [database]> prompt
Returning to default PROMPT of mysql>
mysql>
```

### 8.6.3. Executing SQL Statements from a Text File

The `mysql` client typically is used interactively, like this:

```
shell> mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell `mysql` to read its input from that file. To do so, create a text file `text_file` that contains the statements you wish to execute. Then invoke `mysql` as shown here:

```
shell> mysql db_name < text_file
```

If you place a `USE db_name` statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
shell> mysql < text_file
```

If you are already running `mysql`, you can execute an SQL script file using the `source` or `\.` command:

```
mysql> source file_name
mysql> \. file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ' ;
```

The statement shown outputs `<info_to_display>`.

For more information about batch mode, see Section 3.5, “Using `mysql` in Batch Mode”.

## 8.6.4. `mysql` Tips

This section describes some techniques that can help you use `mysql` more effectively.

### 8.6.4.1. Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with `\G` instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
***** 1. row *****
  msg_nro: 3068
    date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
      reply: monty@no.spam.com
  mail_to: "Thimble Smith" <tim@no.spam.com>
    sbj: UTF-8
    txt: >>>> "Thimble" == Thimble Smith writes:
```

```
Thimble> Hi. I think this is a good idea. Is anyone familiar
Thimble> with UTF-8 or Unicode? Otherwise, I'll put this on my
Thimble> TODO list and see what happens.
```

Yes, please do that.

```
Regards,
Monty
  file: inbox-jani-1
  hash: 190402944
1 row in set (0.09 sec)
```

### 8.6.4.2. Using the `--safe-updates` Option

For beginners, a useful startup option is `--safe-updates` (or `--i-am-a-dummy`, which has the same effect). It is helpful for cases when you might have issued a `DELETE FROM tbl_name` statement but forgotten the `WHERE` clause. Normally, such a statement deletes all rows from the table. With `--safe-updates`, you can delete rows only by specifying the key values that identify them. This helps prevent accidents.

When you use the `--safe-updates` option, `mysql` issues the following statement when it connects to the MySQL server:

```
SET SQL_SAFE_UPDATES=1,SQL_SELECT_LIMIT=1000,SQL_MAX_JOIN_SIZE=1000000;
```

See Section 13.5.3, “SET Syntax”.

The SET statement has the following effects:

- You are not allowed to execute an UPDATE or DELETE statement unless you specify a key constraint in the WHERE clause or provide a LIMIT clause (or both). For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;
```

```
UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- The server limits all large SELECT results to 1,000 rows unless the statement includes a LIMIT clause.
- The server aborts multiple-table SELECT statements that probably need to examine more than 1,000,000 row combinations.

To specify limits different from 1,000 and 1,000,000, you can override the defaults by using the `--select_limit` and `--max_join_size` options:

```
shell> mysql --safe-updates --select_limit=500 --max_join_size=10000
```

### 8.6.4.3. Disabling mysql Auto-Reconnect

If the `mysql` client loses its connection to the server while sending a query, it immediately and automatically tries to reconnect once to the server and send the query again. However, even if `mysql` succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id:      1
Current database:  test

Query OK, 1 row affected (1.30 sec)

mysql> SELECT * FROM t;
+-----+
| a     |
+-----+
| NULL |
+-----+
1 row in set (0.05 sec)
```

The `@a` user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have `mysql` terminate with an error if the connection has been lost, you can start the `mysql` client with the `--skip-reconnect` option.

## 8.7. mysqlaccess — Client for Checking Access Privileges

`mysqlaccess` is a diagnostic tool that Yves Carlier has provided for the MySQL distribution. It checks the access privileges for a hostname, username, and database combination. Note that `mysqlaccess` checks access using only the user, db, and host tables. It does not check table, column, or routine privileges specified in the `tables_priv`, `columns_priv`, or `procs_priv` tables.

Invoke `mysqlaccess` like this:

```
shell> mysqlaccess [host_name [user_name [db_name]]] [options]
```

`mysqlaccess` understands the following options:

- `--help, -?`  
Display a help message and exit.
- `--brief, -b`  
Generate reports in single-line tabular format.
- `--commit`  
Copy the new access privileges from the temporary tables to the original grant tables. The grant tables must be flushed for the new privileges to take effect. (For example, execute a `mysqladmin reload` command.)
- `--copy`  
Reload the temporary grant tables from original ones.
- `--db=db_name, -d db_name`  
Specify the database name.
- `--debug=N`  
Specify the debug level. *N* can be an integer from 0 to 3.
- `--host=host_name, -h host_name`  
The hostname to use in the access privileges.
- `--howto`  
Display some examples that show how to use `mysqlaccess`.
- `--old_server`  
Assume that the server is an old MySQL server (before MySQL 3.21) that does not yet know how to handle full `WHERE` clauses.
- `--password[=password], -p[password]`  
The password to use when connecting to the server. If you omit the *password* value following the `--password` or `-p` option on the command line, you are prompted for one.  
Specifying a password on the command line should be considered insecure. See Section 5.9.6, “Keeping Your Password Secure”.
- `--plan`  
Display suggestions and ideas for future releases.
- `--preview`  
Show the privilege differences after making changes to the temporary grant tables.
- `--relnotes`  
Display the release notes.
- `--rhost=host_name, -H host_name`  
Connect to the MySQL server on the given host.

- `--rollback`

Undo the most recent changes to the temporary grant tables.

- `--spassword[=password], -P[password]`

The password to use when connecting to the server as the superuser. If you omit the *password* value following the `--password` or `-P` option on the command line, you are prompted for one.

Specifying a password on the command line should be considered insecure. See Section 5.9.6, “Keeping Your Password Secure”.

- `--superuser=user_name, -U user_name`

Specify the username for connecting as the superuser.

- `--table, -t`

Generate reports in table format.

- `--user=user_name, -u user_name`

The username to use in the access privileges.

- `--version, -v`

Display version information and exit.

If your MySQL distribution is installed in some non-standard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL      = '/usr/local/bin/mysql';      # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error will occur when you run `mysqlaccess`.

## 8.8. `mysqladmin` — Client for Administering a MySQL Server

`mysqladmin` is a client for performing administrative operations. You can use it to check the server's configuration and current status, to create and drop databases, and more.

Invoke `mysqladmin` like this:

```
shell> mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

`mysqladmin` supports the commands described in the following list. Some of the commands take an argument following the command name.

- `create db_name`

Create a new database named *db\_name*.

- `debug`

Tell the server to write debug information to the error log.

- `drop db_name`  
Delete the database named `db_name` and all its tables.
- `extended-status`  
Display the server status variables and their values.
- `flush-hosts`  
Flush all information in the host cache.
- `flush-logs`  
Flush all logs.
- `flush-privileges`  
Reload the grant tables (same as `reload`).
- `flush-status`  
Clear status variables.
- `flush-tables`  
Flush all tables.
- `flush-threads`  
Flush the thread cache.
- `kill id, id, ...`  
Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.
- `old-password new-password`  
This is like the `password` command but stores the password using the old (pre-4.1) password-hashing format. (See Section 5.8.9, “Password Hashing as of MySQL 4.1”.)
- `password new-password`  
Set a new password. This changes the password to `new-password` for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysql-admin` (or any other client program) using the same account, you will need to specify the new password.  
  
If the `new-password` value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotes. On Windows, be sure to use double quotes rather than single quotes; single quotes are not stripped from the password, but rather are interpreted as part of the password. For example:  
  

```
shell> mysqladmin password "my new password"
```
- `ping`  
Check whether the server is alive. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.
- `processlist`

Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See Section 13.5.4.19, “`SHOW PROCESSLIST` Syntax”.)

- `reload`  
Reload the grant tables.
- `refresh`  
Flush all tables and close and open log files.
- `shutdown`  
Stop the server.
- `start-slave`  
Start replication on a slave server.
- `status`  
Display a short server status message.
- `stop-slave`  
Stop replication on a slave server.
- `variables`  
Display the server system variables and their values.
- `version`  
Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
shell> mysqladmin proc stat
+-----+-----+-----+-----+-----+-----+-----+-----+
| Id | User | Host          | db | Command | Time | State | Info          |
+-----+-----+-----+-----+-----+-----+-----+-----+
| 51 | monty | localhost    |    | Query   | 0    |      | show processlist |
+-----+-----+-----+-----+-----+-----+-----+-----+
Uptime: 1473624  Threads: 1  Questions: 39487
Slow queries: 0  Opens: 541  Flush tables: 1
Open tables: 19  Queries per second avg: 0.0268
```

The `mysqladmin status` command result displays the following values:

- `Uptime`  
The number of seconds the MySQL server has been running.
- `Threads`  
The number of active threads (clients).
- `Questions`  
The number of questions (queries) from clients since the server was started.

- `Slow queries`  
The number of queries that have taken more than `long_query_time` seconds. See Section 5.12.4, “The Slow Query Log”.
- `Opens`  
The number of tables the server has opened.
- `Flush tables`  
The number of `flush-*`, `refresh`, and `reload` commands the server has executed.
- `Open tables`  
The number of tables that currently are open.
- `Memory in use`  
The amount of memory allocated directly by `mysqld`. This value is displayed only when MySQL has been compiled with `--with-debug=full`.
- `Maximum memory used`  
The maximum amount of memory allocated directly by `mysqld`. This value is displayed only when MySQL has been compiled with `--with-debug=full`.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options:

- `--help, -?`  
Display a help message and exit.
- `--character-sets-dir=path`  
The directory where character sets are installed. See Section 5.11.1, “The Character Set Used for Data and Sorting”.
- `--compress, -C`  
Compress all information sent between the client and the server if both support compression.
- `--count=N, -c N`  
The number of iterations to make for repeated command execution. This works only with the `--sleep` option.
- `--debug=[debug_options], -# [debug_options]`  
Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysqladmin.trace'`.
- `--default-character-set=charset_name`  
Use `charset_name` as the default character set. See Section 5.11.1, “The Character Set Used for Data and Sorting”.
- `--force, -f`

Do not ask for confirmation for the `drop db_name` command. With multiple commands, continue even if an error occurs.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password` or `-p` option on the command line, you are prompted for one.

Specifying a password on the command line should be considered insecure. See Section 5.9.6, “Keeping Your Password Secure”.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

The connection protocol to use.

- `--relative, -r`

Show the difference between the current and previous values when used with the `--sleep` option. Currently, this option works only with the `extended-status` command.

- `--silent, -s`

Exit silently if a connection to the server cannot be established.

- `--sleep=delay, -i delay`

Execute commands repeatedly, sleeping for *delay* seconds in between. The `--count` option determines the number of iterations.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--user=user_name, -u user_name`

The MySQL username to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

- `--vertical, -E`

Print output vertically. This is similar to `--relative`, but prints output vertically.

- `--wait[=count], -w[count]`

If the connection cannot be established, wait and retry instead of aborting. If a *count* value is given, it indicates the number of times to retry. The default is one time.

You can also set the following variables by using `--var_name=value` syntax:

- `connect_timeout`

The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

- `shutdown_timeout`

The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. *This syntax is deprecated.*

## 8.9. mysqlbinlog — Utility for Processing Binary Log Files

The binary log files that the server generates are written in binary format. To examine these files in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to read relay log files written by a slave server in a replication setup. Relay logs have the same format as binary log files.

Invoke `mysqlbinlog` like this:

```
shell> mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
shell> mysqlbinlog binlog.000003
```

The output includes all events contained in `binlog.000003`. Event information includes the statement executed, the time the statement took, the thread ID of the client that issued it, the timestamp when it was executed, and so forth.

The output from `mysqlbinlog` can be re-executed (for example, by using it as input to `mysql`) to reapply the statements in the log. This is useful for recovery operations after a server crash. For other usage examples, see the discussion later in this section.

Normally, you use `mysqlbinlog` to read binary log files directly and apply them to the local MySQL server. It is also possible to read binary logs from a remote server by using the `--read-from-remote-server` option. When you read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`; they are ignored except when you also use the `--read-from-remote-server` option.

Binary logs and relay logs are discussed further in Section 5.12.3, “The Binary Log”, and Section 6.3.4, “Replication Relay and Status Files”.

`mysqlbinlog` supports the following options:

- `--help, -?`

Display a help message and exit.

- `--character-sets-dir=path`

The directory where character sets are installed. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

- `--database=db_name, -d db_name`

List entries for just this database (local log only).

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical *debug\_options* string is often `'d:t:o,file_name'`.

- `--disable-log-bin, -D`

Disable binary logging. This is useful for avoiding an endless loop if you use the `--to-last-log` option and are sending the output to the same MySQL server. This option also is useful when restoring after a crash to avoid duplication of the statements you have logged.

This option requires that you have the SUPER privilege. It causes `mysqlbinlog` to include a `SET SQL_LOG_BIN=0` statement in its output to disable binary logging of the remaining output. The SET statement is ineffective unless you have the SUPER privilege.

- `--force-read, -f`

With this option, if `mysqlbinlog` reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, `mysqlbinlog` stops if it reads such an event.

- `--hexdump, -H`

Display a hex dump of the log in comments. This output can be helpful for replication debugging. Hex dump format is discussed later in this section. This option was added in MySQL 5.0.16.

- `--host=host_name, -h host_name`

Get the binary log from the MySQL server on the given host.

- `--local-load=path, -l path`

Prepare local temporary files for `LOAD DATA INFILE` in the specified directory.

- `--offset=N, -o N`

Skip the first *N* entries in the log.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password` or `-p` option on the command line, you are prompted for one.

Specifying a password on the command line should be considered insecure. See Section 5.9.6, “Keeping Your Password Secure”.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for connecting to a remote server.

- `--position=N, -j N`

Deprecated. Use `--start-position` instead.

- `--protocol={TCP | SOCKET | PIPE | MEMORY}`

The connection protocol to use.

- `--read-from-remote-server, -R`

Read the binary log from a MySQL server rather than reading a local log file. Any connection parameter options are ignored unless this option is given as well. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`.

- `--result-file=name, -r name`

Direct output to the given file.

- `--short-form, -s`

Display only the statements contained in the log, without any extra information.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--start-datetime=datetime`

Start reading the binary log at the first event having a timestamp equal to or later than the *datetime* argument. The *datetime* value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

```
shell> mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
```

This option is useful for point-in-time recovery. See Section 5.10.2, “Example Backup and Recovery Strategy”.

- `--stop-datetime=datetime`

Stop reading the binary log at the first event having a timestamp equal or posterior to the *datetime* argument. This option is useful for point-in-time recovery. See the description of the `--start-datetime` option for information about the *datetime* value.

- `--start-position=N`

Start reading the binary log at the first event having a position equal to the *N* argument. This option applies to the first log file named on the command line.

- `--stop-position=N`

Stop reading the binary log at the first event having a position equal or greater than the *N* argument. This option applies to the last log file named on the command line.

- `--to-last-log, -t`

Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server`.

- `--user=user_name, -u user_name`

The MySQL username to use when connecting to a remote server.

- `--version, -V`

Display version information and exit.

You can also set the following variable by using `--var_name=value` syntax:

- `open_files_limit`

Specify the number of open file descriptors to reserve.

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. *This syntax is deprecated.*

You can pipe the output of `mysqlbinlog` into the `mysql` client to execute the statements contained in the binary log. This is used to recover from a crash when you have an old backup (see Section 5.10.1, “Database Backups”). For example:

```
shell> mysqlbinlog binlog.000001 | mysql
```

Or:

```
shell> mysqlbinlog binlog.[0-9]* | mysql
```

You can also redirect the output of `mysqlbinlog` to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the `mysql` program.

`mysqlbinlog` has the `--start-position` option, which prints only those statements with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the `--stop-datetime` option (to be able to say, for example, “roll forward my databases to how they were today at 10:30 a.m.”).

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* connection to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -e "source /tmp/statements.sql"
```

`mysqlbinlog` can produce output that reproduces a `LOAD DATA INFILE` operation without the original data file. `mysqlbinlog` copies the data to a temporary file and writes a `LOAD DATA LOCAL INFILE` statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the `--local-load op-`

tion.

Because `mysqlbinlog` converts `LOAD DATA INFILE` statements to `LOAD DATA LOCAL INFILE` statements (that is, it adds `LOCAL`), both the client and the server that you use to process the statements must be configured to allow `LOCAL` capability. See Section 5.7.4, “Security Issues with `LOAD DATA LOCAL`”.

**Warning:** The temporary files created for `LOAD DATA LOCAL` statements are *not* automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like `original_file_name-#-#`.

The `--hexdump` option produces a hex dump of the log contents in comments:

```
shell> mysqlbinlog --hexdump master-bin.000001
```

With the preceding command, the output might look like this:

```
/*!40019 SET @@session.max_insert_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
# at 4
#051024 17:24:13 server id 1  end_log_pos 98
# Position Timestamp  Type  Master ID      Size      Master Pos  Flags
# 00000004 9d fc 5c 43  0f  01 00 00 00    5e 00 00 00  62 00 00 00  00 00
# 00000017 04 00 35 2e 30 2e 31 35  2d 64 65 62 75 67 2d 6c  |..5.0.15.debug.l
# 00000027 6f 67 00 00 00 00 00 00  00 00 00 00 00 00 00 00  |og.....
# 00000037 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00  |.....
# 00000047 00 00 00 00 9d fc 5c 43  13 38 0d 00 08 00 12 00  |.....C.8.....
# 00000057 04 04 04 04 12 00 00 4b  00 04 1a      |.....K...|
#          Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
#          at startup
ROLLBACK;
```

Hex dump output currently contains the following elements. This format might change in the future.

- **Position:** The byte position within the log file.
- **Timestamp:** The event timestamp. In the example shown, '9d fc 5c 43' is the representation of '051024 17:24:13' in hexadecimal.
- **Type:** The type of the log event. In the example shown, '0f' means that the example event is a `FORMAT_DESCRIPTION_EVENT`. The following table lists the possible types.

Type	Name	Meaning
00	UNKNOWN_EVENT	This event should never be present in the log.
01	START_EVENT_V3	This indicates the start of a log file written by MySQL 4 or earlier.
02	QUERY_EVENT	The most common type of events. These contain statements executed on the master.
03	STOP_EVENT	Indicates that master has stopped.
04	ROTATE_EVENT	Written when the master switches to a new log file.
05	INTVAR_EVENT	Used mainly for <code>AUTO_INCREMENT</code> values and when the <code>LAST_INSERT_ID()</code> function is used in the statement.
06	LOAD_EVENT	Used for <code>LOAD DATA INFILE</code> in MySQL 3.23.
07	SLAVE_EVENT	Reserved for future use.
08	CREATE_FILE_EVENT	Used for <code>LOAD DATA INFILE</code> statements. This indicates the start of execution of such a statement. A temporary file is created on the slave.

	NT	Used in MySQL 4 only.
09	AP- PEND_BLOCK_E VENT	Contains data for use in a LOAD DATA INFILE statement. The data is stored in the temporary file on the slave.
0a	EX- EC_LOAD_EVEN T	Used for LOAD DATA INFILE statements. The contents of the temporary file is stored in the table on the slave. Used in MySQL 4 only.
0b	DE- LETE_FILE_EV ENT	Rollback of a LOAD DATA INFILE statement. The temporary file should be deleted on slave.
0c	NEW_LOAD_EVE NT	Used for LOAD DATA INFILE in MySQL 4 and earlier.
0d	RAND_EVENT	Used to send information about random values if the RAND ( ) function is used in the statement.
0e	USER_VAR_EVE NT	Used to replicate user variables.
0f	FORMAT_DESCR IPTION_EVENT	This indicates the start of a log file written by MySQL 5 or later.
10	XID_EVENT	Event indicating commit of an XA transaction.
11	BE- GIN_LOAD_QUE RY_EVENT	Used for LOAD DATA INFILE statements in MySQL 5 and later.
12	EX- ECUTE_LOAD_Q UERY_EVENT	Used for LOAD DATA INFILE statements in MySQL 5 and later.
13	TA- BLE_MAP_EVEN T	Reserved for future use.
14	WRITE_ROWS_E VENT	Reserved for future use.
15	UP- DATE_ROWS_EV ENT	Reserved for future use.
16	DE- LETE_ROWS_EV ENT	Reserved for future use.

- `Master ID`: The server id of the master that created the event.
- `Size`: The size in bytes of the event.
- `Master Pos`: The position of the event in the original master log file.
- `Flags`: 16 flags. Currently, the following flags are used. The others are reserved for the future.

Flag	Name	Meaning
01	LOG_EVENT_BI NLOG_IN_USE_ F	Log file correctly closed. (Used only in FORMAT_DESCRIPTION_EVENT.) If this flag is set (if the flags are, for example, '01 00') in a FORMAT_DESCRIPTION_EVENT, the log file has not been properly closed. Most probably this is because of a master crash (for example, due to power failure).
02		Reserved for future use.
04	LOG_EVENT_TH	Set if the event is dependent on the connection it was executed in (for ex-

	READ_SPECIFIC_F	ample, '04 00'), for example, if the event uses temporary tables.
08	LOG_EVENT_SUPPRESS_USE_F	Set in some circumstances when the event is not dependent on the default database.

The other flags are reserved for future use.

## 8.10. `mysqlcheck` — A Table Maintenance and Repair Program

The `mysqlcheck` client checks, repairs, optimizes, and analyzes tables.

`mysqlcheck` is similar in function to `myisamchk`, but works differently. The main operational difference is that `mysqlcheck` must be used when the `mysqld` server is running, whereas `myisamchk` should be used when it is not. The benefit of using `mysqlcheck` is that you do not have to stop the server to check or repair your tables.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in Chapter 13, *SQL Statement Syntax*.

The MyISAM storage engine supports all four statements, so `mysqlcheck` can be used to perform all four operations on MyISAM tables. Other storage engines do not necessarily support all operations. In such cases, an error message is displayed. For example, if `test.t` is a MEMORY table, an attempt to check it produces this result:

```
shell> mysqlcheck test t
test.t
note      : The storage engine for the table doesn't support check
```

There are three general ways to invoke `mysqlcheck`:

```
shell> mysqlcheck [options] db_name [tables]
shell> mysqlcheck [options] --databases db_name1 [db_name2 db_name3...]
shell> mysqlcheck [options] --all-databases
```

If you do not name any tables following `db_name` or if you use the `--databases` or `--all-databases` option, entire databases are checked.

`mysqlcheck` has a special feature compared to other client programs. The default behavior of checking tables (`--check`) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables on command.

The following names can be used to change `mysqlcheck` default behavior:

<code>mysqlrepair</code>	The default option is <code>--repair</code>
<code>mysqlanalyze</code>	The default option is <code>--analyze</code>
<code>mysqloptimize</code>	The default option is <code>--optimize</code>

`mysqlcheck` supports the following options:

- `--help, -?`  
Display a help message and exit.
- `--all-databases, -A`  
Check all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.
- `--all-in-1, -1`  
Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.
- `--analyze, -a`  
Analyze the tables.
- `--auto-repair`  
If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.
- `--character-sets-dir=path`  
The directory where character sets are installed. See Section 5.11.1, “The Character Set Used for Data and Sorting”.
- `--check, -c`  
Check the tables for errors. This is the default operation.
- `--check-only-changed, -C`  
Check only tables that have changed since the last check or that have not been closed properly.
- `--check-upgrade, -g`  
Invoke `CHECK TABLE` with the `FOR UPGRADE` option to check tables for incompatibilities with the current version of the server. This option was added in MySQL 5.0.19.
- `--compress`  
Compress all information sent between the client and the server if both support compression.
- `--databases, -B`  
Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names.
- `--debug[=debug_options], -# [debug_options]`  
Write a debugging log. A typical `debug_options` string is often `'d:t:o,file_name'`.
- `--default-character-set=charset_name`  
Use `charset_name` as the default character set. See Section 5.11.1, “The Character Set Used for Data and Sorting”.
- `--extended, -e`  
If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- `--fast, -F`

Check only tables that have not been closed properly.

- `--force, -f`

Continue even if an SQL error occurs.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--medium-check, -m`

Do a check that is faster than an `--extended` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--optimize, -o`

Optimize the tables.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password` or `-p` option on the command line, you are prompted for one.

Specifying a password on the command line should be considered insecure. See Section 5.9.6, “Keeping Your Password Secure”.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use.

- `--quick, -q`

If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- `--repair, -r`

Perform a repair that can fix almost anything except unique keys that are not unique.

- `--silent, -s`

Silent mode. Print only error messages.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--tables`

Overrides the `--databases` or `-B` option. All name arguments following the option are regarded as table names.

- `--use-frm`

For repair operations on MyISAM tables, get the table structure from the `.frm` file so that the table can be repaired even if the `.MYI` header is corrupted.

- `--user=user_name, -u user_name`

The MySQL username to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print information about the various stages of program operation.

- `--version, -V`

Display version information and exit.

## 8.11. `mysqldump` — A Database Backup Program

The `mysqldump` client is a backup program originally written by Igor Romanenko. It can be used to dump a database or a collection of databases for backup or for transferring the data to another SQL server (not necessarily a MySQL server). The dump contains SQL statements to create the table or populate it, or both.

If you are doing a backup on the server, and your tables all are MyISAM tables, consider using the `mysqlhotcopy` instead because it can accomplish faster backups and faster restores. See Section 8.12, “`mysqlhotcopy` — A Database Backup Program”.

There are three general ways to invoke `mysqldump`:

```
shell> mysqldump [options] db_name [tables]  
shell> mysqldump [options] --databases db_name1 [db_name2 db_name3...]  
shell> mysqldump [options] --all-databases
```

If you do not name any tables following `db_name` or if you use the `--databases` or `--all-databases` option, entire databases are dumped.

To get a list of the options your version of `mysqldump` supports, execute `mysqldump --help`.

If you run `mysqldump` without the `--quick` or `--opt` option, `mysqldump` loads the whole result set into memory before dumping the result. This can be a problem if you are dumping a big database. The `--opt` option is enabled by default, but can be disabled with `--skip-opt`.

If you are using a recent copy of the `mysqldump` program to generate a dump to be reloaded into a very old MySQL server, you should not use the `--opt` or `--extended-insert` option. Use `--skip-opt` instead.

`mysqldump` supports the following options:

- `--help, -?`

Display a help message and exit.

- `--add-drop-database`

Add a `DROP DATABASE` statement before each `CREATE DATABASE` statement.

- `--add-drop-table`

Add a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-locks`

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See Section 7.2.16, “Speed of `INSERT` Statements”.

- `--all-databases, -A`

Dump all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

- `--allow-keywords`

Allow creation of column names that are keywords. This works by prefixing each column name with the table name.

- `--character-sets-dir=path`

The directory where character sets are installed. See Section 5.11.1, “The Character Set Used for Data and Sorting”.

- `--comments, -i`

Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress additional, use `--skip-comments`.

- `--compact`

Produce less verbose output. This option suppresses comments and enables the `--skip-add-drop-table`, `--no-set-names`, `--skip-disable-keys`, and `--skip-add-locks` options.

- `--compatible=name`

Produce output that is more compatible with other database systems or with older MySQL servers. The value of `name` can be `ansi`, `mysql323`, `mysql40`, `postgresql`, `oracle`, `mssql`, `db2`, `maxdb`, `no_key_options`, `no_table_options`, or `no_field_options`. To use several values, separate them by commas. These values have the same meaning as the corresponding options for setting the server SQL mode. See Section 5.2.5, “The Server SQL Mode”.

This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are currently available for making dump output more compatible. For example, `--compatible=oracle` does not map data types to Oracle types or use Oracle comment syntax.

- `--complete-insert, -c`

Use complete `INSERT` statements that include column names.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--create-options`

Include all MySQL-specific table options in the `CREATE TABLE` statements.

- `--databases, -B`

Dump several databases. Normally, `mysqldump` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` and `USE` statements are included in the output before each new database.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. The *debug\_options* string is often `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysqldump.trace'`.

- `--default-character-set=charset_name`

Use *charset\_name* as the default character set. See Section 5.11.1, “The Character Set Used for Data and Sorting”. If not specified, `mysqldump` uses `utf8`.

- `--delayed-insert`

Write `INSERT DELAYED` statements rather than `INSERT` statements.

- `--delete-master-logs`

On a master replication server, delete the binary logs after performing the dump operation. This option automatically enables `--master-data`.

- `--disable-keys, -K`

For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective for MyISAM tables only.

- `--extended-insert, -e`

Use multiple-row `INSERT` syntax that include several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `-`  
`--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`, `-`  
`--lines-terminated-by=...`

These options are used with the `-T` option and have the same meaning as the corresponding clauses for `LOAD DATA INFILE`. See Section 13.2.5, “`LOAD DATA INFILE` Syntax”.

- `--first-slave, -x`

Deprecated. Now renamed to `--lock-all-tables`.

- `--flush-logs, -F`

Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. Note that if you use this option in combination with the `--all-databases` (or `-A`) option, the logs are flushed *for each database dumped*. The exception is when using `--lock-all-tables` or `--master-data`: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with either `--lock-all-tables` or `--master-data`.

- `--force, -f`

Continue even if an SQL error occurs during a table dump.

- `--host=host_name, -h host_name`

Dump data from the MySQL server on the given host. The default host is `localhost`.

- `--hex-blob`

Dump binary columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, and `BLOB`. As of MySQL 5.0.13, `BIT` columns are affected as well.

- `--ignore-table=db_name.tbl_name`

Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times.

- `--insert-ignore`

Write `INSERT` statements with the `IGNORE` option.

- `--lock-all-tables, -x`

Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`.

- `--lock-tables, -l`

Lock all tables before starting the dump. The tables are locked with `READ LOCAL` to allow concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB` and `BDB`, `--single-transaction` is a much better option, because it does not need to lock the tables at all.

Please note that when dumping multiple databases, `--lock-tables` locks tables for each database separately. So, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

- `--master-data[=value]`

Write the binary log filename and position to the output. This option requires the `RELOAD` privilege and the binary log must be enabled. If the option value is equal to 1, the position and filename are written to the dump output in the form of a `CHANGE MASTER` statement that makes a slave server start from the correct position in the master's binary logs if you use this SQL dump of the master to set up a slave. If the option value is equal to 2, the `CHANGE MASTER` statement is written as an SQL comment. This is the default action if `value` is omitted.

The `--master-data` option turns on `--lock-all-tables`, unless `--single-transaction` also is specified (in which case, a global read lock is only acquired a short time at the beginning of the dump. See also the description for `--single-transaction`). In all cases, any action on logs happens at the exact moment of the dump. This option automatically turns off `--lock-tables`.

- `--no-autocommit`

Enclose the `INSERT` statements for each dumped table within `SET AUTOCOMMIT=0` and `COMMIT` statements.

- `--no-create-db, -n`

This option suppresses the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` or `--all-databases` option is given.

- `--no-create-info, -t`

Do not write `CREATE TABLE` statements that re-create each dumped table.

- `--no-data, -d`

Do not write any row information for the table. This is very useful if you want to dump only the `CREATE TABLE` statement for the table.

- `--opt`

This option is shorthand; it is the same as specifying `--add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset`. It should give you a fast dump operation and produce a dump file that can be reloaded into a MySQL server quickly.

*This option is enabled by default, but can be disabled with `--skip-opt`. To disable only certain of the options enabled by `--opt`, use their `--skip` forms; for example, `--skip-add-drop-table` or `--skip-quick`.*

- `--order-by-primary`

Sorts each table's rows by its primary key, or its first unique index, if such an index exists. This is useful when dumping a MyISAM table to be loaded into an InnoDB table, but will make the dump itself take considerably longer.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password` or `-p` option on the command line, you are prompted for one.

Specifying a password on the command line should be considered insecure. See Section 5.9.6, “Keeping Your Password Secure”.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use.

- `--quick, -q`

This option is useful for dumping large tables. It forces `mysqldump` to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- `--quote-names, -Q`

Quote database, table, and column names within ‘`’ characters. If the `ANSI_QUOTES` SQL mode is enabled, names are quoted within ‘”’ characters. This option is enabled by default. It can be disabled with `--skip-quote-names`, but this option should be given after any option such as `--compatible` that may enable `--quote-names`.

- `--result-file=file, -r file`

Direct output to a given file. This option should be used on Windows to prevent newline ‘\n’ characters from being converted to ‘\r\n’ carriage return/newline sequences.

- `--routines, -R`

Dump stored routines (functions and procedures) from the dumped databases. The output generated by using `--routines` contains `CREATE PROCEDURE` and `CREATE FUNCTION` statements to re-create the routines. However, these statements do not include attributes such as the routine creation and modification timestamps. This means that when the routines are reloaded, they will be created with the timestamps equal to the reload time.

If you require routines to be re-created with their original timestamp attributes, do not use `--routines`. Instead, dump and reload the contents of the `mysql.proc` table directly, using a MySQL account that has appropriate privileges for the `mysql` database.

This option was added in MySQL 5.0.13. Before that, stored routines are not dumped. Routine `DEFINER` values are not dumped until MySQL 5.0.20. This means that before 5.0.20, when routines are reloaded, they will be created with the definer set to the reloading user. If you require routines to be re-created with their original definer, dump and load the contents of the `mysql.proc` table directly as described earlier.

- `--set-charset`

Add `SET NAMES default_character_set` to the output. This option is enabled by default. To suppress the `SET NAMES` statement, use `--skip-set-charset`.

- `--single-transaction`

This option issues a `BEGIN SQL` statement before dumping data from the server. It is useful only with transactional tables such as `InnoDB` and `BDB`, because then it dumps the consistent state of the database at the time when `BEGIN` was issued without blocking any applications.

When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

The `--single-transaction` option and the `--lock-tables` option are mutually exclusive, because `LOCK TABLES` causes any pending transactions to be committed implicitly.

To dump big tables, you should combine this option with `--quick`.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--skip-comments`

See the description for the `--comments` option.

- `--tab=path, -T path`

Produce tab-separated data files. For each dumped table, `mysqldump` creates a `tbl_name.sql` file that contains the `CREATE TABLE` statement that creates the table, and a `tbl_name.txt` file that contains its data. The option value is the directory in which to write the files.

By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-xxx` and `--lines--xxx` options.

**Note:** This option should be used only when `mysqldump` is run on the same machine as the `mysqld` server. You must have the `FILE` privilege, and the server must have permission to write files in the directory that you specify.

- `--tables`

Override the `--databases` or `-B` option. All name arguments following the option are regarded as table names.

- `--triggers`

Dump triggers for each dumped table. This option is enabled by default; disable it with `--skip-triggers`. This option was added in MySQL 5.0.11. Before that, triggers are not

dumped.

- `--tz-utc`

Add `SET TIME_ZONE='+00:00'` to the dump file so that `TIMESTAMP` columns can be dumped and reloaded between servers in different time zones. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change. `--tz-utc` also protects against changes due to daylight saving time. `--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`. This option was added in MySQL 5.0.15.

- `--user=user_name, -u user_name`

The MySQL username to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

- `--where='where_condition', -w 'where_condition'`

Dump only rows selected by the given `WHERE` condition. Note that quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

Examples:

```
--where="user='jimf' "  
-w"userid>1"  
-w"userid<1"
```

- `--xml, -X`

Write dump output as well-formed XML.

You can also set the following variables by using `--var_name=value` syntax:

- `max_allowed_packet`

The maximum size of the buffer for client/server communication. The maximum is 1GB.

- `net_buffer_length`

The initial size of the buffer for client/server communication. When creating multiple-row-insert statements (as with option `--extended-insert` or `--opt`), `mysqldump` creates rows up to `net_buffer_length` length. If you increase this variable, you should also ensure that the `net_buffer_length` variable in the MySQL server is at least this large.

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. *This syntax is deprecated.*

The most common use of `mysqldump` is probably for making a backup of an entire database:

```
shell> mysqldump --opt db_name > backup-file.sql
```

You can read the dump file back into the server like this:

```
shell> mysql db_name < backup-file.sql
```

Or like this:

```
shell> mysql -e "source /path-to-backup/backup-file.sql" db_name
```

mysqldump is also very useful for populating databases by copying data from one MySQL server to another:

```
shell> mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

It is possible to dump several databases with one command:

```
shell> mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > all_databases.sql
```

For InnoDB tables, mysqldump provides a way of making an online backup:

```
shell> mysqldump --all-databases --single-transaction > all_databases.sql
```

This backup just needs to acquire a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If and only if one long updating statement is running when the `FLUSH` statement is issued, the MySQL server may get stalled until that long statement finishes, and then the dump becomes lock-free. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see Section 5.12.3, “The Binary Log”) or at least know the binary log coordinates to which the dump corresponds:

```
shell> mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mysqldump --all-databases --flush-logs --master-data=2  
> all_databases.sql
```

The simultaneous use of `--master-data` and `--single-transaction` provides a convenient way to make an online backup suitable for point-in-time recovery if tables are stored in the InnoDB storage engine.

For more information on making backups, see Section 5.10.1, “Database Backups”, and Section 5.10.2, “Example Backup and Recovery Strategy”.

## 8.12. mysqlhotcopy — A Database Backup Program

`mysqlhotcopy` is a Perl script that was originally written and contributed by Tim Bunce. It uses `LOCK TABLES`, `FLUSH TABLES`, and `cp` or `scp` to make a database backup quickly. It is the

fastest way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. `mysqlhotcopy` works only for backing up MyISAM and ARCHIVE tables. It runs on Unix and NetWare.

```
shell> mysqlhotcopy db_name [/path/to/new_directory]
```

```
shell> mysqlhotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
shell> mysqlhotcopy db_name ./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde ('~'):

```
shell> mysqlhotcopy db_name ./~regex/
```

`mysqlhotcopy` supports the following options:

- `--help, -?`  
Display a help message and exit.
- `--addtodest`  
Do not rename target directory (if it exists); merely add files to it.
- `--allowold`  
Do not abort if a target exists; rename it by adding an `_old` suffix.
- `--checkpoint=db_name.tbl_name`  
Insert checkpoint entries into the specified database *db\_name* and table *tbl\_name*.
- `--chroot=path`  
Base directory of the `chroot` jail in which `mysqld` operates. The *path* value should match that of the `--chroot` option given to `mysqld`.
- `--debug`  
Enable debug output.
- `--dryrun, -n`  
Report actions without performing them.
- `--flushlog`  
Flush logs after all tables are locked.
- `--host=host_name, -h host_name`  
The hostname of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to `localhost` using a Unix socket file.
- `--keepold`  
Do not delete previous (renamed) target when done.
- `--method=command`

The method for copying files (`cp` or `scp`).

- `--noindices`

Do not include full index files in the backup. This makes the backup smaller and faster. The indexes for reloaded tables can be reconstructed later with `myisamchk -rq`.

- `--password=password, -ppassword`

The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs. You can use an option file to avoid giving the password on the command line.

Specifying a password on the command line should be considered insecure. See Section 5.9.6, “Keeping Your Password Secure”.

- `--port=port_num, -P port_num`

The TCP/IP port number to use when connecting to the local server.

- `--quiet, -q`

Be silent except for errors.

- `--record_log_pos=db_name.tbl_name`

Record master and slave status in the specified database `db_name` and table `tbl_name`.

- `--regexp=expr`

Copy all databases with names that match the given regular expression.

- `--resetmaster`

Reset the binary log after locking all the tables.

- `--resetslave`

Reset the `master.info` file after locking all the tables.

- `--socket=path, -S path`

The Unix socket file to use for the connection.

- `--suffix=str`

The suffix for names of copied databases.

- `--tmpdir=path`

The temporary directory. The default is `/tmp`.

- `--user=user_name, -u user_name`

The MySQL username to use when connecting to the server.

`mysqlhotcopy` reads the `[client]` and `[mysqlhotcopy]` option groups from option files.

To execute `mysqlhotcopy`, you must have access to the files for the tables that you are backing up, the `SELECT` privilege for those tables, the `RELOAD` privilege (to be able to execute `FLUSH TABLES`), and the `LOCK TABLES` privilege (to be able to lock the tables).

Use `perldoc` for additional `mysqlhotcopy` documentation, including information about the

structure of the tables needed for the `--checkpoint` and `--record_log_pos` options:

```
shell> perldoc mysqlhotcopy
```

## 8.13. `mysqlimport` — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA INFILE SQL` statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA INFILE` syntax. See Section 13.2.5, “`LOAD DATA INFILE` Syntax”.

Invoke `mysqlimport` like this:

```
shell> mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the filename and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

`mysqlimport` supports the following options:

- `--help, -?`  
Display a help message and exit.
- `--character-sets-dir=path`  
The directory where character sets are installed. See Section 5.11.1, “The Character Set Used for Data and Sorting”.
- `--columns=column_list, -c column_list`  
This option takes a comma-separated list of column names as its value. The order of the column names indicates how to match data file columns with table columns.
- `--compress, -C`  
Compress all information sent between the client and the server if both support compression.
- `--debug[=debug_options], -# [debug_options]`  
Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`.
- `--default-character-set=charset_name`  
Use `charset_name` as the default character set. See Section 5.11.1, “The Character Set Used for Data and Sorting”.
- `--delete, -D`  
Empty the table before importing the text file.
- `--fields-terminated-by=..., --fields-enclosed-by=..., --fields-optionally-enclosed-by=..., --fields-escaped-by=..., --lines-terminated-by=...`  
These options have the same meaning as the corresponding clauses for `LOAD DATA INFILE`. See Section 13.2.5, “`LOAD DATA INFILE` Syntax”.
- `--force, -f`

Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without `--force`, `mysqlimport` exits if a table does not exist.

- `--host=host_name, -h host_name`

Import data to the MySQL server on the given host. The default host is `localhost`.

- `--ignore, -i`

See the description for the `--replace` option.

- `--ignore-lines=N`

Ignore the first *N* lines of the data file.

- `--local, -L`

Read input files locally from the client host.

- `--lock-tables, -l`

Lock *all* tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- `--low-priority`

Use `LOW_PRIORITY` when loading the table.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password` or `-p` option on the command line, you are prompted for one.

Specifying a password on the command line should be considered insecure. See Section 5.9.6, “Keeping Your Password Secure”.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use.

- `--replace, -r`

The `--replace` and `--ignore` options control handling of input rows that duplicate existing rows on unique key values. If you specify `--replace`, new rows replace existing rows that have the same unique key value. If you specify `--ignore`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- `--silent, -s`

Silent mode. Produce output only when errors occur.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--user=user_name, -u user_name`

The MySQL username to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE impptest(id INT, n VARCHAR(30))' test
shell> ed
a
100      Max Sydow
101      Count Dracula
.
w impptest.txt
32
q
shell> od -c impptest.txt
0000000  1  0  0  \t  M  a  x          S  y  d  o  w  \n  1  0
0000020  1  \t  C  o  u  n  t          D  r  a  c  u  l  a  \n
0000040
shell> mysqlimport --local test impptest.txt
test.impptest: Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
shell> mysql -e 'SELECT * FROM impptest' test
+-----+-----+
| id  | n                |
+-----+-----+
| 100 | Max Sydow       |
| 101 | Count Dracula   |
+-----+-----+
```

## 8.14. `mysqlshow` — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly see which databases exist, their tables, or a table's columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. See Section 13.5.4, “`SHOW` Syntax”. The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
shell> mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters ('\*', '?', '%', or '\_'), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. '\*' and '?' characters are converted into SQL '%' and '\_' wildcard characters. This might cause some confusion when you try to display the columns for a table with a '\_' in the name, because in this case, `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra '%' last on the command line as a separate argument.

`mysqlshow` supports the following options:

- `--help, -?`  
Display a help message and exit.
- `--character-sets-dir=path`  
The directory where character sets are installed. See Section 5.11.1, “The Character Set Used for Data and Sorting”.
- `--compress, -C`  
Compress all information sent between the client and the server if both support compression.
- `--count`  
Show the number of rows per table. This can be slow for non-MyISAM tables. This option was added in MySQL 5.0.6.
- `--debug[=debug_options], -# [debug_options]`  
Write a debugging log. The *debug\_options* string often is 'd:t:o,file\_name'.
- `--default-character-set=charset_name`  
Use *charset\_name* as the default character set. See Section 5.11.1, “The Character Set Used for Data and Sorting”.
- `--host=host_name, -h host_name`  
Connect to the MySQL server on the given host.
- `--keys, -k`  
Show table indexes.
- `--password[=password], -p[password]`  
The password to use when connecting to the server. If you use the short option form (-p), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password` or `-p` option on the command line, you are prompted for one.  
  
Specifying a password on the command line should be considered insecure. See Section 5.9.6, “Keeping Your Password Secure”.
- `--port=port_num, -P port_num`  
The TCP/IP port number to use for the connection.
- `--protocol={TCP|SOCKET|PIPE|MEMORY}`  
The connection protocol to use.
- `--show-table-type, -t`

Show a column indicating the table type, as in `SHOW FULL TABLES`. The type is `BASE TABLE` or `VIEW`. This option was added in MySQL 5.0.4.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--status, -i`

Display extra information about each table.

- `--user=user_name, -u user_name`

The MySQL username to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Display version information and exit.

## 8.15. `mysql_zap` — Kill Processes That Match a Pattern

`mysql_zap` kills processes that match a pattern. It uses the `ps` command and Unix signals, so it runs on Unix and Unix-like systems.

Invoke `mysql_zap` like this:

```
shell> mysql_zap [-signal] [-?Ift] pattern
```

A process matches if its output line from the `ps` command contains the pattern. By default, `mysql_zap` asks for confirmation for each process. Respond `y` to kill the process, or `q` to exit `mysql_zap`. For any other response, `mysql_zap` does not attempt to kill the process.

If the `-signal` option is given, it specifies the name or number of the signal to send to each process. Otherwise, `mysql_zap` tries first with `TERM` (signal 15) and then with `KILL` (signal 9).

`mysql_zap` understands the following additional options:

- `--help, -?, -I`

Display a help message and exit.

- `-f`

Force mode. `mysql_zap` attempts to kill each process without confirmation.

- `-t`

Test mode. Display information about each process but do not kill it.

## 8.16. `pererror` — Explain Error Codes

For most system errors, MySQL displays, in addition to an internal text message, the system error code in one of the following styles:

```
message ... (errno: #)
message ... (Errcode: #)
```

You can find out what the error code means by examining the documentation for your system or by using the `pererror` utility.

`pererror` prints a description for a system error code or for a storage engine (table handler) error code.

Invoke `pererror` like this:

```
shell> pererror [options] errorcode ...
```

Example:

```
shell> pererror 13 64
Error code 13: Permission denied
Error code 64: Machine is not on the network
```

To obtain the error message for a MySQL Cluster error code, invoke `pererror` with the `--ndb` option:

```
shell> pererror --ndb errorcode
```

Note that the meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

`pererror` supports the following options:

- `--help`, `--info`, `-I`, `-?`  
Display a help message and exit.
- `--ndb`  
Print the error message for a MySQL Cluster error code.
- `--silent`, `-s`  
Silent mode. Print only the error message.
- `--verbose`, `-v`  
Verbose mode. Print error code and message. This is the default behavior.
- `--version`, `-V`  
Display version information and exit.

## 8.17. `replace` — A String-Replacement Utility

The `replace` utility program changes strings in place in files or on the standard input.

Invoke `replace` in one of the following ways:

```
shell> replace from to [from to] ... -- file [file] ...  
shell> replace from to [from to] ... < file
```

*from* represents a string to look for and *to* represents its replacement. There can be one or more pairs of strings.

Use the `--` option to indicate where the string-replacement list ends and the filenames begin. In this case, any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. `replace` prints a message indicating which of the input files it actually modifies.

If the `--` option is not given, `replace` reads the standard input and writes to the standard output.

`replace` uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps `a` and `b` in the given files, `file1` and `file2`:

```
shell> replace a b b a -- file1 file2 ...
```

The `replace` program is used by `msql2mysql`. See Section 22.9.1, “`msql2mysql` — Convert mSQL Programs for Use with MySQL”.

`replace` supports the following options:

- `-?`, `-I`  
Display a help message and exit.
- `-# debug_options`  
Write a debugging log. The `debug_options` string often is `'d:t:o,file_name'`.
- `-s`  
Silent mode. Print less information what the program does.
- `-v`  
Verbose mode. Print more information about what the program does.
- `-V`  
Display version information and exit.

---

# Chapter 9. Language Structure

This chapter discusses the rules for writing the following elements of SQL statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- User-defined and system variables
- Comments
- Reserved words

## 9.1. Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal values, boolean values, and NULL. The section also covers the various nuances and “gotchas” that you may run into when dealing with these basic types in MySQL.

### 9.1.1. Strings

A string is a sequence of bytes or characters, enclosed within either single quote (‘ ’) or double quote (‘ ’) characters. Examples:

```
'a string'  
"another string"
```

If the `ANSI_QUOTES` SQL mode is enabled, string literals can be quoted only within single quotes because a string quoted within double quotes is interpreted as an identifier.

A *binary string* is a string of bytes that has no character set or collation. A *non-binary string* is a string of characters that has a character set and collation. For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte. For non-binary strings the unit is the character and some character sets allow multi-byte characters. Character value ordering is a function of the string collation.

String literals may have an optional character set introducer and `COLLATE` clause:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1'string';  
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

For more information about these forms of string syntax, see Section 10.3.5, “Character String Literal Character Set and Collation”.

Within a string, certain sequences have special meaning. Each of these sequences begins with a backslash (‘\’), known as the *escape character*. MySQL recognizes the following escape sequences:

<code>\0</code>	An ASCII 0 (NUL) character.
<code>\'</code>	A single quote (‘ ’) character.

<code>\"</code>	A double quote (‘”’) character.
<code>\b</code>	A backspace character.
<code>\n</code>	A newline (linefeed) character.
<code>\r</code>	A carriage return character.
<code>\t</code>	A tab character.
<code>\Z</code>	ASCII 26 (Control-Z). See note following the table.
<code>\\</code>	A backslash (‘\’) character.
<code>\%</code>	A ‘%’ character. See note following the table.
<code>\_</code>	A ‘_’ character. See note following the table.

For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, ‘\x’ is just ‘x’.

These sequences are case sensitive. For example, ‘\b’ is interpreted as a backspace, but ‘\B’ is interpreted as ‘B’.

The ASCII 26 character can be encoded as ‘\Z’ to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use `mysql db_name < file_name`.

The ‘\%’ and ‘\\_’ sequences are used to search for literal instances of ‘%’ and ‘\_’ in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the LIKE operator in Section 12.3.1, “String Comparison Functions”. If you use ‘\%’ or ‘\\_’ in non-pattern-matching contexts, they evaluate to the strings ‘\%’ and ‘\\_’, not to ‘%’ and ‘\_’.

There are several ways to include quote characters within a string:

- A ‘’ inside a string quoted with ‘’ may be written as ‘’’’.
- A “ inside a string quoted with “ may be written as “ ” ”.
- Precede the quote character by an escape character (‘\’).
- A ‘’ inside a string quoted with “” needs no special treatment and need not be doubled or escaped. In the same way, “” inside a string quoted with ‘’’ needs no special treatment.

The following SELECT statements demonstrate how quoting and escaping work:

```
mysql> SELECT 'hello', "hello", ""hello"", 'hel'lo', '\hello';
+-----+-----+-----+-----+
| hello | "hello" | ""hello"" | hel'lo | 'hello |
+-----+-----+-----+-----+
```

```
mysql> SELECT "hello", "'hello'", "'hello'", "hel"lo", "\"hello";
+-----+-----+-----+-----+
| hello | 'hello' | "'hello'" | hel"lo | "\"hello" |
+-----+-----+-----+-----+
```

```
mysql> SELECT 'This\nIs\nFour\nLines';
+-----+
| This
| Is
| Four
| Lines |
+-----+
```

```
mysql> SELECT 'disappearing\ backslash';
+-----+
| disappearing backslash |
+-----+
```

+-----+

If you want to insert binary data into a string column (such as a BLOB column), the following characters must be represented by escape sequences:

NUL	NUL byte (ASCII 0). Represent this character by ‘\0’ (a backslash followed by an ASCII ‘0’ character).
\	Backslash (ASCII 92). Represent this character by ‘\\’.
'	Single quote (ASCII 39). Represent this character by ‘\ ’’.
"	Double quote (ASCII 34). Represent this character by ‘\ ’’.

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the `mysql_real_escape_string()` C API function to escape characters. See Section 22.2.3.52, “`mysql_real_escape_string()`”. The Perl DBI interface provides a `quote` method to convert special characters to the proper escape sequences. See Section 22.4, “MySQL Perl API”. Other language interfaces may provide a similar capability.
- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

## 9.1.2. Numbers

Integers are represented as a sequence of digits. Floats use ‘.’ as a decimal separator. Either type of number may be preceded by ‘-’ or ‘+’ to indicate a negative or positive value, respectively

Examples of valid integers:

```
1221
0
-32
```

Examples of valid floating-point numbers:

```
294.42
-32032.6809e+10
148.00
```

An integer may be used in a floating-point context; it is interpreted as the equivalent floating-point number.

## 9.1.3. Hexadecimal Values

MySQL supports hexadecimal values. In numeric contexts, these act like integers (64-bit precision). In string contexts, these act like binary strings, where each pair of hex digits is converted to a character:

```
mysql> SELECT x'4D7953514C';
-> 'MySQL'
mysql> SELECT 0xa+0;
-> 10
mysql> SELECT 0x5061756c;
```

```
-> 'Paul'
```

The default type of a hexadecimal value is a string. If you want to ensure that the value is treated as a number, you can use `CAST(... AS UNSIGNED)`:

```
mysql> SELECT 0x41, CAST(0x41 AS UNSIGNED);
      -> 'A', 65
```

The `x'hexstring'` syntax is based on standard SQL. The `0x` syntax is based on ODBC. Hexadecimal strings are often used by ODBC to supply values for BLOB columns.

You can convert a string or a number to a string in hexadecimal format with the `HEX()` function:

```
mysql> SELECT HEX('cat');
      -> '636174'
mysql> SELECT 0x636174;
      -> 'cat'
```

## 9.1.4. Boolean Values

The constants `TRUE` and `FALSE` evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.

```
mysql> SELECT TRUE, true, FALSE, false;
      -> 1, 1, 0, 0
```

## 9.1.5. Bit-Field Values

Beginning with MySQL 5.0.3, bit-field values can be written using `b'value'` notation. *value* is a binary value written using zeroes and ones.

Bit-field notation is convenient for specifying values to be assigned to BIT columns:

```
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
```

b+0	BIN(b+0)	OCT(b+0)	HEX(b+0)
255	11111111	377	FF
10	1010	12	A

## 9.1.6. NULL Values

The `NULL` value means “no data.” `NULL` can be written in any lettercase.

Be aware that the `NULL` value is different from values such as 0 for numeric types or the empty string for string types. See Section A.5.3, “Problems with `NULL` Values”.

For text file import or export operations performed with `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, `NULL` is represented by the `\N` sequence. See Section 13.2.5, “`LOAD DATA INFILE` Syntax”.

## 9.2. Database, Table, Index, Column, and Alias Names

Database, table, index, column, and alias names are identifiers. This section describes the allowable syntax for identifiers in MySQL.

The following table describes the maximum length for each type of identifier.

Identifier	Maximum Length	
Database	64	
Table	64	
Column	64	
Index	64	
Alias	255	

There are some restrictions on the characters that may appear in identifiers:

- No identifier can contain ASCII 0 (0x00) or a byte with a value of 255.
- The use of identifier quote characters in identifiers is permitted, although it is best to avoid doing so if possible.
- Database, table, and column names should not end with space characters.
- Database names cannot contain '/', '\', '.', or characters that are not allowed in a directory name.
- Table names cannot contain '/', '\', '.', or characters that are not allowed in a filename.

Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions that stored in `.frm` files and to identifiers stored in the grant tables in the `mysql` database. The sizes of the string columns in the grant tables (and in any other tables) in MySQL 5.0 are given as number of characters. This means that (unlike some earlier versions of MySQL) you can use multi-byte characters without reducing the number of characters allowed for values stored in these columns.

An identifier may be quoted or unquoted. If an identifier is a reserved word or contains special characters, you *must* quote it whenever you refer to it. (Exception: A word that follows a period in a qualified name must be an identifier, so it is not necessary to quote it, even if it is a reserved word.) For a list of reserved words, see Section 9.5, “Treatment of Reserved Words in MySQL”. Special characters are those outside the set of alphanumeric characters from the current character set, ‘\_’, and ‘\$’.

The identifier quote character is the backtick (‘`’):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the `ANSI_QUOTES` SQL mode is enabled, it is also allowable to quote identifiers within double quotes:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax. (...)
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

Note: Because the `ANSI_QUOTES` mode causes the server to interpret double-quoted strings as identifiers, string literals must be enclosed within single quotes when this mode is enabled. They cannot be enclosed within double quotes.

The server SQL mode is controlled as described in Section 5.2.5, “The Server SQL Mode”.

Identifier quote characters can be included within an identifier *if you quote the identifier*. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named a`b that contains a column named c`d:

```
mysql> CREATE TABLE `a``b` (`c`d` INT);
```

It is recommended that you do not use names of the form  $Me$  or  $MeN$ , where  $M$  and  $N$  are integers. For example, avoid using  $1e$  or  $2e2$  as identifiers, because an expression such as  $1e+3$  is ambiguous. Depending on context, it might be interpreted as the expression  $1e + 3$  or as the number  $1e+3$ .

Be careful when using `MD5()` to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

## 9.2.1. Identifier Qualifiers

MySQL allows names that consist of a single identifier or multiple identifiers. The components of a multiple-part name should be separated by period (‘.’) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which the final identifier is interpreted.

In MySQL you can refer to a column using any of the following forms:

Column Reference	Meaning
<i>col_name</i>	The column <i>col_name</i> from whichever table used in the statement contains a column of that name.
<i>tbl_name.col_name</i>	The column <i>col_name</i> from table <i>tbl_name</i> of the default database.
<i>db_name.tbl_name.col_name</i>	The column <i>col_name</i> from table <i>tbl_name</i> of the database <i>db_name</i> .

If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write ``my-table`.`my-column``, not ``my-table.my-column``.

You need not specify a *tbl\_name* or *db\_name.tbl\_name* prefix for a column reference in a statement unless the reference would be ambiguous. Suppose that tables *t1* and *t2* each contain a column *c*, and you retrieve *c* in a `SELECT` statement that uses both *t1* and *t2*. In this case, *c* is ambiguous because it is not unique among the tables used in the statement. You must qualify it with a table name as *t1.c* or *t2.c* to indicate which table you mean. Similarly, to retrieve from a table *t* in database *db1* and from a table *t* in database *db2* in the same statement, you must refer to columns in those tables as *db1.t.col\_name* and *db2.t.col\_name*.

A word that follows a period in a qualified name must be an identifier, so it is not necessary to quote it, even if it is a reserved word.

The syntax *.tbl\_name* means the table *tbl\_name* in the default database. This syntax is accepted for ODBC compatibility because some ODBC programs prefix table names with a ‘.’ character.

## 9.2.2. Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Consequently, the case sensitivity of the underlying operating system determines the case sensitivity of database and table names. This means database and table names are case sensitive in most varieties of Unix, and not case sensitive in Windows. One notable exception is Mac OS X, which is Unix-based but uses a default filesystem type (HFS+) that is not case sensitive. However, Mac OS X also supports UFS volumes, which are case sensitive just as on any Unix. See

Section 1.9.4, “MySQL Extensions to Standard SQL”. The `lower_case_table_names` system variable also affects how the server handles identifier case sensitivity, as described later in this section.

**Note:** Although database and table names are not case sensitive on some platforms, you should not refer to a given database or table using different cases within the same statement. The following statement would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Column, index, stored routine, and trigger names are not case sensitive on any platform, nor are column aliases.

By default, table aliases are case sensitive on Unix, but not so on Windows or Mac OS X. The following statement would not work on Unix, because it refers to the alias both as `a` and as `A`:

```
mysql> SELECT col_name FROM tbl_name AS a
-> WHERE a.col_name = 1 OR A.col_name = 2;
```

However, this same statement is permitted on Windows. To avoid problems caused by such differences, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the `lower_case_table_names` system variable, which you can set when starting `mysqld`. `lower_case_table_names` can take the values shown in the following table. On Unix, the default value of `lower_case_table_names` is 0. On Windows the default value is 1. On Mac OS X, the default value is 2.

Value	Meaning
0	Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement. Name comparisons are case sensitive. Note that if you force this variable to 0 with <code>--lower-case-table-names=0</code> on a case-insensitive filesystem and access MyISAM table names using different lettercases, index corruption may result.
1	Table names are stored in lowercase on disk and name comparisons are not case sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names and table aliases.
2	Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case sensitive. <b>Note:</b> This works <i>only</i> on filesystems that are not case sensitive! InnoDB table names are stored in lowercase, as for <code>lower_case_table_names=1</code> .

If you are using MySQL on only one platform, you don't normally have to change the `lower_case_table_names` variable. However, you may encounter difficulties if you want to transfer tables between platforms that differ in filesystem case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows these two names are considered identical. To avoid data transfer problems stemming from lettercase of database or table names, you have two options:

- Use `lower_case_table_names=1` on all systems. The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you don't see the names in their original lettercase.
- Use `lower_case_table_names=0` on Unix and `lower_case_table_names=2` on Windows. This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your statements always refer to your database and table names with the

correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect.

**Exception:** If you are using InnoDB tables, you should set `lower_case_table_names` to 1 on all platforms to force names to be converted to lowercase.

Note that if you plan to set the `lower_case_table_names` system variable to 1 on Unix, you must first convert your old database and table names to lowercase before restarting `mysqld` with the new variable setting.

## 9.3. User-Defined Variables

You can store a value in a user-defined variable and then refer to it later. This enables you to pass values from one statement to another. *User-defined variables are connection-specific.* That is, a user variable defined by one client cannot be seen or used by other clients. All variables for a given client connection are automatically freed when that client exits.

User variables are written as `@var_name`, where the variable name `var_name` may consist of alphanumeric characters from the current character set, '.', '\_', and '\$'. The default character set is `latin1` (cp1252 West European). This may be changed with the `--default-character-set` option to `mysqld`. See Section 5.11.1, "The Character Set Used for Data and Sorting". A user variable name can contain other characters if you quote it as a string or identifier (for example, `@'my-var'`, `@"my-var"`, or `@`my-var``).

Note: User variable names are case sensitive before MySQL 5.0 and not case sensitive in MySQL 5.0 and up.

One way to set a user-defined variable is by issuing a `SET` statement:

```
SET @var_name = expr [, @var_name = expr] ...
```

For `SET`, either `=` or `:=` can be used as the assignment operator. The `expr` assigned to each variable can evaluate to an integer, real, string, or `NULL` value.

You can also assign a value to a user variable in statements other than `SET`. In this case, the assignment operator must be `:=` and not `=` because `=` is treated as a comparison operator in non-`SET` statements:

```
mysql> SET @t1=0, @t2=0, @t3=0;
mysql> SELECT @t1:=(@t2:=1)+@t3:=4,@t1,@t2,@t3;
+-----+-----+-----+-----+
| @t1:=(@t2:=1)+@t3:=4 | @t1 | @t2 | @t3 |
+-----+-----+-----+-----+
|                    5 |    5 |    1 |    4 |
+-----+-----+-----+-----+
```

User variables may be used in contexts where expressions are allowed. This does not currently include contexts that explicitly require a literal value, such as in the `LIMIT` clause of a `SELECT` statement, or the `IGNORE N LINES` clause of a `LOAD DATA` statement.

If a user variable is assigned a string value, it has the same character set and collation as the string. The coercibility of user variables is implicit as of MySQL 5.0.3. (This is the same coercibility as for table column values.)

**Note:** In a `SELECT` statement, each expression is evaluated only when sent to the client. This means that in a `HAVING`, `GROUP BY`, or `ORDER BY` clause, you cannot refer to an expression that involves variables that are set in the `SELECT` list. For example, the following statement does *not* work as expected:

```
mysql> SELECT (@aa:=id) AS a, (@aa+3) AS b FROM tbl_name HAVING b=5;
```

The reference to `b` in the `HAVING` clause refers to an alias for an expression in the `SELECT` list that uses `@aa`. This does not work as expected: `@aa` contains the value of `id` from the previous selected row, not from the current row.

The general rule is to never assign a value to a user variable in one part of a statement *and* use the same variable in some other part the same statement. You might get the results you expect, but this is not guaranteed.

Another issue with setting a variable and using it in the same statement is that the default result type of a variable is based on the type of the variable at the start of the statement. The following example illustrates this:

```
mysql> SET @a='test';
mysql> SELECT @a,(@a:=20) FROM tbl_name;
```

For this `SELECT` statement, MySQL reports to the client that column one is a string and converts all accesses of `@a` to strings, even though `@a` is set to a number for the second row. After the `SELECT` statement executes, `@a` is regarded as a number for the next statement.

To avoid problems with this behavior, either do not set and use the same variable within a single statement, or else set the variable to `0`, `0.0`, or `' '` to define its type before you use it.

If you refer to a variable that has not been initialized, it has a value of `NULL` and a type of string.

## 9.4. Comment Syntax

MySQL Server supports three comment styles:

- From a `#` character to the end of the line.
- From a `--` sequence to the end of the line. In MySQL, the `--` (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character (such as a space, tab, newline, and so on). This syntax differs slightly from standard SQL comment syntax, as discussed in Section 1.9.5.7, “`--` as the Start of a Comment”.
- From a `/*` sequence to the following `*/` sequence, as in the C programming language. This syntax allows a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.

The following example demonstrates all three comment styles:

```
mysql> SELECT 1+1;      # This comment continues to the end of line
mysql> SELECT 1+1;      -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1+
/*
this is a
multiple-line comment
*/
1;
```

MySQL Server supports some variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server re-

cognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```
CREATE /*!32302 TEMPORARY */ TABLE t (a INT);
```

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.)

## 9.5. Treatment of Reserved Words in MySQL

A common problem stems from trying to use an identifier such as a table or column name that is a reserved word such as `SELECT` or the name of a built-in MySQL data type or function such as `TIMESTAMP` or `GROUP`.

If an identifier is a reserved word, you must quote it as described in Section 9.2, “Database, Table, Index, Column, and Alias Names”. Exception: A word that follows a period in a qualified name must be an identifier, so it is not necessary to quote it, even if it is a reserved word.

You are permitted to use function names as identifiers. For example, `ABS` is acceptable as a column name. However, by default, no whitespace is allowed in function invocations between the function name and the following `(` character. This requirement allows a function call to be distinguished from a reference to a column name.

A side effect of this behavior is that omitting a space in some contexts causes an identifier to be interpreted as a function name. For example, this statement is legal:

```
mysql> CREATE TABLE abs (val INT);
```

But omitting the space after `abs` causes a syntax error because the statement then appears to invoke the `ABS()` function:

```
mysql> CREATE TABLE abs(val INT);
ERROR 1064 (42000) at line 2: You have an error in your SQL
syntax ... near 'abs(val INT)'
```

If the `IGNORE_SPACE` SQL mode is enabled, the server allows function invocations to have whitespace between a function name and the following `(` character. This causes function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in Section 9.2, “Database, Table, Index, Column, and Alias Names”. The server SQL mode is controlled as described in Section 5.2.5, “The Server SQL Mode”.

The words in the following table are explicitly reserved in MySQL 5.0. At some point, you might update to a higher version, so it's a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the words in the table are forbidden by standard SQL as column or table names (for example, `GROUP`). A few are reserved because MySQL needs them and (currently) uses a `yacc` parser. A reserved word can be used as an identifier if you quote it.

ADD	ALL	ALTER

ZEROFILL		

The following are new reserved words in MySQL 5.0: ASENSITIVE, CALL, CONDITION, CONNECTION, CONTINUE, CURSOR, DECLARE, DETERMINISTIC, EACH, ELSEIF, EXIT, FETCH, GOTO, INOUT, INSENSITIVE, ITERATE, LABEL, LEAVE, LOOP, MODIFIES, OUT, READS, RELEASE, REPEAT, RETURN, SCHEMA, SCHEMAS, SENSITIVE, SPECIFIC, SQL, SQLEXCEPTION, SQLSTATE, SQLWARNING, TRIGGER, UNDO, UPGRADE, WHILE.

MySQL allows some keywords to be used as unquoted identifiers because many people previously used them. Examples are those in the following list:

- ACTION
- BIT
- DATE
- ENUM
- NO
- TEXT
- TIME
- TIMESTAMP

---

# Chapter 10. Character Set Support

MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. You can specify character sets at the server, database, table, and column level. MySQL supports the use of character sets for the MyISAM, MEMORY, NDBCluster, and InnoDB storage engines.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment
- Syntax for specifying character sets and collations
- Affected functions and operations
- Unicode support
- The character sets and collations that are available, with notes

Character set issues affect data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about character set-related issues in client/server communication, see Section 10.4, “Connection Character Sets and Collations”.

## 10.1. Character Sets and Collations in General

A *character set* is a set of symbols and encodings. A *collation* is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: ‘A’, ‘B’, ‘a’, ‘b’. We give each letter a number: ‘A’ = 0, ‘B’ = 1, ‘a’ = 2, ‘b’ = 3. The letter ‘A’ is a symbol, the number 0 is the **encoding** for ‘A’, and the combination of all four letters and their encodings is a **character set**.

Suppose that we want to compare two string values, ‘A’ and ‘B’. The simplest way to do this is to look at the encodings: 0 for ‘A’ and 1 for ‘B’. Because 0 is less than 1, we say ‘A’ is less than ‘B’. What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a *binary collation*.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters ‘a’ and ‘b’ as equivalent to ‘A’ and ‘B’; (2) then compare the encodings. We call this a *case-insensitive collation*. It's a little more complex than a binary collation.

In real life, most character sets have many characters: not just ‘A’ and ‘B’ but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life, most collations have many rules, not just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a

mark attached to a character as in German ‘Ö’), and for multiple-character mappings (such as the rule that ‘Ö’ = ‘OE’ in one of the two German collations).

MySQL can do these things for you:

- Store strings using a variety of character sets
- Compare strings using a variety of collations
- Mix strings with different character sets or collations in the same server, the same database, or even the same table
- Allow specification of character set and collation at any level

In these respects, MySQL is far ahead of most other database management systems. However, to use these features effectively, you need to know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.

## 10.2. Character Sets and Collations in MySQL

The MySQL server can support multiple character sets. To list the available character sets, use the `SHOW CHARACTER SET` statement. A partial listing follows. For more complete information, see Section 10.9, “Character Sets and Collations That MySQL Supports”.

```
mysql> SHOW CHARACTER SET;
```

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
dec8	DEC West European	dec8_swedish_ci	1
cp850	DOS West European	cp850_general_ci	1
hp8	HP West European	hp8_english_ci	1
koi8r	KOI8-R Relcom Russian	koi8r_general_ci	1
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
swe7	7bit Swedish	swe7_swedish_ci	1
ascii	US ASCII	ascii_general_ci	1
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
hebrew	ISO 8859-8 Hebrew	hebrew_general_ci	1
tis620	TIS620 Thai	tis620_thai_ci	1
euckr	EUC-KR Korean	euckr_korean_ci	2
koi8u	KOI8-U Ukrainian	koi8u_general_ci	1
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
greek	ISO 8859-7 Greek	greek_general_ci	1
cp1250	Windows Central European	cp1250_general_ci	1
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
...			

Any given character set always has at least one collation. It may have several collations. To list the collations for a character set, use the `SHOW COLLATION` statement. For example, to see the collations for the `latin1` (cp1252 West European) character set, use this statement to find those collation names that begin with `latin1`:

```
mysql> SHOW COLLATION LIKE 'latin1%';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_german1_ci	latin1	5			0
latin1_swedish_ci	latin1	8	Yes	Yes	1
latin1_danish_ci	latin1	15			0
latin1_german2_ci	latin1	31		Yes	2

latin1_bin	latin1	47	Yes	1
latin1_general_ci	latin1	48		0
latin1_general_cs	latin1	49		0
latin1_spanish_ci	latin1	94		0

The `latin1` collations have the following meanings:

Collation	Meaning
<code>latin1_german1_ci</code>	German DIN-1
<code>latin1_swedish_ci</code>	Swedish/Finnish
<code>latin1_danish_ci</code>	Danish/Norwegian
<code>latin1_german2_ci</code>	German DIN-2
<code>latin1_bin</code>	Binary according to <code>latin1</code> encoding
<code>latin1_general_ci</code>	Multilingual (Western European)
<code>latin1_general_cs</code>	Multilingual (ISO Western European), case sensitive
<code>latin1_spanish_ci</code>	Modern Spanish

Collations have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has one collation that is the *default collation*. For example, the default collation for `latin1` is `latin1_swedish_ci`. The output for `SHOW CHARACTER SET` indicates which collation is the default for each displayed character set.
- There is a convention for collation names: They start with the name of the character set with which they are associated, they usually include a language name, and they end with `_ci` (case insensitive), `_cs` (case sensitive), or `_bin` (binary).

## 10.3. Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The following description may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

`CHARACTER SET` is used in clauses that specify a character set. `CHARSET` may be used as a synonym for `CHARACTER SET`.

### 10.3.1. Server Character Set and Collation

MySQL Server has a server character set and a server collation. These can be set at server startup and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start `mysqld`. You can use `--character-set-server` for the character set. Along with it, you can add `--collation-server` for the collation. If you don't specify a character set, that is the same as saying `--character-set-server=latin1`. If you specify only a character set (for example, `latin1`) but not a collation, that is the same as saying `--character-set-server=latin1 --collation-server=latin1_swedish_ci` because `latin1_swedish_ci` is the default collation for `latin1`. Therefore, the following three commands all have the same effect:

```
shell> mysqld
shell> mysqld --character-set-server=latin1
shell> mysqld --character-set-server=latin1 \
       --collation-server=latin1_swedish_ci
```

One way to change the settings is by recompiling. If you want to change the default server character set and collation when building from sources, use: `--with-charset` and `--with-collation` as arguments for `configure`. For example:

```
shell> ./configure --with-charset=latin1
```

Or:

```
shell> ./configure --with-charset=latin1 \
       --with-collation=latin1_german1_ci
```

Both `mysqld` and `configure` verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The current server character set and collation can be determined from the values of the `character_set_server` and `collation_server` system variables. These variables can be changed at runtime.

## 10.3.2. Database Character Set and Collation

Every database has a database character set and a database collation. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```
CREATE DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]

ALTER DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]
```

The keyword `SCHEMA` can be used instead of `DATABASE`.

All database options are stored in a text file named `db.opt` that can be found in the database directory.

The `CHARACTER SET` and `COLLATE` clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Example:

```
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` were specified, then character set *X* and collation *Y*.
- If `CHARACTER SET X` was specified without `COLLATE`, then character set *X* and its default collation.
- If `COLLATE Y` was specified without `CHARACTER SET`, then the character set associated with *Y* and collation *Y*.

- Otherwise, the server character set and server collation.

The database character set and collation are used as default values if the table character set and collation are not specified in `CREATE TABLE` statements. They have no other purpose.

The character set and collation for the default database can be determined from the values of the `character_set_database` and `collation_database` system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, `character_set_server` and `collation_server`.

### 10.3.3. Table Character Set and Collation

Every table has a table character set and a table collation. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```
CREATE TABLE tbl_name (column_list)
    [[DEFAULT] CHARACTER SET charset_name] [COLLATE collation_name]

ALTER TABLE tbl_name
    [[DEFAULT] CHARACTER SET charset_name] [COLLATE collation_name]
```

Example:

```
CREATE TABLE t1 ( ... ) CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` were specified, then character set `X` and collation `Y`.
- If `CHARACTER SET X` was specified without `COLLATE`, then character set `X` and its default collation.
- If `COLLATE Y` was specified without `CHARACTER SET`, then the character set associated with `Y` and collation `Y`.
- Otherwise, the database character set and collation.

The table character set and collation are used as default values if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

### 10.3.4. Column Character Set and Collation

Every “character” column (that is, a column of type `CHAR`, `VARCHAR`, or `TEXT`) has a column character set and a column collation. Column definition syntax has optional clauses for specifying the column character set and collation:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)
    [CHARACTER SET charset_name] [COLLATE collation_name]
```

Example:

```
CREATE TABLE Table1
(
    column1 VARCHAR(5) CHARACTER SET latin1 COLLATE latin1_german1_ci
);
```

MySQL chooses the column character set and collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` were specified, then character set *X* and collation *Y* are used.
- If `CHARACTER SET X` was specified without `COLLATE`, then character set *X* and its default collation are used.
- If `COLLATE Y` was specified without `CHARACTER SET`, then the character set associated with *Y* and collation *Y*.
- Otherwise, the table character set and collation are used.

The `CHARACTER SET` and `COLLATE` clauses are standard SQL.

### 10.3.5. Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

A character string literal may have an optional character set introducer and `COLLATE` clause:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT 'string';
SELECT _latin1'string';
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

For the simple statement `SELECT 'string'`, the string has the character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that is about to follow uses character set *X*.” Because this has confused people in the past, we emphasize that an introducer does not cause any conversion; it is strictly a signal that does not change the string's value. An introducer is also legal before standard hex literal and numeric hex literal notation (`x'literal'` and `0xnnnn`), and before `?` (parameter substitution when using prepared statements within a programming language interface).

Examples:

```
SELECT _latin1 x'AABBCC';
SELECT _latin1 0xAABBCC;
SELECT _latin1 ?;
```

MySQL determines a literal's character set and collation in the following manner:

- If both `_X` and `COLLATE Y` were specified, then character set *X* and collation *Y* are used.
- If `_X` is specified but `COLLATE` is not specified, then character set *X* and its default collation are used.
- Otherwise, the character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.

Examples:

- A string with `latin1` character set and `latin1_german1_ci` collation:  

```
SELECT _latin1'Müller' COLLATE latin1_german1_ci;
```
- A string with `latin1` character set and its default collation (that is, `latin1_swedish_ci`):  

```
SELECT _latin1'Müller';
```
- A string with the connection default character set and collation:  

```
SELECT 'Müller';
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

## 10.3.6. National Character Set

Standard SQL defines `NCHAR` or `NATIONAL CHAR` as a way to indicate that a `CHAR` column should use some predefined character set. MySQL 5.0 uses `utf8` as this predefined character set. For example, these data type declarations are equivalent:

```
CHAR(10) CHARACTER SET utf8
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:

```
VARCHAR(10) CHARACTER SET utf8
NATIONAL VARCHAR(10)
NCHAR VARCHAR(10)
NATIONAL CHARACTER VARYING(10)
NATIONAL CHAR VARYING(10)
```

You can use `N'literal'` to create a string in the national character set. These two statements are equivalent:

```
SELECT N'some text';
SELECT _utf8'some text';
```

For information on upgrading character sets to MySQL 5.0 from versions prior to 4.1, see the *MySQL 3.23, 4.0, 4.1 Reference Manual*.

## 10.3.7. Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

### Example 1: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that's straightforward. Notice that there is no problem with storing a `latin1` column in a `latin2` table.

**Example 2: Table and Column Definition**

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

**Example 3: Table and Column Definition**

```
CREATE TABLE t1
(
  c1 CHAR(10)
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

**Example 4: Database, Table, and Column Definition**

```
CREATE DATABASE d1
  DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_ci;
USE d1;
CREATE TABLE t1
(
  c1 CHAR(10)
);
```

We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column `c1` is `latin2` and its collation is `latin2_czech_ci`.

## 10.3.8. Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```
CREATE TABLE t1 (f1 CHAR(N) UNICODE);
CREATE TABLE t1 (f1 CHAR(N) CHARACTER SET ucs2);
```

## 10.4. Connection Character Sets and Collations

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The server character set and collation can be determined from the values of the `character_set_server` and `collation_server` system variables.

- The character set and collation of the default database can be determined from the values of the `character_set_database` and `collation_database` system variables.

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has connection-related character set and collation system variables.

Consider what a “connection” is: It's what you make when you connect to the server. The client sends SQL statements, such as queries, over the connection to the server. The server sends responses, such as result sets, over the connection back to the client. This leads to several questions about character set and collation handling for client connections, each of which can be answered in terms of system variables:

- What character set is the statement in when it leaves the client?

The server takes the `character_set_client` system variable to be the character set in which statements are sent by the client.

- What character set should the server translate a statement to after receiving it?

For this, the server uses the `character_set_connection` and `collation_connection` system variables. It converts statements sent by the client from `character_set_client` to `character_set_connection` (except for string literals that have an introducer such as `_latin1` or `_utf8`). `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence.

- What character set should the server translate to before shipping result sets or error messages back to the client?

The `character_set_results` system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, and result metadata such as column names.

You can fine-tune the settings for these variables, or you can depend on the defaults (in which case, you can skip the rest of this section).

There are two statements that affect the connection character sets:

```
SET NAMES 'charset_name'  
SET CHARACTER SET charset_name
```

`SET NAMES` indicates what character set the client will use to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server “future incoming messages from this client are in character set `cp1251`.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement.)

A `SET NAMES 'x'` statement is equivalent to these three statements:

```
SET character_set_client = x;  
SET character_set_results = x;  
SET character_set_connection = x;
```

Setting `character_set_connection` to `x` also sets `collation_connection` to the default collation for `x`.

`SET CHARACTER SET` is similar to `SET NAMES` but sets the connection character set and colla-

tion to be those of the default database. A `SET CHARACTER SET x` statement is equivalent to these three statements:

```
SET character_set_client = x;
SET character_set_results = x;
SET collation_connection = @@collation_database;
```

Setting `collation_connection` also sets `character_set_connection` to the character set associated with the collation.

When a client connects, it sends to the server the name of the character set that it wants to use. The server uses the name to set the `character_set_client`, `character_set_results`, and `character_set_connection` system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

With the `mysql` client, it is not necessary to execute `SET NAMES` every time you start up if you want to use a character set different from the default. You can add the `--default-character-set` option setting to your `mysql` statement line, or in your option file. For example, the following option file setting changes the three character set variables set to `koi8r` each time you invoke `mysql`:

```
[mysql]
default-character-set=koi8r
```

Example: Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET latin1` before issuing the `SELECT` statement, the server converts the `latin2` values to `latin1` just before sending results back. Conversion may be lossy if there are characters that are not in both character sets.

If you do not want the server to perform any conversion of result sets, set `character_set_results` to `NULL`:

```
SET character_set_results = NULL;
```

**Note:** Currently, UCS-2 cannot be used as a client character set, which means that `SET NAMES 'ucs2'` does not work.

To see the values of the character set and collation system variables that apply to your connection, use these statements:

```
SHOW VARIABLES LIKE 'character_set%';
SHOW VARIABLES LIKE 'collation%';
```

## 10.5. Collation Issues

The following sections discuss various aspects of character set collations.

### 10.5.1. Using `COLLATE` in SQL Statements

With the `COLLATE` clause, you can override whatever the default collation is for a comparison. `COLLATE` may be used in various parts of SQL statements. Here are some examples:

- With `ORDER BY`:

```
SELECT k
FROM t1
```

```
ORDER BY k COLLATE latin1_german2_ci;
```

- With AS:

```
SELECT k COLLATE latin1_german2_ci AS k1
FROM t1
ORDER BY k1;
```

- With GROUP BY:

```
SELECT k
FROM t1
GROUP BY k COLLATE latin1_german2_ci;
```

- With aggregate functions:

```
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;
```

- With DISTINCT:

```
SELECT DISTINCT k COLLATE latin1_german2_ci
FROM t1;
```

- With WHERE:

```
SELECT *
FROM t1
WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
```

```
SELECT *
FROM t1
WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
```

- With HAVING:

```
SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
```

## 10.5.2. COLLATE Clause Precedence

The COLLATE clause has high precedence (higher than `|`), so the following two expressions are equivalent:

```
x || y COLLATE z
x || (y COLLATE z)
```

## 10.5.3. BINARY Operator

The BINARY operator casts the string following it to a binary string. This is an easy way to force a comparison to be done byte by byte rather than character by character. BINARY also causes trailing spaces to be significant.

```
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
-> 0
```

`BINARY str` is shorthand for `CAST(str AS BINARY)`.

The `BINARY` attribute in character column definitions has a different effect. A character column defined with the `BINARY` attribute is assigned the binary collation of the column's character set. Every character set has a binary collation. For example, the binary collation for the `latin1` character set is `latin1_bin`, so if the table default character set is `latin1`, these two column definitions are equivalent:

```
CHAR(10) BINARY
CHAR(10) CHARACTER SET latin1 COLLATE latin1_bin
```

The effect of `BINARY` as a column attribute differs from its effect prior to MySQL 4.1. Formerly, `BINARY` resulted in a column that was treated as a binary string. A binary string is a string of bytes that has no character set or collation, which differs from a non-binary character string that has a binary collation. For both types of strings, comparisons are based on the numeric values of the string unit, but for non-binary strings the unit is the character and some character sets allow multi-byte characters. Section 11.4.2, “The `BINARY` and `VARBINARY` Types”.

The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as a binary data type. For example, the following pairs of definitions are equivalent:

```
CHAR(10) CHARACTER SET binary
BINARY(10)

VARCHAR(10) CHARACTER SET binary
VARBINARY(10)

TEXT CHARACTER SET binary
BLOB
```

## 10.5.4. Some Special Cases Where the Collation Determination Is Tricky

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column `x`:

```
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```

However, when multiple operands are involved, there can be ambiguity. For example:

```
SELECT x FROM T WHERE x = 'Y';
```

Should this query use the collation of the column `x`, or of the string literal `'Y'`?

Standard SQL resolves such questions using what used to be called “coercibility” rules. Basically, this means: Both `x` and `'Y'` have collations, so which collation takes precedence? This can be diffi-

cult to resolve, but the following rules cover most situations:

- An explicit `COLLATE` clause has a coercibility of 0. (Not coercible at all.)
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column or a stored routine parameter or local variable has a coercibility of 2.
- A “system constant” (the string returned by functions such as `USER()` or `VERSION()`) has a coercibility of 3.
- A literal's collation has a coercibility of 4.
- `NULL` or an expression that is derived from `NULL` has a coercibility of 5.

The preceding coercibility values are current as of MySQL 5.0.3. In MySQL 5.0 prior to 5.0.3, there is no system constant or ignorable coercibility. Functions such as `USER()` have a coercibility of 2 rather than 3, and literals have a coercibility of 3 rather than 4.

Those rules resolve ambiguities in the following manner:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then it is an error if the collations aren't the same.

Examples:

<code>column1 = 'A'</code>	Use collation of <code>column1</code>
<code>column1 = 'A' COLLATE x</code>	Use collation of 'A'
<code>column1 COLLATE x = 'A' COLLATE y</code>	Error

The `COERCIBILITY()` function can be used to determine the coercibility of a string expression:

```
mysql> SELECT COERCIBILITY('A' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(VERSION());
-> 3
mysql> SELECT COERCIBILITY('A');
-> 4
```

See Section 12.9.3, “Information Functions”.

## 10.5.5. Collations Must Be for the Right Character Set

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the `latin2_bin` collation is not legal with the `latin1` character set:

```
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid
for CHARACTER SET 'latin1'
```

## 10.5.6. An Example of the Effect of Collation

Suppose that column `X` in table `T` has these `latin1` column values:

Muffler  
Müller  
MX Systems  
MySQL

Suppose also that the column values are retrieved using the following statement:

```
SELECT X FROM T ORDER BY X COLLATE collation_name;
```

The following table shows the resulting order of the values if we use `ORDER BY` with different collations:

<code>latin1_swedish_ci</code>	<code>latin1_german1_ci</code>	<code>latin1_german2_ci</code>
Muffler	Muffler	Müller
MX Systems	Müller	Muffler
Müller	MX Systems	MX Systems
MySQL	MySQL	MySQL

The character that causes the different sort orders in this example is the U with two dots over it (ü), which the Germans call “U-umlaut.”

- The first column shows the result of the `SELECT` using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
- The second column shows the result of the `SELECT` using the German DIN-1 rule, which says that U-umlaut sorts with U.
- The third column shows the result of the `SELECT` using the German DIN-2 rule, which says that U-umlaut sorts with UE.

## 10.6. Operations Affected by Character Set Support

This section describes operations that take character set information into account.

### 10.6.1. Result Strings

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, `UPPER(X)` returns a string whose character set and collation are the same as that of `X`. The same applies for `INSTR()`, `LCASE()`, `LOWER()`, `LTRIM()`, `MID()`, `REPEAT()`, `REPLACE()`, `REVERSE()`, `RIGHT()`, `RPAD()`, `RTRIM()`, `SOUNDEX()`, `SUBSTRING()`, `TRIM()`, `UCASE()`, and `UPPER()`.

Note: The `REPLACE()` function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has no character set or collation. This can be checked by using the `CHARSET()` and `COLLATION()` functions, both of which return `binary` to indicate that their argument is a binary string:

```
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+-----+-----+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
+-----+-----+
| binary              | binary                 |
+-----+-----+
```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit `COLLATE X` occurs, use *X*.
- If explicit `COLLATE X` and `COLLATE Y` occur, raise an error.
- Otherwise, if all collations are *X*, use *X*.
- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is *X*. The same applies for `UNION`, `||`, `CONCAT()`, `ELT()`, `GREATEST()`, `IF()`, and `LEAST()`.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` and `collation_connection` system variables. This applies to `CAST()`, `CHAR()`, `CONV()`, `FORMAT()`, `HEX()`, and `SPACE()`.

## 10.6.2. CONVERT() and CAST()

`CONVERT()` provides a way to convert data between different character sets. The syntax is:

```
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```
SELECT CONVERT(_latin1'Müller' USING utf8);
INSERT INTO utf8table (utf8column)
    SELECT CONVERT(latin1field USING utf8) FROM latin1table;
```

`CONVERT(... USING ...)` is implemented according to the standard SQL specification.

You may also use `CAST()` to convert a string to a different character set. The syntax is:

```
CAST(character_string AS character_data_type CHARACTER SET charset_name)
```

Example:

```
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8);
```

If you use `CAST()` without specifying `CHARACTER SET`, the resulting character set and collation are defined by the `character_set_connection` and `collation_connection` system variables. If you use `CAST()` with `CHARACTER SET X`, the resulting character set and collation are *X* and the default collation of *X*.

You may not use a `COLLATE` clause inside a `CAST()`, but you may use it outside. That is, `CAST(... COLLATE ...)` is illegal, but `CAST(...) COLLATE ...` is legal.

Example:

```
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8) COLLATE utf8_bin;
```

### 10.6.3. SHOW Statements and INFORMATION\_SCHEMA

Several SHOW statements provide additional character set information. These include SHOW CHARACTER SET, SHOW COLLATION, SHOW CREATE DATABASE, SHOW CREATE TABLE and SHOW COLUMNS. These statements are described here briefly. For more information, see Section 13.5.4, “SHOW Syntax”.

INFORMATION\_SCHEMA has several tables that contain information similar to that displayed by the SHOW statements. For example, the CHARACTER\_SETS and COLLATIONS tables contain the information displayed by SHOW CHARACTER SET and SHOW COLLATION. Chapter 20, *The INFORMATION\_SCHEMA Database*.

The SHOW CHARACTER SET command shows all available character sets. It takes an optional LIKE clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
```

Charset	Description	Default collation	Maxlen
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1

The output from SHOW COLLATION includes all available character sets. It takes an optional LIKE clause that indicates which collation names to match. For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_german1_ci	latin1	5			0
latin1_swedish_ci	latin1	8	Yes	Yes	0
latin1_danish_ci	latin1	15			0
latin1_german2_ci	latin1	31		Yes	2
latin1_bin	latin1	47		Yes	0
latin1_general_ci	latin1	48			0
latin1_general_cs	latin1	49			0
latin1_spanish_ci	latin1	94			0

SHOW CREATE DATABASE displays the CREATE DATABASE statement that creates a given database:

```
mysql> SHOW CREATE DATABASE test;
```

Database	Create Database
test	CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */

If no COLLATE clause is shown, the default collation for the character set applies.

SHOW CREATE TABLE is similar, but displays the CREATE TABLE statement to create a given table. The column definitions indicate any character set specifications, and the table options include character set information.

The `SHOW COLUMNS` statement displays the collations of a table's columns when invoked as `SHOW FULL COLUMNS`. Columns with `CHAR`, `VARCHAR`, or `TEXT` data types have collations. Numeric and other non-character types have no collation (indicated by `NULL` as the `Collation` value). For example:

```
mysql> SHOW FULL COLUMNS FROM person\G
***** 1. row *****
      Field: id
      Type: smallint(5) unsigned
      Collation: NULL
      Null: NO
      Key: PRI
      Default: NULL
      Extra: auto_increment
      Privileges: select,insert,update,references
      Comment:
***** 2. row *****
      Field: name
      Type: char(60)
      Collation: latin1_swedish_ci
      Null: NO
      Key:
      Default:
      Extra:
      Privileges: select,insert,update,references
      Comment:
```

The character set is not part of the display but is implied by the collation name.

## 10.7. Unicode Support

MySQL 5.0 supports two character sets for storing Unicode data:

- `ucs2`, the UCS-2 Unicode character set.
- `utf8`, the UTF-8 encoding of the Unicode character set.

In UCS-2 (binary Unicode representation), every character is represented by a two-byte Unicode code with the most significant byte first. For example: `LATIN CAPITAL LETTER A` has the code `0x0041` and it is stored as a two-byte sequence: `0x00 0x41`. `CYRILLIC SMALL LETTER YERU` (Unicode `0x044B`) is stored as a two-byte sequence: `0x04 0x4B`. For Unicode characters and their codes, please refer to the Unicode Home Page [<http://www.unicode.org/>].

Currently, UCS-2 cannot be used as a client character set, which means that `SET NAMES 'ucs2'` does not work.

The UTF-8 character set (transform Unicode representation) is an alternative way to store Unicode data. It is implemented according to RFC 3629. The idea of the UTF-8 character set is that various Unicode characters are encoded using byte sequences of different lengths:

- Basic Latin letters, digits, and punctuation signs use one byte.
- Most European and Middle East script letters fit into a two-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.
- Korean, Chinese, and Japanese ideographs use three-byte sequences.

RFC 3629 describes encoding sequences that take from one to four bytes. Currently, MySQL sup-

port for UTF-8 does not include four-byte sequences. (An older standard for UTF-8 encoding is given by RFC 2279, which describes UTF-8 sequences that take from one to six bytes. RFC 3629 renders RFC 2279 obsolete; for this reason, sequences with five and six bytes are no longer used.)

**Tip:** To save space with UTF-8, use `VARCHAR` instead of `CHAR`. Otherwise, MySQL must reserve three bytes for each character in a `CHAR CHARACTER SET utf8` column because that is the maximum possible length. For example, MySQL must reserve 30 bytes for a `CHAR(10) CHARACTER SET utf8` column.

## 10.8. UTF-8 for Metadata

*Metadata* is “the data about the data.” Anything that *describes* the database — as opposed to being the *contents* of the database — is metadata. Thus column names, database names, usernames, version names, and most of the string results from `SHOW` are metadata. This is also true of the contents of tables in `INFORMATION_SCHEMA`, because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

- All metadata must be in the same character set. Otherwise, neither the `SHOW` commands nor `SELECT` statements for tables in `INFORMATION_SCHEMA` would work properly because different rows in the same column of the results of these operations would be in different character sets.
- Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the `USER()`, `CURRENT_USER()`, `SESSION_USER()`, `SYSTEM_USER()`, `DATABASE()`, and `VERSION()` functions have the UTF-8 character set by default.

The server sets the `character_set_system` system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_system | utf8 |
+-----+-----+
```

Storage of metadata using Unicode does *not* mean that the server returns headers of columns and the results of `DESCRIBE` functions in the `character_set_system` character set by default. When you use `SELECT column1 FROM t`, the name `column1` itself is returned from the server to the client in the character set determined by the value of the `character_set_results` system variable, which has a default value of `latin1`. If you want the server to pass metadata results back in a different character set, use the `SET NAMES` statement to force the server to perform character set conversion. `SET NAMES` sets the `character_set_results` and other related system variables. (See Section 10.4, “Connection Character Sets and Collations”.) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client perform the conversion, but this option is not always available for all clients.

If `character_set_results` is set to `NULL`, no conversion is performed and the server returns metadata using its original character set (the set indicated by `character_set_system`).

Error messages returned from the server to the client are converted to the client character set auto-

matically, as with metadata.

If you are using (for example) the `USER()` function for comparison or assignment within a single statement, don't worry. MySQL performs some automatic conversion for you.

```
SELECT * FROM Table1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```
INSERT INTO Table1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` are automatically converted to `latin1` before the assignment. Automatic conversion is not fully implemented yet, but should work correctly in a later version.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings.

## 10.9. Character Sets and Collations That MySQL Supports

MySQL supports 70+ collations for 30+ character sets. This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the allowable collations are listed.

You can always list the available character sets and their default collations with the `SHOW CHARACTER SET` statement:

```
mysql> SHOW CHARACTER SET;
```

Charset	Description	Default collation
big5	Big5 Traditional Chinese	big5_chinese_ci
dec8	DEC West European	dec8_swedish_ci
cp850	DOS West European	cp850_general_ci
hp8	HP West European	hp8_english_ci
koi8r	KOI8-R Relcom Russian	koi8r_general_ci
latin1	cp1252 West European	latin1_swedish_ci
latin2	ISO 8859-2 Central European	latin2_general_ci
swe7	7bit Swedish	swe7_swedish_ci
ascii	US ASCII	ascii_general_ci
ujis	EUC-JP Japanese	ujis_japanese_ci
sjis	Shift-JIS Japanese	sjis_japanese_ci
hebrew	ISO 8859-8 Hebrew	hebrew_general_ci
tis620	TIS620 Thai	tis620_thai_ci
euckr	EUC-KR Korean	euckr_korean_ci
koi8u	KOI8-U Ukrainian	koi8u_general_ci
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci
greek	ISO 8859-7 Greek	greek_general_ci
cp1250	Windows Central European	cp1250_general_ci
gbk	GBK Simplified Chinese	gbk_chinese_ci
latin5	ISO 8859-9 Turkish	latin5_turkish_ci
armscii8	ARMSCII-8 Armenian	armscii8_general_ci
utf8	UTF-8 Unicode	utf8_general_ci
ucs2	UCS-2 Unicode	ucs2_general_ci
cp866	DOS Russian	cp866_general_ci
keybcs2	DOS Kamenicky Czech-Slovak	keybcs2_general_ci
macce	Mac Central European	macce_general_ci
macroman	Mac West European	macroman_general_ci

cp852	DOS Central European	cp852_general_ci
latin7	ISO 8859-13 Baltic	latin7_general_ci
cp1251	Windows Cyrillic	cp1251_general_ci
cp1256	Windows Arabic	cp1256_general_ci
cp1257	Windows Baltic	cp1257_general_ci
binary	Binary pseudo charset	binary
geostd8	GEOSTD8 Georgian	geostd8_general_ci
cp932	SJIS for Windows Japanese	cp932_japanese_ci
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci

## 10.9.1. Unicode Character Sets

MySQL has two Unicode character sets. You can store text in about 650 languages using these character sets.

- ucs2 (UCS-2 Unicode) collations:
  - ucs2\_bin
  - ucs2\_czech\_ci
  - ucs2\_danish\_ci
  - ucs2\_esperanto\_ci
  - ucs2\_estonian\_ci
  - ucs2\_general\_ci (default)
  - ucs2\_hungarian\_ci
  - ucs2\_icelandic\_ci
  - ucs2\_latvian\_ci
  - ucs2\_lithuanian\_ci
  - ucs2\_persian\_ci
  - ucs2\_polish\_ci
  - ucs2\_roman\_ci
  - ucs2\_romanian\_ci
  - ucs2\_slovak\_ci
  - ucs2\_slovenian\_ci
  - ucs2\_spanish2\_ci
  - ucs2\_spanish\_ci
  - ucs2\_swedish\_ci
  - ucs2\_turkish\_ci
  - ucs2\_unicode\_ci
- utf8 (UTF-8 Unicode) collations:
  - utf8\_bin

- `utf8_czech_ci`
- `utf8_danish_ci`
- `utf8_esperanto_ci`
- `utf8_estonian_ci`
- `utf8_general_ci` (default)
- `utf8_hungarian_ci`
- `utf8_icelandic_ci`
- `utf8_latvian_ci`
- `utf8_lithuanian_ci`
- `utf8_persian_ci`
- `utf8_polish_ci`
- `utf8_roman_ci`
- `utf8_romanian_ci`
- `utf8_slovak_ci`
- `utf8_slovenian_ci`
- `utf8_spanish2_ci`
- `utf8_spanish_ci`
- `utf8_swedish_ci`
- `utf8_turkish_ci`
- `utf8_unicode_ci`

The `ucs2_esperanto_ci` and `utf8_esperanto_ci` collations were added in MySQL 5.0.13. The `ucs2_hungarian_ci` and `utf8_hungarian_ci` collations were added in MySQL 5.0.19.

MySQL implements the `utf8_unicode_ci` collation according to the Unicode Collation Algorithm (UCA) described at <http://www.unicode.org/reports/tr10/>. The collation uses the version-4.0.0 UCA weight keys: <http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>. The following discussion uses `utf8_unicode_ci`, but it is also true for `ucs2_unicode_ci`.

Currently, the `utf8_unicode_ci` collation has only partial support for the Unicode Collation Algorithm. Some characters are not supported yet. Also, combining marks are not fully supported. This affects primarily Vietnamese and some minority languages in Russia such as Udmurt, Tatar, Bashkir, and Mari.

The most significant feature in `utf8_unicode_ci` is that it supports expansions; that is, when one character compares as equal to combinations of other characters. For example, in German and some other languages ‘ß’ is equal to ‘ss’.

`utf8_general_ci` is a legacy collation that does not support expansions. It can make only one-to-one comparisons between characters. This means that comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`.

For example, the following equalities hold in both `utf8_general_ci` and `utf8_unicode_ci`:

Ä = A  
Ö = O  
Ü = U

A difference between the collations is that this is true for `utf8_general_ci`:

ß = s

Whereas this is true for `utf8_unicode_ci`:

ß = ss

MySQL implements language-specific collations for the `utf8` character set only if the ordering with `utf8_unicode_ci` does not work well for a language. For example, `utf8_unicode_ci` works fine for German and French, so there is no need to create special `utf8` collations for these two languages.

`utf8_general_ci` also is satisfactory for both German and French, except that 'ß' is equal to 's', and not to 'ss'. If this is acceptable for your application, then you should use `utf8_general_ci` because it is faster. Otherwise, use `utf8_unicode_ci` because it is more accurate.

`utf8_swedish_ci`, like other `utf8` language-specific collations, is derived from `utf8_unicode_ci` with additional language rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

Û = Y < Ö

The `utf8_spanish_ci` and `utf8_spanish2_ci` collations correspond to modern Spanish and traditional Spanish, respectively. In both collations, 'ñ' (n-tilde) is a separate letter between 'n' and 'o'. In addition, for traditional Spanish, 'ch' is a separate letter between 'c' and 'd', and 'll' is a separate letter between 'l' and 'm'.

## 10.9.2. West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- `ascii` (US ASCII) collations:
  - `ascii_bin`
  - `ascii_general_ci` (default)
- `cp850` (DOS West European) collations:
  - `cp850_bin`
  - `cp850_general_ci` (default)
- `dec8` (DEC Western European) collations:
  - `dec8_bin`
  - `dec8_swedish_ci` (default)

- hp8 (HP Western European) collations:
  - hp8\_bin
  - hp8\_english\_ci (default)
- latin1 (cp1252 West European) collations:
  - latin1\_bin
  - latin1\_danish\_ci
  - latin1\_general\_ci
  - latin1\_general\_cs
  - latin1\_german1\_ci
  - latin1\_german2\_ci
  - latin1\_spanish\_ci
  - latin1\_swedish\_ci (default)

latin1 is the default character set. MySQL's latin1 is the same as the Windows cp1252 character set. This means it is the same as the official ISO 8859-1 or IANA (Internet Assigned Numbers Authority) latin1, but IANA latin1 treats the code points between 0x80 and 0x9f as “undefined,” whereas cp1252, and therefore MySQL's latin1, assign characters for those positions. For example, 0x80 is the Euro sign. For the “undefined” entries in cp1252, MySQL translates 0x81 to Unicode 0x0081, 0x8d to 0x008d, 0x8f to 0x008f, 0x90 to 0x0090, and 0x9d to 0x009d.

The latin1\_swedish\_ci collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The latin1\_german1\_ci and latin1\_german2\_ci collations are based on the DIN-1 and DIN-2 standards, where DIN stands for *Deutsches Institut für Normung* (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.”

- latin1\_german1\_ci (dictionary) rules:

Ä = A  
Ö = O  
Û = U  
ß = s

- latin1\_german2\_ci (phone-book) rules:

Ä = AE  
Ö = OE  
Û = UE  
ß = ss

In the latin1\_spanish\_ci collation, ‘ñ’ (n-tilde) is a separate letter between ‘n’ and ‘o’.

- macroman (Mac West European) collations:
  - macroman\_bin
  - macroman\_general\_ci (default)

- swe7 (7bit Swedish) collations:
  - swe7\_bin
  - swe7\_swedish\_ci (default)

### 10.9.3. Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, and Poland.

- cp1250 (Windows Central European) collations:
  - cp1250\_bin
  - cp1250\_croatian\_ci
  - cp1250\_czech\_cs
  - cp1250\_general\_ci (default)
- cp852 (DOS Central European) collations:
  - cp852\_bin
  - cp852\_general\_ci (default)
- keybcs2 (DOS Kamenicky Czech-Slovak) collations:
  - keybcs2\_bin
  - keybcs2\_general\_ci (default)
- latin2 (ISO 8859-2 Central European) collations:
  - latin2\_bin
  - latin2\_croatian\_ci
  - latin2\_czech\_cs
  - latin2\_general\_ci (default)
  - latin2\_hungarian\_ci
- macce (Mac Central European) collations:
  - macce\_bin
  - macce\_general\_ci (default)

### 10.9.4. South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- armSCII8 (ARMSII-8 Armenian) collations:

- `armscii8_bin`
- `armscii8_general_ci` (default)
- `cp1256` (Windows Arabic) collations:
  - `cp1256_bin`
  - `cp1256_general_ci` (default)
- `geostd8` (GEOSTD8 Georgian) collations:
  - `geostd8_bin`
  - `geostd8_general_ci` (default)
- `greek` (ISO 8859-7 Greek) collations:
  - `greek_bin`
  - `greek_general_ci` (default)
- `hebrew` (ISO 8859-8 Hebrew) collations:
  - `hebrew_bin`
  - `hebrew_general_ci` (default)
- `latin5` (ISO 8859-9 Turkish) collations:
  - `latin5_bin`
  - `latin5_turkish_ci` (default)

## 10.9.5. Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

- `cp1257` (Windows Baltic) collations:
  - `cp1257_bin`
  - `cp1257_general_ci` (default)
  - `cp1257_lithuanian_ci`
- `latin7` (ISO 8859-13 Baltic) collations:
  - `latin7_bin`
  - `latin7_estonian_cs`
  - `latin7_general_ci` (default)
  - `latin7_general_cs`

## 10.9.6. Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, and

Ukrainian languages.

- cp1251 (Windows Cyrillic) collations:
  - cp1251\_bin
  - cp1251\_bulgarian\_ci
  - cp1251\_general\_ci (default)
  - cp1251\_general\_cs
  - cp1251\_ukrainian\_ci
- cp866 (DOS Russian) collations:
  - cp866\_bin
  - cp866\_general\_ci (default)
- koi8r (KOI8-R Relcom Russian) collations:
  - koi8r\_bin
  - koi8r\_general\_ci (default)
- koi8u (KOI8-U Ukrainian) collations:
  - koi8u\_bin
  - koi8u\_general\_ci (default)

## 10.9.7. Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See Section 10.9.7.1, “The cp932 Character Set”, for additional information about the cp932 and sjis character sets.

- big5 (Big5 Traditional Chinese) collations:
  - big5\_bin
  - big5\_chinese\_ci (default)
- cp932 (SJIS for Windows Japanese) collations:
  - cp932\_bin
  - cp932\_japanese\_ci (default)
- eucjpms (UJIS for Windows Japanese) collations:
  - eucjpms\_bin
  - eucjpms\_japanese\_ci (default)
- euckr (EUC-KR Korean) collations:
  - euckr\_bin

- `euckr_korean_ci` (default)
- `gb2312` (GB2312 Simplified Chinese) collations:
  - `gb2312_bin`
  - `gb2312_chinese_ci` (default)
- `gbk` (GBK Simplified Chinese) collations:
  - `gbk_bin`
  - `gbk_chinese_ci` (default)
- `sjis` (Shift-JIS Japanese) collations:
  - `sjis_bin`
  - `sjis_japanese_ci` (default)
- `tis620` (TIS620 Thai) collations:
  - `tis620_bin`
  - `tis620_thai_ci` (default)
- `ujis` (EUC-JP Japanese) collations:
  - `ujis_bin`
  - `ujis_japanese_ci` (default)

### 10.9.7.1. The `cp932` Character Set

#### Why is `cp932` needed?

In MySQL, the `sjis` character set corresponds to the `Shift_JIS` character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See <http://www.iana.org/assignments/character-sets>.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to `Shift_JIS` that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of `Shift_JIS` and its exact name is Microsoft Windows Codepage : 932 or `cp932`. In addition to the characters supported by `Shift_JIS`, `cp932` supports extension characters such as NEC special characters, NEC selected — IBM extended characters, and IBM extended characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.
- Character sets are converted via Unicode (`ucs2`).
- The `sjis` character set does not support the conversion of these extension characters.
- There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL `cp932` character set is designed to solve these problems. It is available as of MySQL 5.0.3.

Because MySQL supports character set conversion, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

### How does `cp932` differ from `sjis`?

The `cp932` character set differs from `sjis` in the following ways:

- `cp932` supports NEC special characters, NEC selected — IBM extended characters, and IBM selected characters.
- Some `cp932` characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to `cp932`, one of the code points must be selected. For this “round trip conversion,” the rule recommended by Microsoft is used. (See <http://support.microsoft.com/kb/170559/EN-US/>.)

The conversion rule works like this:

- If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.
- If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.
- If the character is in both IBM selected characters and NEC selected — IBM extended characters, use the code point of IBM extended characters.

The table shown at <http://www.microsoft.com/globaldev/reference/dbcs/932.htm> provides information about the Unicode values of `cp932` characters. For `cp932` table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (ucs2) encoding. For table entries with an underlined two-digit value appears, there is a range of `cp932` character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the `cp932` characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters:

[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_87.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_87.htm)

- NEC selected — IBM extended characters:

[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_ED.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_ED.htm)  
[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_EE.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_EE.htm)

- IBM selected characters:

[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_FA.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_FA.htm)  
[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_FB.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_FB.htm)  
[http://www.microsoft.com/globaldev/reference/dbcs/932/932\\_FC.htm](http://www.microsoft.com/globaldev/reference/dbcs/932/932_FC.htm)

- Starting from version 5.0.3, `cp932` supports conversion of user-defined characters in combination with `ujis`, and solves the problems with `sjis/ujis` conversion. For details, please refer to <http://www.opengroup.org/jvc/cde/sjis-euc-e.html>.

For some characters, conversion to and from `ucs2` is different for `sjis` and `cp932`. The following

tables illustrate these differences.

Conversion to ucs2:

<b>sjis/cp932 Value</b>	<b>sjis -&gt; ucs2 Conversion</b>	<b>cp932 -&gt; ucs2 Conversion</b>
5C	005C	005C
7E	007E	007E
815C	2015	2015
815F	005C	FF3C
8160	301C	FF5E
8161	2016	2225
817C	2212	FF0D
8191	00A2	FFE0
8192	00A3	FFE1
81CA	00AC	FFE2

Conversion from ucs2:

<b>ucs2 value</b>	<b>ucs2 -&gt; sjis Conversion</b>	<b>ucs2 -&gt; cp932 Conversion</b>
005C	815F	5C
007E	7E	7E
00A2	8191	3F
00A3	8192	3F
00AC	81CA	3F
2015	815C	815C
2016	8161	3F
2212	817C	3F
2225	3F	8161
301C	8160	3F
FF0D	3F	817C
FF3C	3F	815F
FF5E	3F	8160
FFE0	3F	8191
FFE1	3F	8192
FFE2	3F	81CA

Users of any Japanese character sets should be aware that using `-character-set-client-handshake` (or `-skip-character-set-client-handshake`) has an important effect. See Section 5.2.1, “mysqld Command Options”.

---

# Chapter 11. Data Types

MySQL supports a number of data types in several categories: numeric types, date and time types, and string (character) types. This chapter first gives an overview of these data types, and then provides a more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overview is intentionally brief. The more detailed descriptions later in the chapter should be consulted for additional information about particular data types, such as the allowable formats in which you can specify values.

MySQL also supports extensions for handling spatial data. Chapter 16, *Spatial Extensions*, provides information about these data types.

Several of the data type descriptions use these conventions:

- *M* indicates the maximum display width for integer types. For floating-point and fixed-point types, *M* is the total number of digits. For string types, *M* is the maximum length. The maximum allowable value of *M* depends on the data type.
- *D* applies to floating-point and fixed-point types and indicates the number of digits following the decimal point. The maximum possible value is 30, but should be no greater than  $M-2$ .
- Square brackets (‘[’ and ‘]’) indicate optional parts of type definitions.

## 11.1. Data Type Overview

### 11.1.1. Overview of Numeric Types

A summary of the numeric data types follows. For additional information, see Section 11.2, “Numeric Types”. Storage requirements are given in Section 11.5, “Data Type Storage Requirements”.

*M* indicates the maximum display width. The maximum legal display width is 255. Display width is unrelated to the storage size or range of values a type can contain, as described in Section 11.2, “Numeric Types”.

If you specify ZEROFILL for a numeric column, MySQL automatically adds the UNSIGNED attribute to the column.

SERIAL is an alias for BIGINT UNSIGNED NOT NULL AUTO\_INCREMENT UNIQUE.

SERIAL DEFAULT VALUE in the definition of an integer column is an alias for NOT NULL AUTO\_INCREMENT UNIQUE.

**Warning:** When you use subtraction between integer values where one is of type UNSIGNED, the result is unsigned unless the NO\_UNSIGNED\_SUBTRACTION SQL mode is enabled. See Section 12.8, “Cast Functions and Operators”.

- BIT[ (*M*) ]

A bit-field type. *M* indicates the number of bits per value, from 1 to 64. The default is 1 if *M* is omitted.

This data type was added in MySQL 5.0.3 for MyISAM, and extended in 5.0.5 to MEMORY, InnoDB, and BDB. Before 5.0.3, BIT is a synonym for TINYINT(1).

- TINYINT[ (*M*) ] [UNSIGNED] [ZEROFILL]

A very small integer. The signed range is -128 to 127. The unsigned range is 0 to 255.

- `BOOL`, `BOOLEAN`

These types are synonyms for `TINYINT(1)`. A value of zero is considered false. Non-zero values are considered true.

In the future, full boolean type handling will be introduced in accordance with standard SQL.

- `SMALLINT[(M)] [UNSIGNED] [ZEROFILL]`

A small integer. The signed range is `-32768` to `32767`. The unsigned range is `0` to `65535`.

- `MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]`

A medium-sized integer. The signed range is `-8388608` to `8388607`. The unsigned range is `0` to `16777215`.

- `INT[(M)] [UNSIGNED] [ZEROFILL]`

A normal-size integer. The signed range is `-2147483648` to `2147483647`. The unsigned range is `0` to `4294967295`.

- `INTEGER[(M)] [UNSIGNED] [ZEROFILL]`

This type is a synonym for `INT`.

- `BIGINT[(M)] [UNSIGNED] [ZEROFILL]`

A large integer. The signed range is `-9223372036854775808` to `9223372036854775807`. The unsigned range is `0` to `18446744073709551615`.

Some things you should be aware of with respect to `BIGINT` columns:

- All arithmetic is done using signed `BIGINT` or `DOUBLE` values, so you should not use unsigned big integers larger than `9223372036854775807` (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a `BIGINT` value to a `DOUBLE`.

MySQL can handle `BIGINT` in the following cases:

- When using integers to store large unsigned values in a `BIGINT` column.
- In `MIN(col_name)` or `MAX(col_name)`, where `col_name` refers to a `BIGINT` column.
- When using operators (+, -, \*, and so on) where both operands are integers.
- You can always store an exact integer value in a `BIGINT` column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.
- The -, +, and \* operators use `BIGINT` arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than `9223372036854775807`.
- `FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]`

A small (single-precision) floating-point number. Allowable values are `-3.402823466E+38` to `-1.175494351E-38`, `0`, and `1.175494351E-38` to `3.402823466E+38`. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

*M* is the total number of decimal digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits allowed by the hardware. A single-precision

cision floating-point number is accurate to approximately 7 decimal places.

UNSIGNED, if specified, disallows negative values.

Using FLOAT might give you some unexpected problems because all calculations in MySQL are done with double precision. See Section A.5.7, “Solving Problems with No Matching Rows”.

- DOUBLE[ (*M*, *D*) ] [ UNSIGNED ] [ ZEROFILL ]

A normal-size (double-precision) floating-point number. Allowable values are  $-1.7976931348623157E+308$  to  $-2.2250738585072014E-308$ , 0, and  $2.2250738585072014E-308$  to  $1.7976931348623157E+308$ . These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

*M* is the total number of decimal digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits allowed by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

UNSIGNED, if specified, disallows negative values.

- DOUBLE PRECISION[ (*M*, *D*) ] [ UNSIGNED ] [ ZEROFILL ], REAL[ (*M*, *D*) ] [ UNSIGNED ] [ ZEROFILL ]

These types are synonyms for DOUBLE. Exception: If the REAL\_AS\_FLOAT SQL mode is enabled, REAL is a synonym for FLOAT rather than DOUBLE.

- FLOAT(*p*) [ UNSIGNED ] [ ZEROFILL ]

A floating-point number. *p* represents the precision in bits, but MySQL uses this value only to determine whether to use FLOAT or DOUBLE for the resulting data type. If *p* is from 0 to 24, the data type becomes FLOAT with no *M* or *D* values. If *p* is from 25 to 53, the data type becomes DOUBLE with no *M* or *D* values. The range of the resulting column is the same as for the single-precision FLOAT or double-precision DOUBLE data types described earlier in this section.

FLOAT(*p*) syntax is provided for ODBC compatibility.

- DECIMAL[ (*M* [, *D*]) ] [ UNSIGNED ] [ ZEROFILL ]

For MySQL 5.0.3 and above:

A packed “exact” fixed-point number. *M* is the total number of decimal digits (the precision) and *D* is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the ‘-’ sign are not counted in *M*. If *D* is 0, values have no decimal point or fractional part. The maximum number of digits (*M*) for DECIMAL is 65 (64 from 5.0.3 to 5.0.5). The maximum number of supported decimals (*D*) is 30. If *D* is omitted, the default is 0. If *M* is omitted, the default is 10.

UNSIGNED, if specified, disallows negative values.

All basic calculations (+, -, \*, /) with DECIMAL columns are done with a precision of 65 digits.

Before MySQL 5.0.3:

An unpacked fixed-point number. Behaves like a CHAR column; “unpacked” means the number is stored as a string, using one character for each digit of the value. *M* is the total number of digits and *D* is the number of digits after the decimal point. The decimal point and (for negative numbers) the ‘-’ sign are not counted in *M*, although space for them is reserved. If *D* is 0, values have no decimal point or fractional part. The maximum range of DECIMAL values is the same as for DOUBLE, but the actual range for a given DECIMAL column may be constrained by the choice of *M* and *D*. If *D* is omitted, the default is 0. If *M* is omitted, the default is 10.

UNSIGNED, if specified, disallows negative values.

The behavior used by the server for DECIMAL columns in a table depends on the version of MySQL used to create the table. If your server is from MySQL 5.0.3 or higher, but you have DECIMAL columns in tables that were created before 5.0.3, the old behavior still applies to those columns. To convert the tables to the newer DECIMAL format, dump them with `mysqldump` and reload them.

- DEC[(M[,D])] [UNSIGNED] [ZEROFILL], NUMERIC[(M[,D])] [UNSIGNED] [ZEROFILL], FIXED[(M[,D])] [UNSIGNED] [ZEROFILL]

These types are synonyms for DECIMAL. The FIXED synonym is available for compatibility with other database systems.

## 11.1.2. Overview of Date and Time Types

A summary of the temporal data types follows. For additional information, see Section 11.3, “Date and Time Types”. Storage requirements are given in Section 11.5, “Data Type Storage Requirements”.

For the DATETIME and DATE range descriptions, “supported” means that although earlier values might work, there is no guarantee.

The SUM() and AVG() aggregate functions do not work with temporal values. (They convert the values to numbers, which loses the part after the first non-numeric character.) To work around this problem, you can convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name ;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name ;
```

- DATE

A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays DATE values in 'YYYY-MM-DD' format, but allows you to assign values to DATE columns using either strings or numbers.

- DATETIME

A date and time combination. The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'. MySQL displays DATETIME values in 'YYYY-MM-DD HH:MM:SS' format, but allows you to assign values to DATETIME columns using either strings or numbers.

- TIMESTAMP[(M)]

A timestamp. The range is '1970-01-01 00:00:00' to partway through the year 2037.

A TIMESTAMP column is useful for recording the date and time of an INSERT or UPDATE operation. By default, the first TIMESTAMP column in a table is automatically set to the date and time of the most recent operation if you do not assign it a value yourself. You can also set any TIMESTAMP column to the current date and time by assigning it a NULL value. Variations on automatic initialization and update properties are described in Section 11.3.1.1, “TIMESTAMP Properties as of MySQL 4.1”.

A TIMESTAMP value is returned as a string in the format 'YYYY-MM-DD HH:MM:SS' with a display width fixed at 19 characters. To obtain the value as a number, you should add +0 to the timestamp column.

**Note:** The TIMESTAMP format that was used prior to MySQL 4.1 is not supported in MySQL 5.0; see *MySQL 3.23, 4.0, 4.1 Reference Manual* for information regarding the old format.

- `TIME`

A time. The range is `'-838:59:59'` to `'838:59:59'`. MySQL displays `TIME` values in `'HH:MM:SS'` format, but allows you to assign values to `TIME` columns using either strings or numbers.

- `YEAR[(2|4)]`

A year in two-digit or four-digit format. The default is four-digit format. In four-digit format, the allowable values are 1901 to 2155, and 0000. In two-digit format, the allowable values are 70 to 69, representing years from 1970 to 2069. MySQL displays `YEAR` values in `YYYY` format, but allows you to assign values to `YEAR` columns using either strings or numbers.

### 11.1.3. Overview of String Types

A summary of the string data types follows. For additional information, see Section 11.4, “String Types”. Storage requirements are given in Section 11.5, “Data Type Storage Requirements”.

In some cases, MySQL may change a string column to a type different from that given in a `CREATE TABLE` or `ALTER TABLE` statement. See Section 13.1.5.1, “Silent Column Specification Changes”.

In MySQL 4.1 and up, string data types include some features that you may not have encountered in working with previous versions of MySQL (prior to 4.1):

- Column definitions for many string data types can include a `CHARACTER SET` attribute to specify the character set. (`CHARSET` is a synonym for `CHARACTER SET`.) The `COLLATE` attribute specifies a collation for the the character set. These attributes apply to `CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, and `SET`. For example:

```
CREATE TABLE t
(
  c1 VARCHAR(20) CHARACTER SET utf8,
  c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
);
```

This table definition creates a column named `c1` that has a character set of `utf8` with the default collation for that character set, and a column named `c2` that has a character set of `latin1` and a case-sensitive collation.

- MySQL 5.0 interprets length specifications in character column definitions in character units. (Previously, MySQL interpreted lengths in bytes.)
- For `CHAR`, `VARCHAR`, and the `TEXT` types, the `BINARY` attribute causes the column to be assigned the binary collation of the column character set. (Previously, `BINARY` caused a column to store binary strings.)
- Character column sorting and comparison are based on the character set assigned to the column. (Previously, sorting and comparison were based on the collation of the server character set.) For `CHAR` and `VARCHAR` columns, you can declare the column with a binary collation or the `BINARY` attribute to cause sorting and comparison to use the underlying character code values rather than a lexical ordering.

Chapter 10, *Character Set Support*, provides additional information about use of character sets in MySQL.

- `[NATIONAL] CHAR(M) [BINARY | ASCII | UNICODE]`

A fixed-length string that is always right-padded with spaces to the specified length when stored.

$M$  represents the column length. The range of  $M$  is 0 to 255 characters.

**Note:** Trailing spaces are removed when CHAR values are retrieved.

Before MySQL 5.0.3, a CHAR column with a length specification greater than 255 is converted to the smallest TEXT type that can hold values of the given length. For example, CHAR(500) is converted to TEXT, and CHAR(200000) is converted to MEDIUMTEXT. This is a compatibility feature. However, this conversion causes the column to become a variable-length column, and also affects trailing-space removal.

In MySQL 5.0.3 and later, if you attempt to set the length of a CHAR greater than 255, the CREATE TABLE or ALTER TABLE statement in which this is done fails with an error:

```
mysql> CREATE TABLE c1 (col1 INT, col2 CHAR(500));
ERROR 1074 (42000): Column length too big for column 'col' (max = 255);
use BLOB or TEXT instead
mysql> SHOW CREATE TABLE c1;
ERROR 1146 (42S02): Table 'test.c1' doesn't exist
```

CHAR is shorthand for CHARACTER. NATIONAL CHAR (or its equivalent short form, NCHAR) is the standard SQL way to define that a CHAR column should use some predefined character set. MySQL 4.1 and up utf8 as this predefined character set. Section 10.3.6, “National Character Set”.

The BINARY attribute is shorthand for specifying the binary collation of the column character set. In this case, sorting and comparison are based on numeric character values.

The ASCII attribute is shorthand for CHARACTER SET latin1.

The UNICODE attribute is shorthand for CHARACTER SET ucs2.

The CHAR BYTE data type is an alias for the BINARY type. This is a compatibility feature.

MySQL allows you to create a column of type CHAR(0). This is useful primarily when you have to be compliant with old applications that depend on the existence of a column but that do not actually use its value. CHAR(0) is also quite nice when you need a column that can take only two values: A CHAR(0) column that is not defined as NOT NULL occupies only one bit and can take only the values NULL and ' ' (the empty string).

- CHAR

This type is a synonym for CHAR(1).

- [NATIONAL] VARCHAR( $M$ ) [BINARY]

A variable-length string.  $M$  represents the maximum column length. In MySQL 5.0, the range of  $M$  is 0 to 255 before MySQL 5.0.3, and 0 to 65,535 in MySQL 5.0.3 and later. (The actual maximum length of a VARCHAR in MySQL 5.0 is determined by the maximum row size and the character set you use. The maximum *effective* length starting with MySQL 5.0.3 is 65,532 bytes.)

**Note:** Before 5.0.3, trailing spaces were removed when VARCHAR values were stored, which differs from the standard SQL specification.

Prior to MySQL 5.0.3, a VARCHAR column with a length specification greater than 255 was converted to the smallest TEXT type that could hold values of the given length. For example, VARCHAR(500) was converted to TEXT, and VARCHAR(200000) was converted to MEDIUMTEXT. This was a compatibility feature. However, this conversion affected trailing-space removal.

VARCHAR is shorthand for CHARACTER VARYING.

The BINARY attribute is shorthand for specifying the binary collation of the column character

set. In this case, sorting and comparison are based on numeric character values.

VARCHAR values are stored using as many characters as are needed, plus one byte to record the length (two bytes for columns that are declared with a length longer than 255).

- BINARY(*M*)

The BINARY type is similar to the CHAR type, but stores binary byte strings rather than non-binary character strings.

- VARBINARY(*M*)

The VARBINARY type is similar to the VARCHAR type, but stores binary byte strings rather than non-binary character strings.

- TINYBLOB

A BLOB column with a maximum length of 255 ( $2^8 - 1$ ) bytes.

- TINYTEXT

A TEXT column with a maximum length of 255 ( $2^8 - 1$ ) characters.

- BLOB[ (*M*) ]

A BLOB column with a maximum length of 65,535 ( $2^{16} - 1$ ) bytes.

An optional length *M* can be given for this type. If this is done, MySQL creates the column as the smallest BLOB type large enough to hold values *M* bytes long.

- TEXT[ (*M*) ]

A TEXT column with a maximum length of 65,535 ( $2^{16} - 1$ ) characters.

An optional length *M* can be given for this type. If this is done, MySQL creates the column as the smallest TEXT type large enough to hold values *M* characters long.

- MEDIUMBLOB

A BLOB column with a maximum length of 16,777,215 ( $2^{24} - 1$ ) bytes.

- MEDIUMTEXT

A TEXT column with a maximum length of 16,777,215 ( $2^{24} - 1$ ) characters.

- LONGBLOB

A BLOB column with a maximum length of 4,294,967,295 or 4GB ( $2^{32} - 1$ ) bytes. The maximum *effective* (permitted) length of LONGBLOB columns depends on the configured maximum packet size in the client/server protocol and available memory.

- LONGTEXT

A TEXT column with a maximum length of 4,294,967,295 or 4GB ( $2^{32} - 1$ ) characters. The maximum *effective* (permitted) length of LONGTEXT columns depends on the configured maximum packet size in the client/server protocol and available memory.

- ENUM('value1', 'value2', ...)

An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special '' error value. An ENUM column can have a maximum of 65,535 distinct values. ENUM values are represented internally as integers.

- SET('value1', 'value2', ...)

A set. A string object that can have zero or more values, each of which must be chosen from the list of values `'value1'`, `'value2'`, ... A SET column can have a maximum of 64 members. SET values are represented internally as integers.

## 11.1.4. Data Type Default Values

The `DEFAULT value` clause in a data type specification indicates a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that you can specify `CURRENT_TIMESTAMP` as the default for a `TIMESTAMP` column. See Section 11.3.1.1, “TIMESTAMP Properties as of MySQL 4.1”.

Prior to MySQL 5.0.2, if a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.

If the column cannot take `NULL` as the value, MySQL defines the column with an explicit `DEFAULT` clause, using the implicit default value for the column data type. Implicit defaults are defined as follows:

- For numeric types other than integer types declared with the `AUTO_INCREMENT` attribute, the default is 0. For an `AUTO_INCREMENT` column, the default value is the next value in the sequence.
- For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. For the first `TIMESTAMP` column in a table, the default value is the current date and time. See Section 11.3, “Date and Time Types”.
- For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

`BLOB` and `TEXT` columns cannot be assigned a default value.

As of MySQL 5.0.2, if a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause. This is the same as before 5.0.2.

If the column cannot take `NULL` as the value, MySQL defines the column with no explicit `DEFAULT` clause. For data entry, if an `INSERT` or `REPLACE` statement includes no value for the column, MySQL handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is not enabled, MySQL sets the column to the implicit default value for the column data type.
- If strict mode is enabled, an error occurs for transactional tables and the statement is rolled back. For non-transactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, the preceding rows will have been inserted.

Suppose that a table `t` is defined as follows:

```
CREATE TABLE t (i INT NOT NULL);
```

In this case, `i` has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because `DEFAULT(i)` cannot produce a value:

```
INSERT INTO t VALUES();
INSERT INTO t VALUES(DEFAULT);
INSERT INTO t VALUES(DEFAULT(i));
```

See Section 5.2.5, “The Server SQL Mode”.

For a given table, you can use the `SHOW CREATE TABLE` statement to see which columns have an explicit `DEFAULT` clause.

## 11.2. Numeric Types

MySQL supports all of the standard SQL numeric data types. These types include the exact numeric data types (`INTEGER`, `SMALLINT`, `DECIMAL`, and `NUMERIC`), as well as the approximate numeric data types (`FLOAT`, `REAL`, and `DOUBLE PRECISION`). The keyword `INT` is a synonym for `INTEGER`, and the keyword `DEC` is a synonym for `DECIMAL`. For numeric type storage requirements, see Section 11.5, “Data Type Storage Requirements”.

As of MySQL 5.0.3, a `BIT` data type is available for storing bit-field values. (Before 5.0.3, MySQL interprets `BIT` as `TINYINT(1)`.) In MySQL 5.0.3, `BIT` is supported only for `MyISAM`. MySQL 5.0.5 extends `BIT` support to `MEMORY`, `InnoDB`, and `BDB`.

As an extension to the SQL standard, MySQL also supports the integer types `TINYINT`, `MEDIUMINT`, and `BIGINT`. The following table shows the required storage and range for each of the integer types.

Type	Bytes	Minimum Value (Signed/Unsigned)	Maximum Value (Signed/Unsigned)
<code>TINYINT</code>	1	-128 0	127 255
<code>SMALLINT</code>	2	-32768 0	32767 65535
<code>MEDIUMINT</code>	3	-8388608 0	8388607 16777215
<code>INT</code>	4	-2147483648 0	2147483647 4294967295
<code>BIGINT</code>	8	-9223372036854775808 0	9223372036854775807 18446744073709551615

Another extension is supported by MySQL for optionally specifying the display width of an integer value in parentheses following the base keyword for the type (for example, `INT(4)`). This optional display width specification is used to left-pad the display of values having a width less than the width specified for the column.

The display width does *not* constrain the range of values that can be stored in the column, nor the number of digits that are displayed for values having a width exceeding that specified for the column.

When used in conjunction with the optional extension attribute `ZEROFILL`, the default padding of spaces is replaced with zeroes. For example, for a column declared as `INT(5) ZEROFILL`, a value of 4 is retrieved as 00004. Note that if you store larger values than the display width in an integer column, you may experience problems when MySQL generates temporary tables for some

complicated joins, because in these cases MySQL assumes that the data fits into the original column width.

All integer types can have an optional (non-standard) attribute `UNSIGNED`. Unsigned values can be used when you want to allow only non-negative numbers in a column and you need a larger upper numeric range for the column. For example, if an `INT` column is `UNSIGNED`, the size of the column's range is the same but its endpoints shift from `-2147483648` and `2147483647` up to `0` and `4294967295`.

Floating-point and fixed-point types also can be `UNSIGNED`. As with integer types, this attribute prevents negative values from being stored in the column. However, unlike the integer types, the upper range of column values remains the same.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

For floating-point data types, MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

The `FLOAT` and `DOUBLE` data types are used to represent approximate numeric data values. For `FLOAT` the SQL standard allows an optional specification of the precision (but not the range of the exponent) in bits following the keyword `FLOAT` in parentheses. MySQL also supports this optional precision specification, but the precision value is used only to determine storage size. A precision from 0 to 23 results in a four-byte single-precision `FLOAT` column. A precision from 24 to 53 results in an eight-byte double-precision `DOUBLE` column.

MySQL allows a non-standard syntax: `FLOAT(M,D)` or `REAL(M,D)` or `DOUBLE PRECISION(M,D)`. Here, “(M,D)” means that values are displayed with up to *M* digits in total, of which *D* digits may be after the decimal point. For example, a column defined as `FLOAT(7,4)` will look like `-999.9999` when displayed. MySQL performs rounding when storing values, so if you insert `999.00009` into a `FLOAT(7,4)` column, the approximate result is `999.0001`.

MySQL treats `DOUBLE` as a synonym for `DOUBLE PRECISION` (a non-standard extension). MySQL also treats `REAL` as a synonym for `DOUBLE PRECISION` (a non-standard variation), unless the `REAL_AS_FLOAT` SQL mode is enabled.

For maximum portability, code requiring storage of approximate numeric data values should use `FLOAT` or `DOUBLE PRECISION` with no specification of precision or number of digits.

The `DECIMAL` and `NUMERIC` data types are used to store exact numeric data values. In MySQL, `NUMERIC` is implemented as `DECIMAL`. These types are used to store values for which it is important to preserve exact precision, for example with monetary data.

As of MySQL 5.0.3, `DECIMAL` and `NUMERIC` values are stored in binary format. Previously, they were stored as strings, with one character used for each digit of the value, the decimal point (if the scale is greater than 0), and the ‘-’ sign (for negative numbers). See Chapter 21, *Precision Math*.

When declaring a `DECIMAL` or `NUMERIC` column, the precision and scale can be (and usually is) specified; for example:

```
salary DECIMAL(5,2)
```

In this example, 5 is the precision and 2 is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point. If the scale is 0, `DECIMAL` and `NUMERIC` values contain no decimal point or fractional part.

Standard SQL requires that the `salary` column be able to store any value with five digits and two decimals. In this case, therefore, the range of values that can be stored in the `salary` column is from `-999.99` to `999.99`. MySQL enforces this limit as of MySQL 5.0.3. Before 5.0.3, on the positive end of the range, the column could actually store numbers up to `9999.99`. (For positive numbers, MySQL 5.0.2 and earlier used the byte reserved for the sign to extend the upper end of the range.)

In standard SQL, the syntax `DECIMAL(M)` is equivalent to `DECIMAL(M, 0)`. Similarly, the syntax `DECIMAL` is equivalent to `DECIMAL(M, 0)`, where the implementation is allowed to decide the value of *M*. MySQL supports both of these variant forms of the `DECIMAL` and `NUMERIC` syntax. The default value of *M* is 10.

The maximum number of digits for `DECIMAL` or `NUMERIC` is 65 (64 from MySQL 5.0.3 to 5.0.5). Before MySQL 5.0.3, the maximum range of `DECIMAL` and `NUMERIC` values is the same as for `DOUBLE`, but the actual range for a given `DECIMAL` or `NUMERIC` column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are allowed by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the allowable number of digits.)

As of MySQL 5.0.3, the `BIT` data type is used to store bit-field values. A type of `BIT(M)` allows for storage of *M*-bit values. *M* can range from 1 to 64.

To specify bit values, `b'value'` notation can be used. *value* is a binary value written using zeroes and ones. For example, `b'111'` and `b'10000000'` represent 7 and 128, respectively. See Section 9.1.5, “Bit-Field Values”.

If you assign a value to a `BIT(M)` column that is less than *M* bits long, the value is padded on the left with zeroes. For example, assigning a value of `b'101'` to a `BIT(6)` column is, in effect, the same as assigning `b'000101'`.

When asked to store a value in a numeric column that is outside the data type's allowable range, MySQL's behavior depends on the SQL mode in effect at the time. For example, if no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the range and stores the resulting value instead. However, if the mode is set to `TRADITIONAL`, MySQL rejects a value that is out of range with an error, and the insert fails, in accordance with the SQL standard.

In non-strict mode, when an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range. If you store 256 into a `TINYINT` or `TINYINT UNSIGNED` column, MySQL stores 127 or 255, respectively. When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Conversions that occur due to clipping when MySQL is not operating in strict mode are reported as warnings for `ALTER TABLE`, `LOAD DATA INFILE`, `UPDATE`, and multiple-row `INSERT` statements. When MySQL is operating in strict mode, these statements fail, and some or all of the values will not be inserted or changed, depending on whether the table is a transactional table and other factors. For details, see Section 5.2.5, “The Server SQL Mode”.

## 11.3. Date and Time Types

The date and time types for representing temporal values are `DATETIME`, `DATE`, `TIMESTAMP`, `TIME`, and `YEAR`. Each temporal type has a range of legal values, as well as a “zero” value that may be used when you specify an illegal value that MySQL cannot represent. The `TIMESTAMP` type has special automatic updating behavior, described later on. For temporary type storage requirements, see Section 11.5, “Data Type Storage Requirements”.

Starting from MySQL 5.0.2, MySQL gives warnings or errors if you try to insert an illegal date. By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See Section 5.2.5, “The Server SQL Mode”.) You can get MySQL to accept certain dates, such as `'1999-11-31'`, by using the `ALLOW_INVALID_DATES` SQL mode. (Before 5.0.2, this mode was the default behavior for MySQL.) This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 0 to 12 and that the day is in the range from 0 to 31. These ranges are defined to include zero because MySQL allows you to store dates where the day or month and day are zero in a `DATE` or `DATETIME` column. This is extremely useful for applications that need to store a birthdate for which you do not know the exact date. In this case, you simply store the date as `'1999-00-00'`

or '1999-01-00'. If you store dates such as these, you should not expect to get correct results for functions such as `DATE_SUB()` or `DATE_ADD` that require complete dates. (If you do *not* want to allow zero in dates, you can use the `NO_ZERO_IN_DATE SQL` mode).

MySQL also allows you to store '0000-00-00' as a “dummy date” (if you are not using the `NO_ZERO_DATE SQL` mode). This is in some cases is more convenient (and uses less space in data and index) than using `NULL` values.

Here are some general considerations to keep in mind when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). Only the formats described in the following sections are supported. It is expected that you supply legal values. Unpredictable results may occur if you use values in other formats.
- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using the following rules:
  - Year values in the range 70-99 are converted to 1970-1999.
  - Year values in the range 00-69 are converted to 2000-2069.
- Although MySQL tries to interpret values in several formats, dates always must be given in year-month-day order (for example, '98-09-04'), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, '09-04-98', '04-09-98').
- MySQL automatically converts a date or time type value to a number if the value is used in a numeric context and vice versa.
- By default, when MySQL encounters a value for a date or time type that is out of range or otherwise illegal for the type (as described at the beginning of this section), it converts the value to the “zero” value for that type. The exception is that out-of-range `TIME` values are clipped to the appropriate endpoint of the `TIME` range.

The following table shows the format of the “zero” value for each type. Note that the use of these values produces warnings if the `NO_ZERO_DATE SQL` mode is enabled.

Data Type	“Zero” Value
<code>DATETIME</code>	'0000-00-00 00:00:00'
<code>DATE</code>	'0000-00-00'
<code>TIMESTAMP</code>	'0000-00-00 00:00:00'
<code>TIME</code>	'00:00:00'
<code>YEAR</code>	0000

- The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values '0' or 0, which are easier to write.
- “Zero” date or time values used through MyODBC are converted automatically to `NULL` in MyODBC 2.50.12 and above, because ODBC cannot handle such values.

### 11.3.1. The `DATETIME`, `DATE`, and `TIMESTAMP` Types

The `DATETIME`, `DATE`, and `TIMESTAMP` types are related. This section describes their characteristics, how they are similar, and how they differ.

The `DATETIME` type is used when you need values that contain both date and time information. MySQL retrieves and displays `DATETIME` values in 'YYYY-MM-DD HH:MM:SS' format. The

supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'.

The DATE type is used when you need only a date value, without a time part. MySQL retrieves and displays DATE values in 'YYYY-MM-DD' format. The supported range is '1000-01-01' to '9999-12-31'.

For the DATETIME and DATE range descriptions, “supported” means that although earlier values might work, there is no guarantee.

The TIMESTAMP data type has varying properties, depending on the MySQL version and the SQL mode the server is running in. These properties are described later in this section.

You can specify DATETIME, DATE, and TIMESTAMP values using any of a common set of formats:

- As a string in either 'YYYY-MM-DD HH:MM:SS' or 'YY-MM-DD HH:MM:SS' format. A “relaxed” syntax is allowed: Any punctuation character may be used as the delimiter between date parts or time parts. For example, '98-12-31 11:30:45', '98.12.31 11+30+45', '98/12/31 11\*30\*45', and '98@12@31 11^30^45' are equivalent.
- As a string in either 'YYYY-MM-DD' or 'YY-MM-DD' format. A “relaxed” syntax is allowed here, too. For example, '98-12-31', '98.12.31', '98/12/31', and '98@12@31' are equivalent.
- As a string with no delimiters in either 'YYYYMMDDHHMMSS' or 'YYMMDDHHMMSS' format, provided that the string makes sense as a date. For example, '19970523091528' and '970523091528' are interpreted as '1997-05-23 09:15:28', but '971122129015' is illegal (it has a nonsensical minute part) and becomes '0000-00-00 00:00:00'.
- As a string with no delimiters in either 'YYYYMMDD' or 'YYMMDD' format, provided that the string makes sense as a date. For example, '19970523' and '970523' are interpreted as '1997-05-23', but '971332' is illegal (it has nonsensical month and day parts) and becomes '0000-00-00'.
- As a number in either YYYYMMDDHHMMSS or YYMMDDHHMMSS format, provided that the number makes sense as a date. For example, 19830905132800 and 830905132800 are interpreted as '1983-09-05 13:28:00'.
- As a number in either YYYYMMDD or YYMMDD format, provided that the number makes sense as a date. For example, 19830905 and 830905 are interpreted as '1983-09-05'.
- As the result of a function that returns a value that is acceptable in a DATETIME, DATE, or TIMESTAMP context, such as NOW() or CURRENT\_DATE.

Illegal DATETIME, DATE, or TIMESTAMP values are converted to the “zero” value of the appropriate type ('0000-00-00 00:00:00' or '0000-00-00').

For values specified as strings that include date part delimiters, it is not necessary to specify two digits for month or day values that are less than 10. '1979-6-9' is the same as '1979-06-09'. Similarly, for values specified as strings that include time part delimiters, it is not necessary to specify two digits for hour, minute, or second values that are less than 10. '1979-10-30 1:2:3' is the same as '1979-10-30 01:02:03'.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in YYYYMMDD or YYYYMMDDHHMMSS format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in YYMMDD or YYMMDDHHMMSS format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeroes to the closest length.

Values specified as non-delimited strings are interpreted using their length as given. If the string is 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year,

month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify '9903', thinking that represents March, 1999, MySQL inserts a “zero” date value into your table. This occurs because the year and month values are 99 and 03, but the day part is completely missing, so the value is not a legal date. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, you can use '990300' to insert the value '1999-03-00'.

You can to some extent assign values of one date type to an object of a different date type. However, there may be some alteration of the value or loss of information:

- If you assign a DATE value to a DATETIME or TIMESTAMP object, the time part of the resulting value is set to '00:00:00' because the DATE value contains no time information.
- If you assign a DATETIME or TIMESTAMP value to a DATE object, the time part of the resulting value is deleted because the DATE type stores no time information.
- Remember that although DATETIME, DATE, and TIMESTAMP values all can be specified using the same set of formats, the types do not all have the same range of values. For example, TIMESTAMP values cannot be earlier than 1970 or later than 2037. This means that a date such as '1968-01-01', while legal as a DATETIME or DATE value, is not valid as a TIMESTAMP value and is converted to 0.

Be aware of certain pitfalls when specifying date values:

- The relaxed format allowed for values specified as strings can be deceiving. For example, a value such as '10:11:12' might look like a time value because of the ':' delimiter, but if used in a date context is interpreted as the year '2010-11-12'. The value '10:45:15' is converted to '0000-00-00' because '45' is not a legal month.
- As of 5.0.2, the server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as '2004-04-31' are converted to '0000-00-00' and a warning is generated. With strict mode enabled, invalid dates generate an error. To allow such dates, enable `ALLOW_INVALID_DATES`. See Section 5.2.5, “The Server SQL Mode”, for more information.

Before MySQL 5.0.2, the MySQL server performs only basic checking on the validity of a date: The ranges for year, month, and day are 1000 to 9999, 00 to 12, and 00 to 31, respectively. Any date containing parts not within these ranges is subject to conversion to '0000-00-00'. Please note that this still allows you to store invalid dates such as '2002-04-31'. To ensure that a date is valid, you should perform a check in your application.

- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using the following rules:
  - Year values in the range 00-69 are converted to 2000-2069.
  - Year values in the range 70-99 are converted to 1970-1999.

### 11.3.1.1. **TIMESTAMP Properties as of MySQL 4.1**

**Note:** In older versions of MySQL (prior to 4.1), the properties of the TIMESTAMP data type differed significantly in many ways from what is described in this section. If you need to convert older TIMESTAMP data to work with MySQL 5.0, be sure to see the *MySQL 3.23, 4.0, 4.1 Reference Manual* for details.

TIMESTAMP columns are displayed in the same format as DATETIME columns. In other words, the display width is fixed at 19 characters, and the format is YYYY-MM-DD HH:MM:SS.

The MySQL server can be also be run with the MAXDB SQL mode enabled. When the server runs with this mode enabled, `TIMESTAMP` is identical with `DATETIME`. That is, if this mode is enabled at the time that a table is created, `TIMESTAMP` columns are created as `DATETIME` columns. As a result, such columns use `DATETIME` display format, have the same range of values, and there is no automatic initialization or updating to the current date and time.

To enable MAXDB mode, set the server SQL mode to MAXDB at startup using the `--sql-mode=MAXDB` server option or by setting the global `sql_mode` variable at runtime:

```
mysql> SET GLOBAL sql_mode=MAXDB;
```

A client can cause the server to run in MAXDB mode for its own connection as follows:

```
mysql> SET SESSION sql_mode=MAXDB;
```

Note that the information in the following discussion applies to `TIMESTAMP` columns only for tables not created with MAXDB mode enabled, because such columns are created as `DATETIME` columns.

As of MySQL 5.0.2, MySQL does not accept timestamp values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special value `'0000-00-00 00:00:00'`.

You have considerable flexibility in determining when automatic `TIMESTAMP` initialization and updating occur and which column should have those behaviors:

- For one `TIMESTAMP` column in a table, you can assign the current timestamp as the default value and the auto-update value. It is possible to have the current timestamp be the default value for initializing the column, for the auto-update value, or both. It is not possible to have the current timestamp be the default value for one column and the auto-update value for another column.
- You can specify which `TIMESTAMP` column to automatically initialize or update to the current date and time. This need not be the first `TIMESTAMP` column.

The following rules govern initialization and updating of `TIMESTAMP` columns:

- If a `DEFAULT` value is specified for the first `TIMESTAMP` column in a table, it is not ignored. The default can be `CURRENT_TIMESTAMP` or a constant date and time value.
- `DEFAULT NULL` is the same as `DEFAULT CURRENT_TIMESTAMP` for the *first* `TIMESTAMP` column. For any other `TIMESTAMP` column, `DEFAULT NULL` is treated as `DEFAULT 0`.
- Any single `TIMESTAMP` column in a table can be used as the one that is initialized to the current timestamp or updated automatically.
- In a `CREATE TABLE` statement, the first `TIMESTAMP` column can be declared in any of the following ways:
  - With both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses, the column has the current timestamp for its default value, and is automatically updated.
  - With neither `DEFAULT` nor `ON UPDATE` clauses, it is the same as `DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP`.
  - With a `DEFAULT CURRENT_TIMESTAMP` clause and no `ON UPDATE` clause, the column has the current timestamp for its default value but is not automatically updated.

- With no `DEFAULT` clause and with an `ON UPDATE CURRENT_TIMESTAMP` clause, the column has a default of 0 and is automatically updated.
- With a constant `DEFAULT` value, the column has the given default. If the column has an `ON UPDATE CURRENT_TIMESTAMP` clause, it is automatically updated, otherwise not.

In other words, you can use the current timestamp for both the initial value and the auto-update value, or either one, or neither. (For example, you can specify `ON UPDATE` to enable auto-update without also having the column auto-initialized.)

- `CURRENT_TIMESTAMP` or any of its synonyms (`CURRENT_TIMESTAMP()`, `NOW()`, `LOCALTIME`, `LOCALTIME()`, `LOCALTIMESTAMP`, or `LOCALTIMESTAMP()`) can be used in the `DEFAULT` and `ON UPDATE` clauses. They all mean “the current timestamp.” (`UTC_TIMESTAMP` is not allowed. Its range of values does not align with those of the `TIMESTAMP` column anyway unless the current time zone is UTC.)
- The order of the `DEFAULT` and `ON UPDATE` attributes does not matter. If both `DEFAULT` and `ON UPDATE` are specified for a `TIMESTAMP` column, either can precede the other. For example, these statements are equivalent:

```
CREATE TABLE t (ts TIMESTAMP);
CREATE TABLE t (ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP
                ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t (ts TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
                DEFAULT CURRENT_TIMESTAMP);
```

- To specify automatic default or updating for a `TIMESTAMP` column other than the first one, you must suppress the automatic initialization and update behaviors for the first `TIMESTAMP` column by explicitly assigning it a constant `DEFAULT` value (for example, `DEFAULT 0` or `DEFAULT '2003-01-01 00:00:00'`). Then, for the other `TIMESTAMP` column, the rules are the same as for the first `TIMESTAMP` column, except that if you omit both of the `DEFAULT` and `ON UPDATE` clauses, no automatic initialization or updating occurs.

Example. These statements are equivalent:

```
CREATE TABLE t (
    ts1 TIMESTAMP DEFAULT 0,
    ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
        ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t (
    ts1 TIMESTAMP DEFAULT 0,
    ts2 TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
        DEFAULT CURRENT_TIMESTAMP);
```

You can set the current time zone on a per-connection basis, as described in Section 5.11.8, “MySQL Server Time Zone Support”. `TIMESTAMP` values are stored in UTC, being converted from the current time zone for storage, and converted back to the current time zone upon retrieval. As long as the time zone setting remains constant, you get back the same value you store. If you store a `TIMESTAMP` value, and then change the time zone and retrieve the value, the retrieved value is different than the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the `time_zone` system variable.

You can include the `NULL` attribute in the definition of a `TIMESTAMP` column to allow the column to contain `NULL` values. For example:

```
CREATE TABLE t
(
    ts1 TIMESTAMP NULL DEFAULT NULL,
    ts2 TIMESTAMP NULL DEFAULT 0,
    ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
```

```
);
```

If the `NULL` attribute is not specified, setting the column to `NULL` sets it to the current timestamp. Note that a `TIMESTAMP` column which allows `NULL` values will *not* take on the current timestamp except under one of the following conditions:

- Its default value is defined as `CURRENT_TIMESTAMP`
- `NOW()` or `CURRENT_TIMESTAMP` is inserted into the column

In other words, a `TIMESTAMP` column defined as `NULL` will auto-initialize only if it is created using a definition such as the following:

```
CREATE TABLE t (ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP);
```

Otherwise — that is, if the `TIMESTAMP` column is defined to allow `NULL` values but not using `DEFAULT TIMESTAMP`, as shown here...

```
CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT NULL);  
CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
```

...then you must explicitly insert a value corresponding to the current date and time. For example:

```
INSERT INTO t1 VALUES (NOW());  
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
```

## 11.3.2. The `TIME` Type

MySQL retrieves and displays `TIME` values in `'HH:MM:SS'` format (or `'HHH:MM:SS'` format for large hours values). `TIME` values may range from `'-838:59:59'` to `'838:59:59'`. The hours part may be so large because the `TIME` type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

You can specify `TIME` values in a variety of formats:

- As a string in `'D HH:MM:SS.fraction'` format. You can also use one of the following “relaxed” syntaxes: `'HH:MM:SS.fraction'`, `'HH:MM:SS'`, `'HH:MM'`, `'D HH:MM:SS'`, `'D HH:MM'`, `'D HH'`, or `'SS'`. Here `D` represents days and can have a value from 0 to 34. Note that MySQL does not store the fraction part.
- As a string with no delimiters in `'HHMMSS'` format, provided that it makes sense as a time. For example, `'101112'` is understood as `'10:11:12'`, but `'109712'` is illegal (it has a nonsensical minute part) and becomes `'00:00:00'`.
- As a number in `HHMMSS` format, provided that it makes sense as a time. For example, `101112` is understood as `'10:11:12'`. The following alternative formats are also understood: `SS`, `MMSS`, `HHMMSS`, `HHMMSS.fraction`. Note that MySQL does not store the fraction part.
- As the result of a function that returns a value that is acceptable in a `TIME` context, such as `CURRENT_TIME`.

For `TIME` values specified as strings that include a time part delimiter, it is not necessary to specify two digits for hours, minutes, or seconds values that are less than 10. `'8:3:2'` is the same as `'08:03:02'`.

Be careful about assigning abbreviated values to a `TIME` column. Without colons, MySQL interprets values using the assumption that the two rightmost digits represent seconds. (MySQL interprets `TIME` values as elapsed time rather than as time of day.) For example, you might think of `'1112'` and `1112` as meaning `'11:12:00'` (12 minutes after 11 o'clock), but MySQL interprets them as `'00:11:12'` (11 minutes, 12 seconds). Similarly, `'12'` and `12` are interpreted as `'00:00:12'`. `TIME` values with colons, by contrast, are always treated as time of the day. That is, `'11:12'` mean `'11:12:00'`, not `'00:11:12'`.

By default, values that lie outside the `TIME` range but are otherwise legal are clipped to the closest endpoint of the range. For example, `'-850:00:00'` and `'850:00:00'` are converted to `'-838:59:59'` and `'838:59:59'`. Illegal `TIME` values are converted to `'00:00:00'`. Note that because `'00:00:00'` is itself a legal `TIME` value, there is no way to tell, from a value of `'00:00:00'` stored in a table, whether the original value was specified as `'00:00:00'` or whether it was illegal.

For more restrictive treatment of invalid `TIME` values, enable strict SQL mode to cause errors to occur. See Section 5.2.5, “The Server SQL Mode”.

### 11.3.3. The `YEAR` Type

The `YEAR` type is a one-byte type used for representing years.

MySQL retrieves and displays `YEAR` values in `YYYY` format. The range is 1901 to 2155.

You can specify `YEAR` values in a variety of formats:

- As a four-digit string in the range `'1901'` to `'2155'`.
- As a four-digit number in the range 1901 to 2155.
- As a two-digit string in the range `'00'` to `'99'`. Values in the ranges `'00'` to `'69'` and `'70'` to `'99'` are converted to `YEAR` values in the ranges 2000 to 2069 and 1970 to 1999.
- As a two-digit number in the range 1 to 99. Values in the ranges 1 to 69 and 70 to 99 are converted to `YEAR` values in the ranges 2001 to 2069 and 1970 to 1999. Note that the range for two-digit numbers is slightly different from the range for two-digit strings, because you cannot specify zero directly as a number and have it be interpreted as 2000. You must specify it as a string `'0'` or `'00'` or it is interpreted as 0000.
- As the result of a function that returns a value that is acceptable in a `YEAR` context, such as `NOW()`.

Illegal `YEAR` values are converted to 0000.

### 11.3.4. Y2K Issues and Date Types

As discussed in Section 1.4.5, “Year 2000 Compliance”, MySQL itself is year 2000 (Y2K) safe. However, particular input values presented to MySQL may not be Y2K safe. Any value containing a two-digit year is ambiguous, because the century is unknown. Such values must be interpreted into four-digit form because MySQL stores years internally using four digits.

For `DATETIME`, `DATE`, `TIMESTAMP`, and `YEAR` types, MySQL interprets dates with ambiguous year values using the following rules:

- Year values in the range 00–69 are converted to 2000–2069.
- Year values in the range 70–99 are converted to 1970–1999.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the correct values, you should provide unambiguous input containing four-digit year values.

`ORDER BY` properly sorts `YEAR` values that have two-digit years.

Some functions like `MIN()` and `MAX()` convert a `YEAR` to a number. This means that a value with a two-digit year does not work properly with these functions. The fix in this case is to convert the `TIMESTAMP` or `YEAR` to four-digit year format.

## 11.4. String Types

The string types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`. This section describes how these types work and how to use them in your queries. For string type storage requirements, see Section 11.5, “Data Type Storage Requirements”.

### 11.4.1. The `CHAR` and `VARCHAR` Types

The `CHAR` and `VARCHAR` types are similar, but differ in the way they are stored and retrieved. As of MySQL 5.0.3, they also differ in maximum length and in whether trailing spaces are retained.

The `CHAR` and `VARCHAR` types are declared with a length that indicates the maximum number of characters you want to store. For example, `CHAR(30)` can hold up to 30 characters.

The length of a `CHAR` column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When `CHAR` values are stored, they are right-padded with spaces to the specified length. When `CHAR` values are retrieved, trailing spaces are removed.

Values in `VARCHAR` columns are variable-length strings. The length can be specified as a value from 0 to 255 before MySQL 5.0.3, and 0 to 65,535 in 5.0.3 and later versions. (The maximum effective length of a `VARCHAR` in MySQL 5.0.3 and later is determined by the maximum row size and the character set used. The maximum length overall is 65,532 bytes.)

In contrast to `CHAR`, `VARCHAR` values are stored using only as many characters as are needed, plus one byte to record the length (two bytes for columns that are declared with a length longer than 255).

`VARCHAR` values are not padded when they are stored. Handling of trailing spaces is version-dependent. As of MySQL 5.0.3, trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL. Before MySQL 5.0.3, trailing spaces are removed from values when they are stored into a `VARCHAR` column; this means that the spaces also are absent from retrieved values.

If you assign a value to a `CHAR` or `VARCHAR` column that exceeds the column's maximum length, the value is truncated to fit. If the truncated characters are not spaces, a warning is generated. For truncation of non-space characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.2.5, “The Server SQL Mode”.

Before MySQL 5.0.3, if you need a data type for which trailing spaces are not removed, consider using a `BLOB` or `TEXT` type. Also, if you want to store binary values such as results from an encryption or compression function that might contain arbitrary byte values, use a `BLOB` column rather than a `CHAR` or `VARCHAR` column, to avoid potential problems with trailing space removal that would change data values.

The following table illustrates the differences between `CHAR` and `VARCHAR` by showing the result of storing various string values into `CHAR(4)` and `VARCHAR(4)` columns:

Value	<code>CHAR(4)</code>	Storage Required	<code>VARCHAR(4)</code>	Storage Required
' '	'  '	4 bytes	' '	1 byte
'ab'	'ab  '	4 bytes	'ab'	3 bytes

'abcd'	'abcd'	4 bytes	'abcd'	5 bytes
'abcdefgh'	'abcd'	4 bytes	'abcd'	5 bytes

Note that the values shown as stored in the last row of the table apply *only when not using strict mode*; if MySQL is running in strict mode, values that exceed the column length are *not stored*, and an error results.

If a given value is stored into the CHAR(4) and VARCHAR(4) columns, the values retrieved from the columns are not always the same because trailing spaces are removed from CHAR columns upon retrieval. The following example illustrates this difference:

```
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO vc VALUES ('ab  ', 'ab  ');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT CONCAT('( ', v, ' )'), CONCAT('( ', c, ' )') FROM vc;
+-----+-----+
| CONCAT('( ', v, ' )') | CONCAT('( ', c, ' )') |
+-----+-----+
| (ab  )                | (ab)                  |
+-----+-----+
1 row in set (0.06 sec)
```

Values in CHAR and VARCHAR columns are sorted and compared according to the character set collation assigned to the column.

Note that all MySQL collations are of type PADSPACE. This means that all CHAR and VARCHAR values in MySQL are compared without regard to any trailing spaces. For example:

```
mysql> CREATE TABLE names (myname CHAR(10), yourname VARCHAR(10));
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO names VALUES ('Monty  ', 'Monty  ');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT myname = 'Monty  ', yourname = 'Monty  ' FROM names;
+-----+-----+
| myname = 'Monty  ' | yourname = 'Monty  ' |
+-----+-----+
| 1                  | 1                    |
+-----+-----+
1 row in set (0.00 sec)
```

Note that this is true for all MySQL versions, and it makes no difference whether your version trims trailing spaces from VARCHAR values before storing them. Nor does the server SQL mode make any difference in this regard.

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters will result in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error.

## 11.4.2. The BINARY and VARBINARY Types

The BINARY and VARBINARY types are similar to CHAR and VARCHAR, except that they contain binary strings rather than non-binary strings. That is, they contain byte strings rather than character strings. This means that they have no character set, and sorting and comparison are based on the numeric values of the bytes in the values.

The allowable maximum length is the same for `BINARY` and `VARBINARY` as it is for `CHAR` and `VARCHAR`, except that the length for `BINARY` and `VARBINARY` is a length in bytes rather than in characters.

The `BINARY` and `VARBINARY` data types are distinct from the `CHAR BINARY` and `VARCHAR BINARY` data types. For the latter types, the `BINARY` attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary collation for the column character set to be used, and the column itself contains non-binary character strings rather than binary byte strings. For example, `CHAR(5) BINARY` is treated as `CHAR(5) CHARACTER SET latin1 COLLATE latin1_bin`, assuming that the default character set is `latin1`. This differs from `BINARY(5)`, which stores 5-bytes binary strings that have no character set or collation.

When `BINARY` values are stored, they are right-padded with the `pad` value to the specified length. The `pad` value and how it is handled is version specific:

- As of MySQL 5.0.15, the `pad` value is `0x00` (the zero byte). Values are right-padded with `0x00` on insert, and no trailing bytes are removed on select. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` bytes and spaces are different in comparisons, with `0x00 < space`.

Example: For a `BINARY(3)` column, `'a '` becomes `'a \0'` when inserted. `'a\0'` becomes `'a\0\0'` when inserted. Both inserted values remain unchanged when selected.

- Before MySQL 5.0.15, the `pad` value is space. Values are right-padded with space on insert, and trailing spaces are removed on select. Trailing spaces are ignored in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` bytes and spaces are different in comparisons, with `0x00 < space`.

Example: For a `BINARY(3)` column, `'a '` becomes `'a '` when inserted and `'a'` when selected. `'a\0'` becomes `'a\0 '` when inserted and `'a\0'` when selected.

For `VARBINARY`, there is no padding on insert and no bytes are stripped on select. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` bytes and spaces are different in comparisons, with `0x00 < space`. (Exceptions: Before MySQL 5.0.3, trailing spaces are removed when values are stored. Before MySQL 5.0.15, trailing `0x00` bytes are removed for `ORDER BY` operations.)

Note: The InnoDB storage engine continues to preserve trailing spaces in `BINARY` and `VARBINARY` column values through MySQL 5.0.18. Beginning with MySQL 5.0.19, InnoDB uses trailing space characters in making comparisons as do other MySQL storage engines.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad bytes will result in a duplicate-key error. For example, if a table contains `'a'`, an attempt to store `'a\0'` causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the `BINARY` data type for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how `0x00`-padding of `BINARY` values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)
```

```
mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)
```

```
mysql> SELECT HEX(c), c = 'a', c = 'a\0\0' from t;
```

HEX(c)	c = 'a'	c = 'a\0\0'
610000	0	1

```
+-----+-----+-----+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use `VARBINARY` or one of the BLOB data types instead.

### 11.4.3. The BLOB and TEXT Types

A BLOB is a binary large object that can hold a variable amount of data. The four BLOB types are `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`. These differ only in the maximum length of the values they can hold. The four TEXT types are `TINYTEXT`, `TEXT`, `MEDIUMTEXT`, and `LONGTEXT`. These correspond to the four BLOB types and have the same maximum lengths and storage requirements. See Section 11.5, “Data Type Storage Requirements”. No lettercase conversion for `TEXT` or `BLOB` columns takes place during storage or retrieval.

`BLOB` columns are treated as binary strings (byte strings). `TEXT` columns are treated as non-binary strings (character strings). `BLOB` columns have no character set, and sorting and comparison are based on the numeric values of the bytes in column values. `TEXT` columns have a character set, and values are sorted and compared based on the collation of the character set.

If a `TEXT` column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors will occur for values that differ only in the number of trailing spaces. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error. This is not true for `BLOB` columns.

When not running in strict mode, if you assign a value to a `BLOB` or `TEXT` column that exceeds the data type's maximum length, the value is truncated to fit. If the truncated characters are not spaces, a warning is generated. You can cause an error to occur and the value to be rejected rather than to be truncated with a warning by using strict SQL mode. See Section 5.2.5, “The Server SQL Mode”.

In most respects, you can regard a `BLOB` column as a `VARBINARY` column that can be as large as you like. Similarly, you can regard a `TEXT` column as a `VARCHAR` column. `BLOB` and `TEXT` differ from `VARBINARY` and `VARCHAR` in the following ways:

- There is no trailing-space removal for `BLOB` and `TEXT` columns when values are stored or retrieved. Before MySQL 5.0.3, this differs from `VARBINARY` and `VARCHAR`, for which trailing spaces are removed when values are stored.

Note that `TEXT` is on comparison space extended to fit the compared object, exactly like `CHAR` and `VARCHAR`.

- For indexes on `BLOB` and `TEXT` columns, you must specify an index prefix length. For `CHAR` and `VARCHAR`, a prefix length is optional. See Section 7.4.3, “Column Indexes”.
- `BLOB` and `TEXT` columns cannot have `DEFAULT` values.

`LONG` and `LONG VARCHAR` map to the `MEDIUMTEXT` data type. This is a compatibility feature. If you use the `BINARY` attribute with a `TEXT` data type, the column is assigned the binary collation of the column character set.

MySQL Connector/ODBC defines `BLOB` values as `LONGVARBINARY` and `TEXT` values as `LONGVARCHAR`.

Because `BLOB` and `TEXT` values can be extremely long, you might encounter some constraints in using them:

- Only the first `max_sort_length` bytes of the column are used when sorting. The default value of `max_sort_length` is 1024. This value can be changed using the `-max_sort_length=N` option when starting the `mysqld` server. See Section 5.2.2, “Server System Variables”.

You can make more bytes significant in sorting or grouping by increasing the value of `max_sort_length` at runtime. Any client can change the value of its session `max_sort_length` variable:

```
mysql> SET max_sort_length = 2000;
mysql> SELECT id, comment FROM t
       -> ORDER BY comment;
```

Another way to use `GROUP BY` or `ORDER BY` on a `BLOB` or `TEXT` column containing long values when you want more than `max_sort_length` bytes to be significant is to convert the column value into a fixed-length object. The standard way to do this is with the `SUBSTRING()` function. For example, the following statement causes 2000 bytes of the `comment` column to be taken into account for sorting:

```
mysql> SELECT id, SUBSTRING(comment,1,2000) FROM t
       -> ORDER BY SUBSTRING(comment,1,2000);
```

- The maximum size of a `BLOB` or `TEXT` object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the `max_allowed_packet` variable, but you must do so for both the server and your client program. For example, both `mysql` and `mysqldump` allow you to change the client-side `max_allowed_packet` value. See Section 7.5.2, “Tuning Server Parameters”, Section 8.6, “`mysql` — The MySQL Command-Line Tool”, and Section 8.11, “`mysqldump` — A Database Backup Program”.

Each `BLOB` or `TEXT` value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in `BLOB` or `TEXT` columns. You may find MySQL's string handling functions useful for working with such data. See Section 12.3, “String Functions”. For security and other reasons, it is usually preferable to do so using application code rather than allowing application users the `FILE` privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (<http://forums.mysql.com/>).

## 11.4.4. The `ENUM` Type

An `ENUM` is a string object with a value chosen from a list of allowed values that are enumerated explicitly in the column specification at table creation time.

The value may also be the empty string ( `' '` ) or `NULL` under certain circumstances:

- If you insert an invalid value into an `ENUM` (that is, a string not present in the list of allowed values), the empty string is inserted instead as a special error value. This string can be distinguished from a “normal” empty string by the fact that this string has the numerical value 0. More about this later.

If strict SQL mode is enabled, attempts to insert invalid `ENUM` values result in an error.

- If an `ENUM` column is declared to allow `NULL`, the `NULL` value is a legal value for the column, and the default value is `NULL`. If an `ENUM` column is declared `NOT NULL`, its default value is the first element of the list of allowed values.

Each enumeration value has an index:

- Values from the list of allowable elements in the column specification are numbered beginning with 1.

- The index value of the empty string error value is 0. This means that you can use the following `SELECT` statement to find rows into which invalid `ENUM` values were assigned:

```
mysql> SELECT * FROM tbl_name WHERE enum_col=0;
```

- The index of the `NULL` value is `NULL`.
- The term “index” here refers only to position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as `ENUM('one', 'two', 'three')` can have any of the values shown here. The index of each value is also shown:

Value	Index
<code>NULL</code>	<code>NULL</code>
<code>''</code>	0
<code>'one'</code>	1
<code>'two'</code>	2
<code>'three'</code>	3

An enumeration can have a maximum of 65,535 elements.

Trailing spaces are automatically deleted from `ENUM` member values in the table definition when a table is created.

When retrieved, values stored into an `ENUM` column are displayed using the lettercase that was used in the column definition. Note that `ENUM` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you retrieve an `ENUM` value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an `ENUM` column like this:

```
mysql> SELECT enum_col+0 FROM tbl_name;
```

If you store a number into an `ENUM` column, the number is treated as an index, and the value stored is the enumeration member with that index. (However, this does not work with `LOAD DATA`, which treats all input as strings.) It is not advisable to define an `ENUM` column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of `'0'`, `'1'`, and `'2'`, but numeric index values of 1, 2, and 3:

```
numbers ENUM('0','1','2')
```

`ENUM` values are sorted according to the order in which the enumeration members were listed in the column specification. (In other words, `ENUM` values are sorted according to their index numbers.) For example, `'a'` sorts before `'b'` for `ENUM('a', 'b')`, but `'b'` sorts before `'a'` for `ENUM('b', 'a')`. The empty string sorts before non-empty strings, and `NULL` values sort before all other enumeration values. To prevent unexpected results, specify the `ENUM` list in alphabetical order. You can also use `GROUP BY CAST(col AS CHAR)` or `GROUP BY CONCAT(col)` to make sure that the column is sorted lexically rather than by index number.

If you want to determine all possible values for an `ENUM` column, use `SHOW COLUMNS FROM tbl_name LIKE enum_col` and parse the `ENUM` definition in the `Type` column of the output.

## 11.4.5. The SET Type

A SET is a string object that can have zero or more values, each of which must be chosen from a list of allowed values specified when the table is created. SET column values that consist of multiple set members are specified with members separated by commas (','). A consequence of this is that SET member values should not themselves contain commas.

For example, a column specified as SET('one', 'two') NOT NULL can have any of these values:

```
' '
'one'
'two'
'one,two'
```

A SET can have a maximum of 64 different members.

Trailing spaces are automatically deleted from SET member values in the table definition when a table is created.

When retrieved, values stored in a SET column are displayed using the lettercase that was used in the column definition. Note that SET columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores SET values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a SET value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a SET column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a SET column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as SET('a', 'b', 'c', 'd'), the members have the following decimal and binary values:

SET Member	Decimal Value	Binary Value
'a'	1	0001
'b'	2	0010
'c'	4	0100
'd'	8	1000

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth SET value members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one SET element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. For example, suppose that a column is specified as SET('a', 'b', 'c', 'd'):

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```
mysql> INSERT INTO myset (col) VALUES
-> ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

Then all of these values appear as 'a,d' when retrieved:

```
mysql> SELECT col FROM myset;
+-----+
| col   |
+-----+
| a,d   |
| a,d   |
| a,d   |
| a,d   |
| a,d   |
+-----+
5 rows in set (0.04 sec)
```

If you set a SET column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)
```

```
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level   | Code | Message                                     |
+-----+-----+-----+
| Warning | 1265 | Data truncated for column 'col' at row 1 |
+-----+-----+-----+
1 row in set (0.04 sec)
```

```
mysql> SELECT col FROM myset;
+-----+
| col   |
+-----+
| a,d   |
| a,d   |
| a,d   |
| a,d   |
| a,d   |
| a,d   |
+-----+
6 rows in set (0.01 sec)
```

If strict SQL mode is enabled, attempts to insert invalid SET values result in an error.

SET values are sorted numerically. NULL values sort before non-NULL SET values.

Normally, you search for SET values using the `FIND_IN_SET()` function or the `LIKE` operator:

```
mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value',set_col)>0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';
```

The first statement finds rows where `set_col` contains the `value` set member. The second is similar, but not the same: It finds rows where `set_col` contains `value` anywhere, even as a substring of another set member.

The following statements also are legal:

```
mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';
```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to `'val1,val2'` returns different results than comparing values to `'val2,val1'`. You should specify the values in the same order they are listed in the column definition.

If you want to determine all possible values for a SET column, use `SHOW COLUMNS FROM tbl_name LIKE set_col` and parse the SET definition in the Type column of the output.

## 11.5. Data Type Storage Requirements

The storage requirements for each of the data types supported by MySQL are listed here by category.

The maximum size of a row in a MyISAM table is 65,534 bytes. Each BLOB and TEXT column accounts for only five to nine bytes toward this size.

**Important:** For tables using the NDBCluster storage engine, there is the factor of *4-byte alignment* to be taken into account when calculating storage requirements. This means that all NDB data storage is done in multiples of 4 bytes. Thus, a column value that — in a table using a storage engine other than NDB — would take 15 bytes for storage, requires 16 bytes in an NDB table. This requirement applies in addition to any other considerations that are discussed in this section. For example, in NDBCluster tables, the TINYINT, SMALLINT, MEDIUMINT, and INTEGER (INT) column types each require 4 bytes storage per record.

### Storage Requirements for Numeric Types

Data Type	Storage Required
TINYINT	1 byte
SMALLINT	2 bytes
MEDIUMINT	3 bytes
INT, INTEGER	4 bytes
BIGINT	8 bytes
FLOAT( <i>p</i> )	4 bytes if $0 \leq p \leq 24$ , 8 bytes if $25 \leq p \leq 53$
FLOAT	4 bytes
DOUBLE [PRECISION], REAL	8 bytes
DECIMAL( <i>M</i> , <i>D</i> ), NUMERIC( <i>M</i> , <i>D</i> )	Varies; see following discussion
BIT( <i>M</i> )	approximately $(M+7)/8$ bytes

The storage requirements for DECIMAL (and NUMERIC) are version-specific:

As of MySQL 5.0.3, values for DECIMAL columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table:

Leftover Digits	Number of Bytes
0	0
1	1
2	1
3	2
4	2
5	3
6	3
7	4
8	4
9	4

Before MySQL 5.0.3, DECIMAL columns are represented as strings and storage requirements are:  $M+2$  bytes if  $D > 0$ ,  $M+1$  bytes if  $D = 0$  ( $D+2$ , if  $M < D$ )

**Storage Requirements for Date and Time Types**

Data Type	Storage Required
DATE	3 bytes
DATETIME	8 bytes
TIMESTAMP	4 bytes
TIME	3 bytes
YEAR	1 byte

**Storage Requirements for String Types**

Data Type	Storage Required
CHAR ( <i>M</i> )	<i>M</i> bytes, $0 \leq M \leq 255$
VARCHAR ( <i>M</i> )	<i>Prior to MySQL 5.0.3</i> : <i>L</i> + 1 bytes, where $L \leq M$ and $0 \leq M \leq 255$ . <i>MySQL 5.0.3 and later</i> : <i>L</i> + 1 bytes, where $L \leq M$ and $0 \leq M \leq 255$ or <i>L</i> + 2 bytes, where $L \leq M$ and $256 \leq M \leq 65535$ (see note below).
BINARY ( <i>M</i> )	<i>M</i> bytes, $0 \leq M \leq 255$
VARBINARY ( <i>M</i> )	<i>Prior to MySQL 5.0.3</i> : <i>L</i> + 1 bytes, where $L \leq M$ and $0 \leq M \leq 255$ . <i>MySQL 5.0.3 and later</i> : <i>L</i> + 1 bytes, where $L \leq M$ and $0 \leq M \leq 255$ or <i>L</i> + 2 bytes, where $L \leq M$ and $256 \leq M \leq 65535$ (see note below).
TINYBLOB, TINYTEXT	<i>L</i> +1 byte, where $L < 2^8$
BLOB, TEXT	<i>L</i> +2 bytes, where $L < 2^{16}$
MEDIUMBLOB, MEDIUMTEXT	<i>L</i> +3 bytes, where $L < 2^{24}$
LOB, LONGTEXT	<i>L</i> +4 bytes, where $L < 2^{32}$
' , . . . ENUM( 'value1' , 'value2' )	1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)
SET( 'value1' , 'value2' , . . . )	1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)

For the CHAR, VARCHAR, and TEXT types, the values *L* and *M* in the preceding table should be interpreted as number of characters, and lengths for these types in column specifications indicate the number of characters. For example, to store a TINYTEXT value requires *L* characters plus one byte.

VARCHAR, VARBINARY, and the BLOB and TEXT types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column's maximum possible length
- The character set used for the column

For example, a VARCHAR(10) column can hold a string with a maximum length of 10. Assuming that the column uses the latin1 character set (one byte per character), the actual storage required is the length of the string (*L*), plus one byte to record the length of the string. For the string 'abcd', *L* is 4 and the storage requirement is five bytes. If the same column was instead declared as VARCHAR(500), the string 'abcd' requires  $4 + 2 = 6$  bytes. Two bytes rather than one are required for the prefix because the length of the column is greater than 255 characters.

To calculate the number of *bytes* used to store a particular CHAR, VARCHAR, or TEXT column value, you must take into account the character set used for that column. In particular, when using

the `utf8` Unicode character set, you must keep in mind that not all `utf8` characters use the same number of bytes. For a breakdown of the storage used for different categories of `utf8` characters, see Section 10.7, “Unicode Support”.

**Note:** In MySQL 5.0.3 and later, the *effective* maximum length for a `VARCHAR` or `VARBINARY` column is 65,532.

As of MySQL 5.0.3, the `NDBCLUSTER` engine supports only fixed-width columns. This means that a `VARCHAR` column from a table in a MySQL Cluster will behave as follows:

- If the size of the column is fewer than 256 characters, the column requires one byte extra storage per row.
- If the size of the column is 256 characters or more, the column requires two bytes extra storage per row.

Note that the number of bytes required per character varies according to the character set used. For example, if a `VARCHAR(100)` column in a Cluster table uses the `utf8` character set, then each character requires 3 bytes storage. This means that each record in such a column takes up  $100 \times 3 + 1 = 301$  bytes for storage, regardless of the length of the string actually stored in any given record. For a `VARCHAR(1000)` column in a table using the `NDBCLUSTER` storage engine with the `utf8` character set, each record will use  $1000 \times 3 + 2 = 3002$  bytes storage; that is, the column is 1,000 characters wide, each character requires 3 bytes storage, and each record has a 2-byte overhead because  $1,000 > 256$ .

The `BLOB` and `TEXT` types require 1, 2, 3, or 4 bytes to record the length of the column value, depending on the maximum possible length of the type. See Section 11.4.3, “The `BLOB` and `TEXT` Types”.

`TEXT` and `BLOB` columns are implemented differently in the `NDB Cluster` storage engine, wherein each row in a `TEXT` column is made up of two separate parts. One of these is of fixed size (256 bytes), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which stored in a hidden table. The rows in this second table are always 2,000 bytes long. This means that the size of a `TEXT` column is 256 if  $size \leq 256$  (where  $size$  represents the size of the row); otherwise, the size is  $256 + size + (2000 - (size - 256) \% 2000)$ .

The size of an `ENUM` object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See Section 11.4.4, “The `ENUM` Type”.

The size of a `SET` object is determined by the number of different set members. If the set size is  $N$ , the object occupies  $(N+7) / 8$  bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A `SET` can have a maximum of 64 members. See Section 11.4.5, “The `SET` Type”.

## 11.6. Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, `MEDIUMINT UNSIGNED` is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

Tables created in MySQL 5.0.3 and above uses a new storage format for `DECIMAL` columns. All basic calculation (`+`, `-`, `*`, `/`) with `DECIMAL` columns are done with precision of 65 decimal (base 10) digits. See Section 11.1.1, “Overview of Numeric Types”.

Prior to MySQL 5.0.3, calculations on `DECIMAL` values are performed using double-precision operations. If accuracy is not too important or if speed is the highest priority, the `DOUBLE` type may be good enough. For high precision, you can always convert to a fixed-point type stored in a `BIGINT`. This allows you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

## 11.7. Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL:

Other Vendor Type	MySQL Type
BOOL,	TINYINT
BOOLEAN	TINYINT
CHAR VARYING( <i>M</i> )	VARCHAR( <i>M</i> )
DEC	DECIMAL
FIXED	DECIMAL
FLOAT4	FLOAT
FLOAT8	DOUBLE
INT1	TINYINT
INT2	SMALLINT
INT3	MEDIUMINT
INT4	INT
INT8	BIGINT
LONG VARBINARY	MEDIUMBLOB
LONG VARCHAR	MEDIUMTEXT
LONG	MEDIUMTEXT
MIDDLEINT	MEDIUMINT
NUMERIC	DECIMAL

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> DESCRIBE t;
```

Field	Type	Null	Key	Default	Extra
a	tinyint(1)	YES		NULL	
b	double	YES		NULL	
c	mediumtext	YES		NULL	
d	decimal(10,0)	YES		NULL	

```
4 rows in set (0.01 sec)
```

---

# Chapter 12. Functions and Operators

Expressions can be used at several points in SQL statements, such as in the `ORDER BY` or `HAVING` clauses of `SELECT` statements, in the `WHERE` clause of a `SELECT`, `DELETE`, or `UPDATE` statement, or in `SET` statements. Expressions can be written using literal values, column values, `NULL`, built-in functions, stored functions, user-defined functions, and operators. This chapter describes the functions and operators that are allowed for writing expressions in MySQL. Instructions for writing stored functions and user-defined functions are given in Chapter 17, *Stored Procedures and Functions*, and Section 24.2, “Adding New Functions to MySQL”.

An expression that contains `NULL` always produces a `NULL` value unless otherwise indicated in the documentation for a particular function or operator.

**Note:** By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

You can tell the MySQL server to accept spaces after function names by starting it with the `--sql-mode=IGNORE_SPACE` option. (See Section 5.2.5, “The Server SQL Mode”.) Individual client programs can request this behavior by using the `CLIENT_IGNORE_SPACE` option for `mysql_real_connect()`. In either case, all function names become reserved words.

For the sake of brevity, most examples in this chapter display the output from the `mysql` program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29,9);
+-----+
| mod(29,9) |
+-----+
|          2 |
+-----+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29,9);
-> 2
```

## 12.1. Operators

### 12.1.1. Operator Precedence

Operator precedences are shown in the following list, from lowest precedence to the highest. Operators that are shown together on a line have the same precedence.

```
:=
| |, OR, XOR
&&, AND
NOT
BETWEEN, CASE, WHEN, THEN, ELSE
=, <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, IN
|
&
<<, >>
-, +
*, /, DIV, %, MOD
^
- (unary minus), ~ (unary bit inversion)
!
```

BINARY, COLLATE

The precedence shown for NOT is as of MySQL 5.0.2. For earlier versions, or from 5.0.2 on if the HIGH\_NOT\_PRECEDENCE SQL mode is enabled, the precedence of NOT is the same as that of the ! operator. See Section 5.2.5, “The Server SQL Mode”.

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```
mysql> SELECT 1+2*3;
      -> 7
mysql> SELECT (1+2)*3;
      -> 9
```

## 12.1.2. Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts numbers to strings as necessary, and vice versa.

```
mysql> SELECT 1+'1';
      -> 2
mysql> SELECT CONCAT(2,' test');
      -> '2 test'
```

It is also possible to perform explicit conversions. If you want to convert a number to a string explicitly, use the CAST() or CONCAT() function (CAST() is preferable):

```
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
      -> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
      -> 38.8, '38.8'
```

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are NULL, the result of the comparison is NULL, except for the NULL-safe <=> equality comparison operator. For NULL <=> NULL, the result is true.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a TIMESTAMP or DATETIME column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. Note that this is not done for the arguments to IN()! To be safe, always use complete datetime, date, or time strings when doing comparisons.
- In all other cases, the arguments are compared as floating-point (real) numbers.

The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
      -> 0
mysql> SELECT 7 > '6x';
      -> 1
mysql> SELECT 0 > 'x6';
      -> 0
```

```
mysql> SELECT 0 = 'x6';
-> 1
```

Note that when you are comparing a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If *str\_col* is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value 1, such as '1', ' 1', or '1a'.

Comparisons that use floating-point numbers (or values that are converted to floating-point numbers) are approximate because such numbers are inexact. This might lead to results that appear inconsistent:

```
mysql> SELECT '18015376320243458' = 18015376320243458;
-> 1
mysql> SELECT '18015376320243459' = 18015376320243459;
-> 0
```

Such results can occur because the values are converted to floating-point numbers, which have only 53 bits of precision and are subject to rounding:

```
mysql> SELECT '18015376320243459'+0.0;
-> 1.8015376320243e+16
```

Furthermore, the conversion from string to floating-point and from integer to floating-point do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications.

The results shown will vary on different systems, and can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` so that a value will not be converted implicitly to a float-point number:

```
mysql> SELECT CAST('18015376320243459' AS UNSIGNED) = 18015376320243459;
-> 1
```

For more information about floating-point comparisons, see Section A.5.8, “Problems with Floating-Point Comparisons”.

## 12.1.3. Comparison Functions and Operators

Comparison operations result in a value of 1 (TRUE), 0 (FALSE), or NULL. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

Some of the functions in this section (such as `LEAST()` and `GREATEST()`) return values other than 1 (TRUE), 0 (FALSE), or NULL. However, the value they return is based on comparison operations performed according to the rules described in Section 12.1.2, “Type Conversion in Expression Evaluation”.

To convert a value to a specific type for comparison purposes, you can use the `CAST()` function. String values can be converted to a different character set using `CONVERT()`. See Section 12.8, “Cast Functions and Operators”.

By default, string comparisons are not case sensitive and use the current character set. The default is `latin1` (cp1252 West European), which also works well for English.

- =

Equal:

```
mysql> SELECT 1 = 0;
      -> 0
mysql> SELECT '0' = 0;
      -> 1
mysql> SELECT '0.0' = 0;
      -> 1
mysql> SELECT '0.01' = 0;
      -> 0
mysql> SELECT '.01' = 0.01;
      -> 1
```

- <=>

NULL-safe equal. This operator performs an equality comparison like the = operator, but returns 1 rather than NULL if both operands are NULL, and 0 rather than NULL if one operand is NULL.

```
mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
      -> 1, 1, 0
mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
      -> 1, NULL, NULL
```

- <>, !=

Not equal:

```
mysql> SELECT '.01' <> '0.01';
      -> 1
mysql> SELECT .01 <> '0.01';
      -> 0
mysql> SELECT 'zapp' <> 'zappp';
      -> 1
```

- <=

Less than or equal:

```
mysql> SELECT 0.1 <= 2;
      -> 1
```

- <

Less than:

```
mysql> SELECT 2 < 2;
      -> 0
```

- >=

Greater than or equal:

```
mysql> SELECT 2 >= 2;
      -> 1
```

- >

Greater than:

```
mysql> SELECT 2 > 2;
-> 0
```

- *IS boolean\_value, IS NOT boolean\_value*

Tests a value against a boolean value, where *boolean\_value* can be TRUE, FALSE, or UNKNOWN.

```
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
-> 1, 1, 1
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

*IS [NOT] boolean\_value* syntax was added in MySQL 5.0.2.

- *IS NULL, IS NOT NULL*

Tests whether a value is or is not NULL.

```
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1
mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
-> 1, 1, 0
```

To work well with ODBC programs, MySQL supports the following extra features when using *IS NULL*:

- You can find the row that contains the most recent *AUTO\_INCREMENT* value by issuing a statement of the following form immediately after generating the value:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This behavior can be disabled by setting *SQL\_AUTO\_IS\_NULL=0*. See Section 13.5.3, “*SET Syntax*”.

- For *DATE* and *DATETIME* columns that are declared as *NOT NULL*, you can find the special date '0000-00-00' by using a statement like this:

```
SELECT * FROM tbl_name WHERE date_column IS NULL
```

This is needed to get some ODBC applications to work because ODBC does not support a '0000-00-00' date value.

- *expr BETWEEN min AND max*

If *expr* is greater than or equal to *min* and *expr* is less than or equal to *max*, *BETWEEN* returns 1, otherwise it returns 0. This is equivalent to the expression (*min* <= *expr* AND *expr* <= *max*) if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in Section 12.1.2, “*Type Conversion in Expression Evaluation*”, but applied to all the three arguments.

```
mysql> SELECT 1 BETWEEN 2 AND 3;
-> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
-> 1
mysql> SELECT 2 BETWEEN 2 AND '3';
-> 1
mysql> SELECT 2 BETWEEN 2 AND 'x-3';
-> 0
```

- *expr* NOT BETWEEN *min* AND *max*

This is the same as NOT (*expr* BETWEEN *min* AND *max*).

- COALESCE(*value*, ...)

Returns the first non-NULL value in the list, or NULL if there are no non-NULL values.

```
mysql> SELECT COALESCE(NULL,1);
      -> 1
mysql> SELECT COALESCE(NULL,NULL,NULL);
      -> NULL
```

- GREATEST(*value1*,*value2*,...)

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for LEAST().

```
mysql> SELECT GREATEST(2,0);
      -> 2
mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
      -> 767.0
mysql> SELECT GREATEST('B','A','C');
      -> 'C'
```

Before MySQL 5.0.13, GREATEST() returns NULL only if all arguments are NULL. As of 5.0.13, it returns NULL if any argument is NULL.

- *expr* IN (*value*, ...)

Returns 1 if *expr* is equal to any of the values in the IN list, else returns 0. If all values are constants, they are evaluated according to the type of *expr* and sorted. The search for the item then is done using a binary search. This means IN is very quick if the IN value list consists entirely of constants. Otherwise, type conversion takes place according to the rules described in Section 12.1.2, “Type Conversion in Expression Evaluation”, but applied to all the arguments.

```
mysql> SELECT 2 IN (0,3,5,'wefwf');
      -> 0
mysql> SELECT 'wefwf' IN (0,3,5,'wefwf');
      -> 1
```

The number of values in the IN list is only limited by the `max_allowed_packet` value.

To comply with the SQL standard, IN returns NULL not only if the expression on the left hand side is NULL, but also if no match is found in the list and one of the expressions in the list is NULL.

IN() syntax can also be used to write certain types of subqueries. See Section 13.2.8.3, “Subqueries with ANY, IN, and SOME”.

- *expr* NOT IN (*value*, ...)

This is the same as NOT (*expr* IN (*value*, ...)).

- ISNULL(*expr*)

If *expr* is NULL, ISNULL() returns 1, otherwise it returns 0.

```
mysql> SELECT ISNULL(1+1);
      -> 0
mysql> SELECT ISNULL(1/0);
      -> 1
```

`ISNULL()` can be used instead of `=` to test whether a value is `NULL`. (Comparing a value to `NULL` using `=` always yields false.)

The `ISNULL()` function shares some special behaviors with the `IS NULL` comparison operator. See the description of `IS NULL`.

- `INTERVAL(N, N1, N2, N3, ...)`

Returns 0 if  $N < N1$ , 1 if  $N < N2$  and so on or -1 if  $N$  is `NULL`. All arguments are treated as integers. It is required that  $N1 < N2 < N3 < \dots < Nn$  for this function to work correctly. This is because a binary search is used (very fast).

```
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
      -> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
      -> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
      -> 0
```

- `LEAST(value1, value2, ...)`

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If the return value is used in an `INTEGER` context or all arguments are integer-valued, they are compared as integers.
- If the return value is used in a `REAL` context or all arguments are real-valued, they are compared as reals.
- If any argument is a case-sensitive string, the arguments are compared as case-sensitive strings.
- In all other cases, the arguments are compared as case-insensitive strings.

Before MySQL 5.0.13, `LEAST()` returns `NULL` only if all arguments are `NULL`. As of 5.0.13, it returns `NULL` if any argument is `NULL`.

```
mysql> SELECT LEAST(2, 0);
      -> 0
mysql> SELECT LEAST(34.0, 3.0, 5.0, 767.0);
      -> 3.0
mysql> SELECT LEAST('B', 'A', 'C');
      -> 'A'
```

Note that the preceding conversion rules can produce strange results in some borderline cases:

```
mysql> SELECT CAST(LEAST(3600, 9223372036854775808.0) as SIGNED);
      -> -9223372036854775808
```

This happens because MySQL reads `9223372036854775808.0` in an integer context. The integer representation is not good enough to hold the value, so it wraps to a signed integer.

## 12.1.4. Logical Operators

In SQL, all logical operators evaluate to `TRUE`, `FALSE`, or `NULL` (`UNKNOWN`). In MySQL, these are implemented as 1 (`TRUE`), 0 (`FALSE`), and `NULL`. Most of this is common to different SQL database servers, although some servers may return any non-zero value for `TRUE`.

- NOT, !

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is non-zero, and NOT NULL returns NULL.

```
mysql> SELECT NOT 10;
      -> 0
mysql> SELECT NOT 0;
      -> 1
mysql> SELECT NOT NULL;
      -> NULL
mysql> SELECT ! (1+1);
      -> 0
mysql> SELECT ! 1+1;
      -> 1
```

The last example produces 1 because the expression evaluates the same way as (!1)+1.

Note that the precedence of the NOT operator changed in MySQL 5.0.2. See Section 12.1.1, “Operator Precedence”.

- AND, &&

Logical AND. Evaluates to 1 if all operands are non-zero and not NULL, to 0 if one or more operands are 0, otherwise NULL is returned.

```
mysql> SELECT 1 && 1;
      -> 1
mysql> SELECT 1 && 0;
      -> 0
mysql> SELECT 1 && NULL;
      -> NULL
mysql> SELECT 0 && NULL;
      -> 0
mysql> SELECT NULL && 0;
      -> 0
```

- OR, ||

Logical OR. When both operands are non-NULL, the result is 1 if any operand is non-zero, and 0 otherwise. With a NULL operand, the result is 1 if the other operand is non-zero, and NULL otherwise. If both operands are NULL, the result is NULL.

```
mysql> SELECT 1 || 1;
      -> 1
mysql> SELECT 1 || 0;
      -> 1
mysql> SELECT 0 || 0;
      -> 0
mysql> SELECT 0 || NULL;
      -> NULL
mysql> SELECT 1 || NULL;
      -> 1
```

- XOR

Logical XOR. Returns NULL if either operand is NULL. For non-NULL operands, evaluates to 1 if an odd number of operands is non-zero, otherwise 0 is returned.

```
mysql> SELECT 1 XOR 1;
      -> 0
mysql> SELECT 1 XOR 0;
      -> 1
mysql> SELECT 1 XOR NULL;
```

```
mysql> SELECT 1 XOR 1 XOR 1;
-> 1
```

$a \text{ XOR } b$  is mathematically equal to  $(a \text{ AND } (\text{NOT } b)) \text{ OR } ((\text{NOT } a) \text{ AND } b)$ .

## 12.2. Control Flow Functions

- `CASE value WHEN [compare_value] THEN result [WHEN [compare_value] THEN result ...] [ELSE result] END`

```
CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...] [ELSE result] END
```

The first version returns the *result* where *value=compare\_value*. The second version returns the result for the first condition that is true. If there was no matching result value, the result after `ELSE` is returned, or `NULL` if there is no `ELSE` part.

```
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
-> WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'
mysql> SELECT CASE BINARY 'B'
-> WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
-> NULL
```

The default return type of a `CASE` expression is the compatible aggregated type of all return values, but also depends on the context in which it is used. If used in a string context, the result is returned as a string. If used in a numeric context, then the result is returned as a decimal, real, or integer value.

**Note:** The syntax of the `CASE expression` shown here differs slightly from that of the SQL `CASE statement` described in Section 17.2.10.2, “CASE Statement”, for use inside stored routines. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

- `IF(expr1,expr2,expr3)`

If *expr1* is `TRUE` (*expr1*  $\neq$  0 and *expr1*  $\neq$  `NULL`) then `IF()` returns *expr2*; otherwise it returns *expr3*. `IF()` returns a numeric or string value, depending on the context in which it is used.

```
mysql> SELECT IF(1>2,2,3);
-> 3
mysql> SELECT IF(1<2,'yes','no');
-> 'yes'
mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
-> 'no'
```

If only one of *expr2* or *expr3* is explicitly `NULL`, the result type of the `IF()` function is the type of the non-`NULL` expression.

*expr1* is evaluated as an integer value, which means that if you are testing floating-point or string values, you should do so using a comparison operation.

```
mysql> SELECT IF(0.1,1,0);
-> 0
mysql> SELECT IF(0.1<>0,1,0);
-> 1
```

In the first case shown, `IF(0.1)` returns 0 because 0.1 is converted to an integer value, resulting in a test of `IF(0)`. This may not be what you expect. In the second case, the comparison tests the original floating-point value to see whether it is non-zero. The result of the comparison is used as an integer.

The default return type of `IF()` (which may matter when it is stored into a temporary table) is calculated as follows:

Expression	Return Value
<code>expr2</code> or <code>expr3</code> returns a string	string
<code>expr2</code> or <code>expr3</code> returns a floating-point value	floating-point
<code>expr2</code> or <code>expr3</code> returns an integer	integer

If `expr2` and `expr3` are both strings, the result is case sensitive if either string is case sensitive.

**Note:** There is also an *IF statement*, which differs from the *IF() function* described here. See Section 17.2.10.1, “IF Statement”.

- `IFNULL(expr1, expr2)`

If `expr1` is not NULL, `IFNULL()` returns `expr1`; otherwise it returns `expr2`. `IFNULL()` returns a numeric or string value, depending on the context in which it is used.

```
mysql> SELECT IFNULL(1,0);
-> 1
mysql> SELECT IFNULL(NULL,10);
-> 10
mysql> SELECT IFNULL(1/0,10);
-> 10
mysql> SELECT IFNULL(1/0,'yes');
-> 'yes'
```

The default result value of `IFNULL(expr1, expr2)` is the more “general” of the two expressions, in the order `STRING`, `REAL`, or `INTEGER`. Consider the case of a table based on expressions or where MySQL must internally store a value returned by `IFNULL()` in a temporary table:

```
mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
mysql> DESCRIBE tmp;
+-----+-----+-----+-----+-----+-----+
| Field | Type   | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| test  | char(4)|      |     |         |       |
+-----+-----+-----+-----+-----+-----+
```

In this example, the type of the `test` column is `CHAR(4)`.

- `NULLIF(expr1, expr2)`

Returns NULL if `expr1 = expr2` is true, otherwise returns `expr1`. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END`.

```
mysql> SELECT NULLIF(1,1);
-> NULL
mysql> SELECT NULLIF(1,2);
-> 1
```

Note that MySQL evaluates *expr1* twice if the arguments are not equal.

## 12.3. String Functions

String-valued functions return NULL if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See Section 7.5.2, “Tuning Server Parameters”.

For functions that operate on string positions, the first position is numbered 1.

- `ASCII(str)`

Returns the numeric value of the leftmost character of the string *str*. Returns 0 if *str* is the empty string. Returns NULL if *str* is NULL. `ASCII()` works for characters with numeric values from 0 to 255.

```
mysql> SELECT ASCII('2');
      -> 50
mysql> SELECT ASCII(2);
      -> 50
mysql> SELECT ASCII('dx');
      -> 100
```

See also the `ORD()` function.

- `BIN(N)`

Returns a string representation of the binary value of *N*, where *N* is a longlong (BIGINT) number. This is equivalent to `CONV(N, 10, 2)`. Returns NULL if *N* is NULL.

```
mysql> SELECT BIN(12);
      -> '1100'
```

- `BIT_LENGTH(str)`

Returns the length of the string *str* in bits.

```
mysql> SELECT BIT_LENGTH('text');
      -> 32
```

- `CHAR(N, ... [USING charset_name])`

`CHAR()` interprets each argument *N* as an integer and returns a string consisting of the characters given by the code values of those integers. NULL values are skipped.

```
mysql> SELECT CHAR(77,121,83,81,'76');
      -> 'MySQL'
mysql> SELECT CHAR(77,77.3,'77.3');
      -> 'MMM'
```

As of MySQL 5.0.15, `CHAR()` arguments larger than 255 are converted into multiple result bytes. For example, `CHAR(256)` is equivalent to `CHAR(1,0)`, and `CHAR(256*256)` is equivalent to `CHAR(1,0,0)`:

```
mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
+-----+-----+
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
+-----+-----+
| 0100          | 0100          |
```

```

+-----+-----+
mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
+-----+-----+
| HEX(CHAR(1,0,0)) | HEX(CHAR(256*256)) |
+-----+-----+
| 010000          | 010000          |
+-----+-----+

```

By default, CHAR() returns a binary string. To produce a string in a given character set, use the optional USING clause:

```

mysql> SELECT CHARSET(CHAR(0x65)), CHARSET(CHAR(0x65 USING utf8));
+-----+-----+
| CHARSET(CHAR(0x65)) | CHARSET(CHAR(0x65 USING utf8)) |
+-----+-----+
| binary              | utf8                             |
+-----+-----+

```

If USING is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from CHAR() becomes NULL.

Before MySQL 5.0.15, CHAR() returns a string in the connection character set and the USING clause is unavailable. In addition, each argument is interpreted modulo 256, so CHAR(256) and CHAR(256\*256) both are equivalent to CHAR(0).

- CHAR\_LENGTH(*str*)

Returns the length of the string *str*, measured in characters. A multi-byte character counts as a single character. This means that for a string containing five two-byte characters, LENGTH() returns 10, whereas CHAR\_LENGTH() returns 5.

- CHARACTER\_LENGTH(*str*)

CHARACTER\_LENGTH() is a synonym for CHAR\_LENGTH().

- CONCAT(*str1, str2, ...*)

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are non-binary strings, the result is a non-binary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent binary string form; if you want to avoid that, you can use an explicit type cast, as in this example:

```
SELECT CONCAT(CAST(int_col AS CHAR), char_col);
```

CONCAT() returns NULL if any argument is NULL.

```

mysql> SELECT CONCAT('My', 'S', 'QL');
-> 'MySQL'
mysql> SELECT CONCAT('My', NULL, 'QL');
-> NULL
mysql> SELECT CONCAT(14.3);
-> '14.3'

```

- CONCAT\_WS(*separator, str1, str2, ...*)

CONCAT\_WS() stands for Concatenate With Separator and is a special form of CONCAT(). The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is NULL, the result is NULL.

```
mysql> SELECT CONCAT_WS(',', 'First name', 'Second name', 'Last Name');
```

```
mysql> -> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',', 'First name', NULL, 'Last Name');
mysql> -> 'First name,Last Name'
```

CONCAT\_WS() does not skip empty strings. However, it does skip any NULL values after the separator argument.

- CONV(*N*, *from\_base*, *to\_base*)

Converts numbers between different number bases. Returns a string representation of the number *N*, converted from base *from\_base* to base *to\_base*. Returns NULL if any argument is NULL. The argument *N* is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If *to\_base* is a negative number, *N* is regarded as a signed number. Otherwise, *N* is treated as unsigned. CONV() works with 64-bit precision.

```
mysql> SELECT CONV('a',16,2);
mysql> -> '1010'
mysql> SELECT CONV('6E',18,8);
mysql> -> '172'
mysql> SELECT CONV(-17,10,-18);
mysql> -> '-H'
mysql> SELECT CONV(10+'10'+ '10'+0xa,10,10);
mysql> -> '40'
```

- ELT(*N*, *str1*, *str2*, *str3*, ...)

Returns *str1* if *N* = 1, *str2* if *N* = 2, and so on. Returns NULL if *N* is less than 1 or greater than the number of arguments. ELT() is the complement of FIELD().

```
mysql> SELECT ELT(1, 'ej', 'Heja', 'hej', 'foo');
mysql> -> 'ej'
mysql> SELECT ELT(4, 'ej', 'Heja', 'hej', 'foo');
mysql> -> 'foo'
```

- EXPORT\_SET(*bits*, *on*, *off*[, *separator*[, *number\_of\_bits*]])

Returns a string such that for every bit set in the value *bits*, you get an *on* string and for every reset bit, you get an *off* string. Bits in *bits* are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the *separator* string (the default being the comma character ','). The number of bits examined is given by *number\_of\_bits* (defaults to 64).

```
mysql> SELECT EXPORT_SET(5, 'Y', 'N', ',', '4');
mysql> -> 'Y,N,Y,N'
mysql> SELECT EXPORT_SET(6, '1', '0', ',', '10');
mysql> -> '0,1,1,0,0,0,0,0,0,0'
```

- FIELD(*str*, *str1*, *str2*, *str3*, ...)

Returns the index (position) of *str* in the *str1*, *str2*, *str3*, ... list. Returns 0 if *str* is not found.

If all arguments to FIELD() are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

If *str* is NULL, the return value is 0 because NULL fails equality comparison with any value. FIELD() is the complement of ELT().

```
mysql> SELECT FIELD('ej', 'Hej', 'ej', 'Heja', 'hej', 'foo');
mysql> -> 2
mysql> SELECT FIELD('fo', 'Hej', 'ej', 'Heja', 'hej', 'foo');
```

-> 0

- `FIND_IN_SET(str, strlist)`

Returns a value in the range of 1 to  $N$  if the string *str* is in the string list *strlist* consisting of  $N$  substrings. A string list is a string composed of substrings separated by ',' characters. If the first argument is a constant string and the second is a column of type SET, the `FIND_IN_SET()` function is optimized to use bit arithmetic. Returns 0 if *str* is not in *strlist* or if *strlist* is the empty string. Returns NULL if either argument is NULL. This function does not work properly if the first argument contains a comma (',' ) character.

```
mysql> SELECT FIND_IN_SET('b', 'a,b,c,d');
      -> 2
```

- `FORMAT(X, D)`

Formats the number  $X$  to a format like '#,###,###.##', rounded to  $D$  decimal places, and returns the result as a string. If  $D$  is 0, the result has no decimal point or fractional part.

```
mysql> SELECT FORMAT(12332.123456, 4);
      -> '12,332.1235'
mysql> SELECT FORMAT(12332.1, 4);
      -> '12,332.1000'
mysql> SELECT FORMAT(12332.2, 0);
      -> '12,332'
```

- `HEX(N_or_S)`

If *N\_or\_S* is a number, returns a string representation of the hexadecimal value of  $N$ , where  $N$  is a longlong (BIGINT) number. This is equivalent to `CONV(N, 10, 16)`.

If *N\_or\_S* is a string, returns a hexadecimal string representation of *N\_or\_S* where each character in *N\_or\_S* is converted to two hexadecimal digits.

```
mysql> SELECT HEX(255);
      -> 'FF'
mysql> SELECT HEX(0x616263);
      -> 'abc'
mysql> SELECT HEX('abc');
      -> 616263
```

- `INSERT(str, pos, len, newstr)`

Returns the string *str*, with the substring beginning at position *pos* and *len* characters long replaced by the string *newstr*. Returns the original string if *pos* is not within the length of the string. Replaces the rest of the string from position *pos* if *len* is not within the length of the rest of the string. Returns NULL if any argument is NULL.

```
mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
      -> 'QuWhattic'
mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
      -> 'Quadratic'
mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
      -> 'QuWhat'
```

This function is multi-byte safe.

- `INSTR(str, substr)`

Returns the position of the first occurrence of substring *substr* in string *str*. This is the same as the two-argument form of `LOCATE()`, except that the order of the arguments is reversed.

```
mysql> SELECT INSTR('foobarbar', 'bar');
      -> 4
mysql> SELECT INSTR('xbar', 'foobar');
      -> 0
```

This function is multi-byte safe, and is case sensitive only if at least one argument is a binary string.

- `LCASE(str)`

`LCASE()` is a synonym for `LOWER()`.

- `LEFT(str, len)`

Returns the leftmost *len* characters from the string *str*.

```
mysql> SELECT LEFT('foobarbar', 5);
      -> 'fooba'
```

- `LENGTH(str)`

Returns the length of the string *str*, measured in bytes. A multi-byte character counts as multiple bytes. This means that for a string containing five two-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

```
mysql> SELECT LENGTH('text');
      -> 4
```

- `LOAD_FILE(file_name)`

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full pathname to the file, and you must have the `FILE` privilege. The file must be readable by all and its size less than `max_allowed_packet` bytes.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns `NULL`.

As of MySQL 5.0.19, the `character_set_filesystem` system variable controls interpretation of filenames that are given as literal strings.

```
mysql> UPDATE t
      SET blob_col=LOAD_FILE('/tmp/picture')
      WHERE id=1;
```

- `LOCATE(substr, str)`, `LOCATE(substr, str, pos)`

The first syntax returns the position of the first occurrence of substring *substr* in string *str*. The second syntax returns the position of the first occurrence of substring *substr* in string *str*, starting at position *pos*. Returns 0 if *substr* is not in *str*.

```
mysql> SELECT LOCATE('bar', 'foobarbar');
      -> 4
mysql> SELECT LOCATE('xbar', 'foobar');
      -> 0
mysql> SELECT LOCATE('bar', 'foobarbar', 5);
      -> 7
```

This function is multi-byte safe, and is case-sensitive only if at least one argument is a binary string.

- LOWER(*str*)

Returns the string *str* with all characters changed to lowercase according to the current character set mapping. The default is latin1 (cp1252 West European).

```
mysql> SELECT LOWER('QUADRATICALLY');
      -> 'quadratically'
```

This function is multi-byte safe.

- LPAD(*str*, *len*, *padstr*)

Returns the string *str*, left-padded with the string *padstr* to a length of *len* characters. If *str* is longer than *len*, the return value is shortened to *len* characters.

```
mysql> SELECT LPAD('hi',4,'??');
      -> '??hi'
mysql> SELECT LPAD('hi',1,'??');
      -> 'h'
```

- LTRIM(*str*)

Returns the string *str* with leading space characters removed.

```
mysql> SELECT LTRIM('  barbar');
      -> 'barbar'
```

This function is multi-byte safe.

- MAKE\_SET(*bits*, *str1*, *str2*, ...)

Returns a set value (a string containing substrings separated by ',' characters) consisting of the strings that have the corresponding bit in *bits* set. *str1* corresponds to bit 0, *str2* to bit 1, and so on. NULL values in *str1*, *str2*, ... are not appended to the result.

```
mysql> SELECT MAKE_SET(1,'a','b','c');
      -> 'a'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice','world');
      -> 'hello,world'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice',NULL,'world');
      -> 'hello'
mysql> SELECT MAKE_SET(0,'a','b','c');
      -> ''
```

- MID(*str*, *pos*, *len*)

MID(*str*, *pos*, *len*) is a synonym for SUBSTRING(*str*, *pos*, *len*).

- OCT(*N*)

Returns a string representation of the octal value of *N*, where *N* is a longlong (BIGINT) number. This is equivalent to CONV(*N*, 10, 8). Returns NULL if *N* is NULL.

```
mysql> SELECT OCT(12);
      -> '14'
```

- OCTET\_LENGTH(*str*)

OCTET\_LENGTH() is a synonym for LENGTH().

- ORD(*str*)

If the leftmost character of the string *str* is a multi-byte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

```
(1st byte code)
+ (2nd byte code × 256)
+ (3rd byte code × 2562) ...
```

If the leftmost character is not a multi-byte character, `ORD()` returns the same value as the `ASCII()` function.

```
mysql> SELECT ORD('2');
      -> 50
```

- `POSITION(substr IN str)`

`POSITION(substr IN str)` is a synonym for `LOCATE(substr, str)`.

- `QUOTE(str)`

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotes and with each instance of single quote ('), backslash ('\'), ASCII NUL, and Control-Z preceded by a backslash. If the argument is NULL, the return value is the word "NULL" without enclosing single quotes.

```
mysql> SELECT QUOTE('Don\'t!');
      -> 'Don\'t!'
mysql> SELECT QUOTE(NULL);
      -> NULL
```

- `REPEAT(str, count)`

Returns a string consisting of the string *str* repeated *count* times. If *count* is less than 1, returns an empty string. Returns NULL if *str* or *count* are NULL.

```
mysql> SELECT REPEAT('MySQL', 3);
      -> 'MySQLMySQLMySQL'
```

- `REPLACE(str, from_str, to_str)`

Returns the string *str* with all occurrences of the string *from\_str* replaced by the string *to\_str*. `REPLACE()` performs a case-sensitive match when searching for *from\_str*.

```
mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
      -> 'WwWwWw.mysql.com'
```

This function is multi-byte safe.

- `REVERSE(str)`

Returns the string *str* with the order of the characters reversed.

```
mysql> SELECT REVERSE('abc');
      -> 'cba'
```

This function is multi-byte safe.

- `RIGHT(str, len)`

Returns the rightmost *len* characters from the string *str*.

```
mysql> SELECT RIGHT('foobarbar', 4);
       -> 'rbar'
```

This function is multi-byte safe.

- `RPAD(str, len, padstr)`

Returns the string *str*, right-padded with the string *padstr* to a length of *len* characters. If *str* is longer than *len*, the return value is shortened to *len* characters.

```
mysql> SELECT RPAD('hi', 5, '?');
       -> 'hi???'
mysql> SELECT RPAD('hi', 1, '?');
       -> 'h'
```

This function is multi-byte safe.

- `RTRIM(str)`

Returns the string *str* with trailing space characters removed.

```
mysql> SELECT RTRIM('barbar ');
       -> 'barbar'
```

This function is multi-byte safe.

- `SOUNDEX(str)`

Returns a soundex string from *str*. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the `SOUNDEX()` function returns an arbitrarily long string. You can use `SUBSTRING()` on the result to get a standard soundex string. All non-alphabetic characters in *str* are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

```
mysql> SELECT SOUNDEX('Hello');
       -> 'H400'
mysql> SELECT SOUNDEX('Quadratically');
       -> 'Q36324'
```

**Note:** This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

- `expr1 SOUNDS LIKE expr2`

This is the same as `SOUNDEX(expr1) = SOUNDEX(expr2)`.

- `SPACE(N)`

Returns a string consisting of *N* space characters.

```
mysql> SELECT SPACE(6);
       -> '      '
```

- `SUBSTRING(str, pos)`, `SUBSTRING(str FROM pos)`,  
`SUBSTRING(str, pos, len)`, `SUBSTRING(str FROM pos FOR len)`

The forms without a *len* argument return a substring from string *str* starting at position *pos*. The forms with a *len* argument return a substring *len* characters long from string *str*, start-

ing at position *pos*. The forms that use FROM are standard SQL syntax. It is also possible to use a negative value for *pos*. In this case, the beginning of the substring is *pos* characters from the end of the string, rather than the beginning. A negative value may be used for *pos* in any of the forms of this function.

```
mysql> SELECT SUBSTRING('Quadratically',5);
      -> 'ratically'
mysql> SELECT SUBSTRING('foobarbar' FROM 4);
      -> 'barbar'
mysql> SELECT SUBSTRING('Quadratically',5,6);
      -> 'ratika'
mysql> SELECT SUBSTRING('Sakila', -3);
      -> 'ila'
mysql> SELECT SUBSTRING('Sakila', -5, 3);
      -> 'aki'
mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);
      -> 'ki'
```

This function is multi-byte safe.

If *len* is less than 1, the result is the empty string.

SUBSTR() is a synonym for SUBSTRING().

- SUBSTRING\_INDEX(*str*,*delim*,*count*)

Returns the substring from string *str* before *count* occurrences of the delimiter *delim*. If *count* is positive, everything to the left of the final delimiter (counting from the left) is returned. If *count* is negative, everything to the right of the final delimiter (counting from the right) is returned. SUBSTRING\_INDEX() performs a case-sensitive match when searching for *delim*.

```
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
      -> 'www.mysql'
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
      -> 'mysql.com'
```

This function is multi-byte safe.

- TRIM([{BOTH | LEADING | TRAILING} [*remstr*] FROM] *str*), TRIM([*remstr* FROM] *str*)

Returns the string *str* with all *remstr* prefixes or suffixes removed. If none of the specifiers BOTH, LEADING, or TRAILING is given, BOTH is assumed. *remstr* is optional and, if not specified, spaces are removed.

```
mysql> SELECT TRIM(' bar ');
      -> 'bar'
mysql> SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx');
      -> 'barxxx'
mysql> SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx');
      -> 'bar'
mysql> SELECT TRIM(TRAILING 'xyz' FROM 'barxyz');
      -> 'barx'
```

This function is multi-byte safe.

- UCASE(*str*)

UCASE() is a synonym for UPPER().

- UNHEX(*str*)

Performs the inverse operation of `HEX(str)`. That is, it interprets each pair of hexadecimal digits in the argument as a number and converts it to the character represented by the number. The resulting characters are returned as a binary string.

```
mysql> SELECT UNHEX('4D7953514C');
      -> 'MySQL'
mysql> SELECT 0x4D7953514C;
      -> 'MySQL'
mysql> SELECT UNHEX(HEX('string'));
      -> 'string'
mysql> SELECT HEX(UNHEX('1267'));
      -> '1267'
```

- `UPPER(str)`

Returns the string *str* with all characters changed to uppercase according to the current character set mapping. The default is `latin1 (cp1252 West European)`.

```
mysql> SELECT UPPER('Hej');
      -> 'HEJ'
```

This function is multi-byte safe.

## 12.3.1. String Comparison Functions

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case sensitive, the comparison is performed in case-sensitive fashion.

- `expr LIKE pat [ESCAPE 'escape_char']`

Pattern matching using SQL simple regular expression comparison. Returns 1 (TRUE) or 0 (FALSE). If either *expr* or *pat* is NULL, the result is NULL.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Per the SQL standard, `LIKE` performs matching on a per-character basis, thus it can produce results different from the `=` comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' LIKE 'ae' COLLATE latin1_german2_ci |
+-----+
|                                           0 |
+-----+
mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' = 'ae' COLLATE latin1_german2_ci |
+-----+
|                                           1 |
+-----+
```

With `LIKE` you can use the following two wildcard characters in the pattern:

Character	Description
%	Matches any number of characters, even zero characters

_	Matches exactly one character
---	-------------------------------

```
mysql> SELECT 'David!' LIKE 'David_';
-> 1
mysql> SELECT 'David!' LIKE '%D%v%';
-> 1
```

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the ESCAPE character, ‘\’ is assumed.

String	Description
\%	Matches one ‘%’ character
\_	Matches one ‘_’ character

```
mysql> SELECT 'David!' LIKE 'David\_';
-> 0
mysql> SELECT 'David_' LIKE 'David\_';
-> 1
```

To specify a different escape character, use the ESCAPE clause:

```
mysql> SELECT 'David_' LIKE 'David|_' ESCAPE '|';
-> 1
```

The escape sequence should be empty or one character long. As of MySQL 5.0.16, if the NO\_BACKSLASH\_ESCAPES SQL mode is enabled, the sequence cannot be empty.

The following two statements illustrate that string comparisons are not case sensitive unless one of the operands is a binary string:

```
mysql> SELECT 'abc' LIKE 'ABC';
-> 1
mysql> SELECT 'abc' LIKE BINARY 'ABC';
-> 0
```

In MySQL, LIKE is allowed on numeric expressions. (This is an extension to the standard SQL LIKE.)

```
mysql> SELECT 10 LIKE '1%';
-> 1
```

**Note:** Because MySQL uses C escape syntax in strings (for example, ‘\n’ to represent a newline character), you must double any ‘\’ that you use in LIKE strings. For example, to search for ‘\n’, specify it as ‘\\n’. To search for ‘\’, specify it as ‘\\\\’; this is because the backslashes are stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against. (Exception: At the end of the pattern string, backslash can be specified as ‘\\’. At the end of the string, backslash stands for itself because there is nothing following to escape.)

- *expr* NOT LIKE *pat* [ESCAPE '*escape\_char*']

This is the same as NOT (*expr* LIKE *pat* [ESCAPE '*escape\_char*']).

- *expr* NOT REGEXP *pat*, *expr* NOT RLIKE *pat*

This is the same as NOT (*expr* REGEXP *pat*).

- `expr REGEXP pat` `expr RLIKE pat`

Performs a pattern match of a string expression `expr` against a pattern `pat`. The pattern can be an extended regular expression. The syntax for regular expressions is discussed in Appendix G, *Regular Expressions*. Returns 1 if `expr` matches `pat`; otherwise it returns 0. If either `expr` or `pat` is NULL, the result is NULL. RLIKE is a synonym for REGEXP, provided for mSQL compatibility.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

**Note:** Because MySQL uses the C escape syntax in strings (for example, ‘\n’ to represent the newline character), you must double any ‘\’ that you use in your REGEXP strings.

REGEXP is not case sensitive, except when used with binary strings.

```
mysql> SELECT 'Monty!' REGEXP 'm%y%';
-> 0
mysql> SELECT 'Monty!' REGEXP '.*';
-> 1
mysql> SELECT 'new*\n*line' REGEXP 'new\\*.*\\*line';
-> 1
mysql> SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
-> 1 0
mysql> SELECT 'a' REGEXP '^[a-d]';
-> 1
```

REGEXP and RLIKE use the current character set when deciding the type of a character. The default is latin1 (cp1252 West European). **Warning:** These operators are not multi-byte safe.

- `STRCMP(expr1,expr2)`

STRCMP() returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

```
mysql> SELECT STRCMP('text', 'text2');
-> -1
mysql> SELECT STRCMP('text2', 'text');
-> 1
mysql> SELECT STRCMP('text', 'text');
-> 0
```

STRCMP() uses the current character set when performing comparisons. This makes the default comparison behavior case insensitive unless one or both of the operands are binary strings.

## 12.4. Numeric Functions

### 12.4.1. Arithmetic Operators

The usual arithmetic operators are available. Note that in the case of -, +, and \*, the result is calculated with BIGINT (64-bit) precision if both arguments are integers. If one of the arguments is an unsigned integer, and the other argument is also an integer, the result is an unsigned integer. See Section 12.8, “Cast Functions and Operators”.

- +

Addition:

```
mysql> SELECT 3+5;
-> 8
```

- -

Subtraction:

```
mysql> SELECT 3-5;
      -> -2
```

- -

Unary minus. This operator changes the sign of the argument.

```
mysql> SELECT - 2;
      -> -2
```

**Note:** If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `-` on integers that may have the value of  $-2^{63}$ .

- \*

Multiplication:

```
mysql> SELECT 3*5;
      -> 15
mysql> SELECT 18014398509481984*18014398509481984.0;
      -> 324518553658426726783156020576256.0
mysql> SELECT 18014398509481984*18014398509481984;
      -> 0
```

The result of the last expression is incorrect because the result of the integer multiplication exceeds the 64-bit range of `BIGINT` calculations. (See Section 11.2, “Numeric Types”.)

- /

Division:

```
mysql> SELECT 3/5;
      -> 0.60
```

Division by zero produces a `NULL` result:

```
mysql> SELECT 102/(1-1);
      -> NULL
```

A division is calculated with `BIGINT` arithmetic only if performed in a context where its result is converted to an integer.

- DIV

Integer division. Similar to `FLOOR()`, but is safe with `BIGINT` values.

```
mysql> SELECT 5 DIV 2;
      -> 2
```

## 12.4.2. Mathematical Functions

All mathematical functions return `NULL` in the event of an error.

- `ABS(X)`

Returns the absolute value of  $X$ .

```
mysql> SELECT ABS(2);
      -> 2
mysql> SELECT ABS(-32);
      -> 32
```

This function is safe to use with `BIGINT` values.

- `ACOS(X)`

Returns the arc cosine of  $X$ , that is, the value whose cosine is  $X$ . Returns `NULL` if  $X$  is not in the range  $-1$  to  $1$ .

```
mysql> SELECT ACOS(1);
      -> 0
mysql> SELECT ACOS(1.0001);
      -> NULL
mysql> SELECT ACOS(0);
      -> 1.5707963267949
```

- `ASIN(X)`

Returns the arc sine of  $X$ , that is, the value whose sine is  $X$ . Returns `NULL` if  $X$  is not in the range  $-1$  to  $1$ .

```
mysql> SELECT ASIN(0.2);
      -> 0.20135792079033
mysql> SELECT ASIN('foo');
```

```
+-----+
| ASIN('foo') |
+-----+
|           0 |
+-----+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
```

Level	Code	Message
Warning	1292	Truncated incorrect DOUBLE value: 'foo'

- `ATAN(X)`

Returns the arc tangent of  $X$ , that is, the value whose tangent is  $X$ .

```
mysql> SELECT ATAN(2);
      -> 1.1071487177941
mysql> SELECT ATAN(-2);
      -> -1.1071487177941
```

- `ATAN(Y, X), ATAN2(Y, X)`

Returns the arc tangent of the two variables  $X$  and  $Y$ . It is similar to calculating the arc tangent of  $Y / X$ , except that the signs of both arguments are used to determine the quadrant of the result.

```
mysql> SELECT ATAN(-2, 2);
      -> -0.78539816339745
mysql> SELECT ATAN2(PI(), 0);
```

-> 1.5707963267949

- `CEILING(X)`, `CEIL(X)`

Returns the smallest integer value not less than  $X$ .

```
mysql> SELECT CEILING(1.23);
      -> 2
mysql> SELECT CEIL(-1.23);
      -> -1
```

These two functions are synonymous. Note that the return value is converted to a `BIGINT`.

- `COS(X)`

Returns the cosine of  $X$ , where  $X$  is given in radians.

```
mysql> SELECT COS(PI());
      -> -1
```

- `COT(X)`

Returns the cotangent of  $X$ .

```
mysql> SELECT COT(12);
      -> -1.5726734063977
mysql> SELECT COT(0);
      -> NULL
```

- `CRC32(expr)`

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is `NULL` if the argument is `NULL`. The argument is expected to be a string and (if possible) is treated as one if it is not.

```
mysql> SELECT CRC32('MySQL');
      -> 3259397556
mysql> SELECT CRC32('mysql');
      -> 2501908538
```

- `DEGREES(X)`

Returns the argument  $X$ , converted from radians to degrees.

```
mysql> SELECT DEGREES(PI());
      -> 180
mysql> SELECT DEGREES(PI() / 2);
      -> 90
```

- `EXP(X)`

Returns the value of  $e$  (the base of natural logarithms) raised to the power of  $X$ .

```
mysql> SELECT EXP(2);
      -> 7.3890560989307
mysql> SELECT EXP(-2);
      -> 0.13533528323661
mysql> SELECT EXP(0);
      -> 1
```

- `FLOOR(X)`

Returns the largest integer value not greater than *X*.

```
mysql> SELECT FLOOR(1.23);
      -> 1
mysql> SELECT FLOOR(-1.23);
      -> -2
```

Note that the return value is converted to a `BIGINT`.

- `FORMAT(X,D)`

Formats the number *X* to a format like '`#,###,###.##`', rounded to *D* decimal places, and returns the result as a string. For details, see Section 12.3, "String Functions".

- `LN(X)`

Returns the natural logarithm of *X*; that is, the base-*e* logarithm of *X*.

```
mysql> SELECT LN(2);
      -> 0.69314718055995
mysql> SELECT LN(-2);
      -> NULL
```

This function is synonymous with `LOG(X)`.

- `LOG(X)`, `LOG(B,X)`

If called with one parameter, this function returns the natural logarithm of *X*.

```
mysql> SELECT LOG(2);
      -> 0.69314718055995
mysql> SELECT LOG(-2);
      -> NULL
```

If called with two parameters, this function returns the logarithm of *X* for an arbitrary base *B*.

```
mysql> SELECT LOG(2,65536);
      -> 16
mysql> SELECT LOG(10,100);
      -> 2
```

`LOG(B,X)` is equivalent to `LOG(X) / LOG(B)`.

- `LOG2(X)`

Returns the base-2 logarithm of *X*.

```
mysql> SELECT LOG2(65536);
      -> 16
mysql> SELECT LOG2(-100);
      -> NULL
```

`LOG2()` is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression `LOG(X) / LOG(2)`.

- `LOG10(X)`

Returns the base-10 logarithm of *X*.

```
mysql> SELECT LOG10(2);
      -> 0.30102999566398
mysql> SELECT LOG10(100);
      -> 2
mysql> SELECT LOG10(-100);
      -> NULL
```

$\text{LOG}_{10}(X)$  is equivalent to  $\text{LOG}(10, X)$ .

- $\text{MOD}(N, M), N \% M, N \text{ MOD } M$

Modulo operation. Returns the remainder of  $N$  divided by  $M$ .

```
mysql> SELECT MOD(234, 10);
      -> 4
mysql> SELECT 253 \% 7;
      -> 1
mysql> SELECT MOD(29, 9);
      -> 2
mysql> SELECT 29 MOD 9;
      -> 2
```

This function is safe to use with `BIGINT` values.

`MOD()` also works on values that have a fractional part and returns the exact remainder after division:

```
mysql> SELECT MOD(34.5, 3);
      -> 1.5
```

- $\text{PI}()$

Returns the value of  $\pi$  (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

```
mysql> SELECT PI();
      -> 3.141593
mysql> SELECT PI()+0.00000000000000000000;
      -> 3.141592653589793116
```

- $\text{POW}(X, Y), \text{POWER}(X, Y)$

Returns the value of  $X$  raised to the power of  $Y$ .

```
mysql> SELECT POW(2, 2);
      -> 4
mysql> SELECT POW(2, -2);
      -> 0.25
```

- $\text{RADIANS}(X)$

Returns the argument  $X$ , converted from degrees to radians. (Note that  $\pi$  radians equals 180 degrees.)

```
mysql> SELECT RADIANS(90);
      -> 1.5707963267949
```

- $\text{RAND}(), \text{RAND}(N)$

Returns a random floating-point value  $v$  between 0 and 1 inclusive (that is, in the range  $0 \leq v$

$\leq 1.0$ ). If an integer argument  $N$  is specified, it is used as the seed value, which produces a repeatable sequence.

```
mysql> SELECT RAND();
      -> 0.9233482386203
mysql> SELECT RAND(20);
      -> 0.15888261251047
mysql> SELECT RAND(20);
      -> 0.15888261251047
mysql> SELECT RAND();
      -> 0.63553050033332
mysql> SELECT RAND();
      -> 0.70100469486881
mysql> SELECT RAND(20);
      -> 0.15888261251047
```

To obtain a random integer  $R$  in the range  $i \leq R \leq j$ , use the expression `FLOOR(i + RAND() * (j - i))`. For example, to obtain a random integer in the range of 7 to 12 inclusive, you could use the following statement:

```
SELECT FLOOR(7 + (RAND() * 5));
```

You cannot use a column with `RAND()` values in an `ORDER BY` clause, because `ORDER BY` would evaluate the column multiple times. However, you can retrieve rows in random order like this:

```
mysql> SELECT * FROM tbl_name ORDER BY RAND();
```

`ORDER BY RAND()` combined with `LIMIT` is useful for selecting a random sample from a set of rows:

```
mysql> SELECT * FROM table1, table2 WHERE a=b AND c<d -> ORDER BY RAND() LIMIT
```

Note that `RAND()` in a `WHERE` clause is re-evaluated every time the `WHERE` is executed.

`RAND()` is not meant to be a perfect random generator, but instead is a fast way to generate *ad hoc* random numbers which is portable between platforms for the same MySQL version.

- `ROUND(X), ROUND(X, D)`

Returns the argument  $X$ , rounded to the nearest integer. With two arguments, returns  $X$  rounded to  $D$  decimal places.  $D$  can be negative to cause  $D$  digits left of the decimal point of the value  $X$  to become zero.

```
mysql> SELECT ROUND(-1.23);
      -> -1
mysql> SELECT ROUND(-1.58);
      -> -2
mysql> SELECT ROUND(1.58);
      -> 2
mysql> SELECT ROUND(1.298, 1);
      -> 1.3
mysql> SELECT ROUND(1.298, 0);
      -> 1
mysql> SELECT ROUND(23.298, -1);
      -> 20
```

The return type is the same type as that of the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places).

Before MySQL 5.0.3, the behavior of `ROUND()` when the argument is halfway between two in-

tegers depends on the C library implementation. Different implementations round to the nearest even number, always up, always down, or always toward zero. If you need one kind of rounding, you should use a well-defined function such as `TRUNCATE ( )` or `FLOOR ( )` instead.

As of MySQL 5.0.3, `ROUND ( )` uses the precision math library for exact-value arguments when the first argument is a decimal value:

- For exact-value numbers, `ROUND ( )` uses the “round half up” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND ( )` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For more information, see Chapter 21, *Precision Math*.

- `SIGN(X)`

Returns the sign of the argument as -1, 0, or 1, depending on whether *X* is negative, zero, or positive.

```
mysql> SELECT SIGN(-32);
-> -1
mysql> SELECT SIGN(0);
-> 0
mysql> SELECT SIGN(234);
-> 1
```

- `SIN(X)`

Returns the sine of *X*, where *X* is given in radians.

```
mysql> SELECT SIN(PI());
-> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
-> 0
```

- `SQRT(X)`

Returns the square root of a non-negative number *X*.

```
mysql> SELECT SQRT(4);
-> 2
mysql> SELECT SQRT(20);
-> 4.4721359549996
mysql> SELECT SQRT(-16);
-> NULL
```

- `TAN(X)`

Returns the tangent of  $X$ , where  $X$  is given in radians.

```
mysql> SELECT TAN(PI());
      -> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
      -> 1.5574077246549
```

- TRUNCATE( $X, D$ )

Returns the number  $X$ , truncated to  $D$  decimal places. If  $D$  is 0, the result has no decimal point or fractional part.  $D$  can be negative to cause  $D$  digits left of the decimal point of the value  $X$  to become zero.

```
mysql> SELECT TRUNCATE(1.223,1);
      -> 1.2
mysql> SELECT TRUNCATE(1.999,1);
      -> 1.9
mysql> SELECT TRUNCATE(1.999,0);
      -> 1
mysql> SELECT TRUNCATE(-1.999,1);
      -> -1.9
mysql> SELECT TRUNCATE(122,-2);
      -> 100
mysql> SELECT TRUNCATE(10.28*100,0);
      -> 1028
```

All numbers are rounded toward zero.

## 12.5. Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See Section 11.3, “Date and Time Types”, for a description of the range of values each date and time type has and the valid formats in which values may be specified.

Here is an example that uses date functions. The following query selects all rows with a *date\_col* value from within the last 30 days:

```
mysql> SELECT something FROM tbl_name
      -> WHERE DATE_SUB(CURDATE(),INTERVAL 30 DAY) <= date_col;
```

Note that the query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as NOW() within a single query always produce the same result (for our purposes a single query also includes a call to a stored routine or trigger and all sub-routines called by that routine/trigger). This principle also applies to CURDATE(), CURTIME(), UTC\_DATE(), UTC\_TIME(), UTC\_TIMESTAMP(), and to any of their synonyms.

The CURRENT\_TIMESTAMP(), CURRENT\_TIME(), CURRENT\_DATE(), and FROM\_UNIXTIME() functions return values in the connection's current time zone, which is available as the value of the time\_zone system variable. In addition, UNIX\_TIMESTAMP() assumes that its argument is a datetime value in the current time zone. See Section 5.11.8, “MySQL Server Time Zone Support”.

Some date functions can be used with “zero” dates or incomplete dates such as '2001-11-00',

whereas others cannot. Functions that extract parts of dates typically work with incomplete dates. For example:

```
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
       -> 0, 0
```

Other functions expect complete dates and return NULL for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```
mysql> SELECT DATE_ADD('2006-05-00',INTERVAL 1 DAY);
       -> NULL
mysql> SELECT DAYNAME('2006-05-00');
       -> NULL
```

- `ADDDATE(date,INTERVAL expr type),ADDDATE(expr,days)`

When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for `DATE_ADD()`. The related function `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL` argument, see the discussion for `DATE_ADD()`.

```
mysql> SELECT DATE_ADD('1998-01-02', INTERVAL 31 DAY);
       -> '1998-02-02'
mysql> SELECT ADDDATE('1998-01-02', INTERVAL 31 DAY);
       -> '1998-02-02'
```

When invoked with the `days` form of the second argument, MySQL treats it as an integer number of days to be added to `expr`.

```
mysql> SELECT ADDDATE('1998-01-02', 31);
       -> '1998-02-02'
```

- `ADDTIME(expr,expr2)`

`ADDTIME()` adds `expr2` to `expr` and returns the result. `expr` is a time or datetime expression, and `expr2` is a time expression.

```
mysql> SELECT ADDTIME('1997-12-31 23:59:59.999999',
       ->                '1 1:1:1.000002');
       -> '1998-01-02 01:01:01.000001'
mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
       -> '03:00:01.999997'
```

- `CONVERT_TZ(dt,from_tz,to_tz)`

`CONVERT_TZ()` converts a datetime value `dt` from the time zone given by `from_tz` to the time zone given by `to_tz` and returns the resulting value. Time zones are specified as described in Section 5.11.8, “MySQL Server Time Zone Support”. This function returns NULL if the arguments are invalid.

If the value falls out of the supported range of the `TIMESTAMP` type when converted from `from_tz` to UTC, no conversion occurs. The `TIMESTAMP` range is described in Section 11.1.2, “Overview of Date and Time Types”.

```
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','GMT','MET');
       -> '2004-01-01 13:00:00'
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','+00:00','+10:00');
       -> '2004-01-01 22:00:00'
```

**Note:** To use named time zones such as 'MET' or 'Europe/Moscow', the time zone tables must be properly set up. See Section 5.11.8, “MySQL Server Time Zone Support”, for instruc-

tions.

If you intend to use `CONVERT_TZ()` while other tables are locked with `LOCK TABLES`, you must also lock the `mysql.time_zone_name` table.

- `CURDATE()`

Returns the current date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT CURDATE();
      -> '1997-12-15'
mysql> SELECT CURDATE() + 0;
      -> 19971215
```

- `CURRENT_DATE, CURRENT_DATE()`

`CURRENT_DATE` and `CURRENT_DATE()` are synonyms for `CURDATE()`.

- `CURTIME()`

Returns the current time as a value in 'HH:MM:SS' or HHMMSS format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT CURTIME();
      -> '23:50:26'
mysql> SELECT CURTIME() + 0;
      -> 235026
```

- `CURRENT_TIME, CURRENT_TIME()`

`CURRENT_TIME` and `CURRENT_TIME()` are synonyms for `CURTIME()`.

- `CURRENT_TIMESTAMP, CURRENT_TIMESTAMP()`

`CURRENT_TIMESTAMP` and `CURRENT_TIMESTAMP()` are synonyms for `NOW()`.

- `DATE(expr)`

Extracts the date part of the date or datetime expression *expr*.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
      -> '2003-12-31'
```

- `DATEDIFF(expr, expr2)`

`DATEDIFF()` returns the number of days between the start date *expr* and the end date *expr2*. *expr* and *expr2* are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('1997-12-31 23:59:59', '1997-12-30');
      -> 1
mysql> SELECT DATEDIFF('1997-11-30 23:59:59', '1997-12-31');
      -> -31
```

- `DATE_ADD(date, INTERVAL expr type), DATE_SUB(date, INTERVAL expr type)`

These functions perform date arithmetic. *date* is a DATETIME or DATE value specifying the starting date. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is a string; it may start with a '-' for negative intervals. *type* is a keyword indicating how the expression should be interpreted.

The `INTERVAL` keyword and the `type` specifier are not case sensitive.

The following table shows the expected form of the `expr` argument for each `type` value.

<i>type</i> Value	Expected <i>expr</i> Format
MICROSECOND	MICROSECONDS
SECOND	SECONDS
MINUTE	MINUTES
HOURL	HOURS
DAY	DAYS
WEEK	WEEKS
MONTH	MONTHS
QUARTER	QUARTERS
YEAR	YEARS
SECOND_MICROSECOND	'SECONDS.MICROSECONDS'
MINUTE_MICROSECOND	'MINUTES.MICROSECONDS'
MINUTE_SECOND	'MINUTES:SECONDS'
HOURL_MICROSECOND	'HOURS.MICROSECONDS'
HOURL_SECOND	'HOURS:MINUTES:SECONDS'
HOURL_MINUTE	'HOURS:MINUTES'
DAY_MICROSECOND	'DAYS.MICROSECONDS'
DAY_SECOND	'DAYS HOURS:MINUTES:SECONDS'
DAY_MINUTE	'DAYS HOURS:MINUTES'
DAY_HOURL	'DAYS HOURS'
YEAR_MONTH	'YEARS-MONTHS'

The values `QUARTER` and `WEEK` are available beginning with MySQL 5.0.0.

MySQL allows any punctuation delimiter in the `expr` format. Those shown in the table are the suggested delimiters. If the `date` argument is a `DATE` value and your calculations involve only `YEAR`, `MONTH`, and `DAY` parts (that is, no time parts), the result is a `DATE` value. Otherwise, the result is a `DATETIME` value.

Date arithmetic also can be performed using `INTERVAL` together with the `+` or `-` operator:

```
date + INTERVAL expr type
date - INTERVAL expr type
```

`INTERVAL expr type` is allowed on either side of the `+` operator if the expression on the other side is a date or datetime value. For the `-` operator, `INTERVAL expr type` is allowed only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```
mysql> SELECT '1997-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '1998-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '1997-12-31';
-> '1998-01-01'
mysql> SELECT '1998-01-01' - INTERVAL 1 SECOND;
-> '1997-12-31 23:59:59'
mysql> SELECT DATE_ADD('1997-12-31 23:59:59',
-> INTERVAL 1 SECOND);
-> '1998-01-01 00:00:00'
mysql> SELECT DATE_ADD('1997-12-31 23:59:59',
```

```

->                                INTERVAL 1 DAY);
mysql> SELECT DATE_ADD('1997-12-31 23:59:59',
->                                INTERVAL '1:1' MINUTE_SECOND);
-> '1998-01-01 00:01:00'
mysql> SELECT DATE_SUB('1998-01-01 00:00:00',
->                                INTERVAL '1 1:1:1' DAY_SECOND);
-> '1997-12-30 22:58:59'
mysql> SELECT DATE_ADD('1998-01-01 00:00:00',
->                                INTERVAL '-1 10' DAY_HOUR);
-> '1997-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
->                                INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'

```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the *type* keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a *type* of `DAY_SECOND`, the value of *expr* is expected to have days, hours, minutes, and seconds parts. If you specify a value like `'1:10'`, MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, `'1:10' DAY_SECOND` is interpreted in such a way that it is equivalent to `'1:10' MINUTE_SECOND`. This is analogous to the way that MySQL interprets `TIME` values as representing elapsed time rather than as a time of day.

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```

mysql> SELECT DATE_ADD('1999-01-01', INTERVAL 1 DAY);
-> '1999-01-02'
mysql> SELECT DATE_ADD('1999-01-01', INTERVAL 1 HOUR);
-> '1999-01-01 01:00:00'

```

If you add `MONTH`, `YEAR_MONTH`, or `YEAR` and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```

mysql> SELECT DATE_ADD('1998-01-30', INTERVAL 1 MONTH);
-> '1998-02-28'

```

Date arithmetic operations require complete dates and do not work with incomplete dates such as `'2006-07-00'` or badly malformed dates:

```

mysql> SELECT DATE_ADD('2006-07-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL

```

- `DATE_FORMAT(date, format)`

Formats the *date* value according to the *format* string.

The following specifiers may be used in the *format* string. The `'%'` character is required before format specifier characters.

Specifier	Description
<code>%a</code>	Abbreviated weekday name (Sun..Sat)
<code>%b</code>	Abbreviated month name (Jan..Dec)
<code>%c</code>	Month, numeric (0..12)

%D	Day of the month with English suffix (0th, 1st, 2nd, 3rd, ...)
%d	Day of the month, numeric (00..31)
%e	Day of the month, numeric (0..31)
%f	Microseconds (000000..999999)
%H	Hour (00..23)
%h	Hour (01..12)
%I	Hour (01..12)
%i	Minutes, numeric (00..59)
%j	Day of year (001..366)
%k	Hour (0..23)
%l	Hour (1..12)
%M	Month name (January..December)
%m	Month, numeric (00..12)
%P	AM or PM
%r	Time, 12-hour (hh:mm:ss followed by AM or PM)
%S	Seconds (00..59)
%s	Seconds (00..59)
%T	Time, 24-hour (hh:mm:ss)
%U	Week (00..53), where Sunday is the first day of the week
%u	Week (00..53), where Monday is the first day of the week
%V	Week (01..53), where Sunday is the first day of the week; used with %X
%v	Week (01..53), where Monday is the first day of the week; used with %x
%W	Weekday name (Sunday..Saturday)
%w	Day of the week (0=Sunday..6=Saturday)
%X	Year for the week where Sunday is the first day of the week, numeric, four digits; used with %V
%x	Year for the week, where Monday is the first day of the week, numeric, four digits; used with %v
%Y	Year, numeric, four digits
%y	Year, numeric (two digits)
%%	A literal '%' character
%x	x, for any 'x' not listed above

Ranges for the month and day specifiers begin with zero due to the fact that MySQL allows the storing of incomplete dates such as '2004-00-00'.

```
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00', '%W %M %Y');
-> 'Saturday October 1997'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
                        '%D %y %a %d %m %b %j');
-> '4th 97 Sat 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
                        '%H %k %I %r %T %S %w');
-> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

- DAY(*date*)

DAY() is a synonym for DAYOFMONTH().

- DAYNAME(*date*)

Returns the name of the weekday for *date*.

```
mysql> SELECT DAYNAME('1998-02-05');
      -> 'Thursday'
```

- DAYOFMONTH(*date*)

Returns the day of the month for *date*, in the range 0 to 31.

```
mysql> SELECT DAYOFMONTH('1998-02-03');
      -> 3
```

- DAYOFWEEK(*date*)

Returns the weekday index for *date* (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

```
mysql> SELECT DAYOFWEEK('1998-02-03');
      -> 3
```

- DAYOFYEAR(*date*)

Returns the day of the year for *date*, in the range 1 to 366.

```
mysql> SELECT DAYOFYEAR('1998-02-03');
      -> 34
```

- EXTRACT(*type* FROM *date*)

The EXTRACT() function uses the same kinds of interval type specifiers as DATE\_ADD() or DATE\_SUB(), but extracts parts from the date rather than performing date arithmetic.

```
mysql> SELECT EXTRACT(YEAR FROM '1999-07-02');
      -> 1999
mysql> SELECT EXTRACT(YEAR_MONTH FROM '1999-07-02 01:02:03');
      -> 199907
mysql> SELECT EXTRACT(DAY_MINUTE FROM '1999-07-02 01:02:03');
      -> 20102
mysql> SELECT EXTRACT(MICROSECOND
      -> FROM '2003-01-02 10:30:00.00123');
      -> 123
```

- FROM\_DAYS(*N*)

Given a day number *N*, returns a DATE value.

```
mysql> SELECT FROM_DAYS(729669);
      -> '1997-10-07'
```

Use FROM\_DAYS() with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See Section 12.6, “What Calendar Is Used By MySQL?”.

- FROM\_UNIXTIME(*unix\_timestamp*),  
FROM\_UNIXTIME(*unix\_timestamp*,*format*)

Returns a representation of the *unix\_timestamp* argument as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context. *unix\_timestamp* is an internal timestamp value such as is produced by the UNIX\_TIMESTAMP() function.

If *format* is given, the result is formatted according to the *format* string, which is used the same way as listed in the entry for the DATE\_FORMAT() function.

```
mysql> SELECT FROM_UNIXTIME(875996580);
      -> '1997-10-04 22:23:00'
mysql> SELECT FROM_UNIXTIME(875996580) + 0;
      -> 19971004222300
mysql> SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(),
      ->                                '%Y %D %M %h:%i:%s %x');
      -> '2003 6th August 06:22:58 2003'
```

Note: If you use UNIX\_TIMESTAMP() and FROM\_UNIXTIME() to convert between TIMESTAMP values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the UNIX\_TIMESTAMP() function.

- GET\_FORMAT(DATE | TIME | DATETIME,  
'EUR' | 'USA' | 'JIS' | 'ISO' | 'INTERNAL')

Returns a format string. This function is useful in combination with the DATE\_FORMAT() and the STR\_TO\_DATE() functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the DATE\_FORMAT() function description). ISO format refers to ISO 9075, not ISO 8601.

Function Call	Result
GET_FORMAT(DATE, 'USA')	'%m.%d.%Y'
GET_FORMAT(DATE, 'JIS')	'%Y-%m-%d'
GET_FORMAT(DATE, 'ISO')	'%Y-%m-%d'
GET_FORMAT(DATE, 'EUR')	'%d.%m.%Y'
GET_FORMAT(DATE, 'INTERNAL')	'%Y%m%d'
GET_FORMAT(DATETIME, 'USA')	'%Y-%m-%d-%H.%i.%s'
GET_FORMAT(DATETIME, 'JIS')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME, 'ISO')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME, 'EUR')	'%Y-%m-%d-%H.%i.%s'
GET_FORMAT(DATETIME, 'INTERNAL')	'%Y%m%d%H%i%s'
GET_FORMAT(TIME, 'USA')	'%h:%i:%s %p'
GET_FORMAT(TIME, 'JIS')	'%H:%i:%s'
GET_FORMAT(TIME, 'ISO')	'%H:%i:%s'
GET_FORMAT(TIME, 'EUR')	'%H.%i.%S'
GET_FORMAT(TIME, 'INTERNAL')	'%H%i%s'

TIMESTAMP can also be used as the first argument to GET\_FORMAT(), in which case the function returns the same values as for DATETIME.

```
mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
      -> '03.10.2003'
```

```
mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
       -> '2003-10-31'
```

- HOUR(*time*)

Returns the hour for *time*. The range of the return value is 0 to 23 for time-of-day values. However, the range of TIME values actually is much larger, so HOUR can return values greater than 23.

```
mysql> SELECT HOUR('10:05:03');
       -> 10
mysql> SELECT HOUR('272:59:59');
       -> 272
```

- LAST\_DAY(*date*)

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns NULL if the argument is invalid.

```
mysql> SELECT LAST_DAY('2003-02-05');
       -> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
       -> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
       -> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
       -> NULL
```

- LOCALTIME, LOCALTIME()

LOCALTIME and LOCALTIME() are synonyms for NOW().

- LOCALTIMESTAMP, LOCALTIMESTAMP()

LOCALTIMESTAMP and LOCALTIMESTAMP() are synonyms for NOW().

- MAKEDATE(*year*,*dayofyear*)

Returns a date, given year and day-of-year values. *dayofyear* must be greater than 0 or the result is NULL.

```
mysql> SELECT MAKEDATE(2001,31), MAKEDATE(2001,32);
       -> '2001-01-31', '2001-02-01'
mysql> SELECT MAKEDATE(2001,365), MAKEDATE(2004,365);
       -> '2001-12-31', '2004-12-30'
mysql> SELECT MAKEDATE(2001,0);
       -> NULL
```

- MAKETIME(*hour*,*minute*,*second*)

Returns a time value calculated from the *hour*, *minute*, and *second* arguments.

```
mysql> SELECT MAKETIME(12,15,30);
       -> '12:15:30'
```

- MICROSECOND(*expr*)

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

```
mysql> SELECT MICROSECOND('12:00:00.123456');
       -> 123456
```

```
mysql> SELECT MICROSECOND('1997-12-31 23:59:59.000010');
-> 10
```

- `MINUTE(time)`

Returns the minute for *time*, in the range 0 to 59.

```
mysql> SELECT MINUTE('98-02-03 10:05:03');
-> 5
```

- `MONTH(date)`

Returns the month for *date*, in the range 0 to 12.

```
mysql> SELECT MONTH('1998-02-03');
-> 2
```

- `MONTHNAME(date)`

Returns the full name of the month for *date*.

```
mysql> SELECT MONTHNAME('1998-02-05');
-> 'February'
```

- `NOW()`

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDH-HMMSS format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT NOW();
-> '1997-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 19971215235026
```

`NOW()` returns a constant time that indicates the time at which the statement began to execute. (Within a stored routine or trigger, `NOW()` returns the time at which the routine or triggering statement began to execute.) This differs from the behavior for `SYSDATE()`, which returns the exact time at which it executes as of MySQL 5.0.13.

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW()          | SLEEP(2) | NOW()          |
+-----+-----+-----+
| 2006-04-12 13:47:36 |          0 | 2006-04-12 13:47:36 |
+-----+-----+-----+
```

```
mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE()      | SLEEP(2) | SYSDATE()      |
+-----+-----+-----+
| 2006-04-12 13:47:44 |          0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

See the description for `SYSDATE()` for additional information about the differences between the two functions.

- `PERIOD_ADD(P,N)`

Adds *N* months to period *P* (in the format YYMM or YYYYMM). Returns a value in the format YYYYMM. Note that the period argument *P* is *not* a date value.

```
mysql> SELECT PERIOD_ADD(9801,2);
      -> 199803
```

- PERIOD\_DIFF(*P1*,*P2*)

Returns the number of months between periods *P1* and *P2*. *P1* and *P2* should be in the format YYMM or YYYYMM. Note that the period arguments *P1* and *P2* are *not* date values.

```
mysql> SELECT PERIOD_DIFF(9802,199703);
      -> 11
```

- QUARTER(*date*)

Returns the quarter of the year for *date*, in the range 1 to 4.

```
mysql> SELECT QUARTER('98-04-01');
      -> 2
```

- SECOND(*time*)

Returns the second for *time*, in the range 0 to 59.

```
mysql> SELECT SECOND('10:05:03');
      -> 3
```

- SEC\_TO\_TIME(*seconds*)

Returns the *seconds* argument, converted to hours, minutes, and seconds, as a value in 'HH:MM:SS' or HHMMSS format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT SEC_TO_TIME(2378);
      -> '00:39:38'
mysql> SELECT SEC_TO_TIME(2378) + 0;
      -> 3938
```

- STR\_TO\_DATE(*str*,*format*)

This is the inverse of the DATE\_FORMAT() function. It takes a string *str* and a format string *format*. STR\_TO\_DATE() returns a DATETIME value if the format string contains both date and time parts, or a DATE or TIME value if the string contains only date or time parts.

The date, time, or datetime values contained in *str* should be given in the format indicated by *format*. For the specifiers that can be used in *format*, see the DATE\_FORMAT() function description. If *str* contains an illegal date, time, or datetime value, STR\_TO\_DATE() returns NULL. Starting from MySQL 5.0.3, an illegal value also produces a warning.

Range checking on the parts of date values is as described in Section 11.3.1, “The DATETIME, DATE, and TIMESTAMP Types”. This means, for example, that “zero” dates or dates with part values of 0 are allowed unless the SQL mode is set to disallow such values.

```
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
      -> '0000-00-00'
mysql> SELECT STR_TO_DATE('04/31/2004', '%m/%d/%Y');
      -> '2004-04-31'
```

- SUBDATE(*date*, INTERVAL *expr type*), SUBDATE(*expr*,*days*)

When invoked with the INTERVAL form of the second argument, SUBDATE() is a synonym

for `DATE_SUB()`. For information on the `INTERVAL` argument, see the discussion for `DATE_ADD()`.

```
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
      -> '1997-12-02'
mysql> SELECT SUBDATE('1998-01-02', INTERVAL 31 DAY);
      -> '1997-12-02'
```

The second form allows the use of an integer value for *days*. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression *expr*.

```
mysql> SELECT SUBDATE('1998-01-02 12:00:00', 31);
      -> '1997-12-02 12:00:00'
```

**Note:** You cannot use format "%X%V" to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, then you should also specify the weekday:

```
mysql> SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
      -> '2004-10-18'
```

- `SUBTIME(expr, expr2)`

`SUBTIME()` subtracts *expr2* from *expr* and returns the result. *expr* is a time or datetime expression, and *expr2* is a time expression.

```
mysql> SELECT SUBTIME('1997-12-31 23:59:59.999999', '1 1:1:1.000002');
      -> '1997-12-30 22:58:58.999997'
mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
      -> '-00:59:59.999999'
```

- `SYSDATE()`

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDH-HMMSS format, depending on whether the function is used in a string or numeric context.

As of MySQL 5.0.13, `SYSDATE()` returns the time at which it executes. This differs from the behavior for `NOW()`, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored routine or trigger, `NOW()` returns the time at which the routine or triggering statement began to execute.)

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW()          | SLEEP(2) | NOW()          |
+-----+-----+-----+
| 2006-04-12 13:47:36 |          0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE()      | SLEEP(2) | SYSDATE()      |
+-----+-----+-----+
| 2006-04-12 13:47:44 |          0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

Because `SYSDATE()` can return different values even within the same statement, and is not affected by `SET TIMESTAMP`, it is non-deterministic and therefore unsafe for replication. If that

is a problem, you can start the server with the `--sysdate-is-now` option to cause `SYS-DATE()` to be an alias for `NOW()`.

- `TIME(expr)`

Extracts the time part of the time or datetime expression `expr` and returns it as a string.

```
mysql> SELECT TIME('2003-12-31 01:02:03');
      -> '01:02:03'
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
      -> '01:02:03.000123'
```

- `TIMEDIFF(expr,expr2)`

`TIMEDIFF()` returns the time between the start time `expr` and the end time `expr2`. `expr` and `expr2` are time or date-and-time expressions, but both must be of the same type.

```
mysql> SELECT TIMEDIFF('2000:01:01 00:00:00',
      -> '2000:01:01 00:00:00.000001');
      -> '-00:00:00.000001'
mysql> SELECT TIMEDIFF('1997-12-31 23:59:59.000001',
      -> '1997-12-30 01:01:01.000002');
      -> '46:58:57.999999'
```

- `TIMESTAMP(expr)`, `TIMESTAMP(expr,expr2)`

With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr` and returns the result as a datetime value.

```
mysql> SELECT TIMESTAMP('2003-12-31');
      -> '2003-12-31 00:00:00'
mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
      -> '2004-01-01 00:00:00'
```

- `TIMESTAMPADD(interval,int_expr,datetime_expr)`

Adds the integer expression `int_expr` to the date or datetime expression `datetime_expr`. The unit for `int_expr` is given by the `interval` argument, which should be one of the following values: `FRAC_SECOND`, `SECOND`, `MINUTE`, `HOURL`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

The `interval` value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

```
mysql> SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
      -> '2003-01-02 00:01:00'
mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
      -> '2003-01-09'
```

`TIMESTAMPADD()` is available as of MySQL 5.0.0.

- `TIMESTAMPDIFF(interval,datetime_expr1,datetime_expr2)`

Returns the integer difference between the date or datetime expressions `datetime_expr1` and `datetime_expr2`. The unit for the result is given by the `interval` argument. The legal values for `interval` are the same as those listed in the description of the `TIMESTAMPADD()` function.

```
mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
      -> 3
mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
```

-> -1

TIMESTAMPDIFF() is available as of MySQL 5.0.0.

- TIME\_FORMAT(*time*, *format*)

This is used like the DATE\_FORMAT() function, but the *format* string may contain format specifiers only for hours, minutes, and seconds. Other specifiers produce a NULL value or 0.

If the *time* value contains an hour part that is greater than 23, the %H and %k hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

- TIME\_TO\_SEC(*time*)

Returns the *time* argument, converted to seconds.

```
mysql> SELECT TIME_TO_SEC('22:23:00');
-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

- TO\_DAYS(*date*)

Given a date *date*, returns a day number (the number of days since year 0).

```
mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('1997-10-07');
-> 729669
```

TO\_DAYS() is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See Section 12.6, “What Calendar Is Used By MySQL?”, for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in Section 11.3, “Date and Time Types”. For example, '1997-10-07' and '97-10-07' are seen as identical dates:

```
mysql> SELECT TO_DAYS('1997-10-07'), TO_DAYS('97-10-07');
-> 729669, 729669
```

- UNIX\_TIMESTAMP(), UNIX\_TIMESTAMP(*date*)

If called with no argument, returns a Unix timestamp (seconds since '1970-01-01 00:00:00' UTC) as an unsigned integer. If UNIX\_TIMESTAMP() is called with a *date* argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. *date* may be a DATE string, a DATETIME string, a TIMESTAMP, or a number in the format YYMMDD or YYYYMMDD. The server interprets *date* as a value in the current time zone and converts it to an internal value in UTC. Clients can set their time zone as described in Section 5.11.8, “MySQL Server Time Zone Support”.

```
mysql> SELECT UNIX_TIMESTAMP();
-> 882226357
mysql> SELECT UNIX_TIMESTAMP('1997-10-04 22:23:00');
-> 875996580
```

When `UNIX_TIMESTAMP` is used on a `TIMESTAMP` column, the function returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion. If you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns 0.

Note: If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes, it is possible for two `UNIX_TIMESTAMP()` to map two `TIMESTAMP` values to the same Unix timestamp value. `FROM_UNIXTIME()` will map that value back to only one of the original `TIMESTAMP` values. Here is an example, using `TIMESTAMP` values in the CET time zone:

```
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT FROM_UNIXTIME(1111885200);
+-----+
| FROM_UNIXTIME(1111885200) |
+-----+
| 2005-03-27 03:00:00 |
+-----+
```

If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast the result to signed integers. See Section 12.8, “Cast Functions and Operators”.

- `UTC_DATE, UTC_DATE()`

Returns the current UTC date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
-> '2003-08-14', 20030814
```

- `UTC_TIME, UTC_TIME()`

Returns the current UTC time as a value in 'HH:MM:SS' or HHMMSS format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753
```

- `UTC_TIMESTAMP, UTC_TIMESTAMP()`

Returns the current UTC date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS format, depending on whether the function is used in a string or numeric context.

```
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
-> '2003-08-14 18:08:04', 20030814180804
```

- `WEEK(date[, mode])`

This function returns the week number for *date*. The two-argument form of `WEEK()` allows you to specify whether the week starts on Sunday or Monday and whether the return value

should be in the range from 0 to 53 or from 1 to 53. If the *mode* argument is omitted, the value of the `default_week_format` system variable is used. See Section 5.2.2, “Server System Variables”.

The following table describes how the *mode* argument works.

Mode	First day of week	Range	Week 1 is the first week ...
0	Sunday	0-53	with a Sunday in this year
1	Monday	0-53	with more than 3 days this year
2	Sunday	1-53	with a Sunday in this year
3	Monday	1-53	with more than 3 days this year
4	Sunday	0-53	with more than 3 days this year
5	Monday	0-53	with a Monday in this year
6	Sunday	1-53	with more than 3 days this year
7	Monday	1-53	with a Monday in this year

```
mysql> SELECT WEEK('1998-02-20');
-> 7
mysql> SELECT WEEK('1998-02-20',0);
-> 7
mysql> SELECT WEEK('1998-02-20',1);
-> 8
mysql> SELECT WEEK('1998-12-31',1);
-> 53
```

Note that if a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional *mode* argument:

```
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that MySQL should return 52 for the `WEEK()` function, because the given date actually occurs in the 52nd week of 1999. We decided to return 0 instead because we want the function to return “the week number in the given year.” This makes use of the `WEEK()` function reliable when combined with other functions that extract a date part from a date.

If you would prefer the result to be evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional *mode* argument.

```
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the `YEARWEEK()` function:

```
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- `WEEKDAY(date)`

Returns the weekday index for *date* (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

```
mysql> SELECT WEEKDAY('1998-02-03 22:23:00');
-> 1
mysql> SELECT WEEKDAY('1997-11-05');
```

-> 2

- WEEKOFYEAR(*date*)

Returns the calendar week of the date as a number in the range from 1 to 53. WEEKOFYEAR() is a compatibility function that is equivalent to WEEK(*date*, 3).

```
mysql> SELECT WEEKOFYEAR('1998-02-20');
      -> 8
```

- YEAR(*date*)

Returns the year for *date*, in the range 1000 to 9999, or 0 for the “zero” date.

```
mysql> SELECT YEAR('98-02-03');
      -> 1998
```

- YEARWEEK(*date*), YEARWEEK(*date*, *start*)

Returns year and week for a date. The *start* argument works exactly like the *start* argument to WEEK(). The year in the result may be different from the year in the date argument for the first and the last week of the year.

```
mysql> SELECT YEARWEEK('1987-01-01');
      -> 198653
```

Note that the week number is different from what the WEEK() function would return (0) for optional arguments 0 or 1, as WEEK() then returns the week in the context of the given year.

## 12.6. What Calendar Is Used By MySQL?

MySQL uses what is known as a *proleptic Gregorian calendar*.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred:

Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
1	2	3	4	15	16	17
18	19	20	21	22	23	24
25	26	27	28	29	30	31

There are no dates between October 4 and October 15. This discontinuity is called the *cutover*. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are non-existent.

A calendar applied to dates when it wasn't actually in use is called *proleptic*. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL DATE or DATETIME values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

## 12.7. Full-Text Search Functions

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
search_modifier: { IN BOOLEAN MODE | WITH QUERY EXPANSION }
```

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type FULLTEXT.
- Full-text indexes can be used only with MyISAM tables, and can be created only for CHAR, VARCHAR, or TEXT columns.
- A FULLTEXT index definition can be given in the CREATE TABLE statement when a table is created, or added later using ALTER TABLE or CREATE INDEX.
- For large datasets, it is much faster to load your data into a table that has no FULLTEXT index and then create the index after that, than to load data into a table that has an existing FULLTEXT index.

Full-text searching is performed using MATCH() ... AGAINST syntax. MATCH() takes a comma-separated list that names the columns to be searched. AGAINST takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a literal string, not a variable or a column name. There are three types of full-text searches:

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Common words such as “some” or “then” are stopwords and do not match if present in the search string. The IN BOOLEAN MODE modifier specifies a boolean search. For more information, see Section 12.7.1, “Boolean Full-Text Searches”.
- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators. The stopword list applies. In addition, words that are present in more than 50% of the rows are considered common and do not match. Full-text searches are natural language searches if no modifier is given.
- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The WITH QUERY EXPANSION modifier specifies a query expansion search. For more information, see Section 12.7.2, “Full-Text Searches with Query Expansion”.

Constraints on full-text searching are listed in Section 12.7.4, “Full-Text Restrictions”.

```
mysql> CREATE TABLE articles (
->   id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
->   title VARCHAR(200),
->   body TEXT,
->   FULLTEXT (title,body)
-> );
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO articles (title,body) VALUES
-> ('MySQL Tutorial','DBMS stands for DataBase ...'),
-> ('How To Use MySQL Well','After you went through a ...'),
-> ('Optimizing MySQL','In this tutorial we will show ...'),
-> ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
-> ('MySQL vs. YourSQL','In the following database comparison ...'),
-> ('MySQL Security','When configured properly, MySQL ...');
```

Query OK, 6 rows affected (0.00 sec)  
 Records: 6 Duplicates: 0 Warnings: 0

```
mysql> SELECT * FROM articles
      -> WHERE MATCH (title,body) AGAINST ('database');
```

id	title	body
5	MySQL vs. YourSQL	In the following database comparison ...
1	MySQL Tutorial	DBMS stands for DataBase ...

2 rows in set (0.00 sec)

The `MATCH()` function performs a natural language search for a string against a *text collection*. A collection is a set of one or more columns included in a `FULLTEXT` index. The search string is given as the argument to `AGAINST()`. For each row in the table, `MATCH()` returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the `MATCH()` list.

By default, the search is performed in case-insensitive fashion. However, you can perform a case-sensitive full-text search by using a binary collation for the indexed columns. For example, a column that uses the `latin1` character set of can be assigned a collation of `latin1_bin` to make it case sensitive for full-text searches.

When `MATCH()` is used in a `WHERE` clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first. Relevance values are non-negative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row, the number of unique words in that row, the total number of words in the collection, and the number of documents (rows) that contain a particular word.

For natural-language full-text searches, it is a requirement that the columns named in the `MATCH()` function be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. If you wanted to search the `title` or `body` separately, you would need to create separate `FULLTEXT` indexes for each column.

It is also possible to perform a boolean search or a search with query expansion. These search types are described in Section 12.7.1, “Boolean Full-Text Searches”, and Section 12.7.2, “Full-Text Searches with Query Expansion”.

The preceding example is a basic illustration that shows how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```
mysql> SELECT id, MATCH (title,body) AGAINST ('Tutorial')
      -> FROM articles;
```

id	MATCH (title,body) AGAINST ('Tutorial')
1	0.65545833110809
2	0
3	0.66266459226608
4	0
5	0
6	0

6 rows in set (0.00 sec)

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, you should specify `MATCH()` twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text

search code only once.

```
mysql> SELECT id, body, MATCH (title,body) AGAINST
-> ('Security implications of running MySQL as root') AS score
-> FROM articles WHERE MATCH (title,body) AGAINST
-> ('Security implications of running MySQL as root');
+-----+-----+-----+
| id | body | score |
+-----+-----+-----+
| 4 | 1. Never run mysqld as root. 2. ... | 1.5219271183014 |
| 6 | When configured properly, MySQL ... | 1.3114095926285 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

The MySQL FULLTEXT implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes (''), but not more than one in a row. This means that aaa'bbb is regarded as one word, but aaa' 'bbb is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the FULLTEXT parser; 'aaa'bbb' would be parsed as aaa'bbb.

The FULLTEXT parser determines where words start and end by looking for certain delimiter characters; for example, ' ' (space), ',' (comma), and '.' (period). If words are not separated by delimiters (as in, for example, Chinese), the FULLTEXT parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a FULLTEXT index, you must preprocess them so that they are separated by some arbitrary delimiter such as '\$'.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is four characters.
- Words in the stopword list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopword list, but it can be overwritten by a user-defined list.

The default stopword list is given in Section 12.7.3, “Full-Text Stopwords”. The default minimum word length and stopword list can be changed as described in Section 12.7.5, “Fine-Tuning MySQL Full-Text Search”.

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Consequently, a word that is present in many documents has a lower weight (and may even have a zero weight), because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row.

Such a technique works best with large collections (in fact, it was carefully tuned this way). For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results. For example, although the word “MySQL” is present in every row of the articles table shown earlier, a search for the word produces no results:

```
mysql> SELECT * FROM articles
-> WHERE MATCH (title,body) AGAINST ('MySQL');
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows. As such, it is effectively treated as a stopword. For large datasets, this is the most desirable behavior: A natural language query should not return every second row from a 1GB table. For small datasets, it may be less desirable.

A word that matches half of the rows in a table is less likely to locate relevant documents. In fact, it most likely finds plenty of irrelevant documents. We all know this happens far too often when we are trying to find something on the Internet with a search engine. It is with this reasoning that rows

containing the word are assigned a low semantic value for *the particular dataset in which they occur*. A given word may exceed the 50% threshold in one dataset but not another.

The 50% threshold has a significant implication when you first try full-text searching to see how it works: If you create a table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results. Be sure to insert at least three rows, and preferably many more. Users who need to bypass the 50% limitation can use the boolean search mode; see Section 12.7.1, “Boolean Full-Text Searches”.

## 12.7.1. Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the `IN BOOLEAN MODE` modifier:

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
      -> AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
```

id	title	body

The `+` and `-` operators indicate that a word is required to be present or absent, respectively, for a match to occur. Thus, this query retrieves all the rows that contain the word “MySQL” but that do *not* contain the word “YourSQL”.

Boolean full-text searches have these characteristics:

- They do not use the 50% threshold.
- They do not automatically sort rows in order of decreasing relevance. You can see this from the preceding query result: The row with the highest relevance is the one that contains “MySQL” twice, but it is listed last, not first.
- They can work even without a `FULLTEXT` index, although a search executed in this fashion would be quite slow.
- The minimum and maximum word length full-text parameters apply.
- The stopword list applies.

The boolean full-text search capability supports the following operators:

- `+`

A leading plus sign indicates that this word *must* be present in each row that is returned.

- `-`

A leading minus sign indicates that this word must *not* be present in any of the rows that are returned.

Note: The `-` operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by `-` returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

By default (when neither + nor - is specified) the word is optional, but the rows that contain it are rated higher. This mimics the behavior of `MATCH() . . . AGAINST()` without the `IN BOOLEAN MODE` modifier.

- > <

These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The > operator increases the contribution and the < operator decreases it. See the example following this list.

- ( )

Parentheses group words into subexpressions. Parenthesized groups can be nested.

- ~

A leading tilde acts as a negation operator, causing the word's contribution to the row's relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the - operator.

- \*

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it should be *appended* to the word to be affected. Words match if they begin with the word preceding the \* operator.

- "

A phrase that is enclosed within double quote ("" ) characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words, performs a search in the `FULLTEXT` index for the words. Prior to MySQL 5.0.3, the engine then performed a substring search for the phrase in the records that were found, so the match must include non-word characters in the phrase. As of MySQL 5.0.3, non-word characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase" in MySQL 5.0.3, but not before.

If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The following examples demonstrate some search strings that use boolean full-text operators:

- 'apple banana'

Find rows that contain at least one of the two words.

- '+apple +juice'

Find rows that contain both words.

- '+apple macintosh'

Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- '+apple -macintosh'

Find rows that contain the word “apple” but not “macintosh”.

- '+apple ~macintosh'

Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for '+apple -macintosh', for which the presence of “macintosh” causes the row not to be returned at all.

- '+apple +( >turnover <strudel)'

Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- 'apple\*'

Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- '"some words"'

Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the ‘”’ characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotes that enclose the search string itself.

## 12.7.2. Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding WITH QUERY EXPANSION following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```
mysql> SELECT * FROM articles
      -> WHERE MATCH (title,body) AGAINST ('database');
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
| 5 | MySQL vs. YourSQL | In the following database comparison ... |
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT * FROM articles
      -> WHERE MATCH (title,body)
      -> AGAINST ('database' WITH QUERY EXPANSION);
+-----+-----+-----+
| id | title | body |
+-----+-----+-----+
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |
| 5 | MySQL vs. YourSQL | In the following database comparison ... |
| 3 | Optimizing MySQL | In this tutorial we will show ... |
+-----+-----+-----+
3 rows in set (0.00 sec)
```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

**Note:** Because blind query expansion tends to increase noise significantly by returning non-relevant documents, it is meaningful to use only when a search phrase is rather short.

### 12.7.3. Full-Text Stopwords

The following table shows the default list of full-text stopwords.

a's	able	about	above	according

## 12.7.4. Full-Text Restrictions

- Full-text searches are supported for MyISAM tables only.
- Full-text searches can be used with most multi-byte character sets. The exception is that for Unicode, the utf8 character set can be used, but not the ucs2 character set.
- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the FULLTEXT parser *cannot determine where words begin and end in these and other such languages*. The implications of this and some workarounds for the problem are described in Section 12.7, “Full-Text Search Functions”.
- Although the use of multiple character sets within a single table is supported, all columns in a FULLTEXT index must use the same character set and collation.
- The MATCH ( ) column list must match exactly the column list in some FULLTEXT index definition for the table, unless this MATCH ( ) is IN BOOLEAN MODE. Boolean-mode searches can be done on non-indexed columns, although they are likely to be slow.
- The argument to AGAINST ( ) must be a constant string.

## 12.7.5. Fine-Tuning MySQL Full-Text Search

MySQL's full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See Section 2.9, "MySQL Installation Using a Source Distribution".

Note that full-text search is carefully tuned for the most effectiveness. Modifying the default behavior or in most cases can actually decrease effectiveness. *Do not alter the MySQL sources unless you know what you are doing.*

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the FULLTEXT indexes in your tables. Instructions for doing this are given at the end of this section.

- The minimum and maximum lengths of words to be indexed are defined by the `ft_min_word_len` and `ft_max_word_len` system variables. (See Section 5.2.2, "Server System Variables".) The default minimum value is four characters; the default maximum is version dependent. If you change either value, you must rebuild your FULLTEXT indexes. For example, if you want three-character words to be searchable, you can set the `ft_min_word_len` variable by putting the following lines in an option file:

```
[mysqld]
ft_min_word_len=3
```

Then you must restart the server and rebuild your FULLTEXT indexes. Note particularly the remarks regarding `myisamchk` in the instructions following this list.

- To override the default stopword list, set the `ft_stopword_file` system variable. (See Section 5.2.2, "Server System Variables".) The variable value should be the pathname of the file containing the stopword list, or the empty string to disable stopword filtering. After changing the value of this variable or the contents of the stopword file, restart the server and rebuild your FULLTEXT indexes.

The stopword list is free-form. That is, you may use any non-alphanumeric character such as newline, space, or comma to separate stopwords. Exceptions are the underscore character ('\_') and a single apostrophe (' ') which are treated as part of a word. The character set of the stopword list is the server's default character set; see Section 10.3.1, "Server Character Set and Collation".

- The 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `myisam/ftdefs.h`:

```
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case. **Note:** By making this change, you *severely* decrease MySQL's ability to provide adequate relevance values for the `MATCH()` function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

- To change the operators used for boolean full-text searches, set the `ft_boolean_syntax` system variable. This variable can be changed while the server is running, but you must have the SUPER privilege to do so. No rebuilding of indexes is necessary in this case. See Section 5.2.2, "Server System Variables", which describes the rules governing how to set this variable.

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopword file itself, you must rebuild your FULLTEXT indexes after making the changes and restarting the server. To rebuild the indexes in this case, it is sufficient to do a QUICK repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Note that if you use `myisamchk` to perform an operation that modifies table indexes (such as `repair` or `analyze`), the FULLTEXT indexes are rebuilt using the *default* full-text parameter values for minimum word length, maximum word length, and stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in MyISAM index files. To avoid the problem if you have modified the minimum or maximum word length or stopword file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE` statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

## 12.8. Cast Functions and Operators

- BINARY

The BINARY operator casts the string following it to a binary string. This is an easy way to force a column comparison to be done byte by byte rather than character by character. This causes the comparison to be case sensitive even if the column isn't defined as BINARY or BLOB. BINARY also causes trailing spaces to be significant.

```
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
-> 0
```

In a comparison, BINARY affects the entire operation; it can be given before either operand with the same result.

BINARY *str* is shorthand for `CAST(str AS BINARY)`.

Note that in some contexts, if you cast an indexed column to BINARY, MySQL is not able to use the index efficiently.

- `CAST(expr AS type)`, `CONVERT(expr,type)`, `CONVERT(expr USING transcoding_name)`

The `CAST()` and `CONVERT()` functions take a value of one type and produce a value of another type.

The *type* can be one of the following values:

- `BINARY[ (N) ]`
- `CHAR[ (N) ]`
- `DATE`
- `DATETIME`
- `DECIMAL`
- `SIGNED [ INTEGER ]`
- `TIME`
- `UNSIGNED [ INTEGER ]`

`BINARY` produces a string with the `BINARY` data type. See Section 11.4.2, “The `BINARY` and `VARBINARY` Types” for a description of how this affects comparisons. If the optional length *N* is given, `BINARY(N)` causes the cast to use no more than *N* bytes of the argument. As of MySQL 5.0.17, values shorter than *N* bytes are padded with `0x00` bytes to a length of *N*.

`CHAR(N)` causes the cast to use no more than *N* characters of the argument.

The `DECIMAL` type is available as of MySQL 5.0.8.

`CAST()` and `CONVERT(... USING ...)` are standard SQL syntax. The non-`USING` form of `CONVERT()` is ODBC syntax.

`CONVERT()` with `USING` is used to convert data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string `'abc'` in the default character set to the corresponding string in the `utf8` character set:

```
SELECT CONVERT('abc' USING utf8);
```

Normally, you cannot compare a `BLOB` value or other binary string in case-insensitive fashion because binary strings have no character set, and thus no concept of lettercase. To perform a case-insensitive comparison, use the `CONVERT()` function to convert the value to a non-binary string. If the character set of the result has a case-insensitive collation, the `LIKE` operation is not case sensitive:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1) FROM tbl_name;
```

To use a different character set, substitute its name for `latin1` in the preceding statement. To ensure that a case-insensitive collation is used, specify a `COLLATE` clause following the `CONVERT()` call.

`CONVERT()` can be used more generally for comparing strings that are represented in different character sets.

The cast functions are useful when you want to create a column with a specific type in a `CREATE ... SELECT` statement:

```
CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE);
```

The functions also can be useful for sorting ENUM columns in lexical order. Normally, sorting of ENUM columns occurs using the internal numeric values. Casting the values to CHAR results in a lexical sort:

```
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

CAST(*str* AS BINARY) is the same thing as BINARY *str*. CAST(*expr* AS CHAR) treats the expression as a string with the default character set.

CAST() also changes the result if you use it as part of a more complex expression such as CONCAT('Date: ',CAST(NOW() AS DATE)).

You should not use CAST() to extract data in different formats but instead use string functions like LEFT() or EXTRACT(). See Section 12.5, “Date and Time Functions”.

To cast a string to a numeric value in numeric context, you normally do not have to do anything other than to use the string value as though it were a number:

```
mysql> SELECT 1+'1';
-> 2
```

If you use a number in string context, the number automatically is converted to a BINARY string.

```
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

MySQL supports arithmetic with both signed and unsigned 64-bit values. If you are using numeric operators (such as + or -) and one of the operands is an unsigned integer, the result is unsigned. You can override this by using the SIGNED and UNSIGNED cast operators to cast the operation to a signed or unsigned 64-bit integer, respectively.

```
mysql> SELECT CAST(1-2 AS UNSIGNED)
-> 18446744073709551615
mysql> SELECT CAST(CAST(1-2 AS UNSIGNED) AS SIGNED);
-> -1
```

Note that if either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, DECIMAL column values are regarded as floating-point values.)

```
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
-> -1.0
```

If you are using a string in an arithmetic operation, this is converted to a floating-point number.

If you convert a “zero” date string to a date, CONVERT() and CAST() return NULL when the NO\_ZERO\_DATE SQL mode is enabled. As of MySQL 5.0.4, they also produce a warning.

## 12.9. Other Functions

### 12.9.1. Bit Functions

MySQL uses BIGINT (64-bit) arithmetic for bit operations, so these operators have a maximum range of 64 bits.

- |

Bitwise OR:

```
mysql> SELECT 29 | 15;
      -> 31
```

The result is an unsigned 64-bit integer.

- &

Bitwise AND:

```
mysql> SELECT 29 & 15;
      -> 13
```

The result is an unsigned 64-bit integer.

- ^

Bitwise XOR:

```
mysql> SELECT 1 ^ 1;
      -> 0
mysql> SELECT 1 ^ 0;
      -> 1
mysql> SELECT 11 ^ 3;
      -> 8
```

The result is an unsigned 64-bit integer.

- <<

Shifts a longlong (BIGINT) number to the left.

```
mysql> SELECT 1 << 2;
      -> 4
```

The result is an unsigned 64-bit integer.

- >>

Shifts a longlong (BIGINT) number to the right.

```
mysql> SELECT 4 >> 2;
      -> 1
```

The result is an unsigned 64-bit integer.

- ~

Invert all bits.

```
mysql> SELECT 5 & ~1;
      -> 4
```

The result is an unsigned 64-bit integer.

- BIT\_COUNT(*N*)

Returns the number of bits that are set in the argument *N*.

```
mysql> SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
       -> 4, 3
```

## 12.9.2. Encryption and Compression Functions

The functions in this section perform encryption and decryption, and compression and uncompression.

**Note:** The encryption and compression functions return binary strings. For many of these functions, the result might contain arbitrary byte values. If you want to store these results, use a BLOB column rather than a CHAR or (before MySQL 5.0.3) VARCHAR column to avoid potential problems with trailing space removal that would change data values.

**Note:** Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using one of the other encryption functions described in this section instead.

- `AES_ENCRYPT(str,key_str)`, `AES_DECRYPT(crypt_str,key_str)`

These functions allow encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” Encoding with a 128-bit key length is used, but you can extend it up to 256 bits by modifying the source. We chose 128 bits because it is much faster and it is secure enough for most purposes.

`AES_ENCRYPT()` encrypts a string and returns a binary string. `AES_DECRYPT()` decrypts the encrypted string and returns the original string. The input arguments may be any length. If either argument is NULL, the result of this function is also NULL.

Because AES is a block-level algorithm, padding is used to encode uneven length strings and so the result string length may be calculated using this formula:

$$16 \times (\text{trunc}(\text{string\_length} / 16) + 1)$$

If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns NULL. However, it is possible for `AES_DECRYPT()` to return a non-NULL value (possibly garbage) if the input data or the key is invalid.

You can use the AES functions to store data in an encrypted form by modifying your queries:

```
INSERT INTO t VALUES (1,AES_ENCRYPT('text','password'));
```

`AES_ENCRYPT()` and `AES_DECRYPT()` can be considered the most cryptographically secure encryption functions currently available in MySQL.

- `COMPRESS(string_to_compress)`

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always NULL. The compressed string can be uncompressed with `UNCOMPRESS()`.

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
       -> 21
mysql> SELECT LENGTH(COMPRESS(''));
       -> 0
mysql> SELECT LENGTH(COMPRESS('a'));
       -> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
```

-> 15

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Non-empty strings are stored as a four-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra '.' character is added to avoid problems with endspace trimming should the result be stored in a CHAR or VARCHAR column. (Use of CHAR or VARCHAR to store compressed strings is not recommended. It is better to use a BLOB column instead.)

- `DECODE(crypt_str,pass_str)`

Decrypts the encrypted string *crypt\_str* using *pass\_str* as the password. *crypt\_str* should be a string returned from `ENCODE()`.

- `ENCODE(str,pass_str)`

Encrypt *str* using *pass\_str* as the password. To decrypt the result, use `DECODE()`.

The result is a binary string of the same length as *str*.

- `DES_DECRYPT(crypt_str[,key_str])`

Decrypts a string encrypted with `DES_ENCRYPT()`. If an error occurs, this function returns NULL.

Note that this function works only if MySQL has been configured with SSL support. See Section 5.9.7, "Using Secure Connections".

If no *key\_str* argument is given, `DES_DECRYPT()` examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the SUPER privilege. The key file can be specified with the `--des-key-file` server option.

If you pass this function a *key\_str* argument, that string is used as the key for decrypting the message.

If the *crypt\_str* argument does not appear to be an encrypted string, MySQL returns the given *crypt\_str*.

- `DES_ENCRYPT(str[, {key_num | key_str}]])`

Encrypts the string with the given key using the Triple-DES algorithm.

Note that this function works only if MySQL has been configured with SSL support. See Section 5.9.7, "Using Secure Connections".

The encryption key to use is chosen based on the second argument to `DES_ENCRYPT()`, if one was given:

Argument	Description
No argument	The first key from the DES key file is used.
<i>key_num</i>	The given key number (0-9) from the DES key file is used.
<i>key_str</i>	The given key string is used to encrypt <i>str</i> .

The key file can be specified with the `--des-key-file` server option.

The return string is a binary string where the first character is `CHAR(128 | key_num)`. If an error occurs, `DES_ENCRYPT()` returns NULL.

The 128 is added to make it easier to recognize an encrypted key. If you use a string key, *key\_num* is 127.

The string length for the result is given by this formula:

$$new\_len = orig\_len + (8 - (orig\_len \% 8)) + 1$$

Each line in the DES key file has the following format:

*key\_num des\_key\_str*

Each *key\_num* value must be a number in the range from 0 to 9. Lines in the file may be in any order. *des\_key\_str* is the string that is used to encrypt the message. There should be at least one space between the number and the key. The first key is the default key that is used if you do not specify any key argument to `DES_ENCRYPT()`.

You can tell MySQL to read new key values from the key file with the `FLUSH DES_KEY_FILE` statement. This requires the `RELOAD` privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

```
mysql> SELECT customer_address FROM customer_table
      > WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');
```

- `ENCRYPT(str[, salt])`

Encrypts *str* using the Unix `crypt()` system call and returns a binary string. The *salt* argument should be a string with at least two characters. If no *salt* argument is given, a random value is used.

```
mysql> SELECT ENCRYPT('hello');
      -> 'VxuFAJXVARROc'
```

`ENCRYPT()` ignores all but the first eight characters of *str*, at least on some systems. This behavior is determined by the implementation of the underlying `crypt()` system call.

If `crypt()` is not available on your system (as is the case with Windows), `ENCRYPT()` always returns `NULL`.

- `MD5(str)`

Calculates an MD5 128-bit checksum for the string. The value is returned as a binary string of 32 hex digits, or `NULL` if the argument was `NULL`. The return value can, for example, be used as a hash key.

```
mysql> SELECT MD5('testing');
      -> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

If you want to convert the value to uppercase, see the description of binary string conversion given in the entry for the `BINARY` operator in Section 12.8, “Cast Functions and Operators”.

See the note regarding the MD5 algorithm at the beginning this section.

- `OLD_PASSWORD(str)`

OLD\_PASSWORD() was added to MySQL when the implementation of PASSWORD() was changed to improve security. OLD\_PASSWORD() returns the value of the old (pre-4.1) implementation of PASSWORD() as a binary string, and is intended to permit you to reset passwords for any pre-4.1 clients that need to connect to your version 5.0 MySQL server without locking them out. See Section 5.8.9, “Password Hashing as of MySQL 4.1”.

- PASSWORD(*str*)

Calculates and returns a password string from the plaintext password *str* and returns a binary string, or NULL if the argument was NULL. This is the function that is used for encrypting MySQL passwords for storage in the Password column of the user grant table.

```
mysql> SELECT PASSWORD('badpwd');
-> '*AAB3E285149C0135D51A520E1940DD3263DC008C'
```

PASSWORD() encryption is one-way (not reversible).

PASSWORD() does not perform password encryption in the same way that Unix passwords are encrypted. See ENCRYPT().

**Note:** The PASSWORD() function is used by the authentication system in MySQL Server; you should *not* use it in your own applications. For that purpose, consider MD5() or SHA1() instead. Also see RFC 2195 for more information about handling passwords and authentication securely in your applications.

- SHA1(*str*), SHA(*str*)

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a binary string of 40 hex digits, or NULL if the argument was NULL. One of the possible uses for this function is as a hash key. You can also use it as a cryptographic function for storing passwords. SHA() is synonymous with SHA1().

```
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

SHA1() can be considered a cryptographically more secure equivalent of MD5(). However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- UNCOMPRESS(*string\_to\_uncompress*)

Uncompresses a string compressed by the COMPRESS() function. If the argument is not a compressed value, the result is NULL. This function requires MySQL to have been compiled with a compression library such as zlib. Otherwise, the return value is always NULL.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

- UNCOMPRESSED\_LENGTH(*compressed\_string*)

Returns the length that the compressed string had before being compressed.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a', 30)));
-> 30
```

## 12.9.3. Information Functions

- `BENCHMARK(count, expr)`

The `BENCHMARK()` function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MySQL processes the expression. The result value is always 0. The intended use is from within the `mysql` client, which reports query execution times:

```
mysql> SELECT BENCHMARK(1000000, ENCODE('hello', 'goodbye'));
+-----+
| BENCHMARK(1000000, ENCODE('hello', 'goodbye')) |
+-----+
| 0 |
+-----+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

- `CHARSET(str)`

Returns the character set of the string argument.

```
mysql> SELECT CHARSET('abc');
      -> 'latin1'
mysql> SELECT CHARSET(CONVERT('abc' USING utf8));
      -> 'utf8'
mysql> SELECT CHARSET(USER());
      -> 'utf8'
```

- `COERCIBILITY(str)`

Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
      -> 0
mysql> SELECT COERCIBILITY(USER());
      -> 3
mysql> SELECT COERCIBILITY('abc');
      -> 4
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

Coercibility	Meaning	Example
0	Explicit collation	Value with <code>COLLATE</code> clause
1	No collation	Concatenation of strings with different collations
2	Implicit collation	Column value
3	System constant	<code>USER()</code> return value
4	Coercible	Literal string
5	Ignorable	<code>NULL</code> or an expression derived from <code>NULL</code>

Before MySQL 5.0.3, the return values are shown as follows, and functions such as `USER()` have a coercibility of 2:

Coercibility	Meaning	Example
--------------	---------	---------

0	Explicit collation	Value with COLLATE clause
1	No collation	Concatenation of strings with different collations
2	Implicit collation	Column value, stored routine parameter or local variable
3	Coercible	Literal string

- `COLLATION(str)`

Returns the collation of the string argument.

```
mysql> SELECT COLLATION('abc');
      -> 'latin1_swedish_ci'
mysql> SELECT COLLATION(_utf8'abc');
      -> 'utf8_general_ci'
```

- `CONNECTION_ID()`

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

```
mysql> SELECT CONNECTION_ID();
      -> 23786
```

- `CURRENT_USER, CURRENT_USER()`

Returns the username and hostname combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. As of MySQL 5.0.10, within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER()` returns the creator of the routine. The return value is a string in the `utf8` character set.

The value of `CURRENT_USER()` can differ from the value of `USER()`.

```
mysql> SELECT USER();
      -> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to
database 'mysql'
mysql> SELECT CURRENT_USER();
      -> '@localhost'
```

The example illustrates that although the client specified a username of `davida` (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as seen by the empty username part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for `davida`.

- `DATABASE()`

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
      -> 'test'
```

- `FOUND_ROWS()`

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include a `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
      -> WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```

The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause. (If the preceding `SELECT` statement does not include the `SQL_CALC_FOUND_ROWS` option, then `FOUND_ROWS()` may return a different result when `LIMIT` is used than when it is not.)

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` allows you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
  - The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
  - If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.
- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

Returns the *first* automatically generated value that was set for an `AUTO_INCREMENT` column by the *most recent* `INSERT` or `UPDATE` statement to affect such a column.

```
mysql> SELECT LAST_INSERT_ID();
      -> 195
```

The ID that was generated is maintained in the server on a *per-connection basis*. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value gener-

ated for most recent statement affecting an `AUTO_INCREMENT` column *by that client*. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not 0).

**Important:** If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row *only*. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```
mysql> USE test;
Database changed
mysql> CREATE TABLE t (
  ->   id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
  ->   name VARCHAR(10) NOT NULL
  -> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO t VALUES (NULL, 'Bob');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t;
+-----+-----+
| id | name |
+-----+-----+
|  1 | Bob  |
+-----+-----+
1 row in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                1 |
+-----+
1 row in set (0.00 sec)

mysql> INSERT INTO t VALUES
  -> (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM t;
+-----+-----+
| id | name |
+-----+-----+
|  1 | Bob  |
|  2 | Mary |
|  3 | Jane |
|  4 | Lisa |
+-----+-----+
4 rows in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                2 |
+-----+
1 row in set (0.00 sec)
```

Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the

first of these rows was 2, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `AUTO_INCREMENT` counter is not incremented and `LAST_INSERT_ID()` returns 0, which reflects that no row was inserted.

If *expr* is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

```
mysql> CREATE TABLE sequence (id INT NOT NULL);
mysql> INSERT INTO sequence VALUES (0);
```

2. Use the table to generate sequence numbers like this:

```
mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
mysql> SELECT LAST_INSERT_ID();
```

The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See Section 22.2.3.36, “`mysql_insert_id()`”.

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

- `ROW_COUNT()`

`ROW_COUNT()` returns the number of rows updated, inserted, or deleted by the preceding statement. This is the same as the row count that the `mysql` client displays and the value from the `mysql_affected_rows()` C API function.

```
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|           3 |
+-----+
1 row in set (0.00 sec)
```

```
mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)
```

```
mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|           2 |
+-----+
1 row in set (0.00 sec)
```

`ROW_COUNT()` was added in MySQL 5.0.1.

- `SCHEMA()`

This function is a synonym for `DATABASE()`. It was added in MySQL 5.0.2.

- `SESSION_USER()`

`SESSION_USER()` is a synonym for `USER()`.

- `SYSTEM_USER()`

`SYSTEM_USER()` is a synonym for `USER()`.

- `USER()`

Returns the current MySQL username and hostname as a string in the `utf8` character set.

```
mysql> SELECT USER();
      -> 'davida@localhost'
```

The value indicates the username you specified when connecting to the server, and the client host from which you connected. The value can be different from that of `CURRENT_USER()`.

You can extract only the username part like this:

```
mysql> SELECT SUBSTRING_INDEX(USER(), '@', 1);
      -> 'davida'
```

- `VERSION()`

Returns a string that indicates the MySQL server version. The string uses the `utf8` character set.

```
mysql> SELECT VERSION();
      -> '5.0.22-standard'
```

Note that if your version string ends with `-log` this means that logging is enabled.

## 12.9.4. Miscellaneous Functions

- `DEFAULT(col_name)`

Returns the default value for a table column. Starting with MySQL 5.0.2, an error results if the column has no default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- `FORMAT(X, D)`

Formats the number `X` to a format like `'#,###,###.##'`, rounded to `D` decimal places, and returns the result as a string. For details, see Section 12.3, “String Functions”.

- `GET_LOCK(str, timeout)`

Tries to obtain a lock with a name given by the string `str`, using a timeout of `timeout` seconds. Returns 1 if the lock was obtained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or `NULL` if an error occurred

(such as running out of memory or the thread was killed with `mysqladmin kill`). If you have a lock obtained with `GET_LOCK()`, it is released when you execute `RELEASE_LOCK()`, execute a new `GET_LOCK()`, or your connection terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` do not interact with transactions. That is, committing a transaction does not release any such locks obtained during the transaction.

This function can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked by one client, `GET_LOCK()` blocks any request by another client for a lock with the same name. This allows clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also allows a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

```
mysql> SELECT GET_LOCK('lock1',10);
-> 1
mysql> SELECT IS_FREE_LOCK('lock2');
-> 1
mysql> SELECT GET_LOCK('lock2',10);
-> 1
mysql> SELECT RELEASE_LOCK('lock2');
-> 1
mysql> SELECT RELEASE_LOCK('lock1');
-> NULL
```

The second `RELEASE_LOCK()` call returns `NULL` because the lock 'lock1' was automatically released by the second `GET_LOCK()` call.

Note: If a client attempts to acquire a lock that is already held by another client, it blocks according to the `timeout` argument. If the blocked client terminates, its thread does not die until the lock request times out. This is a known bug.

- `INET_ATON(expr)`

Given the dotted-quad representation of a network address as a string, returns an integer that represents the numeric value of the address. Addresses may be 4- or 8-byte addresses.

```
mysql> SELECT INET_ATON('209.207.224.40');
-> 3520061480
```

The generated number is always in network byte order. For the example just shown, the number is calculated as  $209 \times 256^3 + 207 \times 256^2 + 224 \times 256 + 40$ .

`INET_ATON()` also understands short-form IP addresses:

```
mysql> SELECT INET_ATON('127.0.0.1'), INET_ATON('127.1');
-> 2130706433, 2130706433
```

**Note:** When storing values generated by `INET_ATON()`, it is recommended that you use an `INT UNSIGNED` column. If you use a (signed) `INT` column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See Section 11.2, “Numeric Types”.

- `INET_NTOA(expr)`

Given a numeric network address (4 or 8 byte), returns the dotted-quad representation of the address as a string.

```
mysql> SELECT INET_NTOA(3520061480);
-> '209.207.224.40'
```

- `IS_FREE_LOCK(str)`

Checks whether the lock named *str* is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and NULL if an error occurs (such as an incorrect argument).

- `IS_USED_LOCK(str)`

Checks whether the lock named *str* is in use (that is, locked). If so, it returns the connection identifier of the client that holds the lock. Otherwise, it returns NULL.

- `MASTER_POS_WAIT(log_name, log_pos[, timeout])`

This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events the slave had to wait for to advance to the specified position. The function returns NULL if the slave SQL thread is not started, the slave's master information is not initialized, the arguments are incorrect, or an error occurs. It returns -1 if the timeout has been exceeded. If the slave SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns NULL. If the slave is past the specified position, the function returns immediately.

If a *timeout* value is specified, `MASTER_POS_WAIT()` stops waiting when *timeout* seconds have elapsed. *timeout* must be greater than 0; a zero or negative *timeout* means no timeout.

- `NAME_CONST(name, value)`

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name.

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

This function was added in MySQL 5.0.12. It is for internal use only. The server uses it when writing statements from stored routines that contain references to local routine variables, as described in Section 17.4, “Binary Logging of Stored Routines and Triggers”. You might see this function in the output from `mysqlbinlog`.

- `RELEASE_LOCK(str)`

Releases the lock named by the string *str* that was obtained with `GET_LOCK()`. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and NULL if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

The `DO` statement is convenient to use with `RELEASE_LOCK()`. See Section 13.2.2, “DO Syntax”.

- `SLEEP(duration)`

Sleeps (pauses) for the number of seconds given by the *duration* argument, then returns 0. If `SLEEP()` is interrupted, it returns 1. The duration may have a fractional part given in microseconds. This function was added in MySQL 5.0.12.

- `UUID()`

Returns a Universal Unique Identifier (UUID) generated according to “DCE 1.1: Remote Pro-

cedure Call” (Appendix A) CAE (Common Applications Environment) Specifications published by The Open Group in October 1997 (Document Number C706, <http://www.opengroup.org/public/pubs/catalog/c706.htm>).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate computers that are not connected to each other.

A UUID is a 128-bit number represented by a string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from a timestamp.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host computer has no Ethernet card, or we do not know how to find the hardware address of an interface on your operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have *very* low probability.

Currently, the MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-0040f4311e29'
```

Note that `UUID()` does not yet work with replication.

- `VALUES(col_name)`

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in `INSERT ... ON DUPLICATE KEY UPDATE` statements and returns `NULL` otherwise. Section 13.2.4.3, “`INSERT ... ON DUPLICATE KEY UPDATE` Syntax”.

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
-> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

## 12.10. Functions and Modifiers for Use with GROUP BY Clauses

### 12.10.1. GROUP BY (Aggregate) Functions

This section describes group (aggregate) functions that operate on sets of values. Unless otherwise stated, group functions ignore `NULL` values.

If you use a group function in a statement containing no `GROUP BY` clause, it is equivalent to grouping on all rows.

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, which loses the part after the first non-numeric character.) To work around this problem, you can convert to numeric units, perform the aggregate operation, and convert back to a

temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

- `AVG([DISTINCT] expr)`

Returns the average value of *expr*. The `DISTINCT` option can be used as of MySQL 5.0.3 to return the average of the distinct values of *expr*.

`AVG()` returns `NULL` if there were no matching rows.

```
mysql> SELECT student_name, AVG(test_score)
->      FROM student
->      GROUP BY student_name;
```

- `BIT_AND(expr)`

Returns the bitwise AND of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns 18446744073709551615 if there were no matching rows. (This is the value of an unsigned `BIGINT` value with all bits set to 1.)

- `BIT_OR(expr)`

Returns the bitwise OR of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns 0 if there were no matching rows.

- `BIT_XOR(expr)`

Returns the bitwise XOR of all bits in *expr*. The calculation is performed with 64-bit (`BIGINT`) precision.

This function returns 0 if there were no matching rows.

- `COUNT(expr)`

Returns a count of the number of non-`NULL` values in the rows retrieved by a `SELECT` statement. The result is a `BIGINT` value.

`COUNT()` returns 0 if there were no matching rows.

```
mysql> SELECT student.student_name, COUNT(*)
->      FROM student, course
->      WHERE student.student_id=course.student_id
->      GROUP BY student_name;
```

`COUNT(*)` is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain `NULL` values.

`COUNT(*)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization applies only to MyISAM tables only, because an exact row count is stored for this storage engine and can be accessed very quickly. For transactional storage engines such as InnoDB and BDB, storing an exact row count is more problematic because multiple transactions

may be occurring, each of which may affect the count.

- `COUNT(DISTINCT expr, [expr...])`

Returns a count of the number of different non-NULL values.

`COUNT(DISTINCT)` returns 0 if there were no matching rows.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain NULL by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside `COUNT(DISTINCT ...)`.

- `GROUP_CONCAT(expr)`

This function returns a string result with the concatenated non-NULL values from a group. It returns NULL if there are no non-NULL values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
             [ASC | DESC] [,col_name ...]]
             [SEPARATOR str_val])
```

```
mysql> SELECT student_name,
->        GROUP_CONCAT(test_score)
->        FROM student
->        GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
->        GROUP_CONCAT(DISTINCT test_score
->                      ORDER BY test_score DESC SEPARATOR ' ')
->        FROM student
->        GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. You can eliminate duplicate values by using `DISTINCT`. If you want to sort values in the result, you should use `ORDER BY` clause. To sort in reverse order, add the `DESC` (descending) keyword to the name of the column you are sorting by in the `ORDER BY` clause. The default is ascending order; this may be specified explicitly using the `ASC` keyword. `SEPARATOR` is followed by the string value that should be inserted between values of result. The default is a comma (`,`). You can eliminate the separator altogether by specifying `SEPARATOR ''`.

You can set a maximum allowed length with the `group_concat_max_len` system variable. (The default value is 1024.) The syntax to do this at runtime is as follows, where *val* is an unsigned integer:

```
SET [SESSION | GLOBAL] group_concat_max_len = val;
```

If a maximum length has been set, the result is truncated to this maximum length.

Beginning with MySQL 5.0.19, the type returned by `GROUP_CONCAT()` is always `VARCHAR` unless `group_concat_max_len` is greater than 512, in which case, it returns a `BLOB`. (Previously, it returned a `BLOB` with `group_concat_max_len` greater than 512 only if the query included an `ORDER BY` clause.)

See also `CONCAT()` and `CONCAT_WS()`: Section 12.3, “String Functions”.

- `MIN([DISTINCT] expr), MAX([DISTINCT] expr)`

Returns the minimum or maximum value of *expr*. `MIN()` and `MAX()` may take a string argument; in such cases they return the minimum or maximum string value. See Section 7.4.5, “How MySQL Uses Indexes”. The `DISTINCT` keyword can be used to find the minimum or maximum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

`MIN()` and `MAX()` return `NULL` if there were no matching rows.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
->      FROM student
->      GROUP BY student_name;
```

For `MIN()`, `MAX()`, and other aggregate functions, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them. This is expected to be rectified in a future MySQL release.

- `STD(expr)` `STDDEV(expr)`

Returns the population standard deviation of *expr*. This is an extension to standard SQL. The `STDDEV()` form of this function is provided for compatibility with Oracle. As of MySQL 5.0.3, the standard SQL function `STDDEV_POP()` can be used instead.

These functions return `NULL` if there were no matching rows.

- `STDDEV_POP(expr)`

Returns the population standard deviation of *expr* (the square root of `VAR_POP()`). This function was added in MySQL 5.0.3. Before 5.0.3, you can use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

`STDDEV_POP()` returns `NULL` if there were no matching rows.

- `STDDEV_SAMP(expr)`

Returns the sample standard deviation of *expr* (the square root of `VAR_SAMP()`). This function was added in MySQL 5.0.3.

`STDDEV_SAMP()` returns `NULL` if there were no matching rows.

- `SUM([DISTINCT] expr)`

Returns the sum of *expr*. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used in MySQL 5.0 to sum only the distinct values of *expr*.

`SUM()` returns `NULL` if there were no matching rows.

- `VAR_POP(expr)`

Returns the population standard variance of *expr*. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. This function was added in MySQL 5.0.3. Before 5.0.3, you can use `VARIANCE()`, which is equivalent but is not standard SQL.

`VAR_POP()` returns `NULL` if there were no matching rows.

- `VAR_SAMP(expr)`

Returns the sample variance of *expr*. That is, the denominator is the number of rows minus one. This function was added in MySQL 5.0.3.

`VAR_SAMP()` returns `NULL` if there were no matching rows.

- `VARIANCE(expr)`

Returns the population standard variance of *expr*. This is an extension to standard SQL. As of MySQL 5.0.3, the standard SQL function `VAR_POP()` can be used instead.

`VARIANCE()` returns `NULL` if there were no matching rows.

## 12.10.2. GROUP BY Modifiers

The `GROUP BY` clause allows a `WITH ROLLUP` modifier that causes extra rows to be added to the summary output. These rows represent higher-level (or super-aggregate) summary operations. `ROLLUP` thus allows you to answer questions at multiple levels of analysis with a single query. It can be used, for example, to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a table named `sales` has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```
CREATE TABLE sales
(
    year      INT NOT NULL,
    country   VARCHAR(20) NOT NULL,
    product   VARCHAR(32) NOT NULL,
    profit    INT
);
```

The table's contents can be summarized per year with a simple `GROUP BY` like this:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year;
+-----+-----+
| year | SUM(profit) |
+-----+-----+
| 2000 |          4525 |
| 2001 |          3010 |
+-----+-----+
```

This output shows the total profit for each year, but if you also want to determine the total profit summed over all years, you must add up the individual values yourself or run an additional query.

Or you can use `ROLLUP`, which provides both levels of analysis with a single query. Adding a `WITH ROLLUP` modifier to the `GROUP BY` clause causes the query to produce another row that shows the grand total over all year values:

```
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year WITH ROLLUP;
+-----+-----+
| year | SUM(profit) |
+-----+-----+
| 2000 |          4525 |
| 2001 |          3010 |
| NULL |          7535 |
+-----+-----+
```

The grand total super-aggregate line is identified by the value `NULL` in the `year` column.

`ROLLUP` has a more complex effect when there are multiple `GROUP BY` columns. In this case, each time there is a “break” (change in value) in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without `ROLLUP`, a summary on the `sales` table based on `year`, `country`, and `product` might look like this:

```
mysql> SELECT year, country, product, SUM(profit)
```

```

-> FROM sales
-> GROUP BY year, country, product;

```

year	country	product	SUM(profit)
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	India	Calculator	150
2000	India	Computer	1200
2000	USA	Calculator	75
2000	USA	Computer	1500
2001	Finland	Phone	10
2001	USA	Calculator	50
2001	USA	Computer	2700
2001	USA	TV	250

The output indicates summary values only at the year/country/product level of analysis. When ROLLUP is added, the query produces several extra rows:

```

mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP;

```

year	country	product	SUM(profit)
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200
2000	India	NULL	1350
2000	USA	Calculator	75
2000	USA	Computer	1500
2000	USA	NULL	1575
2000	NULL	NULL	4525
2001	Finland	Phone	10
2001	Finland	NULL	10
2001	USA	Calculator	50
2001	USA	Computer	2700
2001	USA	TV	250
2001	USA	NULL	3000
2001	NULL	NULL	3010
NULL	NULL	NULL	7535

For this query, adding ROLLUP causes the output to include summary information at four levels of analysis, not just one. Here's how to interpret the ROLLUP output:

- Following each set of product rows for a given year and country, an extra summary row is produced showing the total for all products. These rows have the product column set to NULL.
- Following each set of rows for a given year, an extra summary row is produced showing the total for all countries and products. These rows have the country and products columns set to NULL.
- Finally, following all other rows, an extra summary row is produced showing the grand total for all years, countries, and products. This row has the year, country, and products columns set to NULL.

**Other Considerations When using ROLLUP**

The following items list some behaviors specific to the MySQL implementation of ROLLUP:

When you use ROLLUP, you cannot also use an ORDER BY clause to sort the results. In other words, ROLLUP and ORDER BY are mutually exclusive. However, you still have some control over sort order. GROUP BY in MySQL sorts results, and you can use explicit ASC and DESC keywords with columns named in the GROUP BY list to specify sort order for individual columns. (The higher-level summary rows added by ROLLUP still appear after the rows from which they are calculated, regardless of the sort order.)

LIMIT can be used to restrict the number of rows returned to the client. LIMIT is applied after ROLLUP, so the limit applies against the extra rows added by ROLLUP. For example:

```
mysql> SELECT year, country, product, SUM(profit)
-> FROM sales
-> GROUP BY year, country, product WITH ROLLUP
-> LIMIT 5;
```

year	country	product	SUM(profit)
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200

Using LIMIT with ROLLUP may produce results that are more difficult to interpret, because you have less context for understanding the super-aggregate rows.

The NULL indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the GROUP BY clause following the leftmost one that has changed value. For any column in the result set with a name that is a lexical match to any of those names, its value is set to NULL. (If you specify grouping columns by column number, the server identifies which columns to set to NULL by number.)

Because the NULL values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you cannot test them as NULL values within the query itself. For example, you cannot add HAVING product IS NULL to the query to eliminate from the output all but the super-aggregate rows.

On the other hand, the NULL values do appear as NULL on the client side and can be tested as such using any MySQL client programming interface.

### 12.10.3. GROUP BY and HAVING with Hidden Fields

MySQL extends the use of GROUP BY so that you can use non-aggregated columns or calculations in the SELECT list that do not appear in the GROUP BY clause. You can use this feature to get better performance by avoiding unnecessary column sorting and grouping. For example, you do not need to group on customer.name in the following query:

```
SELECT order.custid, customer.name, MAX(payments)
FROM order, customer
WHERE order.custid = customer.custid
GROUP BY order.custid;
```

In standard SQL, you would have to add customer.name to the GROUP BY clause. In MySQL, the name is redundant.

Do *not* use this feature if the columns you omit from the GROUP BY part are not constant in the group. The server is free to return any value from the group, so the results are indeterminate unless all values are the same.

A similar MySQL extension applies to the HAVING clause. The SQL standard does not allow the HAVING clause to name any column that is not found in the GROUP BY clause if it is not enclosed

in an aggregate function. MySQL allows the use of such columns to simplify calculations. This extension assumes that the non-grouped columns will have the same group-wise values. Otherwise, the result is indeterminate.

If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, the MySQL extension to `GROUP BY` does not apply. That is, columns not named in the `GROUP BY` clause cannot be used in the `SELECT` list or `HAVING` clause if not used in an aggregate function.

In some cases, you can use `MIN()` and `MAX()` to obtain a specific column value even if it isn't unique. The following gives the value of `column` from the row containing the smallest value in the `sort` column:

```
SUBSTR(MIN(CONCAT(RPAD(sort,6,' '),column)),7)
```

See Section 3.6.4, “The Rows Holding the Group-wise Maximum of a Certain Field”.

Note that if you are trying to follow standard SQL, you can't use expressions in `GROUP BY` clauses. You can work around this limitation by using an alias for the expression:

```
SELECT id,FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

MySQL does allow expressions in `GROUP BY` clauses. For example:

```
SELECT id,FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

---

# Chapter 13. SQL Statement Syntax

This chapter describes the syntax for most of the SQL statements supported by MySQL. Additional statement descriptions can be found in the following chapters:

- The `EXPLAIN` statement is discussed in Chapter 7, *Optimization*.
- Statements for writing stored routines are covered in Chapter 17, *Stored Procedures and Functions*.
- Statements for writing triggers are covered in Chapter 18, *Triggers*.
- View-related statements are covered in Chapter 19, *Views*.

## 13.1. Data Definition Statements

### 13.1.1. ALTER DATABASE Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification [, alter_specification] ...
```

```
alter_specification:
    [DEFAULT] CHARACTER SET charset_name
    | [DEFAULT] COLLATE collation_name
```

`ALTER DATABASE` enables you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. To use `ALTER DATABASE`, you need the `ALTER` privilege on the database. `ALTER SCHEMA` is a synonym for `ALTER DATABASE` as of MySQL 5.0.2.

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. Chapter 10, *Character Set Support*, discusses character set and collation names.

The database name can be omitted, in which case the statement applies to the default database.

### 13.1.2. ALTER TABLE Syntax

```
ALTER [IGNORE] TABLE tbl_name
    alter_specification [, alter_specification] ...
```

```
alter_specification:
    ADD [COLUMN] column_definition [FIRST | AFTER col_name ]
    | ADD [COLUMN] (column_definition,...)
    | ADD INDEX [index_name] [index_type] (index_col_name,...)
    | ADD [CONSTRAINT [symbol]]
      PRIMARY KEY [index_type] (index_col_name,...)
    | ADD [CONSTRAINT [symbol]]
      UNIQUE [INDEX] [index_name] [index_type] (index_col_name,...)
    | ADD [FULLTEXT|SPATIAL] [INDEX] [index_name] (index_col_name,...)
    | ADD [CONSTRAINT [symbol]]
      FOREIGN KEY [index_name] (index_col_name,...)
      [reference_definition]
    | ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
    | CHANGE [COLUMN] old_col_name column_definition
      [FIRST|AFTER col_name]
    | MODIFY [COLUMN] column_definition [FIRST | AFTER col_name]
    | DROP [COLUMN] col_name
    | DROP PRIMARY KEY
```

```
DROP INDEX index_name
DROP FOREIGN KEY fk_symbol
DISABLE KEYS
ENABLE KEYS
RENAME [TO] new_tbl_name
ORDER BY col_name
CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
[DEFAULT] CHARACTER SET charset_name [COLLATE collation_name]
DISCARD TABLESPACE
IMPORT TABLESPACE
table_options
```

ALTER TABLE enables you to change the structure of an existing table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change the comment for the table and type of the table.

The syntax for many of the allowable alterations is similar to clauses of the CREATE TABLE statement. This includes *table\_options* modifications, for options such as ENGINE, AUTO\_INCREMENT, and AVG\_ROW\_LENGTH. (However, ALTER TABLE ignores the DATA DIRECTORY and INDEX DIRECTORY table options.) Section 13.1.5, “CREATE TABLE Syntax”, lists all table options. As of MySQL 5.0.22, to prevent inadvertant loss of data, ALTER TABLE cannot be used to change the storage engine of a table to MERGE or BLACKHOLE.

Some operations may result in warnings if attempted on a table for which the storage engine does not support the operation. These warnings can be displayed with SHOW WARNINGS. See Section 13.5.4.25, “SHOW WARNINGS Syntax”.

If you use ALTER TABLE to change a column specification but DESCRIBE *tbl\_name* indicates that your column was not changed, it is possible that MySQL ignored your modification for one of the reasons described in Section 13.1.5.1, “Silent Column Specification Changes”.

In most cases, ALTER TABLE works by making a temporary copy of the original table. The alteration is performed on the copy, and then the original table is deleted and the new one is renamed. While ALTER TABLE is executing, the original table is readable by other clients. Updates and writes to the table are stalled until the new table is ready, and then are automatically redirected to the new table without any failed updates.

If you use ALTER TABLE *tbl\_name* RENAME TO *new\_tbl\_name* without any other options, MySQL simply renames any files that correspond to the table *tbl\_name*. There is no need to create a temporary table. (You can also use the RENAME TABLE statement to rename tables. See Section 13.1.9, “RENAME TABLE Syntax”.)

If you use any option to ALTER TABLE other than RENAME, MySQL always creates a temporary table, even if the data wouldn't strictly need to be copied (such as when you change the name of a column). For MyISAM tables, you can speed up the index re-creation operation (which is the slowest part of the alteration process) by setting the *myisam\_sort\_buffer\_size* system variable to a high value.

- To use ALTER TABLE, you need ALTER, INSERT, and CREATE privileges for the table.
- IGNORE is a MySQL extension to standard SQL. It controls how ALTER TABLE works if there are duplicates on unique keys in the new table or if warnings occur when strict mode is enabled. If IGNORE is not specified, the copy is aborted and rolled back if duplicate-key errors occur. If IGNORE is specified, only the first row is used of rows with duplicates on a unique key. The other conflicting rows are deleted. Incorrect values are truncated to the closest matching acceptable value.
- You can issue multiple ADD, ALTER, DROP, and CHANGE clauses in a single ALTER TABLE statement, separated by commas. This is a MySQL extension to standard SQL, which allows only one of each clause per ALTER TABLE statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- `CHANGE col_name`, `DROP col_name`, and `DROP INDEX` are MySQL extensions to standard SQL.
- `MODIFY` is an Oracle extension to `ALTER TABLE`.
- The word `COLUMN` is optional and can be omitted.
- *column\_definition* clauses use the same syntax for `ADD` and `CHANGE` as for `CREATE TABLE`. Note that this syntax includes the column name, not just its data type. See Section 13.1.5, “CREATE TABLE Syntax”.
- You can rename a column using a `CHANGE old_col_name column_definition` clause. To do so, specify the old and new column names and the type that the column currently has. For example, to rename an `INTEGER` column from `a` to `b`, you can do this:

```
ALTER TABLE t1 CHANGE a b INTEGER;
```

If you want to change a column's type but not the name, `CHANGE` syntax still requires an old and new column name, even if they are the same. For example:

```
ALTER TABLE t1 CHANGE b b BIGINT NOT NULL;
```

You can also use `MODIFY` to change a column's type without renaming it:

```
ALTER TABLE t1 MODIFY b BIGINT NOT NULL;
```

- If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.
- When you change a data type using `CHANGE` or `MODIFY`, MySQL tries to convert existing column values to the new type as well as possible.
- To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last. You can also use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations.
- `ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value, as described in Section 11.1.4, “Data Type Default Values”.
- `DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See Section 13.1.7, “DROP INDEX Syntax”.
- If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well.
- If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use `DROP TABLE` instead.
- `DROP PRIMARY KEY` drops the primary index. *Note:* In older versions of MySQL, if no primary index existed, `DROP PRIMARY KEY` would drop the first `UNIQUE` index in the table. This is not the case in MySQL 5.0, where trying to use `DROP PRIMARY KEY` on a table with no primary key give rises to an error.

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, it is stored before any non-unique index so that MySQL can detect duplicate keys as early as possible.

- `ORDER BY` enables you to create the new table with the rows in a specific order. Note that the table does not remain in this order after inserts and deletes. This option is useful primarily when you know that you are mostly to query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.
- If you use `ALTER TABLE` on a MyISAM table, all non-unique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

This feature can be activated explicitly. `ALTER TABLE ... DISABLE KEYS` tells MySQL to stop updating non-unique indexes for a MyISAM table. `ALTER TABLE ... ENABLE KEYS` then should be used to re-create missing indexes. MySQL does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

- The `FOREIGN KEY` and `REFERENCES` clauses are supported by the InnoDB storage engine, which implements `ADD [CONSTRAINT [symbol]] FOREIGN KEY (... ) REFERENCES ... (...)`. See Section 14.2.6.4, “FOREIGN KEY Constraints”. For other storage engines, the clauses are parsed but ignored. The `CHECK` clause is parsed but ignored by all storage engines. See Section 13.1.5, “CREATE TABLE Syntax”. The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See Section 1.9.5, “MySQL Differences from Standard SQL”.

You cannot add a foreign key and drop a foreign key in separate clauses of a single `ALTER TABLE` statement. You must use separate statements.

- InnoDB supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

You cannot add a foreign key and drop a foreign key in separate clauses of a single `ALTER TABLE` statement. You must use separate statements.

For more information, see Section 14.2.6.4, “FOREIGN KEY Constraints”.

- If you want to change the table default character set and all character columns (`CHAR`, `VARCHAR`, `TEXT`) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

**Warning:** The preceding operation converts column values between the character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;  
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from BLOB columns.

If you specify `CONVERT TO CHARACTER SET binary`, the `CHAR`, `VARCHAR`, and `TEXT` columns are converted to their corresponding binary string types (`BINARY`, `VARBINARY`, `BLOB`). This means that the columns no longer will have a character set and a subsequent `CONVERT TO` operation will not apply to them.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for a new column which you add to a table (for example, with `ALTER TABLE ... ADD column`).

- For an InnoDB table that is created with its own tablespace in an `.ibd` file, that file can be discarded and imported. To discard the `.ibd` file, use this statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

This deletes the current `.ibd` file, so be sure that you have a backup first. Attempting to access the table while the tablespace file is discarded results in an error.

To import the backup `.ibd` file back into the table, copy it into the database directory, and then issue this statement:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

See Section 14.2.3.1, “Using Per-Table Tablespaces”.

With the `mysql_info()` C API function, you can find out how many rows were copied, and (when `IGNORE` is used) how many rows were deleted due to duplication of unique key values. See Section 22.2.3.34, “`mysql_info()`”.

Here are some examples that show uses of `ALTER TABLE`. Begin with a table `t1` that is created as shown here:

```
CREATE TABLE t1 (a INTEGER,b CHAR(10));
```

To rename the table from `t1` to `t2`:

```
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add indexes on column `d` and on column `a`:

```
ALTER TABLE t2 ADD INDEX (d), ADD INDEX (a);
```

To remove column `c`:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,  
ADD PRIMARY KEY (c);
```

Note that we indexed `c` (as a `PRIMARY KEY`), because `AUTO_INCREMENT` columns must be indexed, and also that we declare `c` as `NOT NULL`, because primary key columns cannot be `NULL`.

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers for you automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option. See Section 13.5.3, “SET Syntax”.

From MySQL 5.0.3, you can use the `ALTER TABLE ... AUTO_INCREMENT=value` table option for `InnoDB` tables to set the sequence number for new rows if the value is greater than the maximum value in the `AUTO_INCREMENT` column. *If the value is less than the current maximum value in the column, no error message is given and the current sequence value is not changed.*

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE T2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

**Important:** To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also Section A.7.1, “Problems with `ALTER TABLE`”.

## 13.1.3. CREATE DATABASE Syntax

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
      [create_specification [, create_specification] ...]
```

```
create_specification:
  [DEFAULT] CHARACTER SET charset_name
  | [DEFAULT] COLLATE collation_name
```

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the

CREATE privilege for the database. CREATE SCHEMA is a synonym for CREATE DATABASE as of MySQL 5.0.2.

An error occurs if the database exists and you did not specify IF NOT EXISTS.

*create\_specification* options specify database characteristics. Database characteristics are stored in the `db.opt` file in the database directory. The CHARACTER SET clause specifies the default database character set. The COLLATE clause specifies the default database collation. Chapter 10, *Character Set Support*, discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the CREATE DATABASE statement creates only a directory under the MySQL data directory and the `db.opt` file. Rules for allowable database names are given in Section 9.2, “Database, Table, Index, Column, and Alias Names”.

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of SHOW DATABASES.

You can also use the `mysqladmin` program to create databases. See Section 8.8, “`mysqladmin` — Client for Administering a MySQL Server”.

## 13.1.4. CREATE INDEX Syntax

```
CREATE [UNIQUE|FULLTEXT|SPATIAL] INDEX index_name
      [USING index_type]
      ON tbl_name (index_col_name,...)
```

```
index_col_name:
  col_name [(length)] [ASC | DESC]
```

CREATE INDEX is mapped to an ALTER TABLE statement to create indexes. See Section 13.1.2, “ALTER TABLE Syntax”. For more information about how MySQL uses indexes, see Section 7.4.5, “How MySQL Uses Indexes”.

Normally, you create all indexes on a table at the time the table itself is created with CREATE TABLE. See Section 13.1.5, “CREATE TABLE Syntax”. CREATE INDEX enables you to add indexes to existing tables.

A column list of the form (`col1,col2,...`) creates a multiple-column index. Index values are formed by concatenating the values of the given columns.

For CHAR, VARCHAR, BINARY, and VARBINARY columns, indexes can be created that use only part of a column, using `col_name(length)` syntax to specify an index prefix length. Index entries consist of the first *length* characters of each column value for CHAR and VARCHAR columns, and the first *length* bytes of each column value for BINARY and VARBINARY columns. BLOB and TEXT columns also can be indexed, but a prefix length *must* be given.

The statement shown here creates an index using the first 10 characters of the name column:

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, this index should not be much slower than an index created from the entire name column. Also, using partial columns for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up INSERT operations.

Prefixes can be up to 1000 bytes long (767 bytes for InnoDB tables). Note that prefix limits are measured in bytes, whereas the prefix length in CREATE INDEX statements is interpreted as number of characters for non-binary data types (CHAR, VARCHAR, TEXT). Take this into account when specifying a prefix length for a column that uses a multi-byte character set.

In MySQL 5.0:

- You can add an index on a column that can have NULL values only if you are using the MyISAM, InnoDB, BDB, or MEMORY storage engine.
- You can add an index on a BLOB or TEXT column only if you are using the MyISAM, BDB, or InnoDB storage engine.

An *index\_col\_name* specification can end with ASC or DESC. These keywords are allowed for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

Some storage engines allow you to specify an index type when creating an index. The syntax for the *index\_type* specifier is USING *type\_name*. The allowable *type\_name* values supported by different storage engines are shown in the following table. Where multiple index types are listed, the first one is the default when no *index\_type* specifier is given.

Storage Engine	Allowable Index Types
MyISAM	BTREE
InnoDB	BTREE
MEMORY/HEAP	HASH, BTREE

Examples:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;  
CREATE INDEX id_index USING BTREE ON lookup (id);
```

TYPE *type\_name* can be used as a synonym for USING *type\_name* to specify an index type. However, USING is the preferred form. In addition, the index name that precedes the index type in the index specification syntax is not optional with TYPE: Unlike USING, TYPE is not a reserved word and is interpreted as the index name if no name is given.

If you specify an index type that is not legal for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

FULLTEXT indexes are supported only for MyISAM tables and can include only CHAR, VARCHAR, and TEXT columns. See Section 12.7, “Full-Text Search Functions”.

SPATIAL indexes are supported only for MyISAM tables and can include only spatial columns that are defined as NOT NULL. Chapter 16, *Spatial Extensions*, describes the spatial data types.

## 13.1.5. CREATE TABLE Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name  
    (create_definition,...)  
    [table_options]
```

Or:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name  
    [(create_definition,...)]  
    [table_options] select_statement
```

Or:

```

CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    { LIKE old_tbl_name | (LIKE old_tbl_name) }

create_definition:
    column_definition
    | [CONSTRAINT [symbol]] PRIMARY KEY [index_type] (index_col_name,...)
    | KEY [index_name] [index_type] (index_col_name,...)
    | INDEX [index_name] [index_type] (index_col_name,...)
    | [CONSTRAINT [symbol]] UNIQUE [INDEX]
      [index_name] [index_type] (index_col_name,...)
    | {FULLTEXT|SPATIAL} [INDEX] [index_name] (index_col_name,...)
    | [CONSTRAINT [symbol]] FOREIGN KEY
      [index_name] (index_col_name,...) [reference_definition]
    | CHECK (expr)

column_definition:
    col_name type [NOT NULL | NULL] [DEFAULT default_value]
      [AUTO_INCREMENT] [UNIQUE [KEY] | [PRIMARY] KEY]
      [COMMENT 'string'] [reference_definition]

type:
    TINYINT[(length)] [UNSIGNED] [ZEROFILL]
    SMALLINT[(length)] [UNSIGNED] [ZEROFILL]
    MEDIUMINT[(length)] [UNSIGNED] [ZEROFILL]
    INT[(length)] [UNSIGNED] [ZEROFILL]
    INTEGER[(length)] [UNSIGNED] [ZEROFILL]
    BIGINT[(length)] [UNSIGNED] [ZEROFILL]
    REAL[(length,decimals)] [UNSIGNED] [ZEROFILL]
    DOUBLE[(length,decimals)] [UNSIGNED] [ZEROFILL]
    FLOAT[(length,decimals)] [UNSIGNED] [ZEROFILL]
    DECIMAL(length,decimals) [UNSIGNED] [ZEROFILL]
    NUMERIC(length,decimals) [UNSIGNED] [ZEROFILL]
    DATE
    TIME
    TIMESTAMP
    DATETIME
    YEAR
    CHAR(length) [BINARY | ASCII | UNICODE]
    VARCHAR(length) [BINARY]
    BINARY(length)
    VARBINARY(length)
    TINYBLOB
    BLOB
    MEDIUMBLOB
    LONGBLOB
    TINYTEXT [BINARY]
    TEXT [BINARY]
    MEDIUMTEXT [BINARY]
    LONGTEXT [BINARY]
    ENUM(value1,value2,value3,...)
    SET(value1,value2,value3,...)
    spatial_type

index_col_name:
    col_name [(length)] [ASC | DESC]

reference_definition:
    REFERENCES tbl_name [(index_col_name,...)]
      [MATCH FULL | MATCH PARTIAL | MATCH SIMPLE]
      [ON DELETE reference_option]
      [ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION

table_options: table_option [table_option] ...

table_option:
    {ENGINE|TYPE} [=] engine_name

```

```

AUTO_INCREMENT [=] value
AVG_ROW_LENGTH [=] value
[DEFAULT] CHARACTER SET charset_name [COLLATE collation_name]
CHECKSUM [=] {0 | 1}
COMMENT [=] 'string'
CONNECTION [=] 'connect_string'
MAX_ROWS [=] value
MIN_ROWS [=] value
PACK_KEYS [=] {0 | 1 | DEFAULT}
PASSWORD [=] 'string'
DELAY_KEY_WRITE [=] {0 | 1}
ROW_FORMAT [=] {DEFAULT | DYNAMIC | FIXED | COMPRESSED | REDUNDANT | COMPACT}
UNION [=] (tbl_name[,tbl_name]...)
INSERT_METHOD [=] { NO | FIRST | LAST }
DATA DIRECTORY [=] 'absolute path to directory'
INDEX DIRECTORY [=] 'absolute path to directory'

```

```

select_statement:
    [IGNORE | REPLACE] [AS] SELECT ... (Some legal select statement)

```

CREATE TABLE creates a table with the given name. You must have the CREATE privilege for the table.

Rules for allowable table names are given in Section 9.2, “Database, Table, Index, Column, and Alias Names”. By default, the table is created in the default database. An error occurs if the table exists, if there is no default database, or if the database does not exist.

The table name can be specified as *db\_name.tbl\_name* to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write ``mydb`.`mytbl``, not ``mydb.mytbl``.

You can use the TEMPORARY keyword when creating a table. A TEMPORARY table is visible only to the current connection, and is dropped automatically when the connection is closed. This means that two different connections can use the same temporary table name without conflicting with each other or with an existing non-TEMPORARY table of the same name. (The existing table is hidden until the temporary table is dropped.) To create temporary tables, you must have the CREATE TEMPORARY TABLES privilege.

The keywords IF NOT EXISTS prevent an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the CREATE TABLE statement. *Note:* If you use IF NOT EXISTS in a CREATE TABLE ... SELECT statement, any rows selected by the SELECT part are inserted regardless of whether the table already exists.

MySQL represents each table by an `.frm` table format (definition) file in the database directory. The storage engine for the table might create other files as well. In the case of MyISAM tables, the storage engine creates data and index files. Thus, for each MyISAM table *tbl\_name*, there are three disk files:

File	Purpose
<i>tbl_name</i> .frm	Table format (definition) file
<i>tbl_name</i> .MYD	Data file
<i>tbl_name</i> .MYI	Index file

Chapter 14, *Storage Engines and Table Types*, describes what files each storage engine creates to represent tables.

*type* represents the data type is a column definition. *spatial\_type* represents a spatial data type. For general information on the properties of data types other than the spatial types, see Chapter 11, *Data Types*. For information about spatial data types, see Chapter 16, *Spatial Extensions*.

- If neither `NULL` nor `NOT NULL` is specified, the column is treated as though `NULL` had been specified.
- An integer column can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

To retrieve an `AUTO_INCREMENT` value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 12.9.3, “Information Functions”, and Section 22.2.3.36, “`mysql_insert_id()`”.

If the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled, you can store `0` in `AUTO_INCREMENT` columns as `0` without generating a new sequence value. See Section 5.2.5, “The Server SQL Mode”.

**Note:** There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains `0`.

For MyISAM and BDB tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. See Section 3.6.9, “Using `AUTO_INCREMENT`”.

To make MySQL compatible with some ODBC applications, you can find the `AUTO_INCREMENT` value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

- The attribute `SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.
- Character data types (`CHAR`, `VARCHAR`, `TEXT`) can include `CHARACTER SET` and `COLLATE` attributes to specify the character set and collation for the column. For details, see Chapter 10, *Character Set Support*. `CHARSET` is a synonym for `CHARACTER SET`. Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 5.0 interprets length specifications in character column definitions in characters. (Versions before MySQL 4.1 interpreted them in bytes.)

- The `DEFAULT` clause specifies a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that you can specify `CURRENT_TIMESTAMP` as the default for a `TIMESTAMP` column. See Section 11.3.1.1, “`TIMESTAMP` Properties as of MySQL 4.1”.

If a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as described in Section 11.1.4, “Data Type Default Values”.

`BLOB` and `TEXT` columns cannot be assigned a default value.

- A comment for a column can be specified with the `COMMENT` option. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements.
- `KEY` is normally a synonym for `INDEX`. The key attribute `PRIMARY KEY` can also be specified as just `KEY` when given in a column definition. This was implemented for compatibility with other database systems.
- A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error

occurs if you try to add a new row with a key that matches an existing row. The exception to this is that if a column in the index is allowed to contain NULL values, it can contain multiple NULL values. This exception does not apply to BDB tables, for which a column with a UNIQUE index allows only a single NULL.

- A PRIMARY KEY is a unique index where all key columns must be defined as NOT NULL. If they are not explicitly declared as NOT NULL, MySQL declares them so implicitly (and silently). A table can have only one PRIMARY KEY. If you do not have a PRIMARY KEY and an application asks for the PRIMARY KEY in your tables, MySQL returns the first UNIQUE index that has no NULL columns as the PRIMARY KEY.

In InnoDB tables, having a long PRIMARY KEY wastes a lot of space. (See Section 14.2.13, “InnoDB Table and Index Structures”.)

- In the created table, a PRIMARY KEY is placed first, followed by all UNIQUE indexes, and then the non-unique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated UNIQUE keys.
- A PRIMARY KEY can be a multiple-column index. However, you cannot create a multiple-column index using the PRIMARY KEY key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate PRIMARY KEY(*index\_col\_name*, ...) clause.
- If a PRIMARY KEY or UNIQUE index consists of only one column that has an integer type, you can also refer to the column as *\_rowid* in SELECT statements.
- In MySQL, the name of a PRIMARY KEY is PRIMARY. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (*\_2*, *\_3*, ...) to make it unique. You can see index names for a table using SHOW INDEX FROM *tbl\_name*. See Section 13.5.4.13, “SHOW INDEX Syntax”.
- Some storage engines allow you to specify an index type when creating an index. The syntax for the *index\_type* specifier is USING *type\_name*.

Example:

```
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
  ENGINE = MEMORY;
```

For details about USING, see Section 13.1.4, “CREATE INDEX Syntax”.

For more information about how MySQL uses indexes, see Section 7.4.5, “How MySQL Uses Indexes”.

- In MySQL 5.0, only the MyISAM, InnoDB, BDB, and MEMORY storage engines support indexes on columns that can have NULL values. In other cases, you must declare indexed columns as NOT NULL or an error results.
- With *col\_name(length)* syntax in an index specification, you can create an index that uses only part of a column. Index entries consist of the first *length* characters of each column value for CHAR and VARCHAR columns, and the first *length* bytes of each column value for BINARY and VARBINARY columns. Indexing only a prefix of column values like this can make the index file much smaller. See Section 7.4.3, “Column Indexes”.

The MyISAM, BDB, and InnoDB storage engines support indexing on BLOB and TEXT columns. When indexing a BLOB or TEXT column, you *must* specify a prefix length for the index. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for InnoDB tables). Note that prefix limits are

measured in bytes, whereas the prefix length in `CREATE TABLE` statements is interpreted as number of characters for non-binary data types (`CHAR`, `VARCHAR`, `TEXT`). Take this into account when specifying a prefix length for a column that uses a multi-byte character set.

- An *index\_col\_name* specification can end with `ASC` or `DESC`. These keywords are allowed for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.
- When you use `ORDER BY` or `GROUP BY` on a `TEXT` or `BLOB` column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable. See Section 11.4.3, “The `BLOB` and `TEXT` Types”.
- You can create special `FULLTEXT` indexes, which are used for full-text searches. Only the `MyISAM` storage engine supports `FULLTEXT` indexes. They can be created only from `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; partial indexing is not supported and any prefix length is ignored if specified. See Section 12.7, “Full-Text Search Functions”, for details of operation.
- You can create `SPATIAL` indexes on spatial data types. Spatial types are supported only for `MyISAM` tables and indexed columns must be declared as `NOT NULL`. See Chapter 16, *Spatial Extensions*.
- `InnoDB` tables support checking of foreign key constraints. See Section 14.2, “The `InnoDB` Storage Engine”. Note that the `FOREIGN KEY` syntax in `InnoDB` is more restrictive than the syntax presented for the `CREATE TABLE` statement at the beginning of this section: The columns of the referenced table must always be explicitly named. `InnoDB` supports both `ON DELETE` and `ON UPDATE` actions on foreign keys. For the precise syntax, see Section 14.2.6.4, “`FOREIGN KEY` Constraints”.

For other storage engines, `MySQL Server` parses and ignores the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements. The `CHECK` clause is parsed but ignored by all storage engines. See Section 1.9.5.5, “Foreign Keys”.

- For `MyISAM` tables, each `NULL` column takes one bit extra, rounded up to the nearest byte. The maximum row length in bytes can be calculated as follows:

$$\begin{aligned} \text{row length} = & 1 \\ & + (\text{sum of column lengths}) \\ & + (\text{number of NULL columns} + \text{delete\_flag} + 7) / 8 \\ & + (\text{number of variable-length columns}) \end{aligned}$$

*delete\_flag* is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. *delete\_flag* is 0 for dynamic tables because the flag is stored in the dynamic row header.

These calculations do not apply for `InnoDB` tables, for which storage size is no different for `NULL` columns than for `NOT NULL` columns.

The `ENGINE` table option specifies the storage engine for the table. `TYPE` is a synonym, but `ENGINE` is the preferred option name.

The `ENGINE` table option takes the storage engine names shown in the following table.

Storage Engine	Description
ARCHIVE	The archiving storage engine. See Section 14.8, “The <code>ARCHIVE</code> Storage Engine”.
BDB	Transaction-safe tables with page locking. Also known as <code>BerkeleyDB</code> . See Section 14.5, “The <code>BDB (BerkeleyDB)</code> Storage Engine”.
CSV	Tables that store rows in comma-separated values format. See Section 14.9, “The <code>CSV</code> Storage Engine”.

EXAMPLE	An example engine. See Section 14.6, “The EXAMPLE Storage Engine”.
FEDERATED	Storage engine that accesses remote tables. See Section 14.7, “The FEDERATED Storage Engine”.
HEAP	This is a synonym for MEMORY.
ISAM ( <i>OBSOLETE</i> )	Not available in MySQL 5.0. If you are upgrading to MySQL 5.0 from a previous version, you should convert any existing ISAM tables to MyISAM <i>before</i> performing the upgrade.
InnoDB	Transaction-safe tables with row locking and foreign keys. See Section 14.2, “The InnoDB Storage Engine”.
MEMORY	The data for this storage engine is stored only in memory. See Section 14.4, “The MEMORY (HEAP) Storage Engine”.
MERGE	A collection of MyISAM tables used as one table. Also known as MRG_MyISAM. See Section 14.3, “The MERGE Storage Engine”.
MyISAM	The binary portable storage engine that is the default storage engine used by MySQL. See Section 14.1, “The MyISAM Storage Engine”.
NDBCLUSTER	Clustered, fault-tolerant, memory-based tables. Also known as NDB. See Chapter 15, <i>MySQL Cluster</i> .

If a storage engine is specified that is not available, MySQL uses the default engine instead. Normally, this is MyISAM. For example, if a table definition includes the ENGINE=BDB option but the MySQL server does not support BDB tables, the table is created as a MyISAM table. This makes it possible to have a replication setup where you have transactional tables on the master but tables created on the slave are non-transactional (to get more speed). In MySQL 5.0, a warning occurs if the storage engine specification is not honored.

The other table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use ALTER TABLE to convert the table to use a different storage engine.

- AUTO\_INCREMENT

The initial AUTO\_INCREMENT value for the table. In MySQL 5.0, this works for MyISAM and MEMORY tables. It is also supported for InnoDB as of MySQL 5.0.3. To set the first auto-increment value for engines that do not support the AUTO\_INCREMENT table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the AUTO\_INCREMENT table option in CREATE TABLE statements, you can also use ALTER TABLE *tbl\_name* AUTO\_INCREMENT = *N* to reset the AUTO\_INCREMENT value.

- AVG\_ROW\_LENGTH

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a MyISAM table, MySQL uses the product of the MAX\_ROWS and AVG\_ROW\_LENGTH options to decide how big the resulting table is. If you don't specify either option, the maximum size for a table is 65,536TB of data (4GB before MySQL 5.0.6). (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the `myisam_data_pointer_size` system variable, which was added in MySQL 4.1.2. (See Section 5.2.2, “Server System Variables”.) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you

can increase the default pointer size by setting this variable.

- [DEFAULT] CHARACTER SET

Specify a default character set for the table. CHARSET is a synonym for CHARACTER SET.

- COLLATE

Specify a default collation for the table.

- CHECKSUM

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The CHECKSUM TABLE statement reports the checksum. (MyISAM only.)

- COMMENT

A comment for the table, up to 60 characters long.

- CONNECTION

The connection string for a FEDERATED table. This option is available as of MySQL 5.0.13; before that, use a COMMENT option for the connection string.

- MAX\_ROWS

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather an indicator that the table must be able to store at least this many rows.

- MIN\_ROWS

The minimum number of rows you plan to store in the table.

- PACK\_KEYS

PACK\_KEYS takes effect only with MyISAM tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to DEFAULT tells the storage engine to pack only long CHAR or VARCHAR columns.

If you do not use PACK\_KEYS, the default is to pack strings, but not numbers. If you use PACK\_KEYS=1, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have NULL values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is NULL.)

- PASSWORD

Encrypt the .frm file with a password. This option does nothing in the standard MySQL ver-

sion.

- DELAY\_KEY\_WRITE

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in Section 5.2.2, “Server System Variables”. (MyISAM only.)

- ROW\_FORMAT

Defines how the rows should be stored. For MyISAM tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See Section 14.1.3, “MyISAM Table Storage Formats”.

Starting with MySQL 5.0.3, for InnoDB tables, rows are stored in compact format (`ROW_FORMAT=COMPACT`) by default. The non-compact format used in older versions of MySQL can still be requested by specifying `ROW_FORMAT=REDUNDANT`.

- RAID\_TYPE

RAID support has been removed as of MySQL 5.0. For information on RAID, see <http://dev.mysql.com/doc/refman/4.1/en/create-table.html>.

- UNION

UNION is used when you want to access a collection of identical MyISAM tables as one. This works only with MERGE tables. See Section 14.3, “The MERGE Storage Engine”.

You must have `SELECT`, `UPDATE`, and `DELETE` privileges for the tables you map to a MERGE table. (*Note:* Formerly, all tables used had to be in the same database as the MERGE table itself. This restriction no longer applies.)

- INSERT\_METHOD

If you want to insert data into a MERGE table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for MERGE tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See Section 14.3, “The MERGE Storage Engine”.

- DATA DIRECTORY, INDEX DIRECTORY

By using `DATA DIRECTORY='directory'` or `INDEX DIRECTORY='directory'` you can specify where the MyISAM storage engine should put a table's data file and index file. The directory must be the full pathname to the directory, not a relative path.

These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See Section 7.6.1.2, “Using Symbolic Links for Tables on Unix”, for more complete information.

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,  
-> PRIMARY KEY (a), KEY(b))  
-> ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a MyISAM table with three columns, `a`, `b`, and `c`. Notice that the columns from the SE-

LECT statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
```

```
+----+
|  n  |
+----+
|  1  |
+----+
```

```
mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
```

```
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0
```

```
mysql> SELECT * FROM bar;
```

```
+-----+-----+
|  m    |  n  |
+-----+-----+
| NULL  |  1  |
+-----+-----+
1 row in set (0.00 sec)
```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns.

When creating a table with `CREATE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
  SELECT artist.name, COUNT(work.artist_id) AS number_of_works
  FROM artist LEFT JOIN work ON artist.id = work.artist_id
  GROUP BY artist.id;
```

You can also explicitly specify the data type for a generated column:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

Use `LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, new rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error.

To ensure that the binary log can be used to re-create the original tables, MySQL does not allow concurrent inserts during `CREATE TABLE . . . SELECT`.

### 13.1.5.1. Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a `CREATE TABLE` or `ALTER TABLE` statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

Possible data type changes are given in the following list. These occur prior to MySQL 5.0.3. As of 5.0.3, an error occurs if a column cannot be created using the specified data type.

- `VARCHAR` columns with a length less than four are changed to `CHAR`.
- If any column in a table has a variable length, the entire row becomes variable-length as a result. Therefore, if a table contains any variable-length columns (`VARCHAR`, `TEXT`, or `BLOB`), all `CHAR` columns longer than three characters are changed to `VARCHAR` columns. This does not affect how you use the columns in any way; in MySQL, `VARCHAR` is just a different way to store characters. MySQL performs this conversion because it saves space and makes table operations faster. See Chapter 14, *Storage Engines and Table Types*.
- Before MySQL 5.0.3, a `CHAR` or `VARCHAR` column with a length specification greater than 255 is converted to the smallest `TEXT` type that can hold values of the given length. For example, `VARCHAR(500)` is converted to `TEXT`, and `VARCHAR(200000)` is converted to `MEDIUMTEXT`. Note that this conversion results in a change in behavior with regard to treatment of trailing spaces.

Similar conversions occur for `BINARY` and `VARBINARY`, except that they are converted to a `BLOB` type.

Starting with MySQL 5.0.3, a `CHAR` or `BINARY` column with a length specification greater than 255 is not silently converted. Instead, an error occurs. From MySQL 5.0.6 on, silent conversion of `VARCHAR` and `VARBINARY` columns with a length specification greater than 65,535 does not occur if strict SQL mode is enabled. Instead, an error occurs.

- For a specification of `DECIMAL(M, D)`, if  $M$  is not larger than  $D$ , it is adjusted upward. For example, `DECIMAL(10, 10)` becomes `DECIMAL(11, 10)`.

Other silent column specification changes include changes to attribute or index specifications:

- `TIMESTAMP` display sizes are discarded. Note that `TIMESTAMP` columns have changed considerably in recent versions of MySQL prior to 5.0; for a description of these changes, see the MySQL 3.23, 4.0, 4.1 Reference Manual.
- Columns that are part of a `PRIMARY KEY` are made `NOT NULL` even if not declared that way.
- Trailing spaces are automatically deleted from `ENUM` and `SET` member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See Section 11.7, “Using Data Types from Other Database Engines”.
- If you include a `USING` clause to specify an index type that is not legal for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.

To see whether MySQL used a data type other than the one you specified, issue a `DESCRIBE` or `SHOW CREATE TABLE` statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using `myisampack`. See Section 14.1.3.3, “Compressed Table Characteristics”.

## 13.1.6. DROP DATABASE Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

`DROP DATABASE` drops all tables in the database and deletes the database. Be *very* careful with this statement! To use `DROP DATABASE`, you need the `DROP` privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE` as of MySQL 5.0.2.

`IF EXISTS` is used to prevent an error from occurring if the database does not exist.

If you use `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.

`DROP DATABASE` returns the number of tables that were removed. This corresponds to the number of `.frm` files removed.

The `DROP DATABASE` statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with these extensions:

<code>.BAK</code>	<code>.DAT</code>	<code>.HSH</code>
<code>.MRG</code>	<code>.MYD</code>	<code>.ISD</code>
<code>.MYI</code>	<code>.db</code>	<code>.frm</code>

- All subdirectories with names that consist of two hex digits `00-ff`. These are subdirectories used for RAID tables. (These directories are not removed as of MySQL 5.0, when support for RAID tables was removed. You should convert any existing RAID tables and remove these directories manually before upgrading to MySQL 5.0. See Section 2.11.2, “Upgrading from MySQL 4.1 to 5.0”.)
- The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

You can also drop databases with `mysqladmin`. See Section 8.8, “`mysqladmin` — Client for Administering a MySQL Server”.

## 13.1.7. DROP INDEX Syntax

```
DROP INDEX index_name ON tbl_name
```

`DROP INDEX` drops the index named *index\_name* from the table *tbl\_name*. This statement is mapped to an `ALTER TABLE` statement to drop the index. See Section 13.1.2, “`ALTER TABLE` Syntax”.

## 13.1.8. DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
    tbl_name [, tbl_name] ...
    [RESTRICT | CASCADE]
```

DROP TABLE removes one or more tables. You must have the DROP privilege for each table. All table data and the table definition are *removed*, so *be careful* with this statement!

Use IF EXISTS to prevent an error from occurring for tables that do not exist. A NOTE is generated for each non-existent table when using IF EXISTS. See Section 13.5.4.25, “SHOW WARNINGS Syntax”.

RESTRICT and CASCADE are allowed to make porting easier. For the moment, they do nothing.

**Note:** DROP TABLE automatically commits the current active transaction, unless you use the TEMPORARY keyword.

The TEMPORARY keyword has the following effects:

- The statement drops only TEMPORARY tables.
- The statement does not end an ongoing transaction.
- No access rights are checked. (A TEMPORARY table is visible only to the client that created it, so no check is necessary.)

Using TEMPORARY is a good way to ensure that you do not accidentally drop a non-TEMPORARY table.

## 13.1.9. RENAME TABLE Syntax

```
RENAME TABLE tbl_name TO new_tbl_name
    [, tbl_name2 TO new_tbl_name2] ...
```

This statement renames one or more tables.

The rename operation is done atomically, which means that no other thread can access any of the tables while the rename is running. For example, if you have an existing table `old_table`, you can create another table `new_table` that has the same structure but is empty, and then replace the existing table with the empty one as follows (assuming that `backup_table` does not already exist):

```
CREATE TABLE new_table (...);
RENAME TABLE old_table TO backup_table, new_table TO old_table;
```

If the statement renames more than one table, renaming operations are done from left to right. If you want to swap two table names, you can do so like this (assuming that `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
             new_table TO old_table,
             tmp_table TO new_table;
```

As long as two databases are on the same filesystem, you can use RENAME TABLE to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

As of MySQL 5.0.14, RENAME TABLE also works for views, as long as you do not try to rename a

view into a different database.

When you execute `RENAME`, you cannot have any locked tables or active transactions. You must also have the `ALTER` and `DROP` privileges on the original table, and the `CREATE` and `INSERT` privileges on the new table.

If MySQL encounters any errors in a multiple-table rename, it does a reverse rename for all renamed tables to return everything to its original state.

## 13.2. Data Manipulation Statements

### 13.2.1. DELETE Syntax

Single-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
      [WHERE where_condition]
      [ORDER BY ...]
      [LIMIT row_count]
```

Multiple-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
      tbl_name[.*] [, tbl_name[.*]] ...
FROM table_references
      [WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
      FROM tbl_name[.*] [, tbl_name[.*]] ...
      USING table_references
      [WHERE where_condition]
```

For the single-table syntax, the `DELETE` statement deletes rows from *tbl\_name* and returns the number of rows deleted. The `WHERE` clause, if given, specifies the conditions that identify which rows to delete. With no `WHERE` clause, all rows are deleted. If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted.

For the multiple-table syntax, `DELETE` deletes from each *tbl\_name* the rows that satisfy the conditions. In this case, `ORDER BY` and `LIMIT` cannot be used.

*where\_condition* is an expression that evaluates to true for each row to be deleted. It is specified as described in Section 13.2.7, “SELECT Syntax”.

As stated, a `DELETE` statement with no `WHERE` clause deletes all rows. A faster way to do this, when you do not want to know the number of deleted rows, is to use `TRUNCATE TABLE`. See Section 13.2.9, “TRUNCATE Syntax”.

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is reused later for a BDB table, but not for a MyISAM or InnoDB table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in `AUTOCOMMIT` mode, the sequence starts over for all storage engines except InnoDB and MyISAM. There are some exceptions to this behavior for InnoDB tables, as discussed in Section 14.2.6.3, “How AUTO\_INCREMENT Columns Work in InnoDB”.

For MyISAM and BDB tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for MyISAM tables. See Section 3.6.9, “Using AUTO\_INCREMENT”.

The `DELETE` statement supports the following modifiers:

- If you specify `LOW_PRIORITY`, the server delays execution of the `DELETE` until no other clients are reading from the table.
- For `MyISAM` tables, if you use the `QUICK` keyword, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The `IGNORE` keyword causes MySQL to ignore all errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `OPTION` are returned as warnings.

The speed of delete operations may also be affected by factors discussed in Section 7.2.18, “Speed of `DELETE` Statements”.

In `MyISAM` tables, deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. To reclaim unused space and reduce file sizes, use the `OPTIMIZE TABLE` statement or the `myisamchk` utility to reorganize tables. `OPTIMIZE TABLE` is easier, but `myisamchk` is faster. See Section 13.5.2.5, “`OPTIMIZE TABLE` Syntax”, and Section 8.3, “`myisamchk` — `MyISAM` Table-Maintenance Utility”.

The `QUICK` modifier affects whether index leaves are merged for delete operations. `DELETE QUICK` is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

`DELETE QUICK` is not useful when deleted values lead to undef-filled index blocks spanning a range of index values for which new inserts occur again. In this case, use of `QUICK` can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed `AUTO_INCREMENT` column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using `DELETE QUICK`.

In this scenario, the index blocks associated with the deleted index values become undef-filled but are not merged with other index blocks due to the use of `QUICK`. They remain undef-filled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain undef-filled even if you later use `DELETE` without `QUICK`, unless some of the deleted index values happen to lie in index blocks within or adjacent to the undef-filled blocks. To reclaim unused index space under these circumstances, use `OPTIMIZE TABLE`.

If you are going to delete many rows from a table, it might be faster to use `DELETE QUICK` followed by `OPTIMIZE TABLE`. This rebuilds the index rather than performing many index block merge operations.

The MySQL-specific `LIMIT row_count` option to `DELETE` tells the server the maximum number of rows to be deleted before control is returned to the client. This can be used to ensure that a given `DELETE` statement does not take too much time. You can simply repeat the `DELETE` statement until the number of affected rows is less than the `LIMIT` value.

If the `DELETE` statement includes an `ORDER BY` clause, the rows are deleted in the order specified by the clause. This is really useful only in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'  
ORDER BY timestamp_column LIMIT 1;
```

You can specify multiple tables in a `DELETE` statement to delete rows from one or more tables depending on the particular condition in the `WHERE` clause. However, you cannot use `ORDER BY` or `LIMIT` in a multiple-table `DELETE`. The *table\_references* clause lists the tables involved in the join. Its syntax is described in Section 13.2.7.1, “JOIN Syntax”.

For the first multiple-table syntax, only matching rows from the tables listed before the `FROM` clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the `FROM` clause (before the `USING` clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1, t2, t3 WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1, t2, t3 WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables `t1` and `t2`.

The preceding examples show inner joins that use the comma operator, but multiple-table `DELETE` statements can use any type of join allowed in `SELECT` statements, such as `LEFT JOIN`.

The syntax allows `.*` after the table names for compatibility with Access.

If you use a multiple-table `DELETE` statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the `ON DELETE` capabilities that InnoDB provides to cause the other tables to be modified accordingly.

**Note:** If you provide an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Cross-database deletes are supported for multiple-table deletes, but in this case, you must refer to the tables without using aliases. For example:

```
DELETE test1.tmp1, test2.tmp2 FROM test1.tmp1, test2.tmp2 WHERE ...
```

Currently, you cannot delete from a table and select from the same table in a subquery.

## 13.2.2. DO Syntax

```
DO expr [, expr] ...
```

`DO` executes the expressions but does not return any results. In most respects, `DO` is shorthand for `SELECT expr, ...`, but has the advantage that it is slightly faster when you do not care about the result.

`DO` is useful primarily with functions that have side effects, such as `RELEASE_LOCK()`.

## 13.2.3. HANDLER Syntax

```
HANDLER tbl_name OPEN [ AS alias ]  
HANDLER tbl_name READ index_name { = | >= | <= | < } (value1,value2,...)  
    [ WHERE where_condition ] [LIMIT ... ]  
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }  
    [ WHERE where_condition ] [LIMIT ... ]  
HANDLER tbl_name READ { FIRST | NEXT }
```

```
[ WHERE where_condition ] [ LIMIT ... ]  
HANDLER tbl_name CLOSE
```

The HANDLER statement provides direct access to table storage engine interfaces. It is available for MyISAM and InnoDB tables.

The HANDLER ... OPEN statement opens a table, making it accessible via subsequent HANDLER ... READ statements. This table object is not shared by other threads and is not closed until the thread calls HANDLER ... CLOSE or the thread terminates. If you open the table using an alias, further references to the open table with other HANDLER statements must use the alias rather than the table name.

The first HANDLER ... READ syntax fetches a row where the index specified satisfies the given values and the WHERE condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index *my\_idx* includes three columns named *col\_a*, *col\_b*, and *col\_c*, in that order. The HANDLER statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...  
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...  
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the HANDLER interface to refer to a table's PRIMARY KEY, use the quoted identifier ``PRIMARY``:

```
HANDLER tbl_name READ `PRIMARY` ...
```

The second HANDLER ... READ syntax fetches a row from the table in index order that matches the WHERE condition.

The third HANDLER ... READ syntax fetches a row from the table in natural row order that matches the WHERE condition. It is faster than HANDLER *tbl\_name* READ *index\_name* when a full table scan is desired. Natural row order is the order in which rows are stored in a MyISAM table data file. This statement works for InnoDB tables as well, but there is no such concept because there is no separate data file.

Without a LIMIT clause, all forms of HANDLER ... READ fetch a single row if one is available. To return a specific number of rows, include a LIMIT clause. It has the same syntax as for the SELECT statement. See Section 13.2.7, "SELECT Syntax".

```
HANDLER ... CLOSE closes a table that was opened with HANDLER ... OPEN.
```

HANDLER is a somewhat low-level statement. For example, it does not provide consistency. That is, HANDLER ... OPEN does *not* take a snapshot of the table, and does *not* lock the table. This means that after a HANDLER ... OPEN statement is issued, table data can be modified (by the current thread or other threads) and these modifications might be only partially visible to HANDLER ... NEXT or HANDLER ... PREV scans.

There are several reasons to use the HANDLER interface instead of normal SELECT statements:

- HANDLER is faster than SELECT:
  - A designated storage engine handler object is allocated for the HANDLER ... OPEN. The object is reused for subsequent HANDLER statements for that table; it need not be reinitialized for each one.
  - There is less parsing involved.
  - There is no optimizer or query-checking overhead.

- The table does not have to be locked between two handler requests.
- The handler interface does not have to provide a consistent look of the data (for example, dirty reads are allowed), so the storage engine can use optimizations that `SELECT` does not normally allow.
- For applications that use a low-level ISAM-like interface, `HANDLER` makes it much easier to port them to MySQL.
- `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

## 13.2.4. INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name [(col_name,...)]
  VALUES ({expr | DEFAULT},...), (...),...
  [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  SET col_name={expr | DEFAULT}, ...
  [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name [(col_name,...)]
  SELECT ...
  [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

`INSERT` inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT ... SELECT` is discussed further in Section 13.2.4.1, “`INSERT ... SELECT` Syntax”.

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new rows are used to replace the old rows rather than being discarded. See Section 13.2.6, “`REPLACE` Syntax”.

*tbl\_name* is the table into which rows should be inserted. The columns for which the statement provides values can be specified as follows:

- You can provide a comma-separated list of column names following the table name. In this case, a value for each named column must be provided by the `VALUES` list or the `SELECT` statement.
- If you do not specify a list of column names for `INSERT ... VALUES` or `INSERT ... SELECT`, values for every column in the table must be provided by the `VALUES` list or the `SELECT` statement. If you do not know the order of the columns in the table, use `DESCRIBE tbl_name` to find out.
- The `SET` clause indicates the column names explicitly.

Column values can be given in several ways:

- If you are not running in strict SQL mode, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in Section 11.1.4, “Data Type Default Values”. See also Section 1.9.6.2, “Constraints on Invalid Data”.

If you want an `INSERT` statement to generate an error unless you explicitly specify values for all columns that do not have a default value, you should use strict mode. See Section 5.2.5, “The Server SQL Mode”.

- Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you would have to write out the list of column names corresponding to each value in the `VALUES` list.

You can also use `DEFAULT(col_name)` as a more general form that can be used in expressions to produce a given column's default value.

- If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

In strict mode, an error occurs if any column doesn't have a default value. Otherwise, MySQL uses the implicit default value for any column that does not have an explicitly defined default.

- You can specify an expression `expr` to provide a column value. This might involve type conversion if the type of the expression does not match the type of the column, and conversion of a given value can result in different inserted values depending on the data type. For example, inserting the string `'1999.0e-2'` into an `INT`, `FLOAT`, `DECIMAL(10,6)`, or `YEAR` column results in the values 1999, 19.9921, 19.992100, and 1999 being inserted, respectively. The reason the value stored in the `INT` and `YEAR` columns is 1999 is that the string-to-integer conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the floating-point and fixed-point columns, the string-to-floating-point conversion considers the entire string a valid floating-point value.

An expression `expr` can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

One exception involves columns that contain `AUTO_INCREMENT` values. Because the `AUTO_INCREMENT` value is generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a 0.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of column values, each enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

The values list for each row must be enclosed within parentheses. The following statement is illegal because the number of values in the list does not match the number of column names:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

The rows-affected value for an INSERT can be obtained using the `mysql_affected_rows()` C API function. See Section 22.2.3.1, “`mysql_affected_rows()`”.

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: 100 Duplicates: 0 Warnings: 0
```

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be non-zero.) `Duplicates` indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting NULL into a column that has been declared NOT NULL. For multiple-row INSERT statements or INSERT INTO ... SELECT statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string ( ' ' ) for string types, and the “zero” value for date and time types. INSERT INTO ... SELECT statements are handled the same way as multiple-row inserts because the server does not examine the result set from the SELECT to see whether it returns a single row. (For a single-row INSERT, no warning occurs when NULL is inserted into a NOT NULL column. Instead, the statement fails with an error.)
- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.
- Assigning a value such as '10.34 a' to a numeric column. The trailing non-numeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.
- Inserting a string into a string column (CHAR, VARCHAR, TEXT, or BLOB) that exceeds the column's maximum length. The value is truncated to the column's maximum length.
- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See Section 22.2.3.34, “`mysql_info()`”.

If INSERT inserts a row into a table that has an AUTO\_INCREMENT column, you can find the value used for that column by using the SQL `LAST_INSERT_ID()` function. From within the C API, use the `mysql_insert_id()` function. However, you should note that the two functions do not always behave identically. The behavior of INSERT statements with respect to AUTO\_INCREMENT columns is discussed further in Section 12.9.3, “Information Functions”, and Section 22.2.3.36, “`mysql_insert_id()`”.

The INSERT statement supports the following modifiers:

- If you use the `DELAYED` keyword, the server puts the row or rows to be inserted into a buffer, and the client issuing the `INSERT DELAYED` statement can then continue immediately. If the table is in use, the server holds the rows. When the table is free, the server begins inserting rows, checking periodically to see whether there are any new read requests for the table. If there are, the delayed row queue is suspended until the table becomes free again. See Section 13.2.4.2, “INSERT DELAYED Syntax”.

`DELAYED` is ignored with `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE`.

- If you use the `LOW_PRIORITY` keyword, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time (or even forever) in a read-heavy environment. (This is in contrast to `INSERT DELAYED`, which lets the client continue at once. Note that `LOW_PRIORITY` should normally not be used with MyISAM tables because doing so disables concurrent inserts. See Section 7.3.3, “Concurrent Inserts”.)
- If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used.
- If you use the `IGNORE` keyword, errors that occur while executing the `INSERT` statement are treated as warnings instead. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row still is not inserted, but no error is issued. Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.
- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. See Section 13.2.4.3, “`INSERT ... ON DUPLICATE KEY UPDATE` Syntax”.

### 13.2.4.1. `INSERT ... SELECT` Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
      [INTO] tbl_name [(col_name,...)]
      SELECT ...
      [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for a `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.
- `DELAYED` is ignored with `INSERT ... SELECT`.
- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. (This was not possible in some older versions of MySQL.)
- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not allow concurrent inserts for `INSERT ... SELECT` statements.
- Currently, you cannot insert into a table and select from the same table in a subquery.

In the values part of `ON DUPLICATE KEY UPDATE`, you can refer to columns in other tables, as long as you do not use `GROUP BY` in the `SELECT` part. One side effect is that you must qualify non-unique column names in the values part.

## 13.2.4.2. INSERT DELAYED Syntax

INSERT DELAYED . . .

The DELAYED option for the INSERT statement is a MySQL extension to standard SQL that is very useful if you have clients that cannot or need not wait for the INSERT to complete. This is a common situation when you use MySQL for logging and you also periodically run SELECT and UPDATE statements that take a long time to complete.

When a client uses INSERT DELAYED, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

Another major benefit of using INSERT DELAYED is that inserts from many clients are bundled together and written in one block. This is much faster than performing many separate inserts.

Note that INSERT DELAYED is slower than a normal INSERT if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use INSERT DELAYED only when you are really sure that you need it.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate mysqld forcibly (for example, with kill -9) or if mysqld dies unexpectedly, *any queued rows that have not been written to disk are lost*.

There are some constraints on the use of DELAYED:

- INSERT DELAYED works only with MyISAM, MEMORY, and ARCHIVE tables. See Section 14.1, “The MyISAM Storage Engine”, Section 14.4, “The MEMORY (HEAP) Storage Engine”, and Section 14.8, “The ARCHIVE Storage Engine”.

For MyISAM tables, if there are no free blocks in the middle of the data file, concurrent SELECT and INSERT statements are supported. Under these circumstances, you very seldom need to use INSERT DELAYED with MyISAM.

- INSERT DELAYED should be used only for INSERT statements that specify value lists. The server ignores DELAYED for INSERT . . . SELECT or INSERT . . . ON DUPLICATE KEY UPDATE statements.
- Because the INSERT DELAYED statement returns immediately, before the rows are inserted, you cannot use LAST\_INSERT\_ID() to get the AUTO\_INCREMENT value that the statement might generate.
- DELAYED rows are not visible to SELECT statements until they actually have been inserted.
- DELAYED is ignored on slave replication servers because it could cause the slave to have different data than the master.

The following describes in detail what happens when you use the DELAYED option to INSERT or REPLACE. In this description, the “thread” is the thread that received an INSERT DELAYED statement and “handler” is the thread that handles all INSERT DELAYED statements for a particular table.

- When a thread executes a DELAYED statement for a table, a handler thread is created to process all DELAYED statements for the table, if no such handler already exists.
- The thread checks whether the handler has previously acquired a DELAYED lock; if not, it tells the handler thread to do so. The DELAYED lock can be obtained even if other threads have a READ or WRITE lock on the table. However, the handler waits for all ALTER TABLE locks or FLUSH TABLES statements to finish, to ensure that the table structure is up to date.

- The thread executes the `INSERT` statement, but instead of writing the row to the table, it puts a copy of the final row into a queue that is managed by the handler thread. Any syntax errors are noticed by the thread and reported to the client program.
- The client cannot obtain from the server the number of duplicate rows or the `AUTO_INCREMENT` value for the resulting row, because the `INSERT` returns before the insert operation has been completed. (If you use the C API, the `mysql_info()` function does not return anything meaningful, for the same reason.)
- The binary log is updated by the handler thread when the row is inserted into the table. In case of multiple-row inserts, the binary log is updated when the first row is inserted.
- Each time that `delayed_insert_limit` rows are written, the handler checks whether any `SELECT` statements are still pending. If so, it allows these to execute before continuing.
- When the handler has no more rows in its queue, the table is unlocked. If no new `INSERT DELAYED` statements are received within `delayed_insert_timeout` seconds, the handler terminates.
- If more than `delayed_queue_size` rows are pending in a specific handler queue, the thread requesting `INSERT DELAYED` waits until there is room in the queue. This is done to ensure that `mysqld` does not use all memory for the delayed memory queue.
- The handler thread shows up in the MySQL process list with `delayed_insert` in the Command column. It is killed if you execute a `FLUSH TABLES` statement or kill it with `KILL thread_id`. However, before exiting, it first stores all queued rows into the table. During this time it does not accept any new `INSERT` statements from other threads. If you execute an `INSERT DELAYED` statement after this, a new handler thread is created.

Note that this means that `INSERT DELAYED` statements have higher priority than normal `INSERT` statements if there is an `INSERT DELAYED` handler running. Other update statements have to wait until the `INSERT DELAYED` queue is empty, someone terminates the handler thread (with `KILL thread_id`), or someone executes a `FLUSH TABLES`.

- The following status variables provide information about `INSERT DELAYED` statements:

Status Variable	Meaning
<code>Delayed_insert_threads</code>	Number of handler threads
<code>Delayed_writes</code>	Number of rows written with <code>INSERT DELAYED</code>
<code>Not_flushed_delayed_rows</code>	Number of rows waiting to be written

You can view these variables by issuing a `SHOW STATUS` statement or by executing a `mysql-admin extended-status` command.

### 13.2.4.3. `INSERT ... ON DUPLICATE KEY UPDATE` Syntax

If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. For example, if column `a` is declared as `UNIQUE` and contains the value 1, the following two statements have identical effect:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;

UPDATE table SET c=c+1 WHERE a=1;
```

The rows-affected value is 1 if the row is inserted as a new record and 2 if an existing record is updated.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE table SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only *one* row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY` clause on tables with multiple unique indexes.

You can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the `INSERT ... UPDATE` statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of *col\_name* that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in `INSERT ... UPDATE` statements and returns `NULL` otherwise. Example:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO table (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

The `DELAYED` option is ignored when you use `ON DUPLICATE KEY UPDATE`.

## 13.2.5. LOAD DATA INFILE Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[FIELDS
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number LINES]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]
```

The `LOAD DATA INFILE` statement reads rows from a text file into a table at a very high speed. The filename must be given as a literal string.

`LOAD DATA INFILE` is the complement of `SELECT ... INTO OUTFILE`. (See Section 13.2.7, “`SELECT` Syntax”.) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA INFILE`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, see Section 7.2.16, “Speed of `INSERT` Statements”.

The character set indicated by the `character_set_database` system variable is used to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input.

Note that it is currently not possible to load data files that use the `ucs2` character set.

As of MySQL 5.0.19, the `character_set_filesystem` system variable controls the interpretation of the filename.

You can also load data files by using the `mysqlimport` utility; it operates by sending a `LOAD DATA INFILE` statement to the server. The `--local` option causes `mysqlimport` to read data files from the client host. You can specify the `--compress` option to get better performance over slow networks if the client and server support the compressed protocol. See Section 8.13, “`mysqlimport` — A Data Import Program”.

If you use `LOW_PRIORITY`, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table.

If you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. Using this option affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

The `LOCAL` keyword, if specified, is interpreted with respect to the client end of the connection:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full pathname to specify its exact location. If given as a relative pathname, the name is interpreted relative to the directory in which the client program was started.
- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:
  - If the filename is an absolute pathname, the server uses it as given.
  - If the filename is a relative pathname with one or more leading components, the server searches for the file relative to the server's data directory.
  - If a filename with no leading components is given, the server looks for the file in the database directory of the default database.

Note that, in the non-`LOCAL` case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database. For example, if `db1` is the default database, the following `LOAD DATA` statement reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Windows pathnames are specified using forward slashes rather than backslashes. If you do use backslashes, you must double them.

For security reasons, when reading text files located on the server, the files must either reside in the database directory or be readable by all. Also, to use `LOAD DATA INFILE` on server files, you must have the `FILE` privilege. See Section 5.8.3, “Privileges Provided by MySQL”.

Using `LOCAL` is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the `FILE` privilege to load local files.

`LOCAL` works only if your server and your client both have been enabled to allow it. For example, if `mysqld` was started with `--local-infile=0`, `LOCAL` does not work. See Section 5.7.4, “Security Issues with `LOAD DATA LOCAL`”.

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (here we load the listing of the `/` directory into a table):

```
mkfifo /mysql/db/x/x
chmod 666 /mysql/db/x/x
find / -ls > /mysql/db/x/x
mysql -e "LOAD DATA INFILE 'x' INTO TABLE x" x
```

The `REPLACE` and `IGNORE` keywords control handling of input rows that duplicate existing rows on unique key values:

- If you specify `REPLACE`, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See Section 13.2.6, “`REPLACE Syntax`”.
- If you specify `IGNORE`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, the behavior depends on whether the `LOCAL` keyword is specified. Without `LOCAL`, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With `LOCAL`, the default behavior is the same as if `IGNORE` is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

If you want to ignore foreign key constraints during the load operation, you can issue a `SET FOREIGN_KEY_CHECKS=0` statement before executing `LOAD DATA`.

If you use `LOAD DATA INFILE` on an empty `MyISAM` table, all non-unique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA INFILE` much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and using `ALTER TABLE ... ENABLE KEYS` to re-create the indexes after loading the file. See Section 7.2.16, “`Speed of INSERT Statements`”.

For both the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS` and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, [OPTIONALLY] `ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them.

If you specify no `FIELDS` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
```

If you specify no `LINES` clause, the defaults are the same as if you had written this:

```
LINES TERMINATED BY '\n' STARTING BY ''
```

In other words, the defaults cause `LOAD DATA INFILE` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip over any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret occurrences of tab, newline, or `\` preceded by `\` as literal characters that are part of field values.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use `'\'` to escape instances of tab, newline, or `'\'` that occur within field values.
- Write newlines at the ends of lines.

Backslash is the MySQL escape character within strings, so to write `FIELDS ESCAPED BY '\\'`, you must specify two backslashes for the value to be interpreted as a single backslash.

**Note:** If you have generated the text file on a Windows system, you might have to use `LINES TERMINATED BY '\r\n'` to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as WordPad, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the lines you want to read in have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip over the prefix, *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
  FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be `("abc",1)` and `("def",2)`. The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip over an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA INFILE` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA INFILE` will not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
  FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```

If instead you tried to read in the file with the statement shown following, it wouldn't work because

it instructs `LOAD DATA INFILE` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA INFILE` can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotes. If lines in such a file are terminated by newlines, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\n';
```

Any of the field- or line-handling options can specify an empty string (''). If not empty, the `FIELDS [OPTIONALLY] ENCLOSED BY` and `FIELDS ESCAPED BY` values must be a single character. The `FIELDS TERMINATED BY`, `LINES STARTING BY`, and `LINES TERMINATED BY` values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a `LINES TERMINATED BY '\r\n'` clause.

To read a file containing jokes that are separated by lines consisting of `%%`, you can do this

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '\n%%\n' (joke);
```

`FIELDS [OPTIONALLY] ENCLOSED BY` controls quoting of fields. For output (`SELECT ... INTO OUTFILE`), if you omit the word `OPTIONALLY`, all fields are enclosed by the `ENCLOSED BY` character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string",100.20
"2","a string containing a , comma",102.20
"3","a string containing a \" quote",102.20
"4","a string containing a \", quote and comma",102.20
```

If you specify `OPTIONALLY`, the `ENCLOSED BY` character is used only to enclose values from columns that have a string data type (such as `CHAR`, `BINARY`, `TEXT`, or `ENUM`):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Note that occurrences of the `ENCLOSED BY` character within a field value are escaped by prefixing them with the `ESCAPED BY` character. Also note that if you specify an empty `ESCAPED BY` value, it is possible to inadvertently generate output that cannot be read properly by `LOAD DATA INFILE`. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the `ENCLOSED BY` character, if present, is stripped from the ends of field values. (This is true regardless of whether `OPTIONALLY` is specified; `OPTIONALLY` has no effect on input interpretation.) Occurrences of the `ENCLOSED BY` character preceded by the `ESCAPED BY` character are interpreted as part of the current field value.

If the field begins with the `ENCLOSED BY` character, instances of that character are recognized as terminating a field value only if followed by the field or line `TERMINATED BY` sequence. To avoid ambiguity, occurrences of the `ENCLOSED BY` character within a field value can be doubled and are interpreted as a single instance of the character. For example, if `ENCLOSED BY ' '` is specified, quotes are handled as shown here:

```
"The ""BIG"" boss"  -> The "BIG" boss
The "BIG" boss      -> The "BIG" boss
The ""BIG"" boss    -> The ""BIG"" boss
```

`FIELDS ESCAPED BY` controls how to write or read special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used to prefix the following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII 0 (what is actually written following the escape character is ASCII ‘0’, not a zero-valued byte)

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

For input, if the `FIELDS ESCAPED BY` character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. The exceptions are an escaped ‘0’ or ‘N’ (for example, `\0` or `\N` if the escape character is ‘\’). These sequences are interpreted as ASCII NUL (a zero-valued byte) and `NULL`. The rules for `NULL` handling are described later in this section.

For more information about ‘\’-escape syntax, see Section 9.1, “Literal Values”.

In certain cases, field- and line-handling options interact:

- If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is non-empty, lines are also terminated with `FIELDS TERMINATED BY`.
- If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty (‘ ’), a fixed-row (non-delimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to ‘ ’. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later. Note that fixed-size format does not work if you are using a multi-byte character set.

**Note:** Before MySQL 5.0.6, fixed-row format used the display width of the column. For example, `INT(4)` was read or written using a field with a width of 4. However, if the column contained wider values, they were dumped to their full width, leading to the possibility of a “ragged” field holding values of different widths. Using a field wide enough to hold all values in the field prevents this problem. However, data files written before this change was made might not be reloaded correctly with `LOAD DATA INFILE` for MySQL 5.0.6 and up. This change also affects data files read by `mysqlimport` and written by `mysqldump --tab`, which use `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`.

Handling of NULL values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, NULL is written as a field value of `\N` for output, and a field value of `\N` is read as NULL for input (assuming that the `ESCAPED BY` character is `'\'`).
- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word NULL as its value is read as a NULL value. This differs from the word NULL enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string `'NULL'`.
- If `FIELDS ESCAPED BY` is empty, NULL is written as the word NULL.
- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), NULL is written as an empty string. Note that this causes both NULL values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

Some cases are not supported by `LOAD DATA INFILE`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and BLOB or TEXT columns.
- If you specify one separator that is the same as or a prefix of another, `LOAD DATA INFILE` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY ''' ENCLOSED BY '''
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA INFILE` to stop reading a field or line too early. This happens because `LOAD DATA INFILE` cannot properly determine where the field or line value ends.

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA INFILE` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata (col1,col2,...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table

columns.

Before MySQL 5.0.3, the column list must contain only names of columns in the table being loaded, and the SET clause is not supported. As of MySQL 5.0.3, the column list can contain either column names or user variables. With user variables, the SET clause enables you to perform transformations on their values before assigning the result to columns.

User variables in the SET clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'  
  INTO TABLE t1  
  (column1, @var1)  
  SET column2 = @var1/100;
```

The SET clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'  
  INTO TABLE t1  
  (column1, column2)  
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'  
  INTO TABLE t1  
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and SET clause is subject to the following restrictions:

- Assignments in the SET clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of SET assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an IGNORE clause are not processed for the column/variable list or SET clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, LOAD DATA splits it into fields and uses the values according to the column/variable list and the SET clause, if they are present. Then the resulting row is inserted into the table. If there are BEFORE INSERT or AFTER INSERT triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in Section 11.1.4, “Data Type Default Values”.

An empty field value is interpreted differently than if the field value is missing:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See Section 11.3, “Date and Time Types”.

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`), or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA INFILE` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded using binary notation (for example, `b'011010'`). To work around this, specify the values as regular integers and use the `SET` clause to convert them so that MySQL performs a numeric type conversion and loads them into the `BIT` column properly:

```
shell> cat /tmp/bit_test.txt
2
127
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
      -> INTO TABLE bit_test (@var1) SET b= CAST(@var1 AS SIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+-----+
| bin(b+0) |
+-----+
| 10      |
| 1111111 |
+-----+
2 rows in set (0.00 sec)
```

When the `LOAD DATA INFILE` statement finishes, it returns an information string in the following format:

```
Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
```

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See Section 22.2.3.34, “`mysql_info()`”.

Warnings occur under the same circumstances as when values are inserted via the `INSERT` statement (see Section 13.2.4, “`INSERT` Syntax”), except that `LOAD DATA INFILE` also generates warnings when there are too few or too many fields in the input row. The warnings are not stored anywhere; the number of warnings can be used only as an indication of whether everything went well.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See Section 13.5.4.25, “`SHOW WARNINGS` Syntax”.

## 13.2.6. REPLACE Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
      [INTO] tbl_name [(col_name,...)]
      VALUES ({expr | DEFAULT},...),(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  SET col_name={expr | DEFAULT}, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name [(col_name,...)]
  SELECT ...
```

REPLACE works exactly like INSERT, except that if an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted. See Section 13.2.4, “INSERT Syntax”.

REPLACE is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. If you're looking for a statement that follows the SQL standard, and that either inserts or *updates*, see Section 13.2.4.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”.

Note that unless the table has a PRIMARY KEY or UNIQUE index, using a REPLACE statement makes no sense. It becomes equivalent to INSERT, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the REPLACE statement. Any missing columns are set to their default values, just as happens for INSERT. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as SET *col\_name* = *col\_name* + 1, the reference to the column name on the right hand side is treated as DEFAULT(*col\_name*), so the assignment is equivalent to SET *col\_name* = DEFAULT(*col\_name*) + 1.

To use REPLACE, you must have both the INSERT and DELETE privileges for the table.

The REPLACE statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row REPLACE, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether REPLACE only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

Currently, you cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for REPLACE (and LOAD DATA ... REPLACE):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
  - a. Delete from the table the conflicting row that has the duplicate key value
  - b. Try again to insert the new row into the table

## 13.2.7. SELECT Syntax

```

SELECT
  [ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr, ...
  [FROM table_references]
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}
   [ASC | DESC], ... [WITH ROLLUP]]
  [HAVING where_condition]
  [ORDER BY {col_name | expr | position}
   [ASC | DESC], ...]
  [LIMIT {[offset,] row_count | row_count OFFSET offset}]
  [PROCEDURE procedure_name(argument_list)]
  [INTO OUTFILE 'file_name' export_options
   | INTO DUMPFILE 'file_name']
  [FOR UPDATE | LOCK IN SHARE MODE]]

```

SELECT is used to retrieve rows selected from one or more tables, and can include UNION statements and subqueries. See Section 13.2.7.2, “UNION Syntax”, and Section 13.2.8, “Subquery Syntax”.

The most commonly used clauses of SELECT statements are these:

- Each *select\_expr* indicates a column that you want to retrieve. There must be at least one *select\_expr*.
- *table\_references* indicates the table or tables from which to retrieve rows. Its syntax is described in Section 13.2.7.1, “JOIN Syntax”.
- The WHERE clause, if given, indicates the condition or conditions that rows must satisfy to be selected. *where\_condition* is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no WHERE clause.

In the WHERE clause, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See Chapter 12, *Functions and Operators*.

SELECT can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
-> 2
```

You are allowed to specify DUAL as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

DUAL is purely for compatibility with some other database servers that require a FROM clause. MySQL does not require the clause if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a HAVING clause must come after any GROUP BY clause and before any ORDER BY clause. The exception is that the INTO clause can appear either as shown in the syntax description or immediately preceding the FROM clause.

- A *select\_expr* can be given an alias using *AS alias\_name*. The alias is used as the expression's column name and can be used in *GROUP BY*, *ORDER BY*, or *HAVING* clauses. For example:

```
SELECT CONCAT(last_name,', ',first_name) AS full_name
FROM mytable ORDER BY full_name;
```

The *AS* keyword is optional when aliasing a *select\_expr*. The preceding example could have been written like this:

```
SELECT CONCAT(last_name,', ',first_name) full_name
FROM mytable ORDER BY full_name;
```

However, because the *AS* is optional, a subtle problem can occur if you forget the comma between two *select\_expr* expressions: MySQL interprets the second as an alias name. For example, in the following statement, *columnb* is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using *AS* explicitly when specifying column aliases.

- It is not allowable to use a column alias in a *WHERE* clause, because the column value might not yet be determined when the *WHERE* clause is executed. See Section A.5.4, “Problems with Column Aliases”.
- The *FROM table\_references* clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see Section 13.2.7.1, “JOIN Syntax”. For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias]
        [{USE|IGNORE|FORCE} INDEX (key_list)]
```

The use of *USE INDEX*, *IGNORE INDEX*, *FORCE INDEX* to give the optimizer hints about how to choose indexes is described in Section 13.2.7.1, “JOIN Syntax”.

You can use *SET max\_seeks\_for\_key=value* as an alternative way to force MySQL to prefer key scans instead of table scans. See Section 5.2.2, “Server System Variables”.

- You can refer to a table within the default database as *tbl\_name*, or as *db\_name.tbl\_name* to specify a database explicitly. You can refer to a column as *col\_name*, *tbl\_name.col\_name*, or *db\_name.tbl\_name.col\_name*. You need not specify a *tbl\_name* or *db\_name.tbl\_name* prefix for a column reference unless the reference would be ambiguous. See Section 9.2.1, “Identifier Qualifiers”, for examples of ambiguity that require the more explicit column reference forms.
- A table reference can be aliased using *tbl\_name AS alias\_name* or *tbl\_name alias\_name*:

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
WHERE t1.name = t2.name;
```

```
SELECT t1.name, t2.salary FROM employee t1, info t2
WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in *ORDER BY* and *GROUP BY* clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
ORDER BY region, seed;
```

```
SELECT college, region AS r, seed AS s FROM tournament
ORDER BY r, s;
```

```
SELECT college, region, seed FROM tournament
ORDER BY 2, 3;
```

To sort in reverse order, add the `DESC` (descending) keyword to the name of the column in the `ORDER BY` clause that you are sorting by. The default is ascending order; this can be specified explicitly using the `ASC` keyword.

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- If you use `GROUP BY`, output rows are sorted according to the `GROUP BY` columns as if you had an `ORDER BY` for the same columns. To avoid the overhead of sorting that `GROUP BY` produces, add `ORDER BY NULL`:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
```

- MySQL extends the `GROUP BY` clause so that you can also specify `ASC` and `DESC` after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
```

- MySQL extends the use of `GROUP BY` to allow selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in Section 12.10, “Functions and Modifiers for Use with `GROUP BY` Clauses”.
- `GROUP BY` allows a `WITH ROLLUP` modifier. See Section 12.10.2, “`GROUP BY` Modifiers”.
- The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

A `HAVING` clause can refer to any column or alias named in a `select_expr` in the `SELECT` list or in outer subqueries, and to aggregate functions. However, the SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. To accommodate both standard SQL and the MySQL-specific behavior of being able to refer columns in the `SELECT` list, MySQL 5.0.2 and up allows `HAVING` to refer to columns in the `SELECT` list, columns in the `GROUP BY` clause, columns in outer subqueries, and to aggregate functions.

For example, the following statement works in MySQL 5.0.2 but produces an error for earlier versions:

```
mysql> SELECT COUNT(*) FROM t GROUP BY col1 HAVING col1 = 2;
```

If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:

```
SELECT user, MAX(salary) FROM users
   GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL allows duplicate column names. That is, there can be more than one `select_expr` with the same name. This is an extension to standard SQL. Because MySQL also allows `GROUP BY` and `HAVING` to refer to `select_expr` values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name `a`. To ensure that the correct column is used for grouping, use different names for each `select_expr`.

- When MySQL resolves an unqualified column or alias reference in an `ORDER BY`, `GROUP BY`, or `HAVING` clause, it first searches for the name in the `select_expr` values. If the name is not found, it looks in the columns of the tables named in the `FROM` clause.
- The `LIMIT` clause can be used to constrain the number of rows returned by the `SELECT` statement. `LIMIT` takes one or two numeric arguments, which must both be non-negative integer constants (except when using prepared statements).

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10; # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5; # Retrieve first 5 rows
```

In other words, `LIMIT row_count` is equivalent to `LIMIT 0, row_count`.

For prepared statements, you can use placeholders (supported as of MySQL version 5.0.7). The following statements will return one row from the `tbl` table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

- The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being destroyed. As of MySQL 5.0.19, the `character_set_filesystem` system variable controls the interpretation of the filename.
